Currently however networks with wide geographic coverage operating in the band around the 868 MHz in Europe and 915 MHz in the USA are emerging. An example of this type of system is the one used by SIGFOX, an operator dedicated to the internet of things (IoT - Internet of Things), which, from France, is extending its coverage to Russia and other European countries, also including, from 2015, Italy. [10]

A technology that fits into this trend, but that can be used in private applications (that is, without necessarily requiring the presence of an operator) is the Lo-Ra™ of Semtech technology [4]. The Lo-Ra™ (Long Range) technology can be considered the actual innovation in the IoT world as it extends by a factor of ten the coverage range compared to the de facto standards, such as ZigBee, constituting an infrastructure enabler for new and different application areas, starting from that of monitoring of consumption.

3. The Proposed Solution

In an article that appeared in the chronicle of Bologna in early February 2016 [11] the virtuous and rather isolated example of the Sala Borsa was reported, highlighting its compliance of the legislation limits regarding the maximum temperature allowed inside public buildings. To be fair, the same article also reported the use of coats and scarves by users who were reading in the library. This example shows how the imposition of limits on the permissible temperature in public offices is not always easy to apply, both for technical and technological issues, but also for contour conditions such the time of permanence or the activity carried out in the offices, which can determine a different degree of perception of the temperature. Having said that, however, is crucial to have tools that can detect a possible misuse of energy resources in buildings, starting with those public, enabling energy savings just from the elimination of unnecessary waste, and that constitutes a concrete solution, effective and replicable on a large scale.

The proposed solution is a monitoring system, and not a control system, which aims at providing feedback to the buildings manager on the consumption. The conceptual model of the proposed system is based on a centralized control system of a distributed building stock that could bring significant energy savings with very low investment costs being primarily based on control, intelligence and awareness [5].

The technology Lo-Ra™ of Semtech allows monitoring very extensive building via wireless. It uses a star topology (in which the various nodes-sensors are connected directly to a hub-gateway node and is suitable for low traffic applications (such as monitoring). The advantages of the technology Lo-Ra™ [6] compared to existing technologies for sensor networks are:

- a range 10 times more extended, compared to the short-range technologies, thanks to a 198dB link budget (obtained via a modulation of the spread spectrum type) that allows for connections of up to 15 km in the sub-urban area, 2-5 km in densely populated urban areas and 2 km inside buildings;
- simplified network architecture that avoids the multi-hop and all related problems;
- low consumption of nodes (up to 10 years on battery power);
- very high network capacity: a single-concentrator gateway can connect thousands of nodes (up to 50,000)
- very low cost of the transmitters nodes.

All the above features make the Lo-Ra™ system an optimal solution, in the current scenario, for the implementation of energy monitoring systems of buildings because a single concentrator can cover one or more neighbouring buildings with a star architecture, which eliminates the problems associated with multi-hop (routing problems, latency, etc.) and because is characterized by high energy efficiency which can enable the duration of the batteries of nodes even for several years.

The monitoring system is based on a network of sensors installed in every building that transmit the indoor parameters to a central system in real time. These sensors are low-power and easily replaceable because of radio data transmission and because of being battery powered. The network of sensors, widely distributed within each building, allows the monitoring of the parameters, such as temperature, humidity and brightness, providing useful indications about the consumption resulting from the conditioning system. The transmission system, integrated on each sensor node, transfers the measured data to a single centralized point in real time. In the "control room" the parameter information is stored and processed on a server (remote intelligence). The data analysis module is able to detect in real time any conditions of energy waste, such as the exceeding of the reference temperature thresholds, different for summer and winter [7]. An automatic "warning" system, allows to report any abnormal conditions detected, by sending email or text message to the involved user, which will have to spontaneously provide to

an immediate regulation of local conditioning system and pay more attention on unnecessary consumptions. System web interface allows all users to view at any time and in real time the value of the parameters measured in their own office, favouring the acquisition of a greater awareness of consumption and use of energy resources.

4. The Test Bed

As a test bed has been chosen a building known and verifiable, the headquarters of LepidaSpa, located in a tower of the Bologna exhibition, divided on three floors with a total of thirty offices (Fig. 1, point A).

Figure 1: The Test Bed

In this building, as in all those of the same area, the conditioning system is centralized, with forced convection and independently adjustable in every office. The central conditioning system is switched on and off automatically on the working days from 6.00 to 19.00. The windows of the building are locked. The test bed consists of the installation of a sensor node in each office of all three floors. The lack of constraint on the presence of an electrical power point has allowed to select the most suitable installation point, as close as possible to the workers to measure their real comfort, but so it does not interfere with normal business activities, and also far away from sources of heat or exposure to direct sunlight. Each sensor node is equipped with a temperature, humidity and brightness sensor. The sampling period is 15 minutes, while the data transmission period one hour. In each transmission, therefore, the sensor nodes send 4 samples for each of the three measured parameters, for a total of 12 measures.

An extension of the experimentation has provided, in its terminal stage, the displacement of some sensors in some offices of the adjacent towers to those of LepidaSpa (points G, F and H of Fig. 1), which has allowed to verify the actual coverage of the data transmission system, as well as the monitoring of environmental parameters relating to different entities and buildings.

5. Experimental Data

The monitoring has been focused on the detection of three environmental parameters inside the offices: temperature, humidity and brightness. The parameters were calculated automatically and continuously 24 hours a day, 7 days a week.

The monitoring period lasted a year, from May 2015 to April 2016, and it made possible, therefore, to monitor the use of the air conditioning system both in summer and in winter. Temperature measurements data, coming from the indoor monitoring system, were correlated with outside temperature measurements, coming from ARPA hydro-pluviometric monitoring system installed in the city of Bologna, to allow a deeper understanding in the reading of the data.

5.1. Temperature monitoring

Fig. 2 shows the graphs of the temperatures in Celsius degrees measured by the sensors installed in the offices in July 2015. A correlation between the internal temperatures and the outside temperature (blue sinusoid) can be noticed, but also a dispersion of several degrees in the indoor temperature measurements during the on-time of conditioning systems.

In particular, Fig. 3 shows the comparison of the temperature trend detected in two offices in the period from 29/06/2015 to 05/07/2015. It's evident a rather different use of the air conditioning system on every working day, which it brings a difference of temperature up to a couple of degrees in the hottest hours between the two offices. Office users corresponding to the blue graph appear to have adopted the most efficient use of the conditioning system, since the temperature never drops below 26 degrees. From the chart it may also be noted that the air conditioning system in the office corresponding to the purple graph is always active regardless of the presence or absence of office staff, because it evident that it works when the offices are certainly closed.

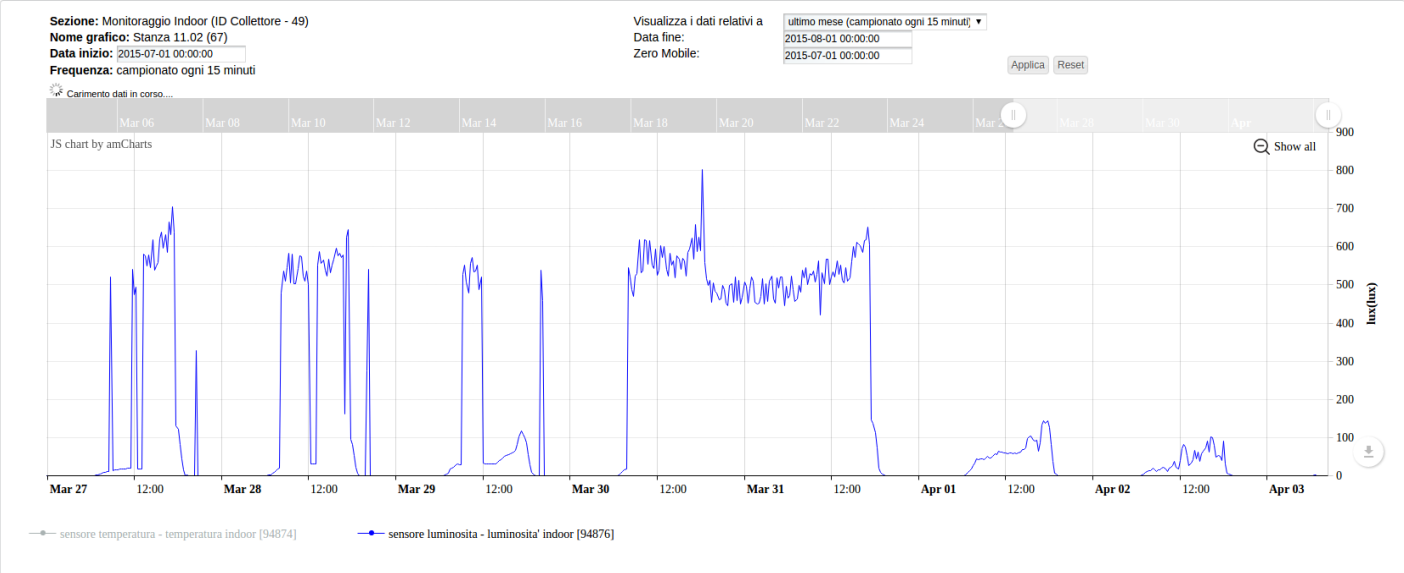

Fig. 4 corresponds to the graphs of the temperatures measured in the offices in February 2016. The variance of the measured values is very high, up to five degrees. The average temperature during working hours is about 25 degrees, with peaks up to over 28.

Fig. 5 shows the comparison between the temperature trend detected in two offices during the first week of February 2016 in which a quite different use of the air conditioning system, even more than in the summer, is evident in all the days of working week. In particular, an average difference of more than two degrees between the temperature of the two offices can be noticed: while the temperature represented by the blue line is always below 24 degrees, the one in the green line is always above 24 degrees, with a typical value of 27 degrees.

5.2. Lighting monitoring

The brightness sensor installed on each sensor node enabled a very interesting lighting monitoring. The graphs corresponding to the data detected by the brightness sensor (expressed in lux) easily highlight the alternation between day and night, as well as the use of artificial light in place of the natural one.

Fig.6 shows a chart related to the lighting monitoring in an office during a week, in which it is evident a generally correct use of the light during the working hours (light-on), the night and the weekend (light-off), except for an occurrence of light left on during the night.

The analysis carried out during one year of testing has shown that the oversights were few. As a matter of fact, only five offices resulted having left the lights on for a total of only 11 occurrences in a year.

5.3. More data analysis

The graphs of the light sensors, as well as main information analysed in the previous paragraph, can provide some additional one, useful in the control and management of buildings and personnel occupying them. In Fig.6, for example, the entry and exit time of the employee sitting in the office can be easily distinguished as well as the proper use of the lights even in the lunch break, during which are kept switched off. The same graph also shows a typical reactivation of lights around 8PM, linked to the presence of the cleaning personnel, authorized to operate only after the working time

6. Conditions of Health and Wellness within the Offices

Environmental parameters monitoring inside the offices are also providing useful information about health and wellness conditions inside workplaces.

As a matter of fact, among the aspects considered in the EHS guidelines for the workplaces and environmental protection in working activities [13], on top of indoor air quality, passive smoking and noise, it is also possible to find indicators on microclimate and lighting matching the data analysis on the environmental monitoring.

6.1. Microclimate

The range of physical and climatic parameters (temperature, relative humidity, air speed) in a confined environment is called microclimate. Thermal wellbeing depends on the performed activity, on the clothing and on individual sensations that can be influenced by environmental parameters such as temperature, relative humidity and air speed. Besides, the spread of microbiological contaminants in a confined area is influenced and enabled by other factors such as temperatures above 26°C and Relative Humidity above 65%.

PERIOD	AIR TEMP.	recommended value	R.H.
Summer	19-24	22	40-60
Winter	17.5 – 21.5	19.5	40-60

Table 1: thermal comfort zone in sedentary working conditions and seasonal clothing

From the data analysis performed, it is possible to identify a significant overpass of the recommended temperature during the months when study was conducted, but it is also possible to note an overall respect of the recommended values for relative humidity, both in winter and in summer, with some isolated cases in the summertime (Fig. 7, Fig. 8).

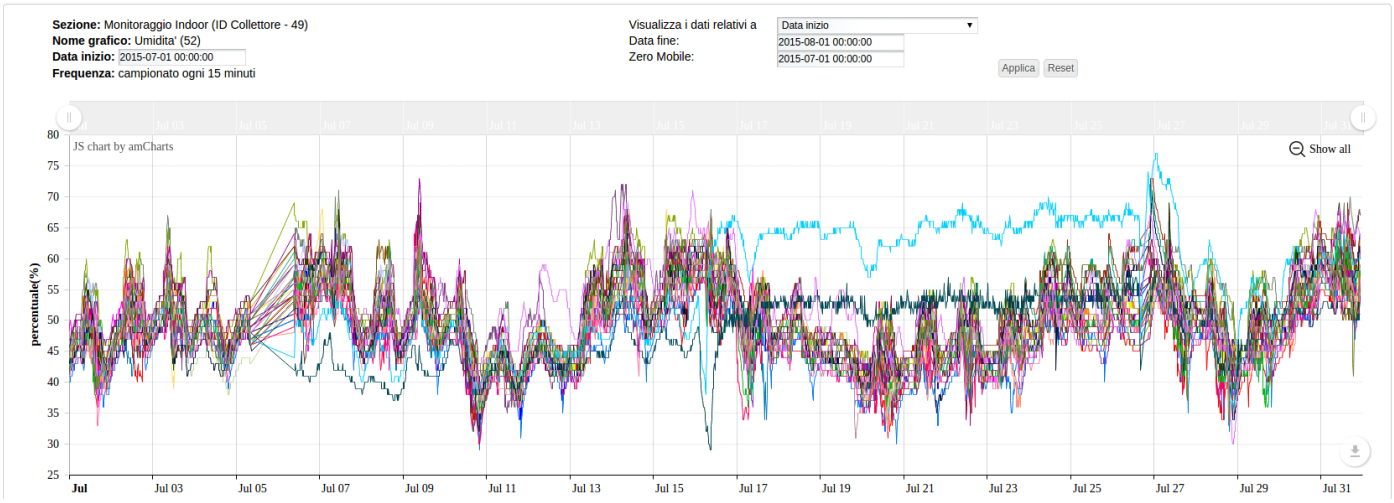

Figure 7: Humidity in the offices in July 2015

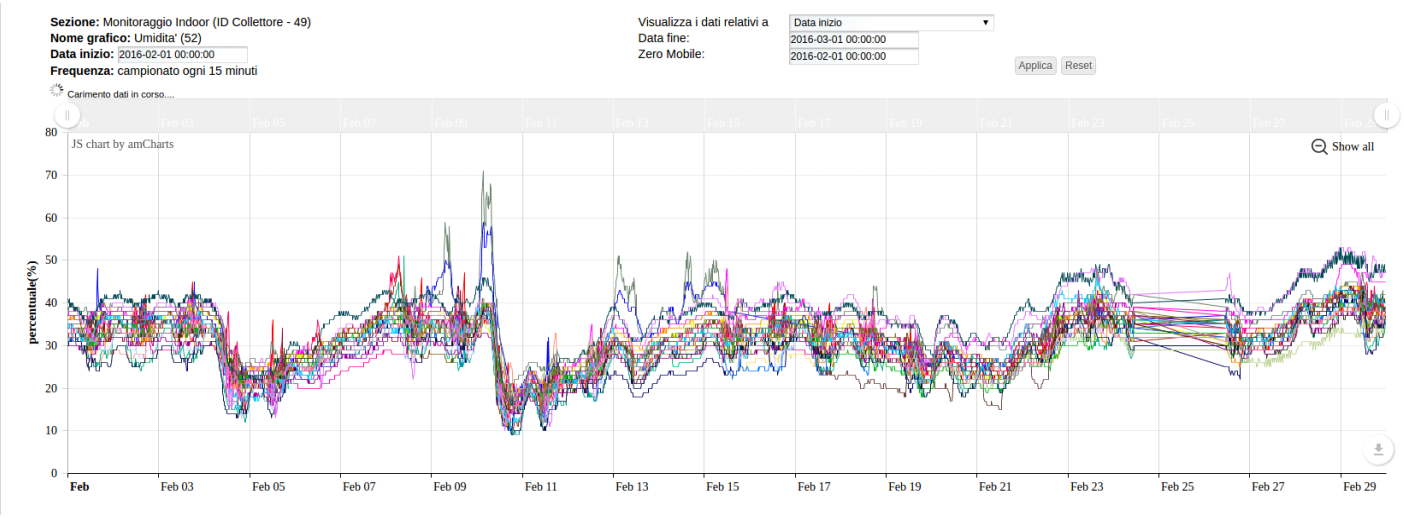

Figure 8: Humidity in the offices in February 2016

6.2. Lighting

The vast majority of the sensorial stimuli in the offices are visual, and eyes are evidently one of the most stressed organs. Natural light, although fundamental, is not sufficient alone to grant an adequate lighting in a confined area, since it is subject to a number of factors, among which the time of the day, the orientation of the room, the weather conditions, etc. In case of insufficient natural lighting, it is therefore necessary to provide a correct artificial lighting. There are several parameters defining a bright room, such as distribution and direction of the light sources, dazzling, etc… as an example, comparing in a table the measured parameters with minimum indoor requirements, it is possible to conclude that offices are correctly lightened (Fig.6).

UFFICI	(ILLUMINAMENTO) LUX
Copy room	300
Structure	500
Data centre	500
Technical Drawings	750

Table 2: Fonte normative: UNI EN 1264-1/2001

7. Energy Saving

Once the power of the light sources is known, the saving that can be achieved if lights are not turned on when nobody's around can be easily calculated

The saving that can be achieved if the room temperatures is lowered by 1°C is much less straightforward to calculate, and even less known. It is reported that each degree Celsius less in the room temperatures is allowing a 7% annual saving on heating costs. Under this assumption, the annual saving can be calculated as

Taking into account that 1 KWh of electricity equals 0,72 Kg of CO2, it is possible to evaluate the quantity of carbon dioxide that is not emitted

These simple formulas tell us that a significant saving is possible even with small actions and good practices that can also

be learnt by means of an awareness system such the one depicted highlighting the waste, misuse or dangerous use of resources.

8. Conclusions

The results of the experiment have shown the effectiveness of the energy monitoring system developed by LepidaSpa, highlighting that there are wide opportunities for savings coming from a more rational use of the heating and air conditioning system inside of LepidaSpa offices. In particular, while it has overall demonstrated a correct use of the lights, it has shown an incorrect use of the heating system in the winter period, detecting a much higher temperature than the allowed limits and much more than any reasonable margin of discretion.

Another important result was the verification of the radio coverage provided by the transmission system. Fig. 1 shows the positioning of the gateway (point A) and the different points in which the coverage has been verified (points B, C, D, E, F, G, H). The only area not covered consists of the E tower, inside which the received signal has not been sufficient to ensure reliable communications. The cause is probably to be identified in the C tower and in the interference caused by its height and its position between the extreme points A and E.

The results have, indeed, demonstrated the adequacy of the new technologies adopted, Lo-Ra™, which allowed the realization of unprecedented solutions and constitutes an enabling element for the IoT paradigm.

The solution illustrated is a real example of "Smart city" application not only because it provides a value-added service for the Public Administration through the use of new technology [13], but also because it has been made by the reuse of the already existing Sensornet platform [14].

The results of the experiment have finally demonstrated the generality and the possibility of large-scale implementation of the system, which can be adopted since now by all PAs of the Emilia-Romagna region interested in the implementation of energy savings policies through the detection of waste within their buildings, as well as of wellbeing conditions in their offices.

ABSTRACT

Recently, the field of prosthetics has seen many accomplishments especially with the integration of technological advancements. In this paper, different arm types (robotic, surgical, bionic, prosthetic and static) are analyzed in terms of resistance, usage, flexibility, cost and potential. Most of these techniques have some problems; they are extremely expensive, hard to install and maintain and may require surgery. Therefore, our work introduces the initial design of an EEG mind controlled smart prosthetic arm. The arm is controlled by the brain commands, obtained from an electroencephalography (EEG) headset, and equipped with a network of smart sensors and actuators that give the patient intelligent feedback about the surrounding environment and the object in contact. This network provides the arm with normal hand functionality, smart reflexes and smooth movements. Various types of sensors are used including temperature, pressure, ultrasonic proximity sensors, accelerometers, potentiometers, strain gauges and gyroscopes. The arm is completely 3D printed built from various lightweight and high strength materials that can handle high impacts and fragile elements as well. Our project requires the use of nine servomotors installed at different places in the arm. Therefore, the static and dynamic modes of servomotors are analyzed. The total cost of the project is estimated to be relatively cheap compared to other previously built arms. Many scenarios are analyzed corresponding to the actions that the prosthetic arm can perform, and an algorithm is created to match these scenarios. Experimental results show that the proposed EEG Mind-controlled Arm is a promising alternative for current solutions that require invasive and expensive surgical procedures.

1. Introduction

In recent studies, the World Health Organization (WHO) reported that about 15% of the world's population suffers from a form of disability, half of which cannot afford health care [1]. Due to various political, economic, scientific, and demographical reasons, the overall rates of amputees and limb dysfunction patients are increasing [2]. There are over 10 million amputees worldwide, out of which 30% are arm amputees [3]. Although prosthetic limbs exist since decades, they are not very natural in terms of operation and interaction with the environment. They require undergoing an invasive surgical procedure [4]. The main goal of such complex procedures is to reassign nerves and allow amputees to control their prosthetic devices by merely thinking about the action they want to perform as stated by the John Hopkins Applied Physics Laboratory.

A team at the John Hopkins University developed a robotic arm in their physics lab that is controlled by brain signals [5]. The arm has 26 joints, and can lift up to 45 pounds. It is based on an idea, which can be altered to fit any need, from someone missing just a hand to an entire limb. Engineers from Ossur, one of the biggest bionic arms markets in the world, designed an artificial bionic advanced leg and it was tested on a farmer who lost a leg [6]. A comparison was made between the bionic and the mechanical artificial legs, in which the engineers noticed some flaws in the mechanical leg, and thus causing the user to fall while walking if wrong amount of pressure was applied to the toe where the leg is

*Taha Beyrouthy, American University of the Middle East, +965 2225 1400 Ext. 1134, Email: taha.beyrouthy@aum.edu.kw

connected. The bionic leg, on the other hand, was constructed out of more than one piece. The knee, the foot and the leg were assembled to create a fully functional bionic limb [7]. This limb has a brain of its own, and can sense what surrounds it by the processors that analyze the inputs. According to the head of this group of engineers, the leg costs more than a few sedan cars.

Prosthetic limbs need to be measured and fitted to the patient for his needs [8]. To apply prosthetics on a patient, intense medical observation and a training course for the patient are needed so that he can use the limb comfortably. There are several techniques used as a means of controlling robotics arms, and the top three methods are highlighted hereafter. The first method is to use an electroencephalogram (EEG) device [9], which will record the person's brain waves when he is thinking of a certain action or implementing a facial expression. These readings are then converted to commands for the arm. The author in [10] states that the mind regulates its activities by electric waves registered in the brain that emits electrochemical impulses having different frequencies, which can be registered by an electroencephalogram. For instance, beta waves are emitted when a person feels nervous or afraid with frequencies ranging from 13 to 60 Hertz. Alpha waves are emitted when a person feels relaxed mentally and physically with frequencies from 7 to 13 Hertz. On the other hand, delta waves are emitted when a person is in a state of unconsciousness. The advancement in technology made it possible to process these EEG frequencies and data directly in real time by the use of a brain-computer interface which is a combination of hardware and software.

The second method is the surgical implantation. The arm is surgically connected to the person's torso. Connections are also made to the nerves to allow the reading of electrical signals so that these signals can then be filtered and converted to commands. The last control method consists in using sensors, which will be connected to the robotic arm in order to take specific readings. Some of the most common sensors used in this case are EMG, gyroscope, and accelerometer sensors. This will allow the user to be aware of the position his arm can be in as well as expand and enclose it. All the arm types used are summarized and compared with each other in Table 1 hereafter in terms of usage, flexibility, cost potential.

Table 1. Arm Types comparison

Arm Type	Usage	Flexibility	Potential
Robotic	Using mounts	Depends on the motors, material and design	Big potential with the rise of 3D printers
Surgical	Surgically Implanted	Depends on the training and the physiotherapy	Very high especially for the war victims
Bionic	Very effective for everyday usage	Depends on how well can the processor analyze the surroundings	Good potential, especially with the microprocessor revolution
Prosthetic	Similar to the surgical limbs, but less medical attention	Very high flexibility (custom made for each person using exact measurements)	Overshadowed by the surgical and the robotic limbs
Static	No mechanical use	Not flexible	No potential

The control techniques used are summarized and compared with each other in Table 2 hereafter in terms of cost, installation, degree of control and accuracy.

Table 2. Control techniques comparison

Type	Approximate Cost (U.S. Dollars)	Installation	Degree of Control	Accuracy
EEG	100 – 400	Detachable	Complete control	Accurate
Surgical	10,000 – 120,000	Permanent	Complete control	Very accurate
Sensors	Below 100	Detachable	Limited	Accurate

The EEG method is not only cost effective, but it is also accurate and gives the patient complete control of the arm. It also gives the user the luxury of taking it off when feeling discomfort. EEG is a noninvasive method of monitoring brain activity. Typically, it uses electrodes placed on the outside of the head, and measures voltage oscillations in the neurons of the brain caused by ionic current. It has been used in medical applications for a very long time. The Emotiv EPOC is an example of an EEG headset with 14 sensors and having an internal sampling rate of 2048 Hz. After filtering the signals, it sends the data to the computer at approximately 128 Hz. The signals are transferred from the headset to the computer through wireless technology. This offers much greater mobility, and instead of requiring a special gel, the electrodes of the EPOC simply need to be dampened using a saline solution that in disinfectant and common.

The project presented in this paper aims to develop a low-cost and versatile human-like prosthetic arm controllable via brain activity using EEG neuro-feedback technology. The arm is equipped with a network of smart sensors and actuators that give the patient intelligent feedback about the surrounding environment and the object in contact. It also allows the arm to react and execute pre-programmed series of actions in critical cases (extremely hot or fragile objects, etc.) A first prototype has been developed to test the prosthetic arm with the embedded electro-mechanical system. This prototype is controlled using flex sensors integrated within a wearable glove. A microcontroller is added to the system, thus allowing to perform programmed actions and tasks. The arm is created using a 3-D printer in order for it to be cost efficient. All parts are printed separately then assembled together. This prototype focuses on the arm-environment interaction. A second prototype based on the EEG

control has also been developed and still under test. Preliminary experimental results show that the EEG technique is a promising and good alternative to other existing techniques.

2. System Architecture

The proposed system is divided into 4 major units [11] as shown in Figure 1:

1- The Input Unit – EEG sensors
2- The Processing Unit – Pattern recognition
3- The Electro-Mechanical Unit - The arm
4- The Interface Unit – Smart sensor network

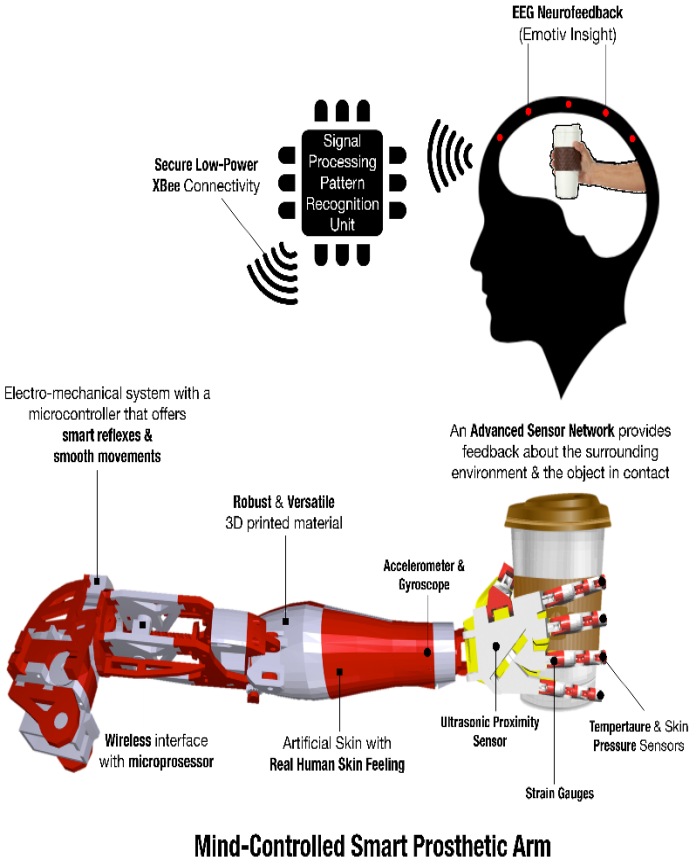

Figure 1. Mind-controlled smart prosthetic arm architecture

2.1. Input Unit

In this unit, brain signals were captured by an array of advanced EEG sensors communicating with a Signal Processing Unit via low-power and secure connectivity using Bluetooth technology. This device has an internal sampling rate of 2048Hz and 14 sensors arranged according to the international 10-20 System as shown in Figure 2 in order to cover the most relevant area over the brain. This allows a maximum and efficient coverage of the brain activity. EEG signals are acquired using the Emotiv EPOC wireless recording headset bearing 14 channels (AF3, F7, F3, FC5, T7, P7, O1, O2, P8, T8, FC6, F4, F8), referenced to the common mode sense [12].

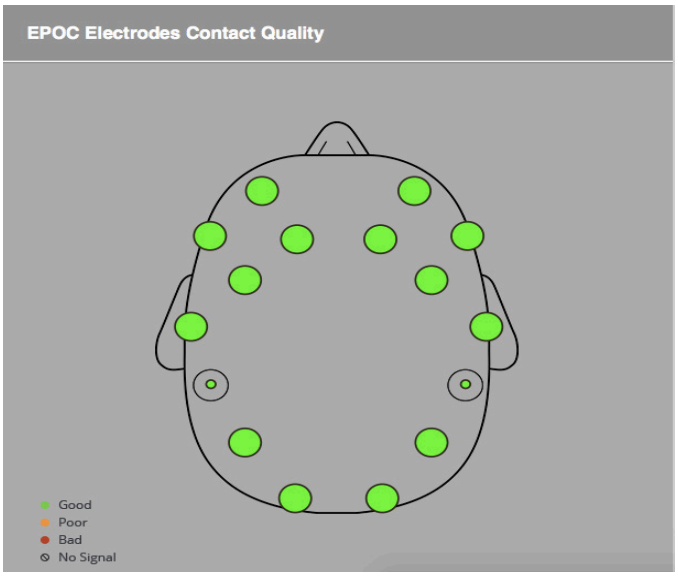

Figure 2. EEG 14-sensor arrangement

2.2. Processing Unit

The EEG signals provided by the input unit were sampled and processed on a lightweight wearable device – the Processing Unit. The processing activity consists of two main parts: a pattern recognition part that identifies different brain behavior captured by the input unit, and a command part that generates a series of commands to be sent to the mechatronics system of the arm.

This unit was programmed to distinguish between several states of the mind representing different levels of "meditation" and "focus". Every mind state was captured and encoded to represent a set of desired tasks to be performed by the arm. Due to the diversity and the complexity of brain wave activities among different humans, machine-learning techniques were required to train patients to specific arm movements according to a set of mind states.

2.3. Electro-mechanical Unit

This unit was designed and built from various lightweight high-strength materials that can handle high impacts and fragile elements as well. It integrated servos capable of handling 800 oz.-in. of stall torque. These servos were strategically placed to minimize hardware and facilitate complex moves. A microcontroller was also integrated to this setup to provide the interface between the Mechanical Unit and the Processing Unit. It can also be programmed to perform a series of predefined movements, allowing the arm to have a sophisticated and realistic real hand behavior.

2.4. Interface Unit – Smart Sensor Network

This unit is composed of a network of smart sensors, including temperature, skin pressure and ultrasonic proximity sensors, accelerometers, potentiometers, strain gauges and gyroscopes. The main features of this unit allow the arm to interact with and adapt to the surrounding environment. Moreover, a bi-directional communication was required to give commands to the arm and provides feedback to the patient. This integrated network of sensors and actuators required custom communication protocols and networking techniques that allow seamless interaction and control between the arm and patient. By default, controlling the

arm was handled by the brain (patient); however, it can be transferred to the arm to proactively protect itself against damage.

Due to its unique features, the proposed Mind-controlled Smart Prosthetic Arm should be able to improve the quality of life for millions of patients and their families around the world. Its low cost design makes it accessible for a wide range of beneficiaries, especially those with limited or no access to advanced health care.

3. Technical Specifications

3.1. Hardware Overview

The Smart Prosthetic Arm architecture was based on an advanced electro-mechanical system controlled by EEG neuro-feedback technology. This architecture is divided into 4 main units in terms of hardware (see Figure 3 and Figure 4) [13]:

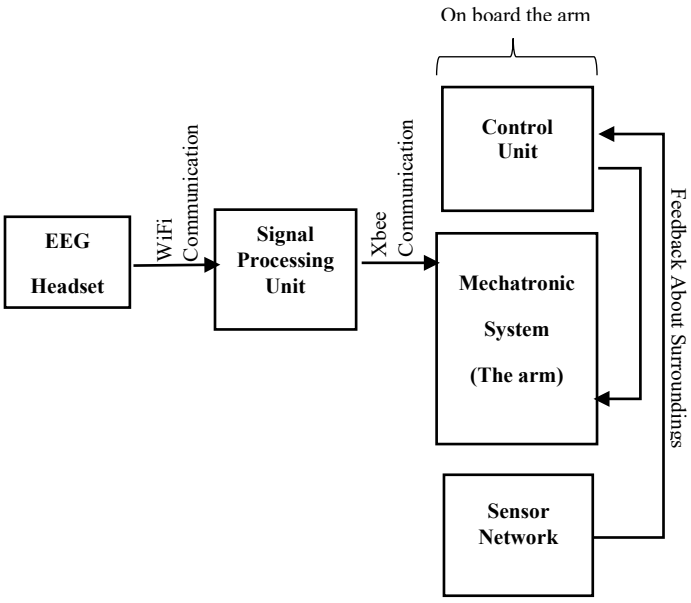

Figure 3. System overview – block diagram

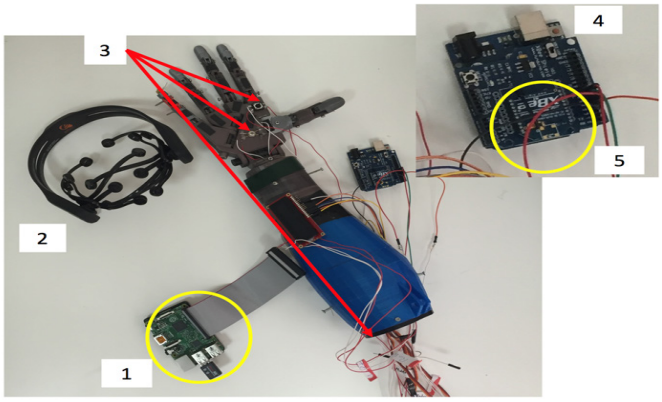

Figure 4. System overview – photo of the actual components

As shown in Figure 4, component number 1 is the processing unit that receives the EEG waves from the headset and communicates with the control unit; component number 2 is the Emotiv EEG headset with 14 sensors; component number 3 corresponds to the embedded sensors (temperature, proximity and touch); component number 4 is the control unit, which is Arduino based; component number 5 is the XBee driver (wireless communication with the processing unit).

The Data Sampling Unit includes 14 EEG sensors implemented in the EEG-based headset. This unit converts EEG signals to digital signals and send them to the processing unit through Bluetooth communication channel.

The Wireless Communication Unit includes low power connection Bluetooth module interfaced with the Raspberry III microcomputer. This part implements a communication protocol between the user (EEG sensors installed on the head) and the embedded microcontroller in the prosthetic arm.

The Computing and Processing Unit: Sampled EEG signals are channeled through the wireless communication unit to reach the Computing and Processing Unit, which is embedded in the arm and includes a Raspberry Pi III microcomputer, interfaced with an Arduino Mega microcontroller that handle the mechanical servo units installed in the arm. The main function of the processing unit is to treat the digitized EEG signals. It is programmed to compare between the headset reading and a set of premeasured patterns related to different states of the mind. Different mind states are captured and encoded to represent a set of desired tasks to be performed by the arm. This Unit is also programmed with multiple hand reflexes, triggered by the smart sensor network embedded in the arm. It gives the arm a human-like behavior via smooth movements and smart reflexes.

Finally, the Electro-Mechanical Unit includes nine servo motors installed on the 3D designed model. The 3D hand model is built from various lightweight high-strength materials that can handle high impacts and fragile elements as well. This unit integrates all servos, which are capable of handling 800 oz.-in. of stall torque. It is embedded in the arm and links servos to joints to perform different motions. The servos are strategically placed to minimize hardware and facilitate complex moves. A microcontroller is also integrated to this setup to provide the interface between the Mechanical Unit and the Processing Unit.

One of the main features of this arm is its affordability, which is accomplished mainly due to the fact that the arm is entirely 3D printed, which is one of the most affordable, yet durable ways of manufacturing such a product in this day.

For the process of building, different materials were used to create a full arm. The usage of different materials provided a more practical build.

The hand was created using a material called EcoPLA, which is PLA mixed with certain chemicals to provide a sense for heat recognition. This material can change color when exposed to heat. The added sensors provide visual aid to the user of the arm so that the user can estimate the heat of the held item. EcoPLA is considered to be a clean material, mainly extruded from starch, corn, and sugar cane, which makes it more environmental friendly. For the mechanical moving parts that need better endurance and will be exposed to more pressure, PLA is also used as the material for the build because of its strength, flexibility, and heat resistance, which makes it more reliable; therefore, it is the best material to

execute the job with no flaws. It is also easily sanded and machined.

For the forearm, shoulder, and elbow, PLA is used to complete the build. PLA is a printing material that is easily machined under normal conditions, on the other hand ABS needs special heating bed during the printing. PLA is also an environment friendly plastic which can be created using a mixture of different plant substances, such as potatoes and corn, yet, it does not bio-degrade easily. PLA is also considered strong and rigid material, yet it has a lower melting temperature which makes it unreliable under pressure.

The project required the use of nine servomotors in different places in the arm. To make sure the hand is able to carry a load varying from 3-5 kg, first we had to know how much torque each servo motor needed. To get that, the following formula shown in (1) for the static mode is used:

$$+M = (L_1 \times \cos(\theta_1) + L_2 \times \cos(\theta_2))x9.8 \quad (1)$$

+M is the momentum; L_1 is the length between the force and the first angle θ_1; L_2 is the length between the force and the second angle θ_2 as shown in Figure 5.

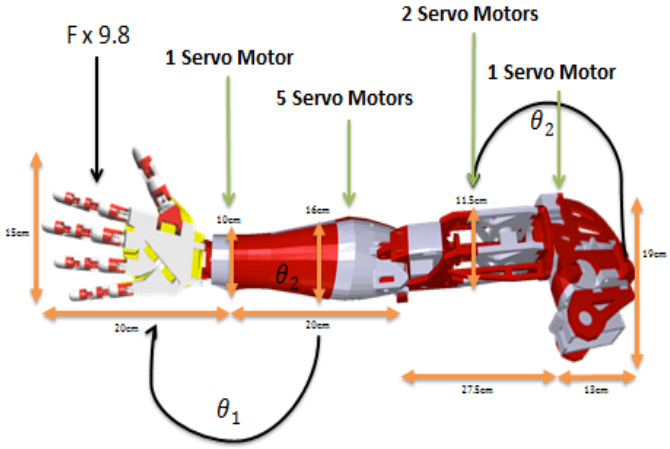

Figure 5. Prosthetic Arm Technical Specifications

For the dynamic mode of the servo motors, friction of the arm parts along with some other parameters were neglected. The following formula shown in (2) is used:

$$M = F \times l + J \times \alpha \quad (2)$$

F is the force applied on the hand; l is the length of the arm; J is the polar movement of inertia; α is the angular acceleration or polar acceleration.

The equation for the dynamic mode shown in (2) changes from one part to another (shoulder, wrist, hand or elbow).

The next calculations are obtained while the hand is in the static mode, not the dynamic mode. While the angles are equal to zero, the servos will be outputting their highest torque in the static mode as shown in Table 3.

Table 3. Load calculation for a servo motor

Mass (Kg)	Force (N)	Wrist S. Torque	Hand S. Torque	Biceps S. Torque	Shoulder S. Torque
1 Kg	9.8	1.96	3.43	6.615	7.889
2 Kg	19.6	3.92	6.86	13.23	15.778
3 Kg	29.4	5.88	10.29	19.845	23.667
5 Kg	49	9.8	17.15	33.075	39.445
7 Kg	68.6	13.72	24.01	46.305	55.223
10 Kg	98	19.6	34.3	66.15	78.89

3.2. Dynamic Modeling of Prosthetic Arm

In the time domain, the mechanical model of the Prosthetic Arm can be represented as a generalized second order differential equation form for the translation motions as shown in (3):

$$f(t) = m\,\frac{d^2x}{dt^2} + C_1\frac{dx}{dt} + K_1.x(t). \quad (3)$$

where: f(t) represents the applied tension forces in the two sides of the tendons to create displacement between fingers at different configurations, m is the mass of the movable part, x(t) is the displacement between fingers at different time, C1 is the friction damping coefficient for the translation motion , K1 is the spring constant . the same model can be restated for the torque $T(t)$ at the elbow and shoulder joints as shown in (4):

$$T(t) = J\,\frac{d^2\theta}{dt^2} + C_2\frac{d\theta}{dt} + K_2.\theta(t). \quad (4)$$

where: J is the mass polar moment of inertia (kg.m2) of the rotated part, θ(t) is the angular displacement (rad.), C2 is the friction damping coefficient for the rotational motion , K2 is the rotational spring constant .

From the multibody dynamic model of the different parts of the Prosthetic Arm, we can get the required toque for each of the 8 motors at all possible movement configurations, the selection design value for the motors specifications was based on the maximum calculated required torque & Power.

3.3. Power Consumption

The power study of the proposed Smart Prosthetic Arm is divided into 2 major parts.

The EEG headset uses a lithium (Li) battery that provides up to 12 hours of continuous use when fully charged. If fully discharged (after 12 hours of usage), it can take up to 4 hours to be recharged. However, the charging process takes between 30 minutes to 2 hours when not fully discharged. Therefore, it is recommended to recharge it before 12 hours of continuous use. For safety reasons, the headset does not work while charging it.

The electro-mechanical system is composed of eight servo motors of rated power 0.5 Watts and 3.5 Watts, which are placed on different parts of the prosthetic arm (wrist, elbow, shoulder and fingers). Three servomotors with a rated power of 3.5 Watts are placed on the wrist, elbow and shoulder area to provide three degrees of freedom. In addition, five servomotors with a rated power 0.5 Watts each are used to control the five fingers. Thus, all the servomotors consume a total power of 13 Watts. A 5V battery with an output current of 2.6 Ampere is required to provide

power to all servomotors embedded in the arm. The wireless communication unit operates when a 50 mA is supplied at 3.3 V, which requires a power of 0.165 Watts to operate.

In addition, a network of smart sensors is used, including temperature, skin pressure and ultrasonic proximity sensors, accelerometers, potentiometers, strain gauges and gyroscopes. These sensors consume a total current of 100 mA. The power consumption of the low-power single board computer (Computing and Processing Unit) is 0.1 Watts corresponding to a current of 30 mA. To power all the units listed above, the system requires a power source with an output current not less than 2.8 A and 5V as output voltage.

Two 10,000 mAh lithium ion batteries are chosen with an output current of 2A each. They include a charging circuit (via USB Cable), and a boost converter that provides 5V DC. These batteries have an 80% efficiency loss on both ends, meaning that it is not recommended to operate the arm while the battery is being charged. With these two batteries, the arm will be operational for 7 continuous hours knowing that the average hand movements per person during a day are equivalent to 1 to 3 hours of continuous movements depending on the daily activity performed. In conclusion, the whole system can be operational for 2 full days.

3.4. Smart Sensors

The sensors included in the proposed solution can be classified in two categories: user-end sensors and environment-end sensors. The first category consists of the 14 EEG sensors presented previously which are installed on the user headset.

As for sensors of the second category, their main feature is to allow the arm to interact and adapt to the surrounding environment, by providing intelligent feedback about critical condition, such as high temperature or pressure, etc. When interfaced with the embedded microprocessor installed on the arm, this network will give the prosthetic arm a human-like behavior with smart reflexes and smooth movements. Note that the feedback coming from some of these sensors will not only be used to operate some servos of the arm, but will also be displayed on small LCD screen mounted on the forearm.

3.5. Control

The proposed system was based on both fully autonomous and semi-autonomous control.

A bi-directional communication channel was implemented between the smart sensor network and the embedded microprocessor in such a way to autonomously control the electro-mechanical unit and provide feedback to the user by displaying it on an LCD mounted on the arm. This setup offered the arm the ability to have smart reflexes when it counters delicate, dangerous and critical situations such as protecting the arm from very hot surface contact or over squeezing fragile objects (glass, human hand, etc…). This integrated network of sensors and actuators requires custom communication protocols and control mechanisms techniques that allow seamless interaction and control hand over between the arm and the user.

By default, the brain signals control the arm movements semi-autonomously via a wireless connection. The EEG headset has a proprietary wireless USB dongle that can be connected to the processing unit via a Bluetooth module. It reads the neuro-electrical signals and interprets them as a set of predefined outputs that reflect facial expressions, mood and conscious intentions. These predefined outputs are received by the processing unit, compared with user-dependent library of pattern and then converted into functions. These functions are then labeled using variables and sent to the Arduino microcontroller through via UART channel. Based on these variables, a certain movement of the arm occurs according to the mapping that is done between the variables and the readings.

4. Project Cost

The cost of the project was divided into components and equipment cost (servo motors, sensors, Bluetooth, Raspberry PI II and EEG-based headset, two USB battery packs), labor costs and the 3D printing cost of the prosthetic arm. All the required components are relatively cheap off-shelf products that can be purchased from multiple providers. The total cost of the system is estimated to be around 1140 USD as shown in Table 4.

Table 4. Cost of project components

Components needed	Approximate Cost (U.S. Dollars)
EEG-based headset (including battery and software)	400
Servo motors	135
Bluetooth module	95
Smart network sensors	150
Raspberry PI II & Arduino Mega	60
Batteries	100
3D model arm	200
Total cost	**1140**

The total cost of the proposed solution is estimated to be relatively affordable and more economical when compared to the existing solutions (surgical, bionic and static prosthetic arms) manufactured by different companies around the world.

5. Testing and Results

During the training session performed, the signals corresponding to valence, engagement, frustration, meditation, short and long-term excitement detected by the Emotiv EPOC headset for 30 and 300 seconds are shown in Figure 6.

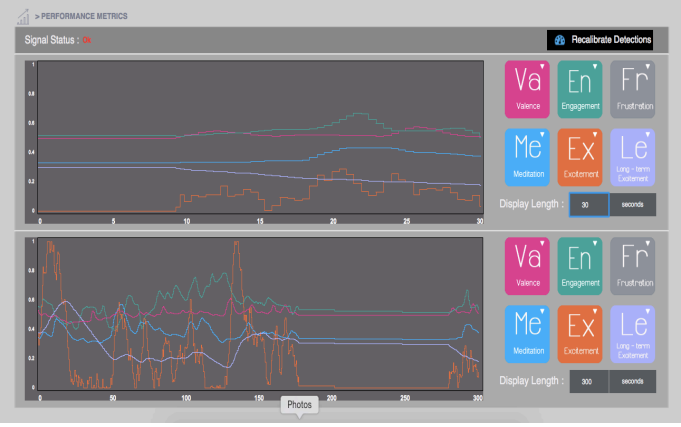

Figure 6. Different signals detected by the Emotiv headset

A 3D cube was displayed, and a training session was available in order to guide the user to move the object either to the left or to the right with his thoughts as shown in Figure *7*. The process started by recording the user's mind when he was not thinking of anything. Then, the user could select an action he prefered to move the object. His thoughts were recorded for the time interval when he was thinking of the object.

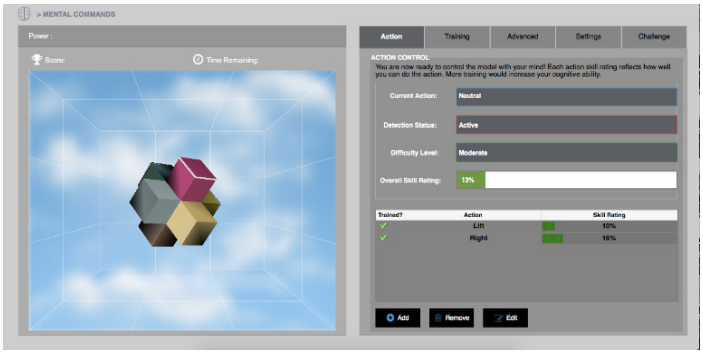

Figure 7. Training session with the 3D cube

Thinking of moving the cube to the left stimulated the hand of the prosthetic arm to close (see Figure 8). However, thinking of moving the cube to the right stimulated the hand to open (see Figure 9).

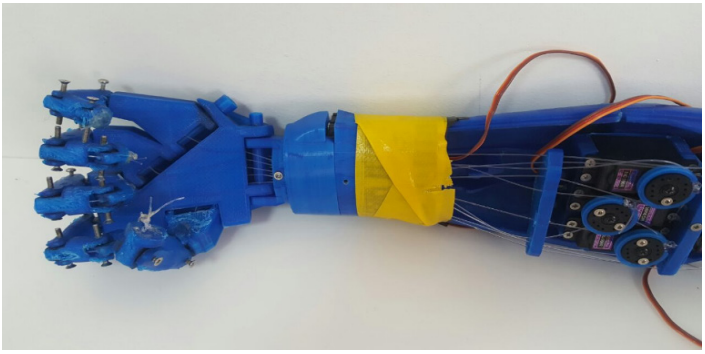

Figure 8. Prosthetic arm – closing hand

Coming up for the scenarios and the algorithms of the arm are one of the things that makes this arm considered as a smart arm. The scenarios simply define the smart reflexes of the arm which can protect the user from the surrounding environment or the people who are communicating with the user. Initially, the arm automatically checks the three sensors (pressure, IR temperature, and proximity). If all of the sensors are in a safe state, the following scenarios can be initiated:

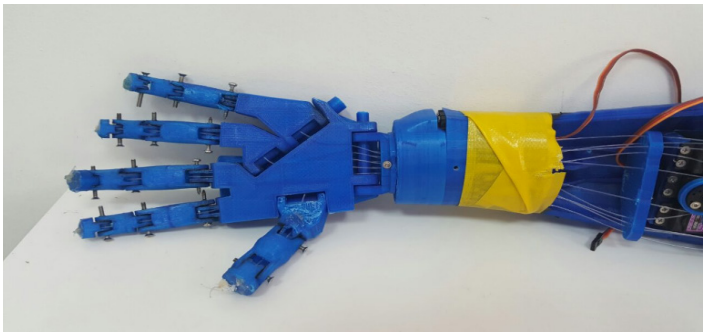

Figure 9. Prosthetic arm – opening hand

Scenario 1: User will be able to initiate brain command and control the arm if all the sensors are in a safe state.

Scenario 2: If the user initiates "Action 1" command, this will enable the handshake. The servomotors in the hand will increment the angle and check if it has the optimum pressure for the handshake. If it reaches it, it will stop automatically.

Scenario 3: If the user imitates "Action 2" command, this will enable the arm to grab a soda can and pour it in a cup. The servo motor in the bicep moves up and stops at a certain degree, then the servo motor in the wrist is rotated so that the soda will be poured in the cup.

On the other hand, if one of the three sensors is not in a safe state, the following scenarios will be taken:

Scenario 4: If the hand holds an object, the temperature sensor, which is embedded within the hand, will measure the temperature. If the temperature is too hot for human skin and reaches the pain threshold, "Action 3" will be automatically initiated. Once Action 3 is initiated a red LED lights up.

Scenario 5: It is the same as the previous scenario, but in this case if the temperature is too hot for the material of the hand itself, "Action 4" is automatically initiated. The servomotors in the hand open the fingers and release the object.

Scenario 6: Here if the proximity sensor which is placed in the back side of the arm reads a distance which is not in the safe range (too close to an object), the servo motors within the shoulder will move the arm forward to keep the arm within a safe range. This is defined as "Action 5".

Finally the code on the Arduino was updated so that all the individual codes were combined together. The codes for each sensor, the codes for testing the servomotors and the codes for the

different gestures based on the input were all put together in a way for the arm to function effortlessly. Within the code, the first thing that was taken into consideration and checked is the sensor network. If the sensors are not in a safe state, they will follow the scenarios as shown previously. Otherwise, the serial port will be checked if it is receiving any data. The serial port is checked because the Arduino communicates with the XBee through a serial connection. If data is being received, it will go through different if statements, each one checking if the input is representing a certain letter. Each letter corresponds either to a raw action (move arm up) or a certain gesture.

The Emotiv EPOC headset has 16 electrodes, which it uses to measure the electromagnetic pulses from the brain. These electromagnetic pulses are created by intentional thoughts, facial expressions and even the mental state of the user. What we will be using for the inputs are the intentional thoughts and the facial expressions.

Before wearing the headset, Saline solution must first be applied to the electrodes. Once the electrodes are damp, they can be connected to the headset. Saline solution is applied in order to increase contact and the quality of the signal read; however, if too much is applied, it could lead to affecting the electrical equipment. Once the user slides the headset on to his head, he/she must insure that the electrodes are placed in the correct position and are in contact with the scalp; this ensures a good signal (green). To get the most accurate output, it is best that all electrodes are green.

The flowchart of the algorithm is shown in Figure 10.

Figure 10. Flowchart of the algorithm

6. Conclusion

The proposed arm hosts state-of-the art technological advancement, communication protocols, control systems, and human interfacing. This gives it great potential in many applications related to the health care field as well as other fields. As long as health care is considered, the idea could be expanded to other body parts as well as to patients having other dysfunctions as nerve damage. On the other hand, many industrial and commercial applications can utilize many features of the proposed arm. Within the health care field, there exists a class of patients who need extra help with their daily lives. This includes elderly people, people under rehabilitation, and people with limited mobility, etc. The proposed arm may be interfaced to a robotic-structure and function as a helper or caregiver to this group of people. It can be programmed to do various functions according to specific patient needs. This may vary from cooking to assistance with bathing or dressing. Another example in the medical field is remote high precision surgical procedures, where surgeons can undergo operations remotely with the aid of the robotic arm. Many industries employ robots in the manufacturing process, many of which can make use of a modified version of the proposed arm. Based on a specific application, this smart arm can be programmed to execute a series of predefined actions, and customized with dedicated sensors, actuators and customized algorithms (such as image and signal processing, gesture and voice recognition etc…). In addition, connecting the arm to the Internet, and making it part of an Internet of Things network (IOT) will increase the performance and productivity of many industry applications. A first prototype is designed, built and was under test. The testing required long training sessions in order first to build a user-dependent library of brain activity patterns, and second to make the user more familiar and comfortable using this hand.

Conflict of Interest

The authors declare no conflict of interest.

Keyphrases
Indexation
Classification

ABSTRACT

The increase of textual information published in Arabic language on the internet, public libraries and administrations requires implementing effective techniques for the extraction of relevant information contained in large corpus of texts. The purpose of indexing is to create a document representation that easily find and identify the relevant information in a set of documents. However, mining textual data is becoming a complicated task, especially when taking semantic into consideration. In this paper, we will present an indexation system based on contextual representation that will take the advantage of semantic links given in a document. Our approach is based on the extraction of keyphrases. Then, each document is represented by its relevant keyphrases instead of its simple keywords. The experimental results confirms the effectiveness of our approach.

1. Introduction

Document indexing is an essential step in the text mining process because it determines how the knowledge contained in the documents is represented. It takes place each time a document is added to the corpus. Indexation must then deal with two main problems, the choice of the most representative terms of each document and the evaluation of their power of representation.

Several approaches are proposed in the literature, particularly in English, but they are unusable for documents in Arabic, given its specific characteristics and the complexity of its morphology, grammar and vocabulary. For instance, association rules and semantic approaches based on external references are more complicated to use on Arabic documents.

The indexation, under all its forms, aims to extract the most relevant descriptors from a given document. The more sophisticated the selection is, the more accurate are the subsequent tasks of text mining using indexation systems, like classification and information retrieval.

Document indexing involves extracting keywords that best represent a document. In spite of the essential role of this phase in the next step of the natural language processing process, few are the works identified at this level [1][2][3].

While preparing this paper, we stopped particularly on descriptor's type extracted from a document in a text mining process. We noticed that stemming is the most used method to represent a document.

This paper is an extension of work originally presented in the 11th International Conference on Intelligent Systems: Theories and Applications (SITA 2016) [4]. It presents a comparison of the two text representation methods: stem-based representation and keyphrase-based representation, as well as their applications and compatibility with the Arabic language. However, our proposed approach can be applied to other languages.

The rest of this paper is organized as following. The second part introduces the related works. The third part is dedicated to the presentation of a conventional text mining process. The fourth part describes the proposed indexing systems and the used methods. We will present and discuss the experimental results in

* Mohamed Salim El Bazzi, IRF-SIC Laboratory, Ibn Zohr University, Agadir, Morocco, Email: elbazzi@yahoo.fr

the fifth section and we conclude by highlighting our contribution and any possible improvements.

2. Related Works

Before starting the keywords extraction, a very important task must be accomplished, which is cleaning and normalizing the text. Tokenization, stop words removal and normalization are frequently used as a preprocessing step. While stemming is the most complicated and discussed issue.

The stemming method consists of extracting the root of a word. In other words, associating the words linked morphologically to the same root. The number of terms is then reduced, which makes the system more effective. This technique reveals a major drawback which is ambiguity.

A root can be defined as a word that cannot be created from other word. For example, the root of the Arabic word ("التصفيات", *the qualifications*) is ("صف", *row*). Although stemming methods cause a big loss of meaning from the original words, these techniques are competitive and provide good classification results. Hence, several works on Arabic text indexing opt for roots as document's descriptors.

Mansour et al. in their work [5], they perform a morphological analysis of the words in a document to extract indexes. First, the authors propose a process of extracting stems. Second, they set up a recognition system of names and verbs, based on rhymes (grammatical patterns) and grammatical rules. A weight is then assigned to each stem taking into account its occurrence and introducing a function indicating how the word is spread in the document

El-Khoribi [6] applied the stemming as a representation of features. Features are represented as vectors that consist of a number of elements equal to the number of classes which the probability of belonging to a class where stems occur. Then a stems lookup table is built from roots and labels of the classes to which they belong. Then, a Hidden Markov Model is used to evaluate the membership of a new document to a class.

Al Molijy et al. [7] used a linguistic method for the extraction of indexes from Arabic documents. Their method is based on the parsing of words document. The proposed algorithm consists of breaking words into N-grams (where N equals 3, 4 or 5), calculate their frequencies, and then retain the first 100 most frequent words, constituting thereby an N-gram document profile. The advantage of this method is the reduction of the number of words representing a document.

Bawaneh et al. [8] compared between the two classifiers K-Nearest Neighbor (KNN) and Naïve Bayesian (NB). The light stemmer was used as feature and TFIDF (Term Frequency – Inverse Document Frequency) measurement as a method of weighting features. The K-NN classifier was considered more efficient.

Gharib et al. [2] applied four classifiers on Arabic corpus which are: SVM (Support Vector Machine), NB, K-NN and Rocchio method, using stemming as features representation technique and TFIDF as weighting method. The Rocchio classifier works better when the feature space is small but the SVM performs better when space becomes larger.

Raheel et al. [3] have shown in a comparative study the influence of the choice of entities representing a document, on manipulating the performance of classifiers. They selected as descriptors, words in their original form, lemmas, roots, and the n-grams. Two classifiers were used, the SVM and Naive Bayesian Networks. SVM based on the 3-grams gave better classification results.

Harrag et al. [9] conducted a comparative study of three pretreatment techniques: light stemming, root-based stemming and dictionary lookup stemming in order to reduce the feature space. Then two classifiers were tested, Artificial Neural Networks and SVM.

Since the stemming is the method of representation which is the most common in text mining preprocessing, several studies have contributed to its improvement [10][11][12][13][14] [15]. However, the extraction of keyphrases has not experienced the same progress [16].

3. Arabic Text Mining Process

المغرب يتجاوز تداعيات أزمة المال هذه السنة
أبدى بنك المغرب ارتياحاً لأداء الاقتصاد في المغرب، خلال 2009، وتوقع أن يتراوح معدل النمو بين 5 إلى 6 في المائة للعام الثاني على التوالي، رغم تداعيات أزمة الاقتصاد العالمية وتأثيرها على إيرادات المغرب من العملات الصعبة والاستثمارات الخارجية.
وتوقع المركزي أن يحقق النمو الاقتصادي 3 إلى 4 في المائة في 2010، ارتباطاً بالإنتاج الزراعي وتحسن أسعار القطاعات الصناعية.

Figure 1: Original text from the used corpus.

3.1. Preprocessing

Before starting the document indexing phase, a very important task is to clean up and standardize the text. The following are the most commonly used steps:

- *Tokenization*

Tokenization is the production of a sequence of segments separated by spaces or punctuation marks. The output is a list of words without neither punctuation, nor special characters.

المغرب يتجاوز تداعيات أزمة المال هذه السنة أبدى بنك المغرب ارتياحاً لأداء الاقتصاد في المغرب خلال 2009 وتوقع أن يتراوح معدل النمو بين 5 إلى 6 في المائة للعام الثاني على التوالي رغم تداعيات أزمة الاقتصاد العالمية وتأثيرها على إيرادات المغرب من العملات الصعبة والاستثمارات الخارجية وتوقع المركزي أن يحقق النمو الاقتصادي 3 إلى 4 في المائة في 2010 ارتباطاً بالإنتاج الزراعي وتحسن أسعار القطاعات الصناعية

Figure 2: text after tokenization.

- *Stop words removal*

Stop words are non-significant terms in a text. It is a about eliminating words whose occurrence is very frequent and do not bring any added value to the process of indexation. These words are usually pronouns, articles and conjunctions.

المغرب يتجاوز تداعيات أزمة المال السنة أبدى بنك المغرب ارتياحاً لأداء الاقتصاد المغرب خلال توقع يتراوح معدل النمو المائة للعام الثاني التوالي تداعيات أزمة الاقتصاد العالمية تأثيرها إيرادات المغرب العملات الصعبة الاستثمارات الخارجية توقع المركزي يحقق النمو الاقتصادي المائة ارتباطاً بالإنتاج الزراعي تحسن أسعار القطاعات الصناعية

Figure 3: text after stop words removal.

- *Stemming*

Stemming can be defined as the process of removing prefixes, infixes and suffixes from words to reduce these words to their stems (roots). To remedy the problem of big loss of meaningful information, the notion of light stemming has been evoked in several works and consists in eliminating just the prefixes and suffixes of a given word without having to go back to its root.

- *Conversions*

The first conversion that can be applied to a document is the elimination of diacritical marks. Diacritical marks are signs added to the top or bottom of the Arabic letters to specify the pronunciation of the word. This phonological role also influences the meaning of this word. Indeed, two words can be written in the same way but differentiated by the addition of different diacritical signs. For example, if the word "عالم" is pronounced (عالم, âalim) it means "scientist", and if pronounced (عالم, âalam) it means "world". This procedure aims to standardize the documents because it is rare to find a fully accented corpus.

مغرب جوز دعا ازم مول سنة ابدى بني مغرب ارتياحا لاداء قصد مغرب خلل وقع روح عدل نمي عوم ثنى ولى رغم دعا ازم قصد علم اثر ردا مغرب عمل صعب ثمر خرج وقع مركز حقق نمي قصد ارتباطا توج زرع حسن سعر قطع صنع

Figure 4: text after stemming and conversions.

The second conversion is that of characters which has for purpose to normalize the letters which can be written in several forms. Thus the characters "إ" ,"أ" and "آ" are replaced by "ا", similarly "ة" is converted into "ه" and "ئ" ,"ي" into "ى". In our system, we did not consider this conversion.

3.2. Term weighting

The weighting of an indexing term is the association of numerical values called weight to that term to represent its power of discrimination for each document in the collection. This characterization is linked to the informativeness of the term for the given document. This notion refers to the amount of meaning that a word carries.

There are several ways to determine the weight of a term. In our case, we have used the TF-IDF (Term-Frequency Inverse Document Frequency) method.

$$Weight_i(j) = TF_{ij} \times IDF_j \quad (1)$$

Where TF_{ij} is the occurrence frequency of term the **j** in a document **i** and IDF_j is the inverse absolute frequency of term **j** in the collection. Thus the weight of a term increases if it is frequent in the document and decreases if it is frequent in the collection.

3.3. Document representation

Document representation is one of the techniques used to reduce the complexity of documents and makes them easier to manipulate, and the document is then transformed from its textual version to a matrix [Document × Term] (Figure 5). The representation of the most used document is the Vector Space Model. The documents are represented by vectors of words. This representation has its own drawbaks as the large dimension of representation and loss of correlation between adjacent words, the thing that leads to the loss of the semantic relationship that exists between the terms in the original document. To overcome these problems, weighting methods are used to assign appropriate weights to the term as shown in Figure 5:

	T_1	T_2	…	T_m	
D_1	w_{11}	w_{12}	…	w_{1m}	C_a
D_2	w_{21}	w_{22}	…	w_{2m}	C_b
…	…	…	…	…	…
D_n	w_{n1}	w_{n2}	…	w_{nm}	C_k

Figure 5 : Document × Terme Matrix.

Each input represents a vector of terms, where w_{nm} is the weight of the term T_m in the document D_n, and C_i is the class assigned to the document D_i.

3.4. Classification

The text classification is an important part of the text mining. It consists in providing a set of learning data (labeled documents) to the classification system. The task is then to determine a classification model that is capable of affecting the correct class for a new document.

Lately, the task of automatic text classification has been widely studied and the progress seems to be efficient in this field [2]. Several classification methods have been compared and proven to be effective, including the Bayesian classifier, decision trees, K-nearest neighbor, Support Vector Machines, neural networks.

The classification of textual documents presents many challenges and difficulties. First, it is difficult to grasp high level semantics and abstract concepts of natural language only a few keywords. This confirms that the efficiency of the indexing step is paramount and entirely decisive.

3.5. Evaluation

Experimental evaluation of classifiers is the last step in the indexing process, and generally attempts to evaluate the effectiveness of a classifier, namely, its ability to make categorization decisions. To this end, there are many measures, each emphasizing one or other property of the system.

We used the most commonly used measures: recall, precision and the f-measure which synthesizes the first two formulas. Let's consider the following nominations:

TP (True positive), FN (False Negative), FP (False positive), TN (True Negative).

$$\textbf{Recall} = \frac{TP}{TP + FN} \quad (2) \qquad \textbf{Precision} = \frac{TP}{TP + FP} \quad (3)$$

$$\textbf{F-measure} = \frac{2 \times recall \times Precision}{(recall + Precision)} \quad (4)$$

4. Proposed Approach: Keyphrases based indexing

4.1. Text features

Descriptors are the units of text that represent its content. There are several categories of descriptors, which attempt, on the one hand, to reduce the size of the document, and on the other hand to preserve its semantic aspect. We quote:

Word: the text is simply segmented into single words after removing stop words.

Lemma: the words of the text are reduced to their canonical forms. The process of lemmatization consists on using grammatical rules to replace verbs by their infinitives and names by their singular forms.

Root (or stem): the stemming process extracts the roots of each word from the text. The words are then associated with their common root.

Concepts: they take the form of a word or group of words, coming from a list of controlled lexicon, generally dictionaries or ontologies.

Keyphrase: it is a sequence of words that describes more perfectly a document than a single word. They maintain better context and semantics. For example, the term "middle east" is more descriptive than "middle" and "east" taken distinctly.

4.2. Keyphrases Extraction Methotds

In this section, we try to give an overview of different used methods for unsupervised keyphrases extraction (table 1). Consequently, our proposed system is completely automatic. The unsupervised methods have the particularity to abstract the specific nature of the processed data.

Table 1: Overview of unsupervised methods for keyphrases extraction

Reference	Approach
Nabil et al. [26]	Combining linguistic methods with statistical methods
Ali et al. [27]	enrich statistical and linguistic information
Mihalcea et al. [28]	A Graph based ranking algorithm
El-Beltagy et al. [29]	Consider the position of the first occurrence of any given phrase
Elshishtawy et al. [30]	Combining the linguistic knowledge and the machine learning techniques
Najadat et al. [31]	Phrase frequency (PF), summation of phrase terms frequencies (Tf), PFIDF (Phrase Frequency - Inverse Document Frequecy), Phrase Position, Title Threshold and phrase distribution
Liu et al. [32]	The best keyphrase must be: understandable, semantically relevant with the document and have high coverage of the whole document
Sarkar et al. [33]	A candidate keyphrase is considered as a sequence of words that does not contain neither punctuations nor stop words, and then this sequence is broken into smaller phrases

4.3. The Used Keyphrases Extraction Method

Our implemented method for keyphrases extraction is inspired from Najadat's [31] approach which uses Phrases frequency. Hence, to extract keyphrases we follow those steps:

1. Segmentation of the text into simple words;
2. Calculating the number of co-occurrences of two (or more) consecutive words. To get a candidate keyphrase, the consecutive words should co-occur at least two times in the given document.
3. Calculate the TFIDF of obtained keyphrases to get the final list of indexes.

5. Results and Discussion

In this work, we have conducted a study about the influence of the choice of features' type on the efficiency of documents indexing. Consequently, experimental results should clarify our hypothesis which considers that keyphrases describe better the content of a document than simple keyword.

For validation, we tested our system on a corpus of 1000 documents of electronic press, extracted from Aljazeera [1] and Alarabiya [2]. This corpus is classified into 3 categories. These categories are: Economics, Politics and Sport.

In this section, a series of experiments was conducted. For each experiment, we used TFIDF as weighting method and the optimal and same Thresholds' values of K-Nearest Neighbor and features selection. Tables 2 and 3 show different classification results obtained for each feature type. These results are expressed through recall, precision and F-measure criteria.

Table 2: classification results using stems

	Recall	Precision	F-measure
Economics	0.164	0.392	0.231
Politics	0.477	0.326	0.387
Sport	0.393	0.351	0.371
Average	**0.345**	**0.356**	**0.350**

Table 3: classification results using keyphrases.

	Recall	Precision	F-measure
Economics	**0.447**	**0.461**	**0.454**
Politics	**0.537**	**0.327**	**0.406**
Sport	0.136	**0.36**	0.197
Average	**0.373**	**0.382**	**0.378**

[1]http://www.aljazeera.net

[2]http://www.alarabiya.net

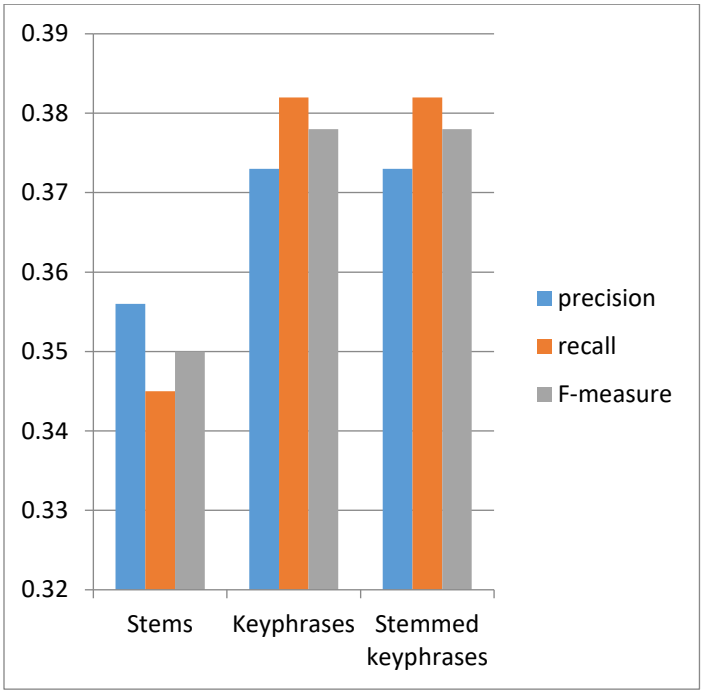
We conducted another test by performing the stemming firstly and then proceeding to extract keyphrases. After this combination, we obtained a list of stemmed-keyphrases. Classification results (table 4) do not show a significant impact of stemming, which explains that the system can stand alone.

Table 4: classification results using stemmed keyphrases.

	Recall	Precision	F-measure
Economics	0.149	0.370	0.212
Politics	**0.731**	0.365	**0.487**
Sport	0.242	**0.410**	0.304
Average	**0.373**	**0.382**	**0.378**

The obtained results show that our approach has an impact on the behavior of the indexes in the classification phase.

Figure 6: Graphic representing the obtained results.



Despite the fact that we were not particularly selective on the keyphrases extraction method, the results are encouraging.

Figure 7: Recall curves depending on each class.

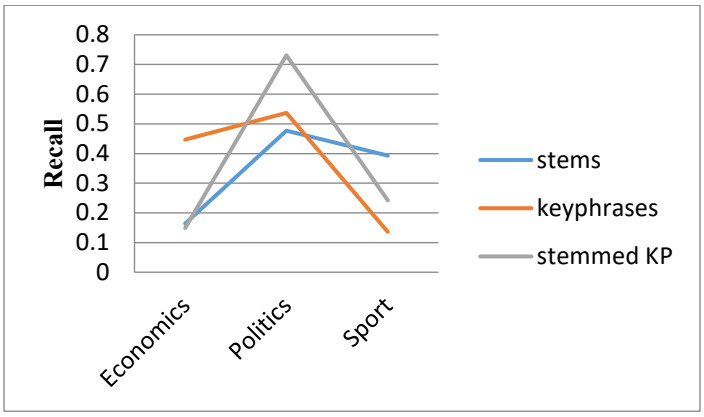


Figure 8: Precision curves depending on each class.

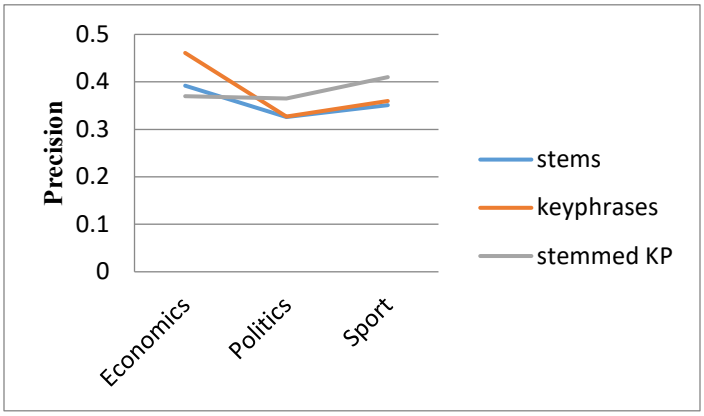

Despite the fact that the results are close for the two approaches (keyphrases and stemmed keyphrases) on average recall and precision (table 3and 4), we clearly distinguish the changes in values according to each domain (figure 7 and 8). This is probably due to the homogeneity of the classes in the corpus. However, our approach reaches up to 73% of recall and 46% of precision in some cases. This leads us to test our approach on other bigger corpus with various classes, and considering adding other improvements.

The experimental results confirms our assumption that keyphrases express better documents than simple keywords. However, this comparison does not, in any way, thwart the approaches presented in related works. Nevertheless, our work could be taken as an advance on what is proposed in the state of the art of Arabic documents indexing.

6. Conclusion

. In this paper, we introduced keyphrases based indexing for Arabic documents. After segmenting texts into simple words, we select candidate terms using the co-occurrence method, then we used the TFIDF formula to obtain the final list of indexes. Our objective is to assess the ability of keyphrases to represent a given document.

On one hand, stemming techniques are used in Arabic text preprocessing to reduce multiple forms of the word to one root. However, the results that we have obtained show that the stem's power of discrimination is relatively low. This may be due to the loss of semantic linking between words during the stemming process. On the other hand, we have proposed a method that extract keyphrases in order to represent document. Although the keyphrases extraction method we used is basic, and based on calculation of frequencies, the results of indexation outperform those obtained by the stem based indexing.

In our future works, we will continue to reveal the semantic information by developing new indexing methods. Nonetheless, we consider developing an efficient method in order to extract Arabic keyphrases. Many other improvements are planned for Arabic document indexation.

ABSTRACT

The concept of renewable energy is increasing day by day because the electrical applications are moving towards utilization of renewable sources and due to this factor electric power is also gaining ground and new type of converters are modelled in order to get high utilization of renewable sources. In this paper, two types of multiport converters are presented which includes a DC-DC converter with a transformer attached and a DC-DC converter without a transformer. The converter with transformer is further subdivided into a full bridge and a half bridge DC-DC converter. The simulation results for all converters are presented and in the end, a case is taken for comparison which involves fixed resistance. The converters are compared with a constant load resistance of 70 ohms in terms of cost, area, complexity, control, isolation, weight and efficiency etc.

1. Introduction

There is an increased trend in the use of multiport converters because of the demand for renewable energy. Electrical applications are moving towards the utilization of renewable energy due to which research in electrical power electronics has increased. With the advancement in renewable energy usage, the DC-DC converter research has also increased and hence multiport converters are being proposed. The multiport converter helps in interfacing multiple sources at a time and delivers power from sources to load simultaneously as well as separately.

In [1] a review of multiport converter is presented. The multiport converters presented in [1] comprises of converters with the transformer attached and detached. The converter with the transformer attached is further subdivided in to Half Bridge Three Port (HBTP) DC-DC Converter and Full Bridge Three Port (FBTP) DC-DC Converter. The advantages and disadvantages of each converter type for each DC-DC converters are presented.

This proposed paper is an extension of [1] where the multiport converters were analyzed at constant load resistance of 70 ohms for each case and they are compared in terms of losses within the converters, area of the converters, cost of converters, controlling of converters and complexity of converters etc.

In [2] an overview is presented regarding multiport converters. The first section contains the information of multiport converter introduction. In the second section, a comparison between the multiport converter and conventional converter is presented.

The conclusion of research involves; every dc-dc converter has its own advantages and disadvantages so it depends upon the applications for which the converter is to be used. In the case of isolation, converters with transformers are to be used while if the isolation is not required then DC-DC converters without transformers are to be used.

In [3] a dc-dc converter topology is presented which has the following advantages:

- Simplification of power conditioning
- Improved utilization of source
- The ports of converter supports bidirectional power flow
- Each port can be controlled individually
- The connected sources of current can be decoupled

*Sarab Al-Chlaihawi, Ph.D. student, University Politehnica of Bucharest, 060042, Romania, +40723062504, sarab.haedar@yahoo.com

With this converter, we can control the level of every individual delivery of power and decouple the associated source of the current in series sources.

In [4] different types of DC to DC converters are used and their computational performances are analyzed along with their efficiencies. The Buck converter gives better computational performance and a high efficiency with the resistance lesser than Resistance at the maximum power point (R_{MPP}) but a low efficiency with the Resistance greater than the R_{MPP}. The Boost converter gave a low computational performance and a low efficiency with the Resistance less than R_{MPP} but a high efficiency with the Resistance greater than R_{MPP}. Similarly, the Buck-Boost converter gave a better computational performance and a high efficiency with the Resistance less than R_{MPP} along with a high efficiency with the Resistance greater than R_{MPP}.

The Cuk converter gave an average computational performance with a medium efficiency with the Resistance less than R_{MPP} but a high efficiency with the Resistance greater than R_{MPP}. The SEPIC converter also gave an average computational performance with a medium efficiency with the Resistance less than R_{MPP} but a high efficiency with the Resistance greater than R_{MPP} while the Zeta Converter gave a better computational performance with a medium efficiency with the Resistance less than R_{MPP} but a high efficiency with the Resistance greater than R_{MPP}.

From the above discussion it can be concluded easily that the buck-boost converter is suitable for Maximum Power Point Tracker (MPPT) because its efficiency is higher in both cases whether the resistance is greater than R_{MPP} or less.

In [5] multiport converters are discussed. The converters are compared in terms of soft switching and isolation. In the conclusion of [5] the advantages and disadvantages of a multi-port dc-dc converter are presented. These are:

- utilization of two or more simultaneous power sources
- lower cost due to semi-conductor elements and fewer passive components
- the power to load can be in higher productions because of multiple sources
- the management of energy can be monitored in a better way

In [6] the comparative study of MPPT algorithm is presented. The MPPT algorithm is used by the controller to get maximum power from the PV panel.

The algorithms presented for comparison are based on Fuzzy Logic for MPPT controller, Incremental Conductance and Perturb & Observe (P&O). The algorithms are tested in standard conditions with atmospheric condition variance. The results obtained are:

- The response of Incremental Conductance algorithm is better at a steady state but it has some errors when compared to the Perturb & Observe algorithm.
- In Perturb & Observe algorithm there is some oscillation at the operating point which results in loss in available power thus PV module efficiency is decreased.
- In Perturb & Observe algorithm the MPP tracking is directly proportional to the step size of perturbation. By higher steps the Maximum Power Point (MPP) is achieved faster but then there are oscillations at steady state.
- The Fuzzy Logic controller provides a better steady state and transient state performance as compared to classical methods. Fuzzy Logic controller tracks MPP with high speed and it has more stability at the steady-state in comparison with Perturb & Observe algorithm and Incremental Conductance algorithm.

For different types and capacities of renewable energy sources, an isolated multiport DC-DC converter is proposed in [7] for its corresponding simultaneous management of power. Only one controllable switch is utilized for each port in which a source is connected. As a result, it has a very limited number of power switches and a very simple topology. The proposed converter's operation and characteristics are explained and analyzed and its applications are discussed.

In order to replace the regular transformer distribution, a solid state transformer (SST) is proposed in [8] which helps enables the formation of power quality features along with providing ports for the integration of the distributed generation (DG) (e.g. photovoltaic (PV)) as well as storage. A quad-active-bridge (QAB) converter based on SST topology is modelled in [8] which facilitates the load isolation along with the isolation of the distributed generation as well as the storage. An average model formulated on the gyrator is developed which helps facilitates a general multi-active-bridge (MAB) converter. Using these expressions, the power ratings of the MAB ports are derived. These results are then applied onto the QAB converter and later on it is analyzed.

For a stand-alone renewable power system application, a systematic strategy is proposed in [9] in order to interface a renewable source, a load and a storage battery with the generated Three-Port Half-Bridge Converters (TPHBCs). If the DC bias current is allowed in the transformer then the half-bridge converter's primary circuit operates as a rectified synchronous buck converter which can help configure a power flow path between the battery and the renewable source which are, as a result, connected in parallel with one of the dividing capacitors. A post and a synchronous regulation has been proposed for various implementations in order to make the voltage on any two of the ports individually controlled.

A three-port converter (TPC) derived from a full-bridge converter (FBC) is proposed in [10] and its systematic approach has been discussed. The methodology helps strips a pair of the switching legs of the corresponding FBCs into two different switching cells with distinct sources attached to it and along with this a DC bias current is also allowed in the transformer. By utilizing the proposed strategy, a full-bridge TPC (FB-TPC) is developed for the applications of the renewable power systems which composes of multiple characteristics which includes: a single-stage power conversion between any two of the three ports, reduced number of devices, an easy and understandable control method and topology.

A three-port DC-DC converter which integrates the photovoltaic (PV) and the power of the battery for a high step-up applications is proposed in [11] in which the topology comprises of two coupled inductors (they help to acquire high step-up voltage

gain and also help reduces the voltage stress produced by the two input switches), two active-clamp circuits (which helps recycles the energy which is stored in the leakage inductors and also improves the efficiency of the system) and five power switches. The operation mode does not require changing in case a transition between the discharging and charging occurs.

The major contribution of the proposed paper is to analyze multiport converters at constant load resistance of 70 ohms for each case and after that, they are compared in terms of losses within the converters, area of the converters, cost of converters, controlling of converters and complexity of converters etc. So this paper is organized as follows:

- Section 2 explains in detail about the Half bridge and Full bridge converters.
- Section 3 discusses the Dual Input Single Output converter (DISO).
- Section 4 is detailed with the comparison between a converter with a transformer and a converter without a transformer.
- Section 5 contains the in depth analyses of the results.
- And at the end in Section 6, the conclusion has been given.

2. Half Bridge Converter and Full Bridge Converter

In the above section, the literature about Multiport converters has been presented. According to the literature the multiport converters have resolved the problems of single input converters and improved the renewable energy interfacing.

The interfaced sources in the multiport converter can be unidirectional or bidirectional and the sources are able to deliver power to load individually and simultaneously. By the use of multiport converters, components are reduced hence cost is reduced, while reliability and power are increased.

The characteristics of multiport converter in comparison with traditional converter are:

- It has a high efficiency.
- It is more reliable.
- It has less number of components but complexity increases.
- Insulation can be attained by adding transformer.
- It supports unidirectional as well as bidirectional power flow.
- It has more control area.
- It has flexibility.

2.1. Operation of converter

Figure 1 shows the half bridge single phase converter. It is composed of two switches (out of which the mostly used switch is MOSFET) and two capacitors, one with source and one with load.

The flow of power inside the inverter varies after every half cycle.

Let the source voltage be 'Vs' for half bridge converter and switching frequency be 'f' and 'T' be the total time of the whole cycle.

$$f = \frac{1}{T} \tag{1}$$

For time $0 < t \leq \frac{T}{2}$ the power flow path is through MOSFET 'S1' and capacitor 'C2'. The voltage obtained at load 'V_L' is

$$V_L = \frac{V_s}{2} \tag{2}$$

For time $\frac{T}{2} < t \leq T$ the power flow path is through the MOSFET 'S2' and capacitor 'C1'. The voltage obtained at load 'V_L' is

$$V_L = -\frac{V_s}{2} \tag{3}$$

It can be seen that the magnitude of 'V_L' is half as half of the voltage is dropped across the capacitor.

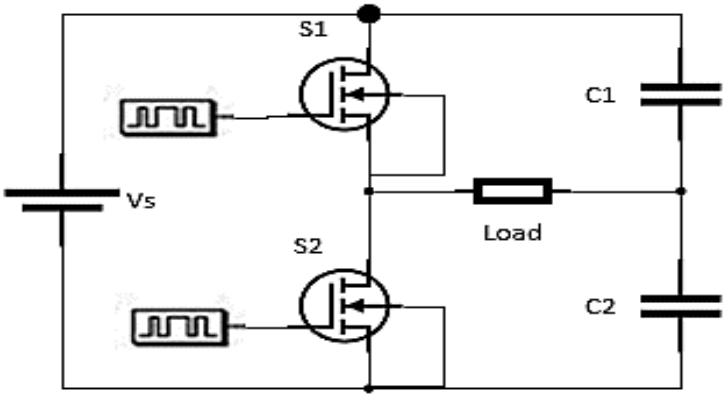

Figure 1: Half Bridge Converter

Figure 2 shows the full bridge single phase converter. It is composed of four switches (of which the mostly used switch is MOSFET), with source and load. The flow of power in the inverter varies after every half cycle.

Let the source voltage for the full bridge converter be 'Vs' and switching frequency is 'f' and 'T' be the total time of the whole cycle.

$$f = \frac{1}{T} \tag{4}$$

For time $0 < t \leq \frac{T}{2}$ the power flow path is through MOSFET 'S1' and MOSFET 'S4'. The voltage obtained at load 'V_L' is

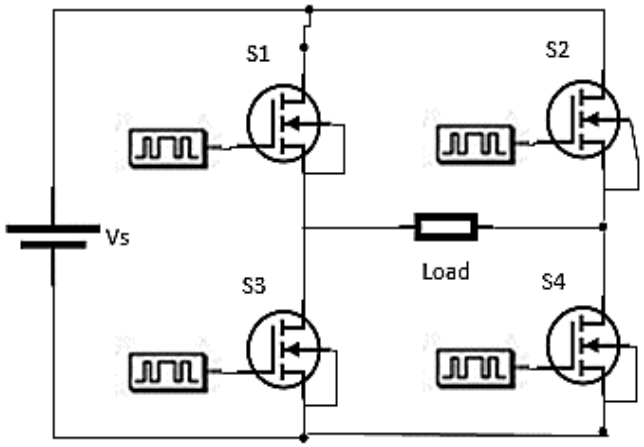
$$V_L = V_s \tag{5}$$

For time $\frac{T}{2} < t \leq T$ the power flow path is via MOSFET 'S2' and MOSFET 'S3'. The voltage obtained at load is 'V_L'

$$V_L = -V_s \tag{6}$$

It can be seen that the magnitude of the voltage at output 'V_L' is increased in comparison to the half bridge converter because half

of the voltage which dropped across the capacitor is now retrieved by using switches instead of capacitors.



The half bridge converter limitation is overcome by using the full bridge converter. So with the help of the full bridge converter, the output voltage is increased.

3. Dual Input Single Output

The dual input single output (DISO) DC-DC converter shown in Figure 3 is presented in [1]. It is a DC-DC converter without a transformer. The converter is composed of one inductor, two capacitors and four switches.

The advantage of this converter is the controlled flow of power between the input and the output. The two input sources are, the unidirectional battery and the PV panel. The use of the battery is to provide power to the load side.

The PV panel is used as a primary source for utilization of the renewable energy while at the secondary source; the battery delivers the power when there is a power reduction from the solar system.

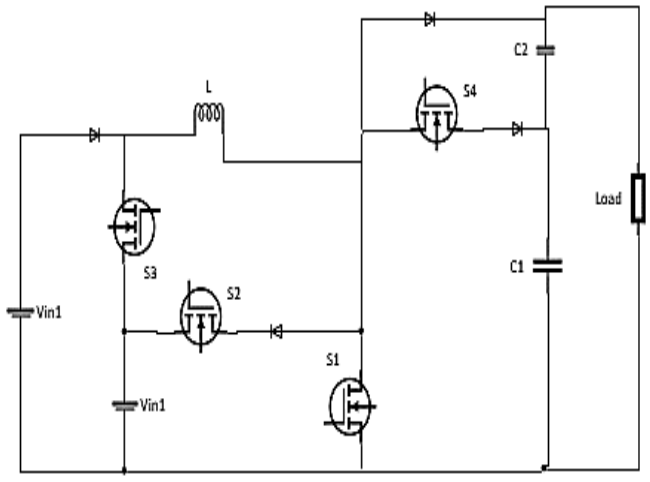


Figure 3: Dual Input Single Output Converter

4. Comparison between Transformer and Transformer-less Multiport Converter

Both the systems, with a transformer and without a transformer, delivers power but with some specifications whether a transformer is required or not in an application, depends on the particular application.

4.1. With transformer

A transformer is used in any of the applications listed below:

- For step up of voltage.
- For step down of voltage.
- For creation of either magnetic or galvanic isolation.
- For reduction of transformer current, Delta-wye transformers should be used.
- Fault current can be restricted.
- For obtaining multiple output voltages, taps in the transformer can be used.

There are also some disadvantages in using transformers:

- Cost increment
- Area increment
- Weight increment
- Reduction in Efficiency

4.2. Without transformer

In comparison to a system with a transformer, the system without a transformer also works, and it has some unique characteristics as well:

- Reduction in Cost
- No heavy circuitry
- Reduction in Weight
- Reduction in number of components
- Efficiency increment
- Fast Response

Some disadvantages of system without transformer are:

- Isolation is not present
- The level of voltage remains the same
- No taps availability as in the case of the transformer

5. Results

5.1. Half Bridge converter

Figure 4 displays the output voltage of the half bridge converter. It can clearly be seen from the graph that the output voltage reaches a maximum magnitude of 19 V after which it stabilizes steadily.

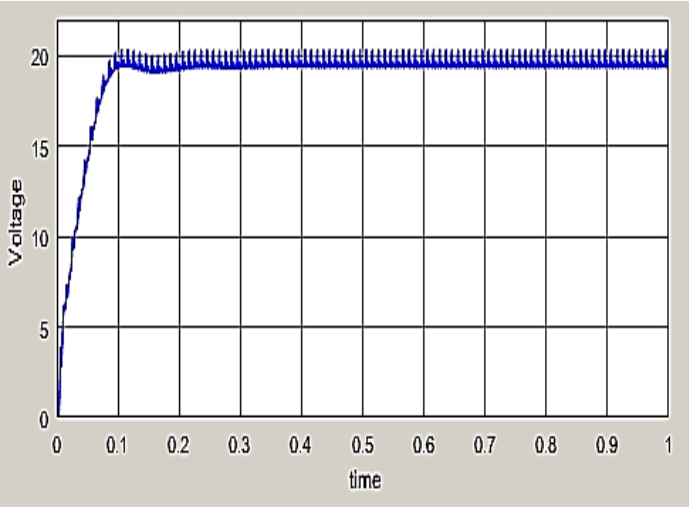

Figure 4: Half Bridge Converter Output Voltage

There is an overshoot produced at 0.1seconds but till 0.2 seconds the voltage stabilizes completely. The ripples produced in the output are due to the capacitor of a smaller magnitude being used. If the value of capacitor is increased the output stabilization time will be high.

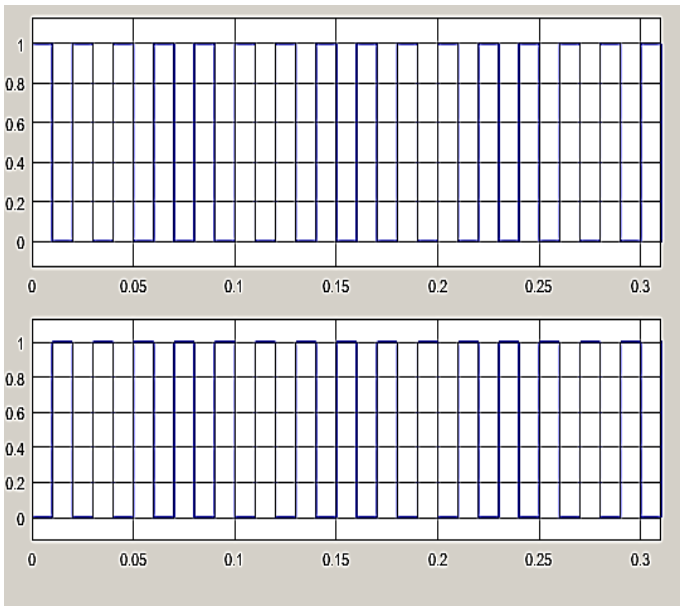

Figure 5: Half bridge Converter Switches Signals

The states of the switches has been displayed in Figure 5, where the first signal displayed has been provided to switch 'S1' while its inverted wave that is displayed in the second signal in Figure 5 is for the switch 'S2'.

This means that while the switch 'S1' is ON, 'S2' will remain OFF and vice versa. Similarly, the same case is observed for the remaining bridges in the converter.

5.2. Full Bridge Converter

In Figure 6, the voltage at the output of the full bridge converter is displayed. It is observed that the voltage can be stabilized at around 190 V till 0.02s with the help of high capacitances.

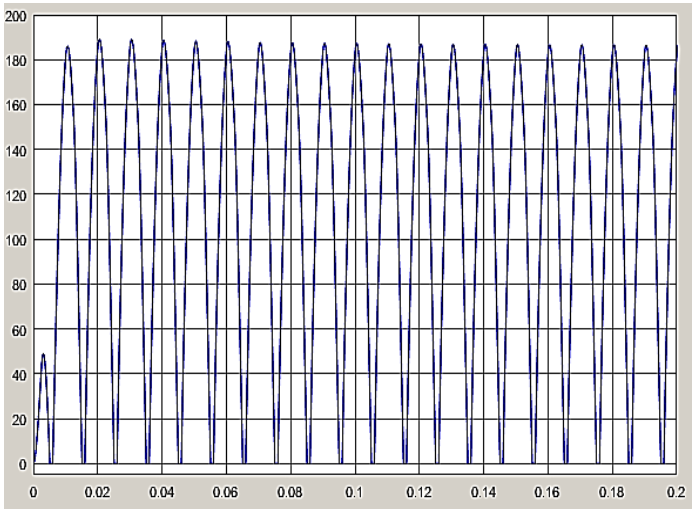

Figure 6: Full Bridge Converter Output Voltage

The produced ripples in the output voltage are a result of using capacitors with small magnitudes. If the magnitude of the capacitors is increased, the output time taken for the converter to stabilize would increase.

The switching signals provided to the H-bridge have been represented in Figure 7. The four signals (from top to bottom) are being provided to the four switches from 'S1', 'S2', 'S3' and 'S4'. For controlling on side of the H-bridge 'S1' and 'S3' are used while 'S2' and 'S4' are used for controlling the other end of the H-bridge. It can be viewed that while 'S1' (signal waveform 1) is switched ON, 'S3' (signal waveform 3) remains OFF and vice versa while when 'S2' (signal waveform 2) is switched ON, 'S4' (signal waveform 4) remains OFF during that interval and vice versa.

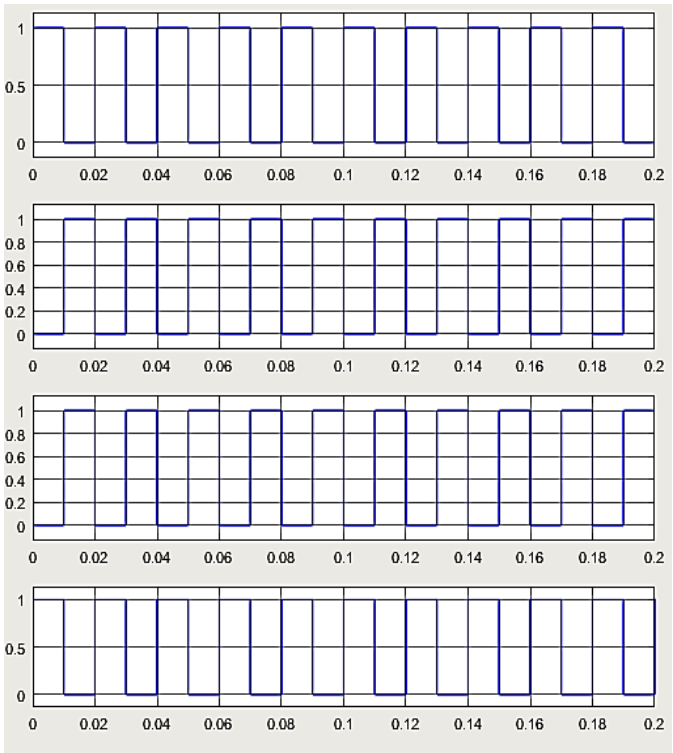

Figure 7: Full Bridge Converter Switches Signals

5.3. Dual Input Single Output

The result obtained at fixed resistance of 70 ohm for all three converters are shown in the table below.

Table: Voltage at inputs and output of multiport DC-DC converter

Type of Converter	Source 1 (V)	Source 2 (V)	Output Voltage (V)
DISO converter (without transformer)	20	20	39
FBTP DC-DC converter (with transformer)	34.5	50	400
HBTP DC-DC converter (with transformer)	34.5	50	152

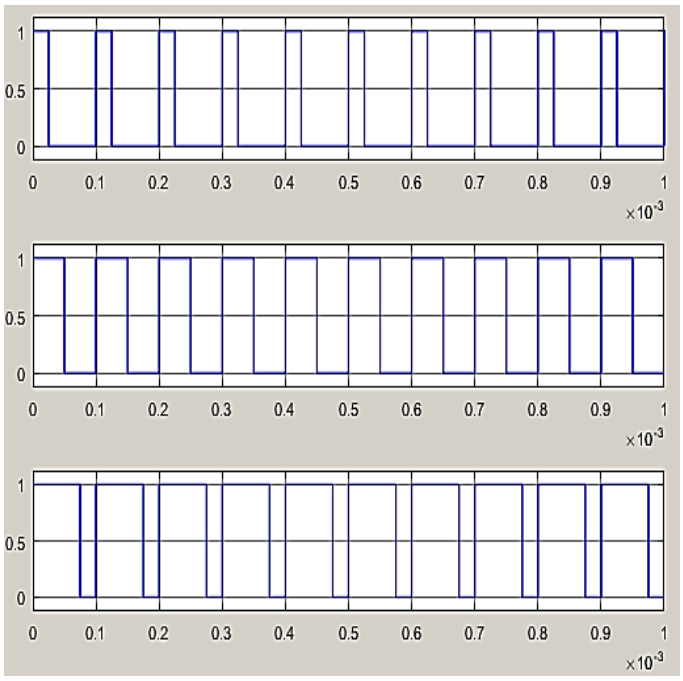

Figure 8: Dual Input Single Output Converter Switches Signals

Figure 8 represents the switching pulses for Dual Input Single Output converter while Figure 9 displays the output voltage for the same DISO converter.

It can be seen from Figure 8 that the switching frequency has been altered a bit for all the three switching signals to a ratio of 0.25%.

The first switch remains ON for 0.25% while the second switch remains ON for 50% and the third one remains ON for 75% for the same time interval (that is from 0 to 0.1ms).

The final output of this converter is displayed in Figure 9, which reaches a maximum of 57V in the overshoot and later on stabilizes at 39V. The time taken for the converter to stabilize in 0.3s.

The efficiency of this converter is quite high compared to the other remaining converters but its major drawback is that one user cannot alter the voltage level in this converter.

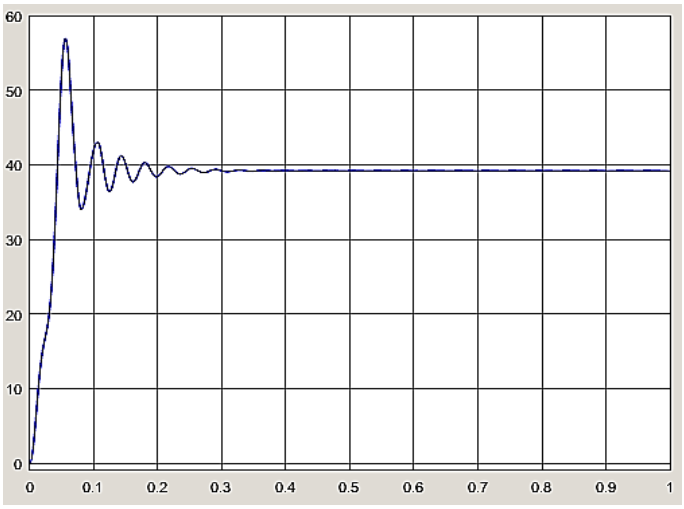

Figure 9: Dual Input Single Output Converter Output Voltage

It can be seen from the above Table that the voltage level of Dual input single output converter remains the same as it is nearly equal to the input source's voltage. The result obtained shows that it is a highly efficient system as losses are very low in this converter. It has a low cost because less number of components are involved in it.

The ripples in the output are very low and the harmonics are not present in this converter. The structure of this converter is quite simple and easy to implement but its control strategy is a complex task.It can be seen from the Table that the input voltage level of the three port full bridge converter is increased. The output result is almost 12 times higher than the input voltage level.

This converter is not efficient as compared to the DISO converter and its cost is higher. The advantage of this converter over the DISO converter is that the voltage level can be increased or decreased as per requirement. The harmonics are less compared to the half bridge converter but the ripples produced in the output are high.

The structure of this converter is complex but its controlling strategy is simple. A little complexity is to cater the switching time of the transistors or switches, so that all the four switches can work properly. It can be seen from the Table that the voltage level of the three port half bridge converter is increased.

The output result is 4.4 times higher than input voltage level. This converter is less efficient compared to the above two converters and its cost is high. In this converter, the efficiency is very low because of high losses in the converter.

The harmonics produced in the output is high and the ripples are also high compared to the full bridge converter. The structure of this converter is not simple but control is quite easy, as only two switches are involved. When one switch is open, the other switch is closed and vice versa.

6. Conclusion

In this paper, multiport converters are discussed. The converters are of different types and a comparison between the converters is presented on the basis of the multiport converter with a transformer and without a transformer. The multiport converters presented in research are divided into two groups. One with a transformer converter and the other without a transformer

converter. The converters with transformer are further subdivided into two parts.

- Full Bridge Three Port DC-DC Converter
- Half Bridge Three Port DC-DC Converter

The advantages of the converter with a transformer are: It steps-up or steps-down the voltage level, provides isolation between the input and output sides, the transformer current can be reduced by Delta-wye transformers, fault current is reduced by impedance, magnetic isolation can be attained and by the taps in transformer we can attain multiple voltages in the output.

The disadvantages of the converter with a transformer are: efficiency reduction, in some cases weight is increased; area increment of converter is also present while the cost also increases. The harmonics components are greater due to the transformer and it has a complex structure (whereas its control is quite easy). Now moving towards the converters without a transformer. The transformer-less converter presented was the Dual Input Single Output converter.

The advantages of the transformer-less converter in comparison to the converter with transformer are: it has a reduced cost factor, less components are used so the area of circuit is reduced. The harmonics are very low and its efficiency is high due to low losses in the converter since the output voltage (39V) is almost equal to the input source voltages (20V each). Its structure is easy to implement.

The disadvantages of transformer-less converter in comparison with the converter with transformer are: only a single level of voltage is obtained, there is no magnetic isolation or galvanic isolation between input and output side, the fault current in not affected as there is no transformer present. The control of this converter is difficult because we have to control more than two pulses at a single time (Source 1 and Source 2).

The complete research work concludes that; every DC-DC converter has its own advantages and disadvantages, so it depends upon the application for which the converter is to be used. For example if we need to change the voltage level, we have to use a converter which contains a transformer while in the case when voltage level change is not required we can use a transformer-less converter.

Wavy FinFET is a hybrid device that integrates FinFET and Ultrathin Body FET technologies on SOI platform to provide high density and drivability without causing area penalty. The problem associated with this device is higher leakage and lower threshold voltage. This problem can be solved by structural modification of the device. This work analyses the performance of Wavy FinFET under various optimization methods such as device/channel engineering, work function engineering, spacer engineering and variation of isolation oxide thickness. The obtained results indicate that optimized Wavy FinFET can act as a solution for low power, highly reliable device topology. Leakage power is found to be reduced by 40.39%, 30.39% and 43.75% with channel engineering techniques such as substrate doping., halo doping and retrograde doping, respectively. Leakage power is lowered by 35.48% and 32.25% with increase in gate work function and isolation oxide thickness respectively. By using high k spacer material 54.77% reduction in leakage is further obtained without compromising drive current. In ADSE(Asymmetric Drain Side Extention) wavy FinFET,leakage is reduced by 61.35%. Whereas in symmetric and asymmetric Dual k wavy FinFET, leakage reduction is found to be 44.19% and 28.25% respectively.

1. Introduction

Gordon Moore predicted the scaling trends in integrated circuits in 1965 [1]. The technology driving factors are reduced cost, improved performance and greater circuit functionality. Scaling causes reduction in gate control over current flow in channel and which will in turn results in short channel effects. In order to mitigate these effects, engineers had to innovate advanced MOSFET structures which can be used in smaller technology nodes. Gate oxide scaling combined with gate length scaling was the traditional MOSFET scaling which ran out in the early 2000's due to leakage limitations. Engineers had to innovate new structures since market was demanding low leakage. Strained silicon is an example of a revolutionary technology that provided improved performance when traditional MOSFET scaling methods were no longer effective [2]. It provided valuable performance enhancements at 90 nm and 65 nm generations. Intel's 45 nm logic technology was the first to introduce high-k + metal gate transistors for improved performance and reduced leakage [3]. Further scaling was achieved using structural change in transistor architecture. A layered silicon-insulator-silicon substrate replaced conventional silicon substrates to form SOI technology[4]. The ultrathin body FET eliminates the leakage paths between source and drain , and thereby control short-channel effects with thin body [5]. Multiple gate devices such as double gate, trigate, pi-gate, GAA devices could achieve better gate control over channel [6]. ITFET (Inverted T channel FET) combines double gate FinFET and single gate SOI to achieve layout efficiency[7].

Wavy FinFET is a hybrid device comprising of FinFET and Ultrathin body FETs [8]. Since UTB (Ultrathin Body) is inserted in the otherwise wasted fin-fin spacing, drivability increases (because of the increased path for current flow) without causing area penalty. The major issues related to wavy FinFET architecture are increase in leakage and reduction in threshold voltage. Optimization are required to mitigate these problems and thereby to obtain better device performance.

* Anju Chakkikavil, Department of Electronics Engineering, College of Engineering Chengannur, 689121, India | Email: anjucraman@gmail.com

In the following session, comparative analysis of trigate SOI FinFET and wavy FinFET are done. After that optimization methods such as channel engineering, work function engineering, spacer engineering and isolation oxide thickness variation are done. Finally the last session concludes this work.

2. Trigate v/s Wavy FinFET

3D structure of Trigate SOI FinFET, segmented trigate SOI FinFET with 3 fins and wavy FinFET having dimensions as per 2013 Overall Roadmap Technology Characteristics Fin-FET parameters specified by the International Technology Roadmap for Semiconductors (ITRS) at the 7-nm technology node [9] were drawn using COGENDA TCAD [10]. In all structures fin height width and fin termination edge are 30nm, 6.8nm and 25nm respectively. Gate length is 18nm and EOT is 0.5nm. The channel is intrinsic and UTB thickness in wavy FinFET is 4.5nm. Fin spacing is 19nm in the case of multifin architecture. The structures are given in Figure 1. It can be seen that Ultrathin body is inserted in the otherwise wasted fin spacing to achieve advantages of two competing technologies. Figure 2 shows the gate cross section of trigate FinFET with single fin, with 3 fins and that of wavy FinFET. We can see that channel area under gate in wavy FinFET is higher compared to that of conventional FinFET.

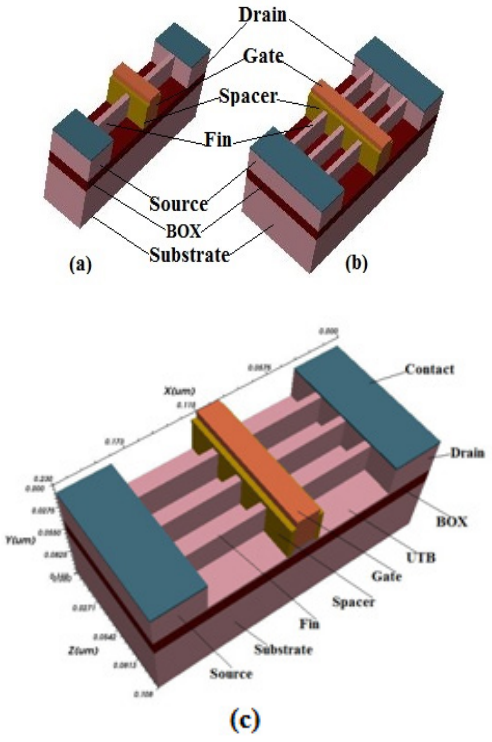

Figure 1.(a) Trigate FinFET with single fin, (b) Trigate FinFET with 3 fins, (c) Wavy FinFET

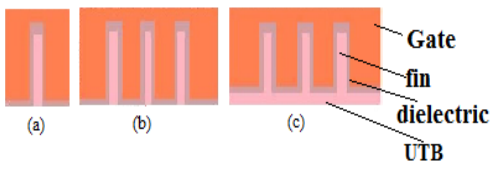

Figure 2. Gate cross section of (a) Trigate FinFET with single fin, (b) Trigate FinFET with 3 fins and (c) Wavy FinFET

Simulations are carried out to analyase the performance of normal trigate FinFET with single fin, trigate FinFET with multiple fins and wavy FinFET. Also the Ultrathin body thickness is varied from 2.5nm to 4.5nm to see the variation of current with ultrathin body thickness. In Table 1, W2.5, W3.5, W4.5 represents wavy FinFET with UTB thickness 2.5nm, 3.5nm, 4.5nm respectively.

Table 1. Comparison of conventional FinFET and wavy FinFET (UTB thickness=2.5nm, 3.5nm, 4.5nm)

Stru Cture	I_{off} (A)	I_{on} (A)	V_t (m V)	SS (m V/d ec)	DIB L
trigate 1 fin	2.05e-13	1.03e-05	372	62	40
trigate 3 fins	3.21e-13	2.43e-05	371	62.8	40.2
W 2.5	1.09e-12	2.79e-05	367	65.7	43.6
W 3.5	3.35e-12	2.95e-05	365	70.2	47.3
W 4.5	1.55e-11	3.82e-05	355	73.9	53

It can be seen that the drive performance of segmented FinFET is better than that of conventional FinFET. In order to increase the drive current further, it is required to array more number of fins which will result in area penalty. At the same time wavy FinFET overcomes this difficulty and current is increased keeping the same footprint area. Also it is found that drive capability and short channel characteristics varies with the thickness of UTB in wavy FinFET. It can be seen that, higher UTB thickness results in I_{ON}. But the problem is along with ON current, OFF current also increases. Threshold voltage of wavy FinFET is lesser compared to that of conventional FinFET which further reduces with increase in UTB thickness.

Due to threshold voltage mismatch between UTB and fins, subthreshold swing and DIBL becomes higher in wavy channel transistor. Hence wavy FinFET has to be optimized to achieve higher I_{ON} with lower leakage power.

3. Optimized Low Power Wavy FinFET

Substrate back biasing is one of the methods for threshold voltage tuning [8]. Reverse back biasing helps to increase the V_t and reduce I_{OFF}. The problem here is that the reduction in leakage is obtained at the expense of ON current. Hence another methods are needed to optimize wavy FinFET, which is discussed in the following sessions of this work.

3.1. Substrate Doping

Doping concentration of the silicon is varied from undoped to 1e17 cm^{-3}. Fig. 3 represents the variation in V_t with doping concentration. V_t increases as doping increases. Table 2 represents the effect of doping on I_{ON}, I_{OFF} and leakage power. Both linear and logarithmic plot of V_{gs}- I_d characteristics with different doping concentration are shown in Figure 4. It can be observed that along with increase in doping concentration, leakage is reduced. Hence leakage power is also reduced. 40.39% reduction in leakage current is obtained by choosing the doping concentration to be 1e17/cm^3. Here a 4.71% reduction in ON current is observed.

Table 2. Effect of doping

Doping (cm^{-3})	I_{off} (A)	I_{on} (A)	P_{leak} (W)
Undoped	1.55e-11	3.82e-05	1.24e-11
1e16	9.79e-12	3.67e-05	7.83e-12
1e17	9.24e-12	3.64e-05	7.39e-12

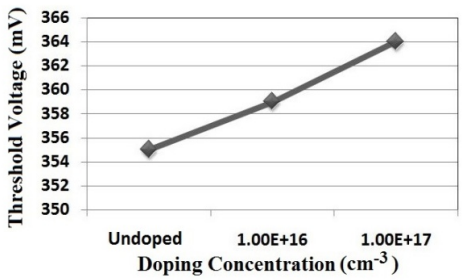

Figure 3. V_t variation with doping concentration

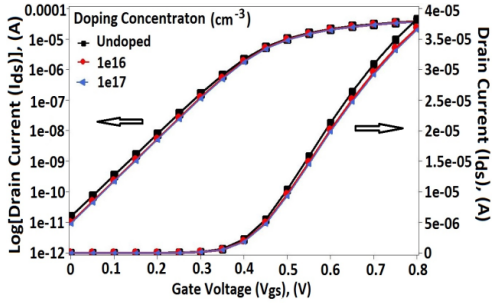

Figure 4. Transfer characteristics with different doping concentration

3.2. Halo and Retrograde Doping

Halo doping can be performed by incorporating highly doped p type region near source and drain ends. Here the drain and source junction depletion region width reduces. It can help in the reduction of DIBL (Drain Induced Barrier Lowering) and punch through. For retrograde doping surface concentration is kept low to increase surface mobility and the subsurface doping is kept high to act as a barrier against punch through [11]. Effect of both halo doping and retrograde doping are shown in Figure 5 and Table 3. By using these methods leakage can be reduced.

Table 3. effect of halo and retrograde doping

	undoped	Halo doping	Retrograde Doping
I_{off}	1.55e-11	1.079e-11	8.718e-12
I_{on}	3.82e-05	3.72e-05	3.696e-05
P_{leak}	1.24e-11	8.632e-12	6.968e-12
DIBL	53	48	45.8

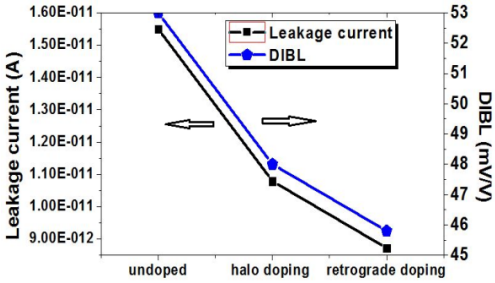

Figure 5. Effect of Halo and retrograde doping

Here the advantage is that we get reduction in leakage power without much sacrificing drive performance. Ion/Ioff ratio also will be higher.

3.3. Work function Engineering

Threshold voltage is dependent work function. Hence by varying gate work function of wavy FinFET, better performance can be achieved. Gate work function is varied from 4.5eV to 4.6 eV. Effect of work function is shown in Figure 6 and Table 4. As the work function increases, threshold voltage increases and leakage reduces. 35.48% reduction in leakage power is obtained by increasing work function to 4.6 eV.

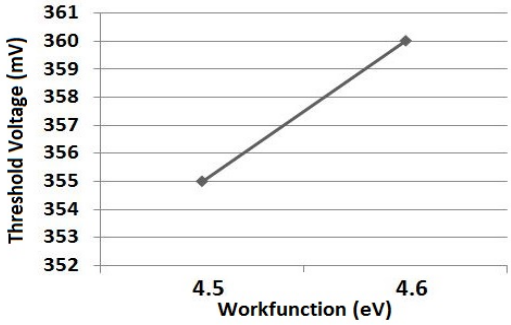

Figure 6. Effect of work function on V_t

Table 4. Effect of work function on performance of wavy FinFET

Work Function(eV)	I_{off} (A)	I_{on}(A)	V_t (mV)	P_{leak}(W)
4.5	1.55e-11	3.82e-05	355	1.24e-11
4.6	1.00e-11	3.73e-05	360	8.00e-12

3.4. Isolation oxide thickness variation

This is a method for leakage suppression. Threshold voltage is directly proportional to isolation oxide thickness. Increasing isolation oxide thickness leads to higher threshold voltage which further leads to reduced leakage. Isolation oxide thickness is varied from 20nm to 40nm. Effect of BOX thickness variation is given in Figure 7. Leakage power is found to be lower in the case of higher oxide thickness.

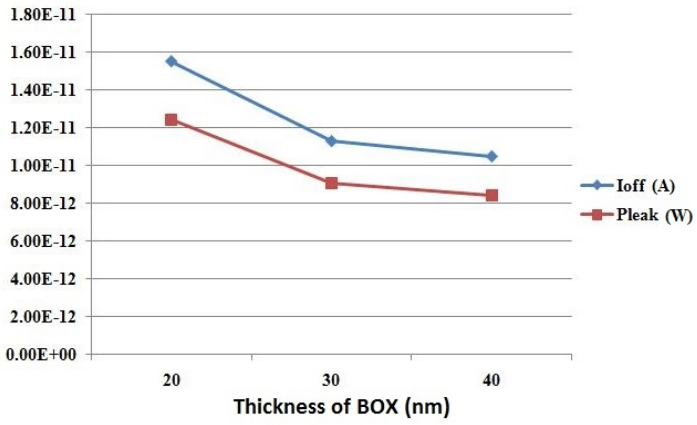

Figure 7. Effect of isolation oxide thickness on I_{off} and leakage power

3.5. High-k Spacer

In sub-20 nm region, short channel effects are reduced using underlap regions. But here on current reduces. Even at high Vds, gate-source/drain barrier restricts source to drain carrier flow. Introduction of high-k spacers can provide strong field coupling from the gate. Effect change in spacer material is checked by using SiO_2 (k=3.9), Si_3N_4 (k=7.5) and Hfo_2 (k=22) as the spacers. Simulation result is shown in Figure 8. As the dielectric constant of the spacer material increases, an increase in I_{on} and reduction in I_{off} can be seen. And thus device can be optimized for lower leakage power and higher I_{on}/I_{off} ratio. Effect of change in spacer material on I_{off}, I_{on}, V_t and leakage power is shown in Table 5.

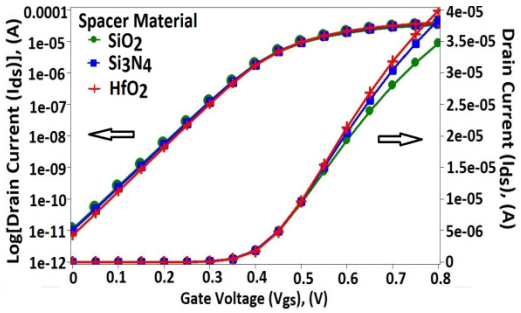

Figure 8. Transfer characteristics of wavy FinFET with different spacer materials

Table 5. Effect of change in spacer material

Material	I_{off}(A)	I_{on}(A)	V_t(mV)	P_{leak}
SiO_2	1.09e-11	3.46e-05	356	8.72e-12
Si_3N_4	1.01e-11	3.84e-05	362	8.08e-12
HfO_2	7.01e-12	3.98e-05	396	5.61e-12

Higher the dielectric strength of spacer, lesser the leakage, and higher the threshold voltage can be obtained which leads to a better device performance. By using HfO2 as the spacer material on both sides of gate, 54.77% reduction in off current is achieved.

3.6. Asymmetric Drain Spacer Extention (ADSE) Wavy FinFET

In asymmetric drain spacer extention FinFET as shown in Figure 9, an additional spacer is introduced only on the drain side to introduce drain-side underlap in FinFET. Thus, bidirectional currents in these transistors are not the same. The spacer thickness at drain side is higher which will result in asymmetry in current and reduction in DIBL. DIBL and OFF current is found to be reduced by using ADSE structure.

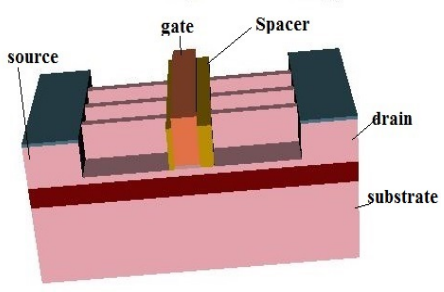

Figure 9: ADSE Wavy FinFET

Effect of ADSE wavy FinFET on drain current is shown in Figure 10. Drain current in logarithmic scale is shown on left Y axis and from which it can be understood that the OFF current is lower in ADSE Wavy FinFET compared to normal wavy FinFET. Here the leakage power is reduced by 61.35% compared to that of normal wavy FinFET.

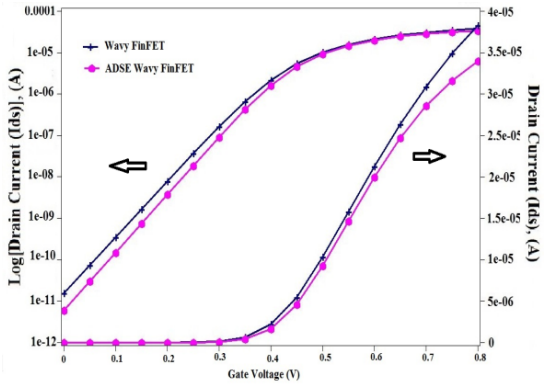

Figure 10: Effect of ADSE Wavy FinFET

3.7. Symmetric and Asymmetric Dual-k Spacer Architecture

The problem associated with high-k spacer is that it increases the fringe capacitance (C_{fr}) that worsens the circuit delay in digital applications [12]. By introducing dual k spacer, instead of single spacer material, inner high-k and outer low-k spacer material is introduced. Interface region between high-k and low k region can make significant changes in device properties. Ion/Ioff can be increased.

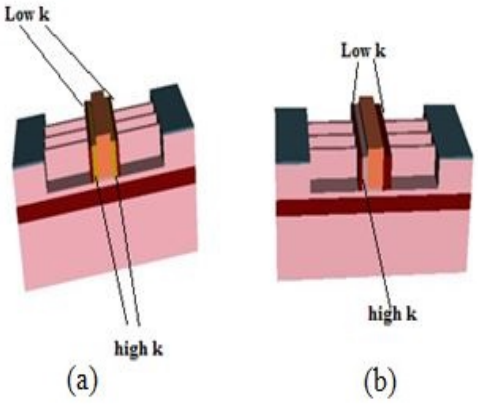

Figure 11: (a)Symmetric dual-k and(b)asymmetrc dual-k wavy FinFET.

In symmetric dual-k as shown in Figure 11(a), there will be dual k spacer on both sides of gate. Where as in asymmetric dual k structure as shown in Figure 11(b), dual k spacer is present only on source side. Effect of introducing symmetric dual-k spacer on leakage power and Ion/Ioff ratio are shown in Figure 12. For dual-k, Si3N4 and HfO2 are used as high k spacers along with SiO2 spacer. 44.948% increase in I_{ON}/I_{OFF} is obtained with symmetric dual-k structure (HfO2- inner high-k spacer) compared to conventional with SiO2 spacer.

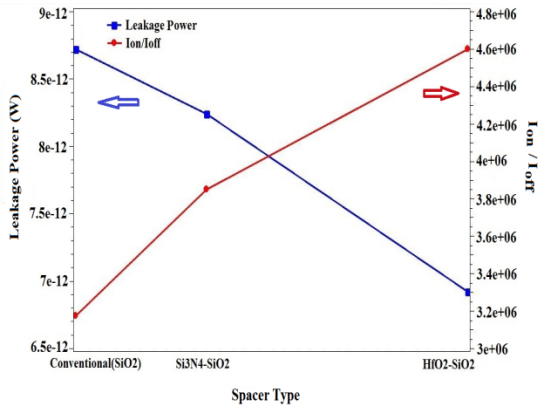

Figure 12: Effect of symmetric dual-k structure

Table 6 shows the effect of introducing asymmetric dual k spacer in wavy FinFET architecture. 28.25% reduction in leakage power is achieved by introducing asymmetric double dielectric spacer in wavy FinFET architecture

Table 6: Effect of asymmetric dual k spacer

Structure	I_{OFF}(A)	I_{ON}(A)	I_{ON}/I_{OFF}	$P_{leakage}$
Wavy FinFET	1.55e-11	3.82e-05	2.46e06	1.24e-11
Asymmetric dual k	1.11e-11	3.76e-05	3.38e06	8.89e-12

3. Conclusion

Since wavy FinFET is a hybrid structure of UTBFET(Ultrathin Body FET) and FinFET, it is found to be better than conventional FinFET in terms of drivability, integration density and area efficiency. The problems associated with wavy FinFET are increased leakage power and degraded SCE. This work could propose structural modifications of wavy FinFET using methods such as channel engineering, work function engineering, variation of isolation oxide thickness and spacer engineering to optimize the device for better performance. I_{ON}/I_{OFF} ratios of optimized structures are given in Figure 13 and Percentage change in leakage power is shown in Table 7. It can be observed that these optimization techniques leads to reduction in leakage and improvement in performance of wavy FinFET.

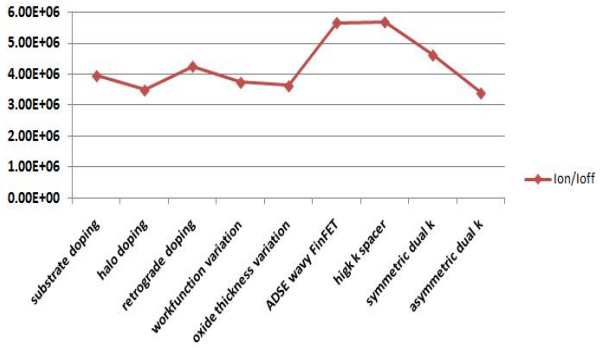

Figure 13: I_{ON}/I_{OFF} in various optimization methods.

Table 7: Percentage change in leakage power and on current with optimization methods

Methods	Value/Percentage reduction in $P_{leakage}$
Unoptimized Wavy FinFET	1.24e-11
Substrate Doping	40.39%
Halo Doping	30.39%
Retrograde Doping	43.75%
Work function Engineering	35.48%
BOX thickness Variation	32..25%
Higk k spacer	54.77%
ADSE wavy FinFET	61.35%
Symmetric dual-k spacer	44.19%
Asymmetric dual-k spacer	28.25%

ABSTRACT

The goal of this paper is to explain the story telling, game design, game play and how is the interaction with the game Program with Ixquic. Here is the description about the new approach to this video game I called Program with Ixquic. Initially focused on an educational video game but now is a hybrid, now has more levels and provides moments of great fun, where each player can have some much fun in each different level and environments of interaction.

1. Introduction

In this article we consider pertinent to ask the following question from which we set out to create this video game. How can you learn to program in object-oriented philosophy with languages such as Java?. To answer this question is that we created a video game that allows players to learn languages such as Java. This video game we call *Program with Ixquic* and we started to create it from the year 2014, conceptualizing and generating ideas, that would allow us to create what we now have a complete and very fun game. *Program with Ixquic.*

Program with *Ixquic*, is a game that started as an educational game to learn object oriented programming in Java language. After some changes now it's an entertainment game with a bit of the topic of education. Program with *Ixquic*, contains three game levels, consisting of a card game, hidden objects and a 3D environment, in Augmented Reality like a fairy tale, where the player can interact and play in different ways to learn some programming.

Fortunately this game has evolved and with this improved remarkably. In this article we show an advance of this development that has been changing over time from being a simple 2D card game to a small *pandora* box full of incredible surprises that each player will enjoy to the maximum.

Program with Ixquic, is a game (in the future a complete *Serious Game*) that contains some ingredients related to training applications, application that improving cognitive functions, memory training, development of mental skills and improvement of strategic skills.

However, there are many applications that are directed to control sensors to calculate heart rate, moods and is applied in either sensory, psychological or motor rehabilitation of the users [8].

2. Serious Games

2.1 How to define a Serious Games

"Serious Games are a mental contest, played with a computer in accordance with specific rules, that uses entertainment to further government or corporate training, education, health, public policy, and strategic communication objectives. [9]"

2.2 What are the objectives of SG?

SGs seek to improve a particular skill of the user interacting with the game. The idea is that while the player interacts more and more with the game will improve some cognitive, sensory or physical ability [9].

3. Story Telling Program with Ixquic

This is the story that starts this video game *Program with Ixquic*, described in a comic that tells the story of a girl named *Cucita* who is one of the characters of *Program with Ixquic*. The story begins in the CDMX in the traffic of a sunny day and *Cucita*

* Tania Patiño, Madagascar Studio, Coyoacán, CDMX, (52)5539813442 & taniapc@live.com.mx

in a moment of thinking about the immortality of the crab, in traffic imagine that it would be a good idea to create a programming application to learn to program in some language programming in basic form. This is the intro of *Program with Ixquic* and from there starts this video game [2], [7],[8].

Figure.1. Story Telling *Program with Ixquic*

4. Game play of Program with Ixquic

Program with Ixquic, consists of a card game, hidden objects and a 3D environment in Augmented Reality with expanded object display, where the player can interact and play in different ways by learning some programming.

To enter the game appears this interface of *Program with Ixquic*:

Figure.2. Interface *Program with Ixquic* [2].

4.1 User-Centered Design in Program with Ixquic

This is an example of how we were creating each level of play, for example, is the card game level, we first generated it with paper and pencil. We tested user to see if it worked and how it worked. Once we have finished, we begin with the design of each letter and each symbol representing an element of nature, a number or a Mayan symbol. This is an application where is involved the user in each phase of the development process which ensures that the final product responds to their needs and characteristics [10]. Then this is the result of the level 1 of the video game *Program with Ixquic.*

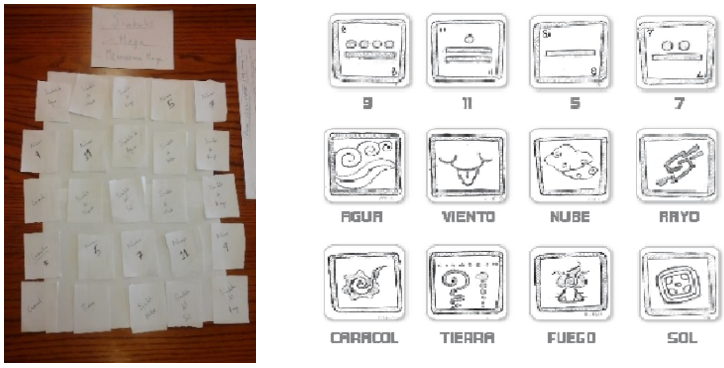

Figure.3.User-Centered Design in *Program with Ixquic*

4.2. Level 1. Card Game

A Card Game, was where we applying the design philosophy and a process related to User-Centered Design (DCU) [10], we understand the requirements and limitations of the end user then we create this type of card game that had magical symbols where we expected that the users can learn and practice in an original way topics related to programming.

This card games comes from ancient times and distinct places in the world: Egypt, India and China. In this case each card has a description of a data structure or a programming concept, thus giving a description of its function[1].

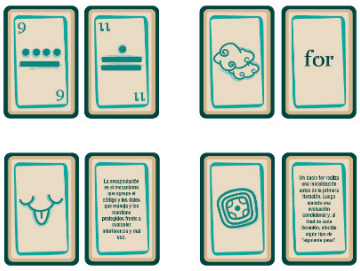

Figure.4. Basic programming concepts

4.3 Level 2 Hidden Figures

In this level called Hidden Figures, we show a landscape where each user have to find (photographs, drawings, graphs, etc.), that are hidden and have to be found. Those things are related to programming concepts or structures, maybe a question is done and then find the thing.

Here is an example of a landscape Yucatán, México, where an investigator have to find many things related to programming topics of Java [6].

Figure.5. Hidden Figures

4.4 Level 4 Augmented Reality

The third level in *Program with Ixquic* is a 3D environment in Augmented Reality with expanded object display. The concept of Augmented Reality brings together a wide variety of user experiences. There are three main categories of RA tools [4],[5].

- Augmented reality games generate immersion experiences.

- Augmented reality 3D visualizer, as it is the case of Augment, allows to place 3D models in real size in the environment, using a 'tracker' to move the model in space.

- Augmented reality browsers enrich the camera viewer with context information. For example, one can point his or her smartphone at a building to visualize a story.

In *Program with Ixquic*, we create a story tale and some interactions with characters in augmented reality technology (RA), and a book with scenarios come to life, allowing gamers to interact with them and experience stories that are told in a more engaging way. This books only need an Internet connection, a camera (it can be a smartphone, a tablet or laptop) to display the tale [2],[3],[4].

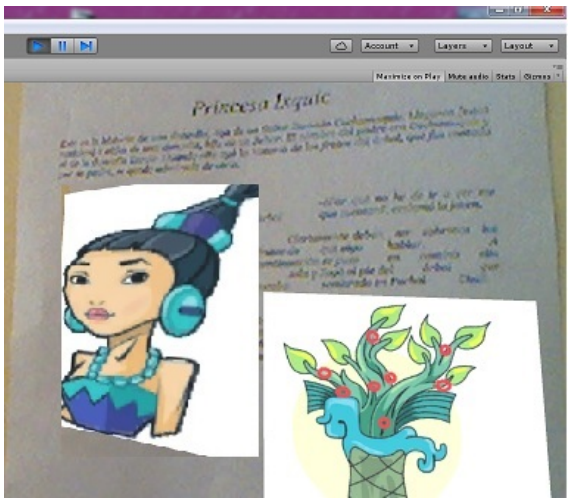

Figure.6. AR *Ixquic Princess Tale*

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

We thank all the team and friends at the National Autonomous University of Mexico, UNAM, specially the Department of Visualization and Virtual Reality, Ixtli, UNAM. Where the development of this Serious Game: Program with Ixquic, started.

Continuing with the creation of *Program with Ixquic,* all the Game Design, Programming levels and Game tests were made at my studio called Madagascar Computer Games and Systems S.A. de C.V. This paper is dedicated to my dear friend *Israel Figueroa Angulo*.

inter-domain

ABSTRACT

To use IP services continually while users are moving with their mobile devices, IP mobility management that enables them to keep IP communication is necessary. Although Mobile IP is a popular method to manage IP mobility, Mobile IP has a problem that there is a possibility of a mobile node (MN) communicating over a redundant route. Then, Software Defined Network (SDN) based IP mobility management has emerged to solve this problem. Most of these solutions focus on intra-domain handovers and routing. However, since wireless network environment has spread, mobile devices move across domains during communication. To deal with this, we need to look upon inter-domain handovers and routing. In this paper, we propose a SDN based IP mobility management scheme considering situation of mobile devices moving across domains. This proposed scheme focuses on inter-domain handovers and introduces efficient functions of management information sharing and inter-domain routing. Experimental results show the desired effects of the proposed scheme: optimizing communication route and keeping the management information exchange traffic low.

1. Introduction

1.1. Background and Overview

This paper is an extension of work originally presented in 2016 18th Asia-Pacific Network Operations and Management Symposium (APNOMS) [1]. Due to the widespread of wireless network environment, it is now possible to use Internet services in various places and scenes, and IP services like file transfer service, remote terminal service, and virtual desktop service are popularly used [2,3]. These services can be used with small-sized devices capable of wireless communication like laptop PCs, smart phones, tablet PCs. We call them mobile node (MN) from now on. MNs are portable, thus people tend to move around while using IP services with MNs. Especially with session continuous IP services, continuity of service during movement may be a problem. When a MN moves and connects to an access point in a different network domain, MN's IP address may change. If MN's IP address changes during communication and communication session is disconnected, this causes some problems that would affect the use of services may occur such as lack of data and logout from services. Thus, IP mobility management is essential for enabling use of IP services while moving.

Mobile IP is one of the IP mobility management standardized by Internet Engineering Task Force (IETF) [4-6]. Mobile IP is a technology to enable continuous communication when a MN moves during a communication. Even when a MN moves to a different domain, it enables the MN to continue its communication with the IP address that it was using before the movement. However, there are cases that a MN's communication route falls into a triangular routing. This might lead to a degrade in quality of service caused by communication delay. Moreover, it is necessary for a MN to be equipped with Mobile IP function, and this leaves a challenge of application to all MNs.

There are some researches that apply Software Defined Network (SDN) to IP mobility management to solve the problems

*Misumi Hata, 2-1-1 Katahira, Aoba-ku, Sendai 980-8577, Japan, +81222175080, Email: m-hata@ci.cc.tohoku.ac.jp

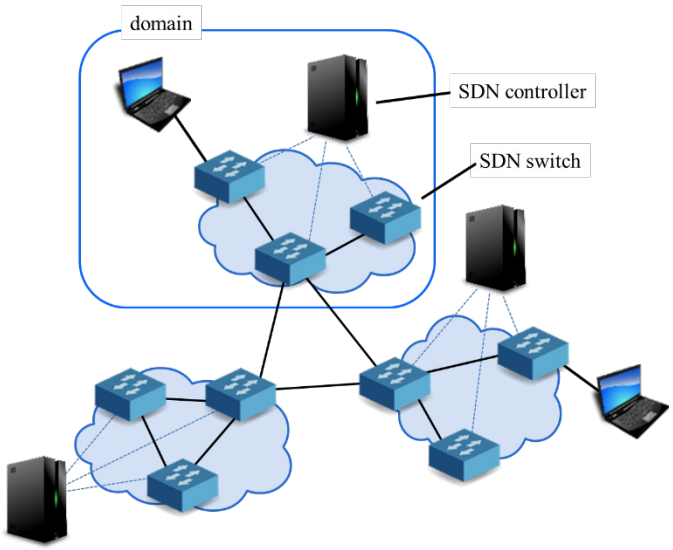

Figure 1 Overview of Software Defined Network (SDN).

mentioned above [7,8]. SDN is a technology to control a network dynamically with a software [9]. We show an overview of SDN in Figure 1. By using SDN, a SDN controller centrally manages SDN switches in their domain and this enables nodes to communicate with suitable route. However, existing researches focus on intra-domain move. To cope with inter-domain movement with SDN, SDN controllers in different domains have to exchange information about movement of a MN. On this occasion, communication cost between SDN controllers may increase and it might become a problem in practical use. Therefore, it is difficult to maintain communication efficiently when a MN makes an inter-domain move.

There were two major trends in ways to handle inter-domain handover with SDN. One approach is to use Mobile IP when inter-domain handovers occurs [8]. By using Mobile IP, SDN controllers doesn't need to search for domains to exchange information of MNs. However, Mobile IP has difficulty in communication route optimization. Another is to announce information of MNs to every controllers in the network [7]. This approach allows the communication routes to be optimized. However, with a network consisted of many domains, communication for the announcement might compress the communication bandwidth. These conventional approaches could only realize efficient data exchange or route optimization.

To overcome both of the problems, we propose an SDN based IP mobility management scheme considering inter-domain handovers. Our proposed scheme consists of two functions. The Management Information Sharing Function (MISF) searches a destination domain of a moved MN effectively and chooses minimum SDN controllers to share minimum information related to MN's communication to manage information efficiently. The Inter-domain Routing Function (IDRF) calculates an appropriate route to allow the MN to continue effective communication.

We also conducted some simulation experiments to confirm the effectiveness of our proposed scheme. The simulation results show that our proposal achieved to optimize communication route and keep traffic between SDN controllers low.

1.2. Novelty and Contribution

To realize efficient inter-domain handovers, we propose a novel scheme to efficiently exchange MNs' information between SDN controllers in each domains and optimize communication route between a MN and a CN. Existing approaches don't realize these two requirements simultaneously because these approaches differ in target, purpose and assumed environment therefore they do not match the purpose of what we concentrate on this time. At the time Mobile IP emerged, route optimization had little meaning because there were not so many candidates of route to be selected. Moreover, it aimed for easy implementation without any modifications in network infrastructure, as it focused on practical use so Mobile IP doesn't have full support to route optimization. The SDN based methods don't aim at covering wide area network and they are approaches for environment with some limitation on scale. Hence they can handle inter-domain handovers but not efficiently. Our proposed scheme realizes 1) efficient information exchange between SDN controllers, and 2) route optimization simultaneously to achieve the inter-domain handovers in large-scaled wide-area network efficiently with functional support of network infrastructure.

With this novelty, mobile communication will be more seamless and delayless. This leads to an improvement of communication quality for users moving around with their communicating MNs. For example, when users with mobile PCs move across domains while downloading data from a cloud server, the disconnection of communication would occur and lead to packet loss. Moreover, when the users move across domains while using interactive-type applications such as remote login terminal or remote virtual desktop environment (VDI), a session would be interrupted. In addition, redundant communication route leads to serious communication delay especially when users are handling large data. By using the proposed scheme, MN users will be able to download or upload their data smoothly and perfectly while moving around. As for the interactive-type applications, MN users will be able to use the services without any termination of the process, even without the applications having the function of switching connections when the IP address changes.

1.3. Paper Organization

In the following sections, we first summarize the problems of Mobile IP and SDN based IP mobility management in section 2. Then we propose the SDN based IP mobility management scheme in section 3, followed by details of functions. In section 4, we evaluate our proposed scheme and show its effectiveness. Finally in section 5, we conclude the paper and discuss future works.

2. Related Work

2.1. Mobile IP

In this section, we introduce related works of IP mobility management and summarize their problems. Internet Engineering Task Force (IETF) standardized Mobile IPv4 to realize IP mobility management [4]. Mobile IPv4 is a protocol to maintain communication between a MN and a Correspondent Node (CN), which communicates with the MN, after the MN moves to other network domain. Figure 2 shows its overview. Mobile IPv4 uses a Home Address (HoA) and a Care-of Address (CoA) to continue communication after MN's move. HoA is an address that MN was using in the source domain and CoA is an address MN is using in the destination domain. The MN registers its binding-cache to its

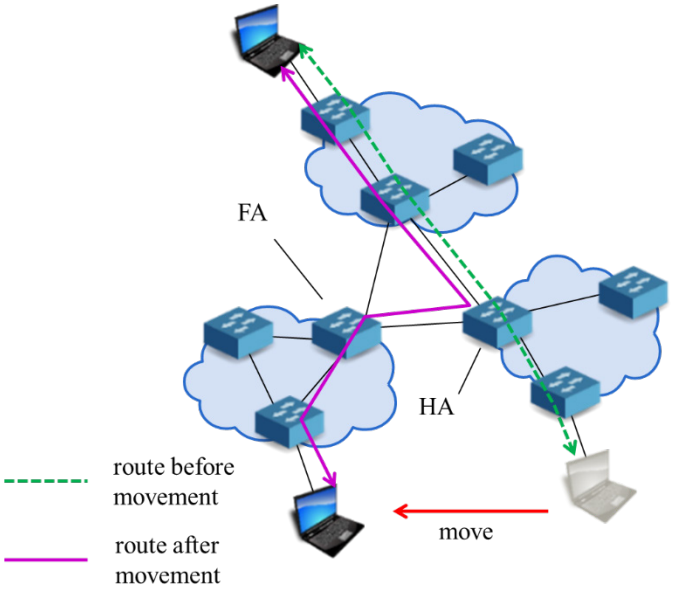

Figure 2 Overview of Mobile IPv4.

Home Agent (HA). Binding-cache is a set of HoA and CoA of a MN. The HA transfers the packets sent to HoA, to CoA. However, there is a possibility that a MN communicate with a CN over a redundant route, which we call triangle routing problem, depending on the location of the HA.

Mobile IPv6 is also standardized by IETF [5]. In addition to functions of Mobile IPv4, Mobile IPv6 has a route optimization function which enables MNs to communicate with the most suitable route. However, this is an optional function so only the MNs with support for route optimization can use this function.

In order to realize IP mobility management, we need to share a variety of information such as HoA, CoA, lifetime of Binding Cache, etc. among a MN, a HA, and a Foreign Agent (FA). IETF standardized Mobile IPv6 Management Information Base [10]. It defines large amount of information needed for Mobile IPv6. It is essential to select where to share plentiful information efficiently to realize IP mobility management. In Mobile IPv4 and Mobile IPv6, the MN registers its binding cache to its HoA. Thus, there is no need of searching for where to share information.

In Mobile IPv4 and Mobile IPv6, the MN needs to conduct IP mobility management. On the other hand, Proxy Mobile IPv6 (PMIPv6) executes IP mobility management on network equipment. Figure 3 shows its overview. The network equipment execute process for IP mobility management in PMIP. Therefore, there is no need of MN to involve in IP mobility management. Local Mobility Anchor keeps bindings of HoA and Proxy-CoA. Mobile Access Gateway (MAG) detects MNs and registers bindings to LMA. After a MN moves, MAG registers the MN's HoA and Proxy-CoA binding to LMA. Packets sent to the MN's HoA are transferred to the MN via LMA. Like Mobile IPv4 and Mobile IPv6, PMIP also has some possibility of triangular routing.

2.2. SDN based IP mobility management

SDN enables us to control networks intensively and flexibly. Therefore, SDN has attracted attentions as a means to solve the route optimization problem. Using SDN, network devices execute

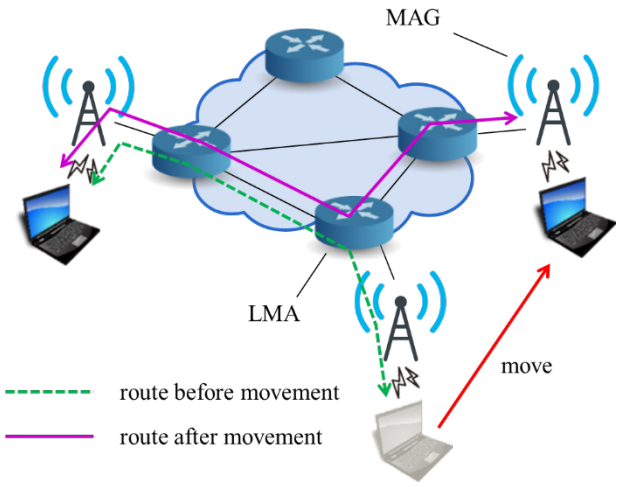

Figure 3 Overview of Proxy Mobile IPv6.

all the IP mobility management processes. Thus, unlike Mobile IPv4 and Mobile IPv6, the MN does not need to be equipped with IP mobility management functions. For this reason, there are some IP mobility management approaches using SDN. Papers [7] and [8] show route optimization mechanisms in the case when intra-domain handover occurs. However, in the case of inter-domain handover, the mechanism in [7] uses Mobile IP, therefore MNs need to be equipped with route optimization function to optimize route after handover. The mechanism in [8] regards inter-domain handover as infrequent and broadcasts this event to all other controllers. Therefore, amount of traffic increases when inter-domain handover occurs frequently in a network consisted by many domains.

2.3. Problems of related works

We summarized the problems of the related works in Table. We confirm that existing works cannot realize intra-domain route optimization, inter-domain route optimization, and efficient selection of domain to share information all together.

The papers [7] and [8] applied SDN to solve the problem of Mobile IP, route optimization, but SDN controllers can only control the network under their managed domain. This means that these approaches focus on intra-domain route. However, in recent network environment, users move freely to various domain networks while using IP services. Therefore, we have to consider the IP mobility management in multiple domain networks.

To realize IP mobility management in multiple domain networks, we need SDN controller in each domain to share information of MNs. However, if a SDN controller broadcasts the information to all other SDN controllers, it might cause large amount of traffic in a situation that inter-domain handover occurs frequently. Hence, we need a mechanism to share information efficiently in multiple domain networks.

3. SDN Based IP Mobility Management Scheme Considering Inter-Domain Handovers

3.1. Overview

In this section, we propose a SDN based IP mobility management scheme considering inter-domain handovers to solve the problems explained in section 2. We first show the

Table Summary of related works

approaches	Mobile IPv4 [4]	Mobile IPv6 [5]	PMIPv6 [6]	Paper [7]	Paper [8]
Intra-domain routing	×	△	△	○	○
Inter-domain routing	×	△	×	○	△
Domain selection to share information	○	○	○	×	○

overview of our proposed scheme and discuss the details of composing functions later. We show the overview of our scheme in Figure 4. This approach realizes inter-domain route optimization while sharing information efficiently with two functions; Management Information Sharing Function and Inter-domain Routing Function.

The Management Information Sharing Function (MISF) searches for the domain which MN was in before movement (source domain) and modifies the domain to exchange MN information to reduce traffic load between SDN controllers. The Inter-domain Routing Function (IDRF) calculates end-to-end route between MN and CN in the domain MN moved into (destination domain) and announces this route only to the domains in the path to optimize inter-domain routes.

We assume that inter-domain topology changes do not occur frequently. Therefore, the SDN controllers have an inter-domain topology information. Inter-domain topology information consists of SDN controller's IP address of each domain, network address of each domain, and inter-domain link information. The functions we mentioned above use this inter-domain topology information to search domain and calculate routes.

We show the components of our proposal in Figure 5. The components include SDN controllers, SDN switches, a MN, and a CN. Our scheme supports IPv4 network with two layers of network: a SDN controller network and a SDN switch network. SDN controller network is consisted of each domain's SDN controller and is used for SDN controllers to exchange information to optimize MN-CN route. SDN switch network is consisted of SDN switches. We call the SDN switch network managed by one SDN controller "domain".

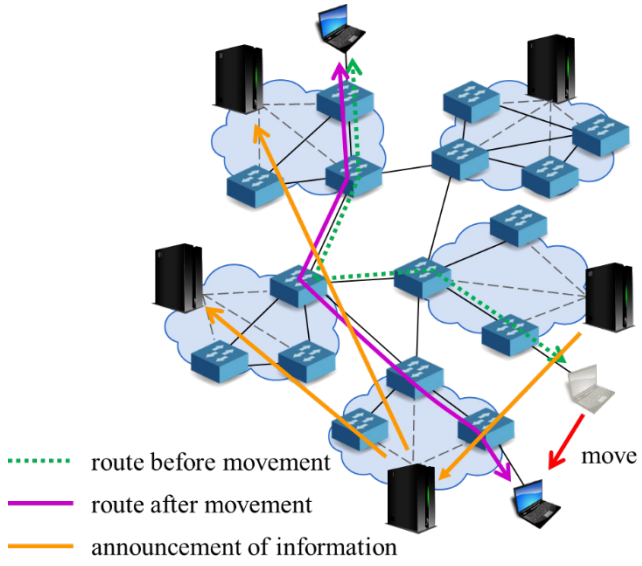

Figure 4 Overview of SDN based IP mobility management considering inter-domain handovers.

3.2. Management Information Sharing Function

We describe the detailed design of MISF with an example. The network we use for explanation is shown in Figure 4. We assume that a MN moves to a destination domain from a source domain during a communication with a CN and the SDN controller of the destination domain detects the connection of the MN. The MN's IP address changes after move. We show below the MAC address, IP address which the MN was using in the source domain (former IP address) and IP address which the MN is using currently in the destination domain (current IP address).

- MAC address: 00:00:00:00:00:11
- former IP address: 10.0.1.1
- current IP address: 10.0.2.1

We define the names of domains and SDN controllers that involve in MN handover as below:

- Domains

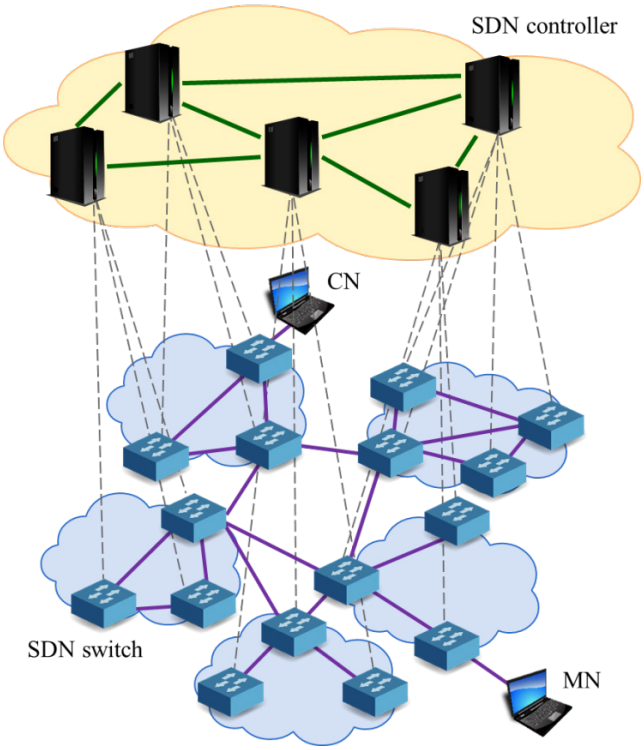

Figure 5 Network configuration.

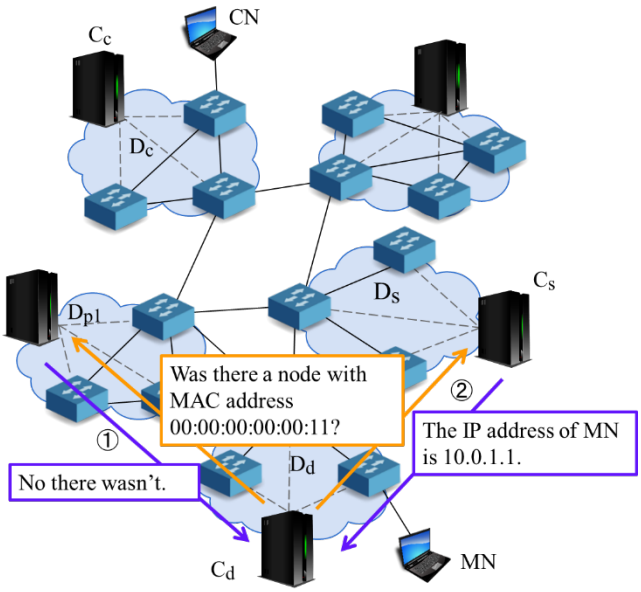

Figure 6 Search for D_s.

- D_d: the domain that MN belongs to after move
- D_s: the domain that MN belongs to before move
- D_c: the domain that CN belongs to

- SDN controllers
  - C_d: SDN controller that manages D_d
  - C_s: SDN controller that manages D_s
  - C_c: SDN controller that manages D_c

We describe the procedure of MISF step by step.

1. C_d searches for D_s based on MAC address of MN.

   C_d sends queries in order from neighboring domains like in Figure 6. SDN controllers of the domains that received the query search their domain to check if MN belonged to, and sends the result to C_d for a reply. When MN was not in their domain, they reply the absence of MN. When MN was in their domain, they reply the IP address MN was using.

2. C_d generates node connection information from the IP address sent from C_s.

   Node connection information consists of following information.

   - MAC address of MN
   - former IP address
   - current IP address

3. C_d sends node connection information to C_c.

   C_d sends the information as shown in Figure 7. On this occasion, C_d gets the IP address of CN from header of the packet sent from MN to CN and derive the information of C_c.

3.3. Inter-domain routing function

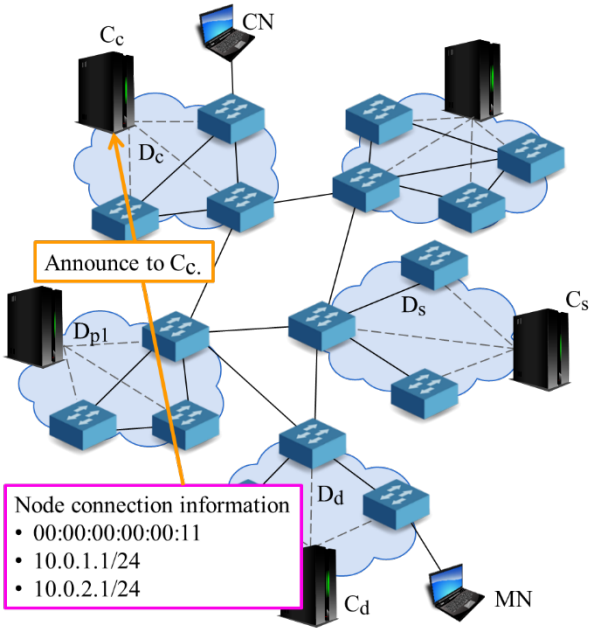

Figure 7 Announcement of node connection information.

Next, we explain the detailed design of IDRF following the example we used in the explanation of MISF in section 3.2.

1. C_d calculates the MN-CN inter-domain route.

   We regard each domain as a node and calculate inter-domain route. We take the number of inter-domain hops (N_{hop}) and the total number of flow entries that are needed to be installed in SDN switches (N_{flow}) into account to select a route that is the shortest and able to suppress the resource consumption of SDN controllers.

2. C_d announces the route information to the SDN controllers of the domains to go via the selected route.

   In the example, C_d announces the route to the domains shown in Figure 8.

3. Each SDN controller generates flow entries based on the received route information and installs them to their corresponding SDN switches.

   Especially, the SDN switch that the CN connects to check flow entries and rewrites the packets sent between the MN and the CN based on the node connection information. This keeps the IP address of the MN seen from the CN the same as before and it enables the communication to continue between the MN and the CN as before movement. Concretely, we set the flow entries as shown below.

   - Rewrite the destination IP address of the packets sent from the CN to the MN from former IP address to current IP address.
   - Rewrite the source IP address of the packets sent from the MN to the CN from current IP address to former IP address.

We would explain the detail of Step 1 mentioned above. Concretely, we choose the route with minimum N_{flow} in the routes with minimum N_{hop} in the following steps.

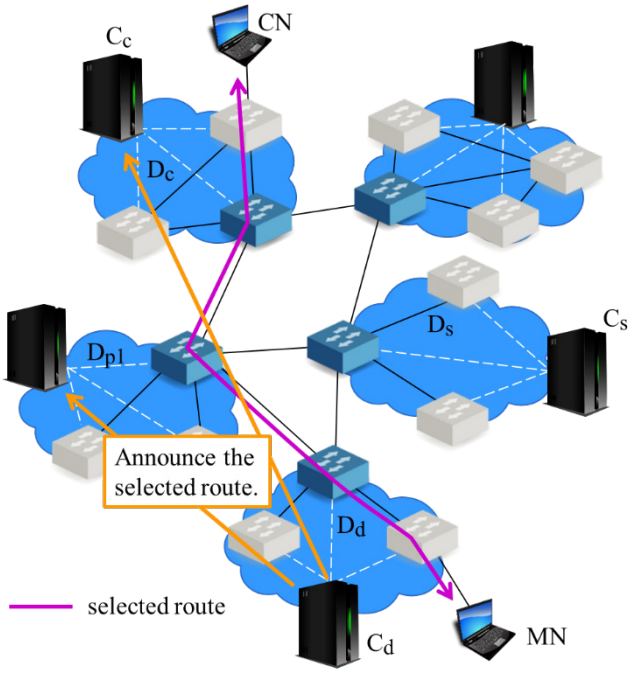

Figure 8 Announcement of inter-domain route.

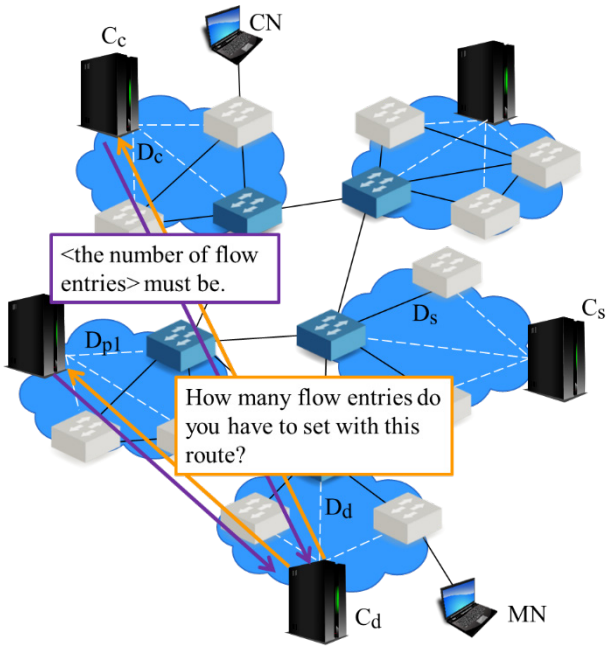

Figure 9 Inquiring N_{flow}.

1. C_d checks for routes with minimum N_{hop} based on inter-domain topology information.

   We use breadth first search algorithm for this search.

2. If there is only one route with minimum N_{hop}, we choose this route as the shortest route. If there are two or more routes with minimum N_{hop}, we then compare N_{flow} of each route.C_d asks SDN controllers of each domain via listed route the number of flow entries they need to install for each route like in Figure 9. The SDN controllers reply the number of flow entries to C_d and C_d calculates N_{flow} of each route.

3. C_d chooses the route with minimum N_{flow} as the finally decided route.

4. Performance Evaluation

4.1. Overview

We carried out simulation experiments to validate an effectiveness of our proposed scheme. Especially, we confirmed the reduction on both communication load between SDN controllers by MISF and reduction effect on communication delay between a MN and a CN by IDRF.

We used OpenDaylight Lithium [11] as SDN controllers, Open vSwitch [12] as SDN switches, and OpenFlow1.3 [13] as the communication protocol between the SDN controllers and the SDN switches. We implemented the two functions we introduced in section 3 into SDN controllers.

We equipped two approaches for comparison with our proposed scheme.

- approach 1: announces move of MN to all domains

  We replaced MISF to a function to announce the movement of MN to all the SDN controllers [8].

- approach 2: transfers packets sent to MN from source domain

  We replaced IDRF to a function to set route via the domain where the MN belongs to before moving [4-7].

We constructed a virtual network as an experimental network with Mininet2.2.1 [14]. The bandwidth capacity of the links between SDN switches are set to 1Mbps and delay of each links is set to 10ms.

The experiments are conducted in the following scenario:

1. A MN moves from D_s to D_d 5 seconds after the MN and a CN started communication.
2. C_d searches for source domain and retrieve former IP address of the MN.
3. C_d generates node connection information and announces it to C_c.
4. C_d calculates new communication route between the MN and the CN.
5. C_d announces the new route and SDN controllers of the domains involved in the new route install flow entries.

In this paper, we carried out three types of experiments.

- Experiment 1: evaluation of MISF
- Experiment 2: evaluation of IDRF
- Experiment 3: comprehensive evaluation of the proposed scheme

4.2. Experiment 1: Evaluation of MISF

In Experiment 1, we focused on traffic loads of communication between SDN controllers. We arranged three networks: each network consists 5, 10, and 15 domains, respectively. The number of inter-domain hops between source domain and destination

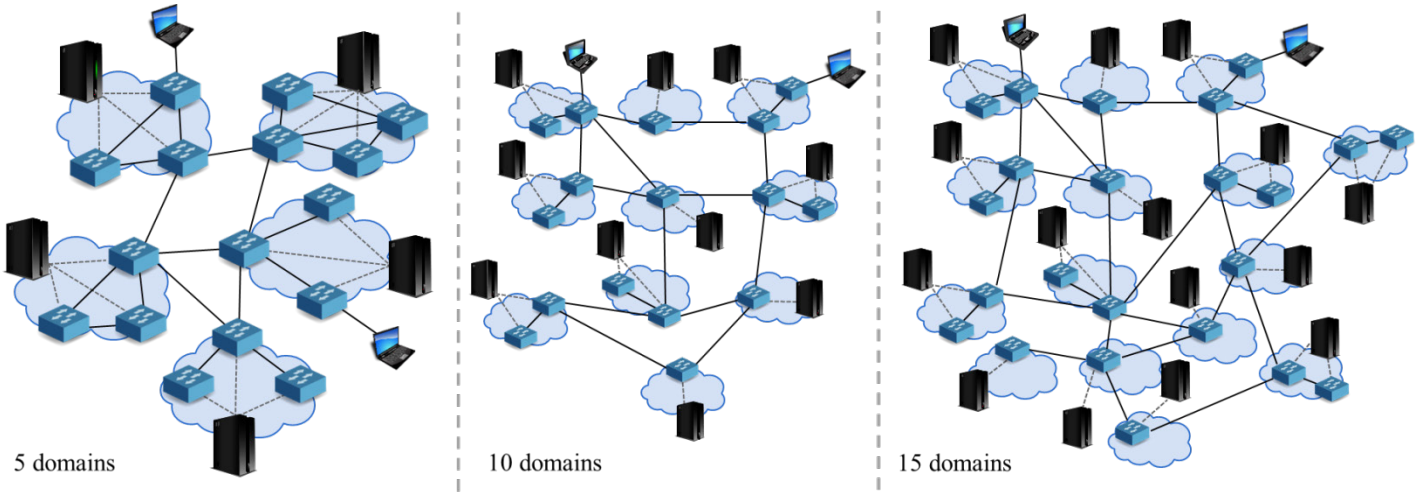

Figure 10 Experimental network topology in Experiment 1.

domain is 1. The domains increase concentrically like shown in Figure 10.

Figure 11 shows how the traffic load changed as the number of domains changed. In case of approach 1, traffic load increased according to the increase of number of domains. In contrast, traffic load in the case of proposed scheme did not raise even though the number of domains increased.

4.3. Experiment 2: Evaluation of IDRF

In Experiment 2, we focused on the delay of communication (Round Trip Time: RTT) between the MN and the CN after MN's move. We arranged a network with 10 domains and set the number of inter-domain hops between D_d and D_s to 1, 2, and 3, respectively, as shown in Figure 12.

Figure 13 shows the result of Experiment 2. In the case of approach 2, RTT increased according to the increase of number of inter-domain hops between D_d and D_s. In contrast, the proposed approach succeeded to keep RTT less than that of approach 2 in any case.

4.4. Experiment 3: Comprehensive evaluation of the proposed scheme

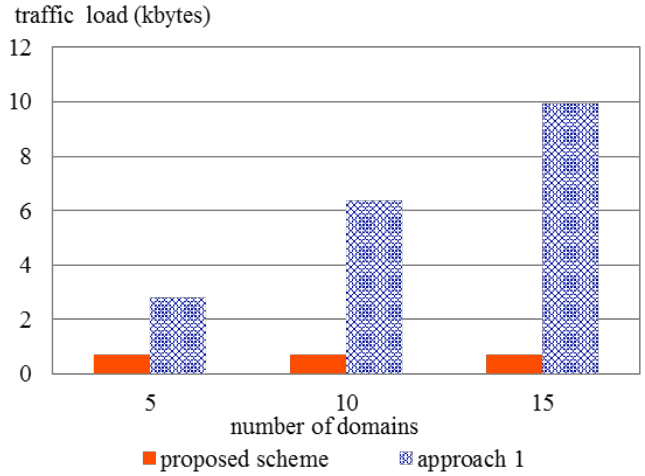

Figure 11 Experimental result 1: Traffic load of communication between SDN controllers.

In Experiment 3, we compared traffic load between SDN controllers and the RTT between the MN and the CN of the proposed scheme, approach 1, and approach 2. We set the parameters as below:

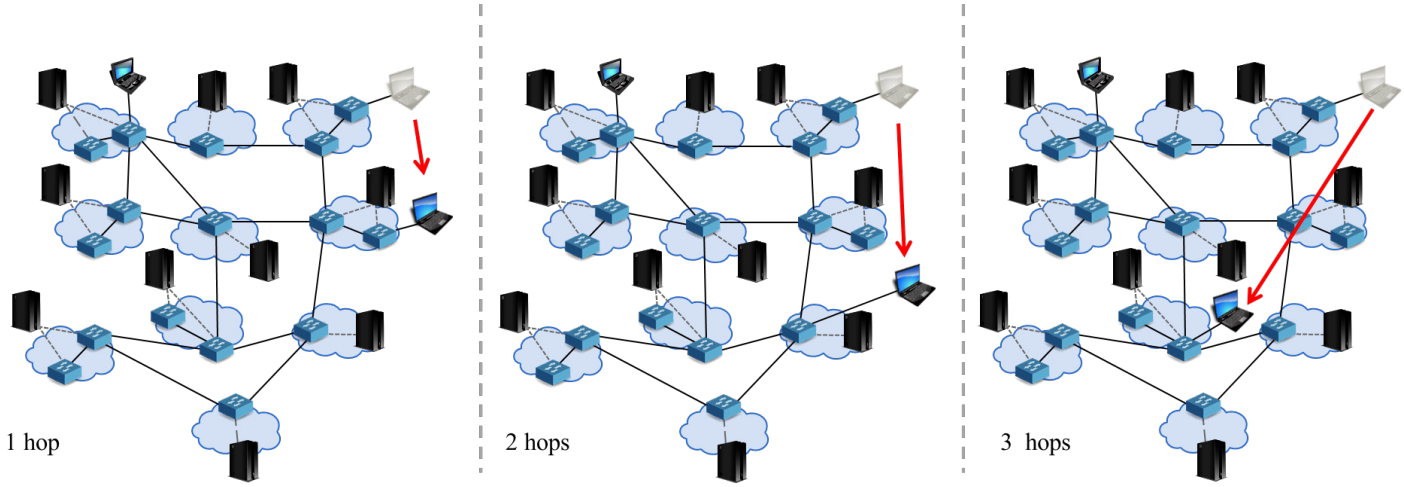

Figure 12 Experimental network in Experiment 2.

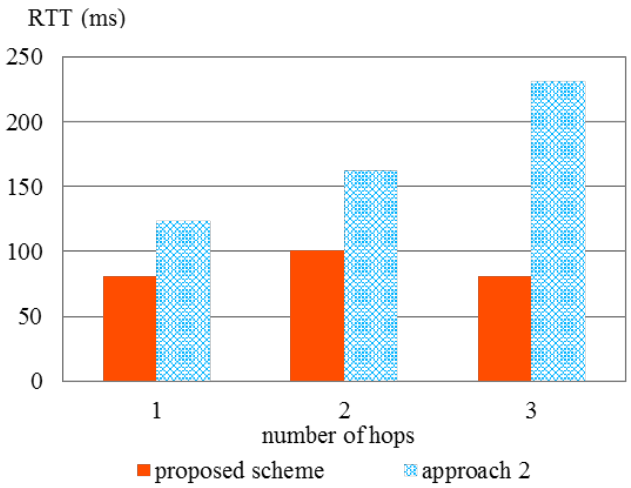

Figure 13 Experimental result 2: RTT between the MN and the CN.

- The number of inter-domain hops between the MN and the CN: 1, 2, 3
- The number of domains consisting an experimental network: 8, 9, 10

Figure 14 shows the topology of network when the number of domains are 8, 9, and 10, respectively. The MN moves as indicated by the arrows in the figure.

We show the traffic load between the SDN controllers for each number of hops between the MN and the CN in Figure 15. Traffic loads increase as D_s gets farther from D_d with the proposed scheme and the approach 2, whereas with the approach 1, traffic load was not affected by the number of hops but influenced by the number of domains.

Figure 16 shows the RTT of the communication between the MN and the CN for each number of domains. With the proposed scheme and the approach 1, RTT differs by the number of hops but is always smaller than that of the approach 2 in any case. With the approach 2, RTT increased as the number of hops between D_s and D_d got bigger. However, the results of the proposed scheme and the approach 1 showed no relevance to the number of hops between D_s and D_d.

4.5. Summary of evaluations

We discuss the results of Experiment 1. In case of the proposed scheme, the closer the source domain was to destination domain, the smaller the traffic load was because our scheme queries from neighbors.

However, the traffic load of the approach 1 increased as the number of domains increased. This is because the approach 1 announces to all the domains in the network regardless of the position of the source domain.

Next, we discuss the results of Experiment 2. In case of the proposed scheme, the number of inter-domain hops does not become larger than the number that can be taken by the approach 2. Therefore, the communication delay in proposed scheme gets smaller than approach 2. This is due to the fact that the longest route the proposed scheme chooses is the same route as the one chosen by approach 2.

Finally, we analyze the results of Experiment 3 according to the following viewpoints: traffic load between SDN controllers and RTT of communication between the MN and the CN after MN's movement.

First we talk about traffic load between SDN controllers. The proposed scheme and approach 1 exceeded approach 2 in traffic load between the SDN controllers. However, as the number of inter-domain hops between source domain and destination domain got bigger, traffic load of the proposed scheme and approach 2 tended to get bigger. For examples, we understand that when D_s and D_d were 3 hops away, traffic load of proposed scheme was pretty similar to that of approach 1 as we can see from Figure 15 (c). As D_s was 3 hops away from D_d, C_d ended up searching all the domains. When D_s and D_d was 2 hops away, traffic load of approach 2 was the biggest of all approaches. Approach 2 used MISF, the same function as the one proposed scheme uses. Thus, the traffic load of this function was the same as that of the proposed scheme. The difference came from the traffic load of IDRF. The difference in the communication route

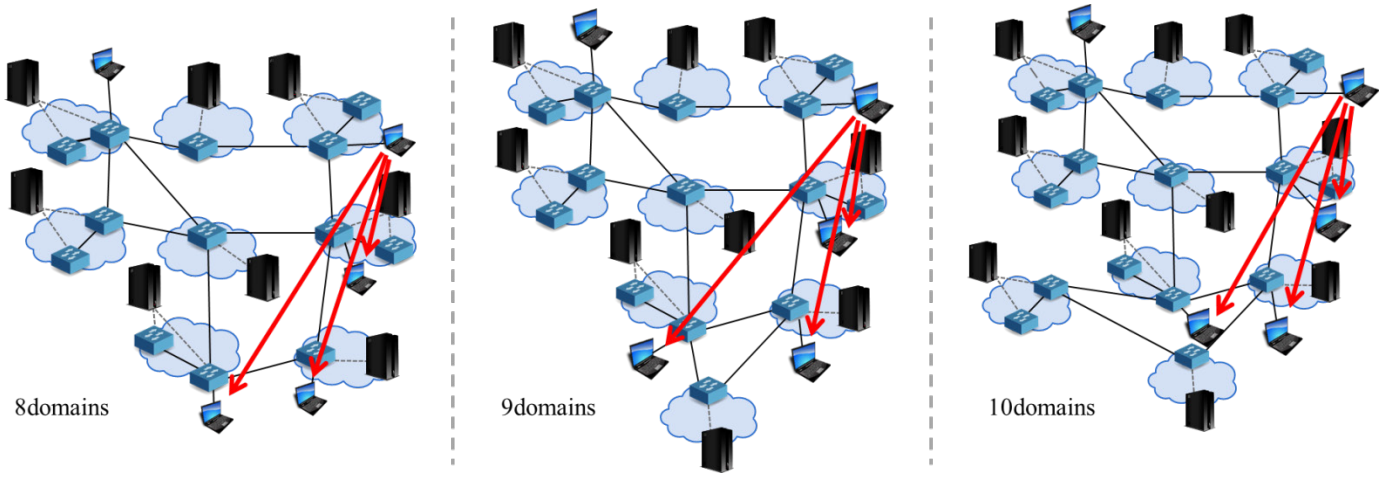

Figure 14 Experimental network topology in Experiment 3.

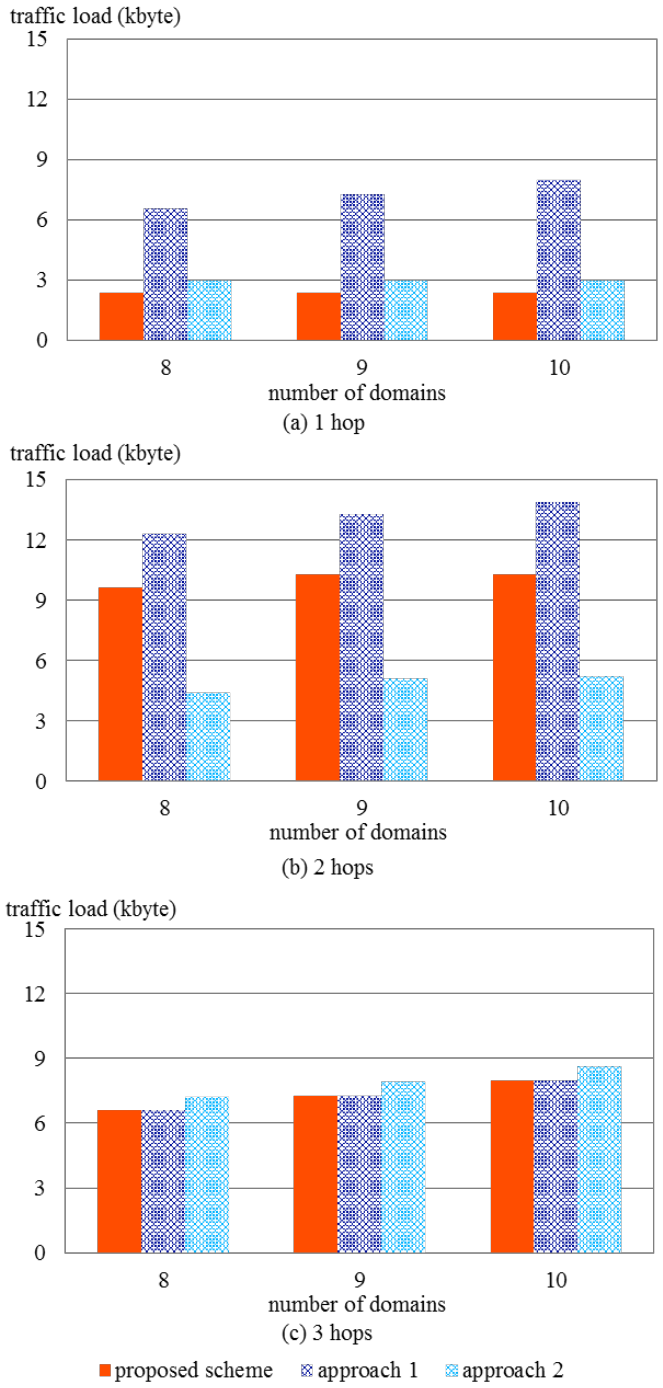

Figure 15 Experimental result 3-1: RTT between the MN and the CN.

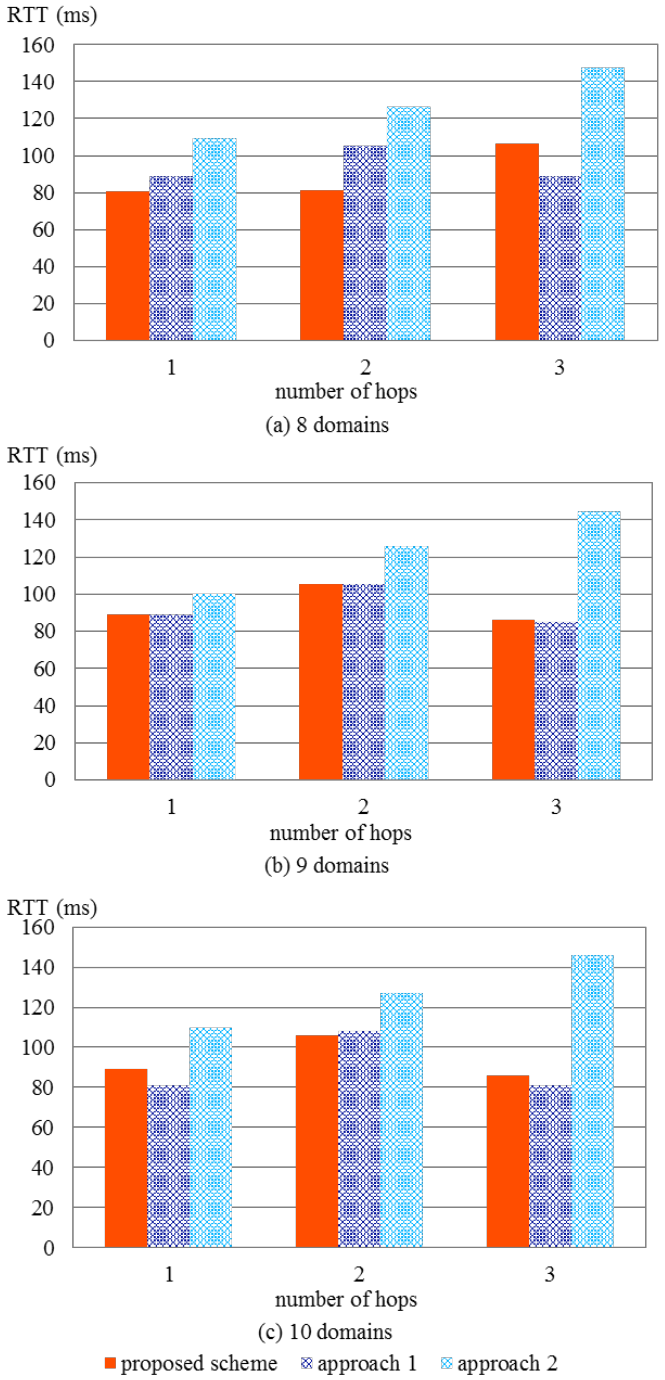

Figure 16 Experimental result 3-1: The traffic load between SDN controllers.

set after MN's movement caused the difference in amount of communication made between SDN controllers and this affected the overall traffic load. Figure 15 (b) shows that when D_s and D_d were 2 hops away, the traffic load of the proposed scheme and approach 1 exceeded the traffic load of approach 2 greatly. In this case, there were several routes with minimum inter-domain hops. Therefore, IDRF queried for the number of flow entries that was needed to be installed for each route. This querying caused the increase of the traffic load. This fact shows that by asking the number of needed flow entries, the traffic load between the SDN controllers increases.

Next, RTT of communication between the MN and the CN after MN's movement. With approach 2, RTT increased as the number of hops between D_s and D_d increased. In approach 2, packets sent to the MN were first sent to D_s and then got transferred to the MN. Thus, the communication route gets longer as the MN moves farther. In contrast, the proposed scheme and approach 1 selected the shortest route regardless of the position of D_s. Therefore, RTT did not get too big. Besides, the transferring route was the longest route that could be chosen in the proposed scheme and approach 2. Thus, these approaches could keep RTT the same as that of approach 2 or smaller.

From the results mentioned above, the approach 1 and the approach 2 can only hold back the RTT of communication between the MN and the CN after MN's move, or traffic load between SDN controllers. However, the proposed scheme is able to deal with both.

4.6. Discussion

These quantitative experimental results mentioned above reveal the contribution of our proposed scheme in practical use. This achievement enables the suppression of the consumption of limited network resources while enabling users of MNs to move around keeping seamless and fast communication even if they moved across domains. For example, consider the situation where many users work with laptop PC or tablet PC to download data from cloud servers or to upload data. The users can smoothly download/upload large data from/to cloud servers while they are moving, like during transit time. Concerning interactive-type applications such as remote login terminal or VDI environment, the users can use the services continuously when the connecting network domain changes.

Generally speaking, to avoid the termination of services or processes when MNs move across network domains, application-level handover function is usually implemented in the applications. When IP address of a MN changes according to the MN's movement, the handover function terminates the transport connection on the previous IP address, and then establishes a new transport connection on the new IP address. By this function, the data communication sessions seem to continue transparently and application logic can handle the sessions seamlessly. However, not all the applications have this feature implemented. This is because the mechanism is relatively complicated and it is necessary to deal with the server side as well. Our approach enables this functionality in network level. It means that all the Internet applications can utilize their network-dependent functions seamlessly in case that MNs move across the network domain.

Furthermore, when a user is at a place that the service areas of different access points overlap, the MN shifts its connecting access point back and forth depending on the link condition even when the user is not moving physically. Proposed scheme can manage this kind of handover and keep communication quality. Meanwhile, a standardization activity of a fast initial setup of Wi-Fi link is progressing as IEEE802.11ai [15]. This function would enable a Wi-Fi client to establish a secure link setup within 100ms. If this standard will widely be used in the above environment, switching of access point may occur very rapidly frequently in near future. There are no technologies currently available to deal with such situations, and we can expect that our proposed scheme will work effectively in such situations.

5. Conclusion

This paper aimed at realizing seamless connection and route optimization in SDN based IP mobility management on inter-domain handovers. It is difficult to realize efficient information exchange between SDN controllers and route optimization together. To solve this problem, we proposed the SDN based IP mobility management scheme considering inter-domain handovers. As simulation results show, we achieved to optimize route while keeping management information exchange traffic between SDN controllers low.

As the future works, we need to improve IDRF. By extending the algorithm to handle weight of paths, we can take more kinds of information into account, such as bandwidth of inter-domain links and network usage.

Conflict of Interest

The authors declare no conflict of interest.

X-ray technology

ABSTRACT

Traditional CT in our industry has been limited to Business card sized samples, due to the Cone Beam x-ray systems used by Electronics manufacturing companies. Inclined or Partial CT provides a slightly different solution showing layers or slices in 2D very well, but due to the partial nature of the scans does not produce very accurate 3D reconstructions. This seminar will look at more sophisticated x-ray systems, including dual tube units, which can image at sub-micron level and have the ability to build an accurate and detailed 3D image of a tablet or smart phone without any stitching or joining of images. With high quality reconstruction software, these images can easily be manipulated to allow key features or failure sites to be easily seen. These systems are being used in Failure Analysis but also in NPI and in the design and development process as CAD data can be overlaid and metrology is also possible with some systems.

1. Introduction

Traditional Electronics CT

Within electronics manufacturing and failure analysis inspection 2D inspection is the primary method of x-ray inspection and traditionally systems were only offering this. CT or 3D then became an option and quality varied dramatically dependant on many factors including: quality of image, stability of x-ray tube, reconstruction software, computing power etc. Time to make a 3D image was also long and to get detailed images could take many hours. This made it something which had very little use in the real world of manufacturing.

However due to the design of the systems and the technology used the biggest issue with CT was that the sample size was roughly the dimensions of a Business Card. This was due to the simple fact that to get good magnification the sample has to be close to the x-ray tube and to build the CT image the sample has to be rotated within the beam of the x-ray tube.

Cone beam technology is standard in the machines used for electronics inspection.

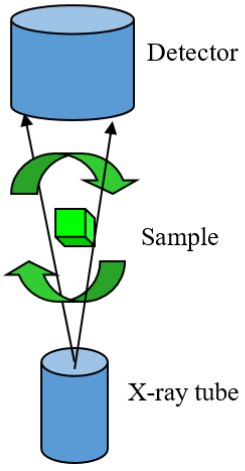

Figure 1 Conventional CT x-ray layout

The tube is at the bottom of the system, the sample held by some form of manipulator and a collector at the top of the system. Or the other way around in some systems, however this can cause issues with the sample colliding with the tube. So, in this type of systems CT is normally a failure analysis technique, unless you are working at the component level.

2. Inclined or partial CT

This is a quite recent technology, the main benefit is that it works by focussing on an area of interest on an assembly or product, the only size limit is the inspection area of the system. The area of interest is set within the x-ray cone beam and the sample or the detector is rotated.

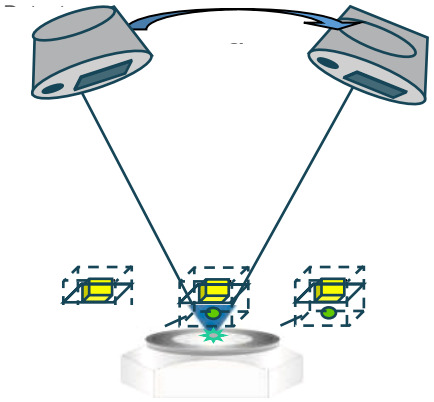

Figure 2 ICT manipulation

A larger number of images are taken, for instance one every degree, these are then processed to make a number of slices. This allows the operator to drill down through the number of slices to check interfaces and other key areas within the images. It is also used for separating components on the top and bottom sides of the board where complex components are 'mirrored' causing issues for traditional 2D x-ray systems. This is due to overlapping images of the components even at an angled view which can cause confusion or make voiding calculations impossible.

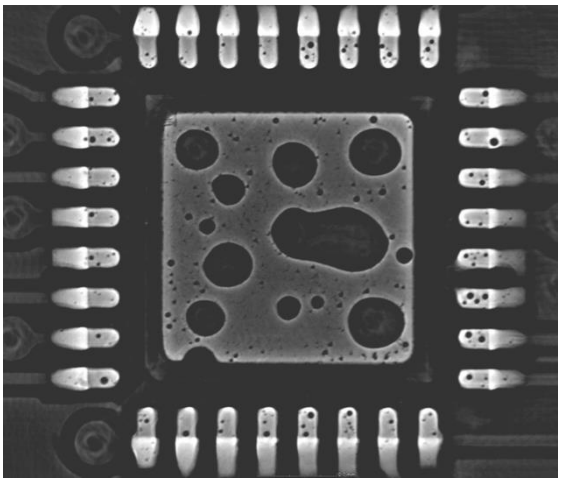

Figure 3 ICT slice showing QFN interface

However, as the captured images are taken at an angle and not by rotating the sample 360 degrees within the beam some data is missing. This means that when the 3D reconstruction is done it is not accurate in some areas as the data is incomplete. To overcome this some systems guestimate what should be there, which makes the image look more real but may not be accurate.

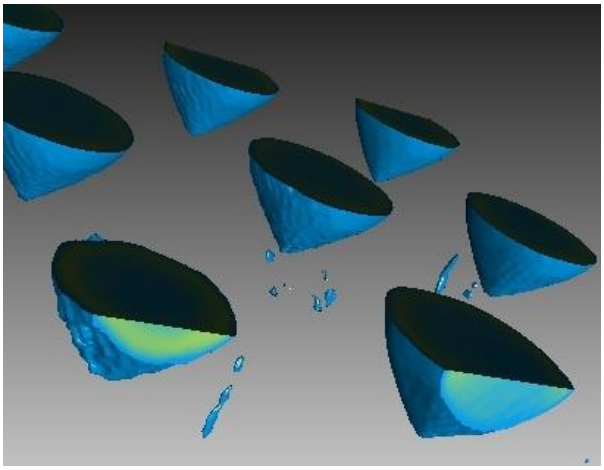

Figure 4 BGA balls showing lack of data

The figure above shows a section through some BGA balls, where the cross section is taken the 3D reconstructed image is accurate but the pointed area of the balls is inaccurate and is a result of lack of gathered data in this area.

3. Cross Over Systems

Background

The lines between NDT and Electronics x-ray inspection have become blurred as smaller features need to be seen in NDT and assembled product CT is being requested by more and more electronic manufacturing companies.

This has led to more flexible platforms being developed which can cope with sub-micron demands and large field of view applications. Certain key features are required to give a system the ability to perform well in both arenas.

Figure 5 Cross Over System

A very stable base is needed for the key components (tube, manipulator and detector), normally Granite is used for this. Very accurate motion systems, with encoder modules made by Heidenheimer or other top quality manufacturers. Rotation tables being very high precision with high end air bearings, giving accurate and repeatable results.

Figure 6 Air bearing rotation table

The higher-powered x-ray tubes also tend to be water cooled with diamond targets to give stable performance for demanding applications and over longer scanning times.

To have the ability to work at the Nano and sub-micron level and also to image larger demanding applications it is normal for these systems to have 2 tube types. This can add to the time needed, however some systems can change tubes at the touch of a button. Even keeping the same focus region when the tubes are changed, this is a great advantage

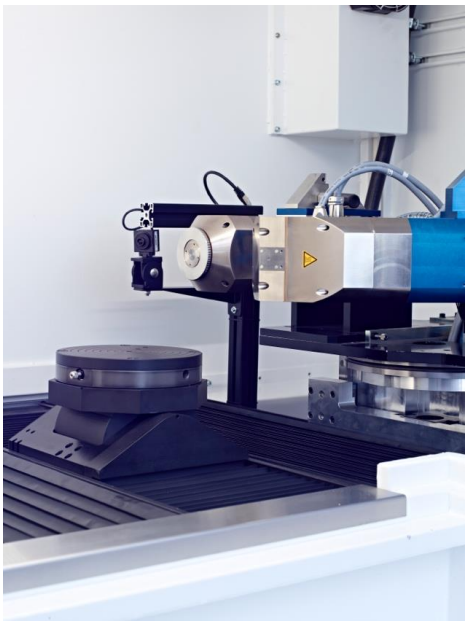

Figure 7 shows two x-ray tubes inside the system

These systems also tend to be larger than the normal off line ones seem in our industry. Partly due to the configuration which is horizontal rather than vertical, the larger and heavier sample sizes and the larger flat panel detectors.

4. New Technologies

Helical scanning

In order to increase the field of view but maintain high magnification helical scanning is used, as well as very accurate manipulation very clever software is needed to control the technology. The tube and the detector rise together allowing the field of view to move up the sample, producing very detailed large image.

The other alternative is to use stitching to join several smaller images together and produce one large image but the accuracy is poor by comparison.

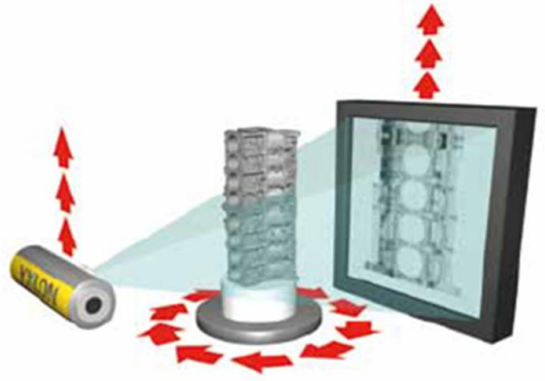

Figure 8 shows helical scanning layout

This allows very detailed images of larger objects to be made as the smart phone below illustrates

Figure 9 Smart phone imaged in a single shot

5. Virtual Rotation Access

This is a software driven technology which allows the operator to select a field of view not in the centre of the rotation table.

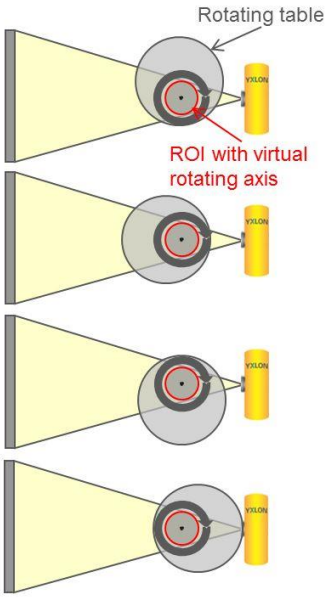

Figure 10 shows virtual rotation in action

It's ideal for hard to hold samples or to make several 3D images without having to reposition the sample multiple times to make the optimum image

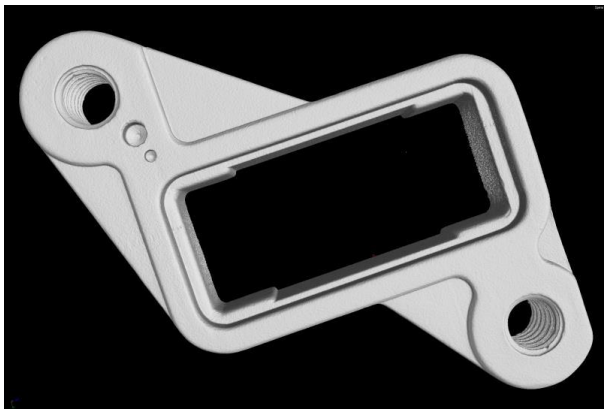

Figure 11a full 3D image of bracket

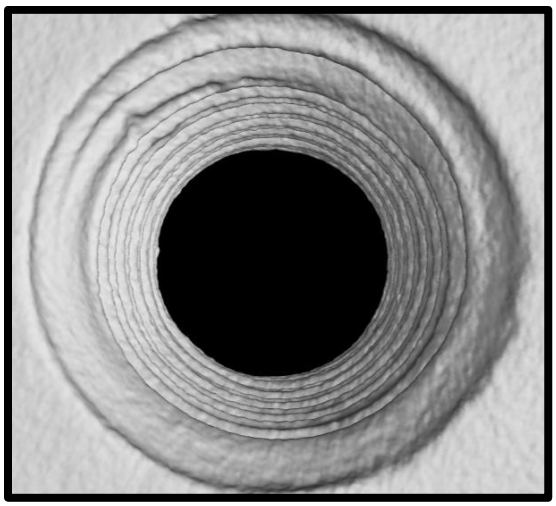

Figure 11b 3D image of mounting hole made by virtual rotation

6. Anti-collision systems

When working with large samples or with those which are offset or held in at an angle the potential for collision and damage increases. The more sophisticated systems use a camera and clever software to check the position of the sample during rotation. This allows the operator to set the sample close to the tube giving high magnification of the image without the potential for damage.

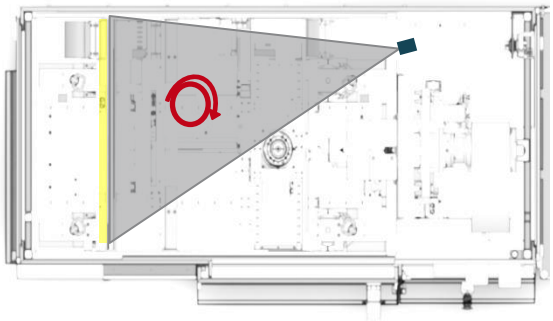

Figure 12 shows camera action for collision prevention

7. Remote Monitoring and Push Messages

This software innovation allows the operator to manage the system remotely or even manage multiple systems.

Continuous communication of inspection progress and health data gives the operator complete control. It displays the system Health Monitor, real time information and alerts. The software works on all Windows tablets and PCs; it allows remote monitoring sending push messages calling the user for direct system interaction e.g. decision expected or scan finished

Figure 13 shows system remote monitor

8. Metrology

Traditional x-ray systems have struggled with measurement accuracy and repeatability, basically they were microscope based and not measurement systems.

Cross Over systems have much more accurate components and active vibration damping, making them metrology based.

The better machines have calibration values related to the PTB certified measurement sphere gauge in a controlled environment at 20°C +/- 0.5°. Some companies offer guaranteed PTB values for a delivered system which can be ordered as optional feature.

8 Bit STM Controller

ABSTRACT

The aim of this paper is to describe mathematical modeling and digital control of a hybrid switching buck converter. This converter belongs to a class of so called hybrid switching converters and contains a resonant capacitor, resonant inductor and a diode in addition to original buck converter components. The dc gain of this converter is shown to be independent of resonant branch parameters. Moreover the dc conversion ratio is derived for both ideal case and including main inductor dc resistance. Small signal model of the converter is derived and is shown to be similar to conventional buck converter. Simulation results in SIMPLIS Software as well as experimental results of digital control using an 8 bit STM microcontroller are presented. The potential advantages and applications of this converter are discussed.

1. Introduction

A new class of switching power converters known as hybrid switching converters has been proposed quite recently by S. Cuk [1], [2]. These converters embody the switching characteristics of two predominant methods of power conversion; square wave PWM switching converters and resonant switching converters. In square wave PWM switching converters, the reactive elements are charged and discharged linearly. Due to this, the semiconductor devices have to be hard switched resulting in significant switching losses. In order to avoid the switching loses, quasi resonant and resonant switching converters were developed. In resonant converters, the reactive elements are charged and discharged in sinusoidal manner resulting in ZVS or ZCS of semiconductor devices depending upon mode of operation. However, the resonant converters suffer from difficult design and control issues. In order to combine the best of the two worlds, a hybrid class of switching converters is proposed by [1], [2]. These converters are essentially derivatives of PWM switching converters and contain additional components as compared to their PWM method counterparts. These additional components, referred to as resonant components, provide capabilities otherwise impossible to achieve with either of the two classes of power converters [3]. The behavior of these resonant components is a hybrid of two methods: they either charge linearly and discharge in resonant manner or vice versa. These characteristics provide improvements over conventional PWM switching converters as will be shown in this paper.

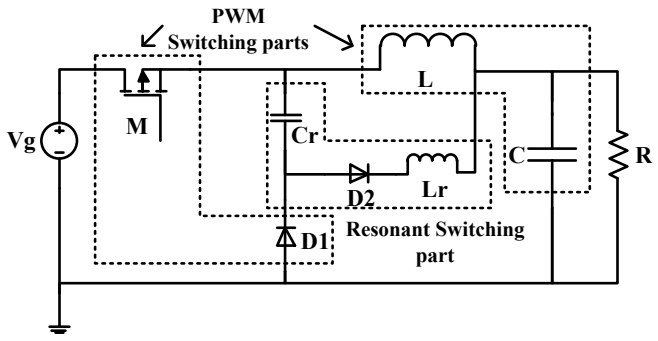

Figure 1 Hybrid Switching Buck Converter

Figure 1 shows the hybrid switching buck converter (HSBC) with PWM switching parts and resonant switching parts highlighted. It can be seen that the converter is essentially a buck converter with additional resonant reactive components i.e. resonant capacitor Cr and inductor Lr along with a diode. The resonant capacitor Cr charges in resonant manner along with the resonant inductor Lr whereas it discharges linearly. The aim of

*Corresponding Author: Muhammad Umar Abbasi, Power Systems Division, SUPARCO Lahore, +92333572393, Email: umareepower@gmail.com

this paper is to mathematically model the dc gain characteristics as well as small signal transfer function of this converter. It will be shown that this converter, though having a different dc gain ratio than a conventional buck converter, can provide similar characteristics as that of buck converter along with advantages such as magnetic size reduction of the main power inductor. Moreover, it is shown that the digital control of this converter can be achieved in a similar fashion as that of a conventional buck converter.

The paper is presented in the following manner: section 2 provides steady state operation and dc gain ratio of the hybrid switching Buck converter. Section 3 provides small signal derivation of HSBC and equivalent circuit is derived. Section 4 provides digital control implementation details around an 8 bit STM microcontroller. Section 5 gives simulation results performed in SIMPLIS software as well as practical example results. In section 6, possible applications of this converter are discussed.

2. Steady State Operation and DC Gain Characteristics

The converter is assumed to be operating in continuous conduction mode. All semiconductor devices are assumed to be ideal. Also it is assumed that the resonant components (Cr and Lr) are much smaller than the main filter components (C and L). For simplicity of analysis, we assume that the on period of the main switch is equal to half of resonant period where resonant period is defined as:

$$Tr = 2 * pi * \sqrt{Lr * Cr} \tag{1}$$

The converter operates in two modes depending on the state of MOSFET switch M. The resulting circuit waveforms along with the equations describing the reactive elements are presented next.

2.1 *MOSFET Switch ON*

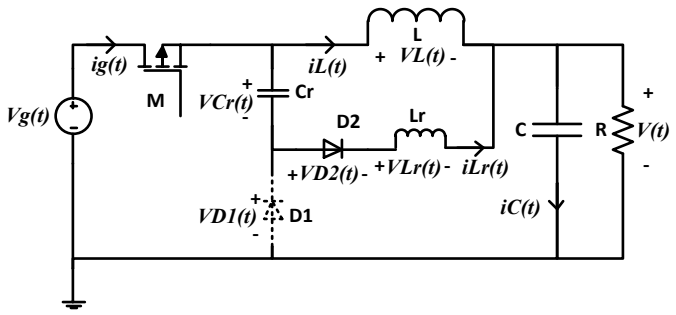

Figure 2 MOSFET ON, D2 ON, D1 OFF

When main MOSFET switch is ON, the diode D1 is reversed biased and diode D2 turns ON. The current flows from input to output charging both the main power inductor and resonant branch comprising of Lr and Cr. The capacitor Cr is charged resonantly. The inductor Lr is volt-sec balanced during this time interval only as the current through Lr flows only when D2 is conducting. This implies a different volt-sec balance approach than the main inductor L which is volt-sec balanced over complete switching period. It is assumed here that the resonant capacitor Cr is initially charged to a voltage level of Vcr1. The important waveforms and associated equations for this mode can be presented as:

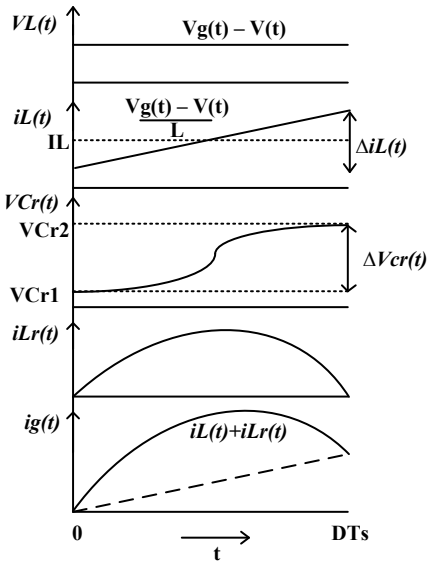

Figure 3 Waveforms in Mode I

$$L\frac{di_L(t)}{dt} = V_g(t) - V(t) \tag{2}$$

$$C\frac{dV(t)}{dt} = i_L(t) + i_{Lr}(t) - \frac{V(t)}{R} \tag{3}$$

$$Lr\frac{di_{Lr}(t)}{dt} = V_g(t) - V_{Cr}(t) - V(t) \tag{4}$$

$$Cr\frac{dV_{Cr}(t)}{dt} = i_{Lr}(t) \tag{5}$$

$$i_g(t) = i_L(t) + i_{Lr}(t) \tag{6}$$

As can be seen, the main inductor Volt-sec equation remains the same as the conventional buck converter. Although the resonant branch is charged sinusoidally, the equations can be written in similar manner as the PWM branch. The V_{Cr} and i_{Lr} can be described as:

$$V_{Cr}(t) = V_{Cr1} \times \cos(\mathrm{w_r} \times (\mathrm{t} - \mathrm{t_0})) \tag{7}$$

$$i_{Lr}(t) = \frac{V_{Cr2}}{Zn}\sin(w_r \times (t - t_0)) \tag{8}$$

Where Zn is the natural impedance and *wr* is the resonant frequency of the resonant branch given as:

$$Zn = \sqrt{\frac{Lr}{Cr}}, \quad w_r = \frac{1}{\sqrt{Lr \times Cr}} \tag{9}$$

As can be seen, the sinusoidal behavior of the resonant branch has no significant effect on the equations of the PWM branch components.

2.2 *MOSFET Switch OFF*

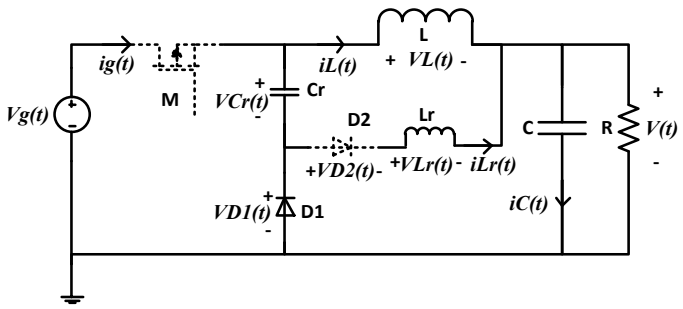

Figure 4 MOSEFT OFF, D2 OFF, D1 ON

When the MOSFET switch is OFF, the current iL(t) traverses through diode D1 which is the freewheeling diode, same as in conventional buck converter. The diode D2 turns off and the resonant capacitor Cr begins to discharge in the quasi linear fashion. The resonant inductor current is zero in this mode. The inductor current has a negative slope as shown in the figure. The important waveforms and associated equations for this mode are:

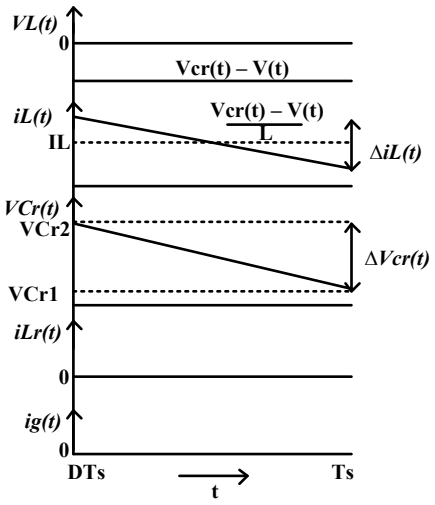

Figure 5 Waveforms in Mode II

$$L\frac{di_L(t)}{dt} = V_{Cr}(t) - V(t) \tag{10}$$

$$C\frac{dV(t)}{dt} = i_L(t) - \frac{V(t)}{R} \tag{11}$$

$$Lr\frac{di_{Lr}(t)}{dt} = 0 \tag{12}$$

$$Cr\frac{dV_{Cr}(t)}{dt} = -i_L(t) \tag{13}$$

$$i_g(t) = 0 \tag{14}$$

As can be seen, the resonant capacitor Cr is quasi linearly discharged from level Vcr2 to Vcr1. The average voltage across Cr will be shown to be equal to difference of input and output voltages. Also note that the inductor Volt-Sec balance equation for mode II is different from conventional buck converter and therein lays the advantage of present topology as will be shown later.

2.3 *DC Gain Characteristics*

The dc gain of hybrid switching buck converter can be derived by applying principle of volt-sec balance on main and resonant inductors as well as principle of charge balance on main and resonant capacitors [4].

For main filter inductor L:

$$L\frac{d\langle i_L(t)\rangle_{Ts}}{dt} = \langle V_L(t)\rangle_{Ts} = D\times(\mathrm{V_g} - \mathrm{V}) + \mathrm{D'}\times(V_{Cr} - V) = 0 \tag{15}$$

Where D is the main switch duty cycle and D'=1-D. Also we have assumed steady state so the time varying quantities are replaced by their dc values. Solving Eq. (2.14) yields:

$$D\times V_g = V - D'\times V_{Cr} \tag{16}$$

Applying Volt-sec balance on resonant inductor Lr yields:

$$Lr\frac{d\langle i_{Lr}(t)\rangle_{Ts}}{dt} = \langle V_{Lr}(t)\rangle_{Ts} = D\times(\mathrm{V_g} - V_{Cr} - \mathrm{V}) + \mathrm{D'}\times(0) = 0 \tag{17}$$

After simplification we get:

$$V_{Cr} = V_g - V \tag{18}$$

Thus the average voltage across resonant capacitor is equal to the difference of input and output voltages. After substituting Eq. (2.17) into Eq. (2.15), we get the desired dc gain as:

$$\frac{V}{V_g} = \frac{1}{2-D} \tag{19}$$

The dc gain is very different from conventional buck converter and (19) suggests that there is a lower limit on the output voltage. For duty ration D=0, we get V = Vg/2. However, in the next section it is shown that this is not the case as main inductor dc resistance reduces the dc gain ratio and thus the converter can traverse almost all the range of output voltage.

Next the principle of capacitor charge balance is applied to main filter capacitor as well as resonant capacitor. For capacitor C, we get:

$$C\frac{d\langle V(t)\rangle_{Ts}}{dt} = \langle i_C(t)\rangle_{Ts} = D\times(\mathrm{I_L}+\mathrm{I_{Lr}}-\frac{V}{R}) + D'\times(\mathrm{I_L}-\frac{V}{R}) = 0 \quad (20)$$

After simplification we get:

$$IL - \frac{V}{R} = -D'\times I_{\mathrm{Lr}} \quad (21)$$

Applying Charge balance on resonant capacitor Cr, we get:

$$Cr\frac{d\langle V_{Cr}(t)\rangle_{Ts}}{dt} = \langle i_{Cr}(t)\rangle_{Ts} = D\times(I_{Lr}) + D'\times(-I_L) = 0 \quad (22)$$

This results into:

$$I_{Lr} = \frac{D'}{D}\times I_L \quad (23)$$

Finally we get relationship between average inductor current and load resistance as follows:

$$IL = \frac{V}{R\times(2-D)} \quad (24)$$

We can also calculate the average value of input current which is the same as main MOSFET average current as follows:

$$\langle i_g(t)\rangle_{Ts} = D\times(I_L + I_{Lr}) \quad (25)$$

After substituting Eq. (2.22) we get:

$$I_g = I_L \quad (26)$$

A summary of DC characteristics of conventional buck converter and hybrid switching buck converter is presented in a tabular form.

Table 1 DC Characteristics Comparison

DC Characteristic	Conventional Buck Converter	Hybrid Switching Buck Converter
Voltage Gain	D	$\frac{1}{2-D}$
Average Inductor Current	$\frac{V}{R}$	$\frac{V}{R\times(2-D)}$
Average Input Current	$\frac{D\times V}{R}$	$\frac{V}{R\times(2-D)}$
Average Switch Voltage	V_g	V
Main Inductor ripple Δi_L	$\frac{V_g DD'Ts}{L}$	$\frac{VDD'Ts}{L}$
VD1	V_g	V

From the above table, following advantages of Hybrid Switching Buck converter can be summarized:

- The inductor current ripple is reduced. This implies that for the same switching frequency, hybrid switching buck converter requires smaller main power inductor. This advantage is achieved without increasing switching frequency.
- Both MOSFET and freewheeling diode voltage ratings are reduced. Low voltage switches with better switching features can be used.

2.4 DC Gain with Inductor DC Resistance

Finally, we derive the DC gain including main inductor dc resistance. For reference, the circuit is produced here including inductor dc resistance:

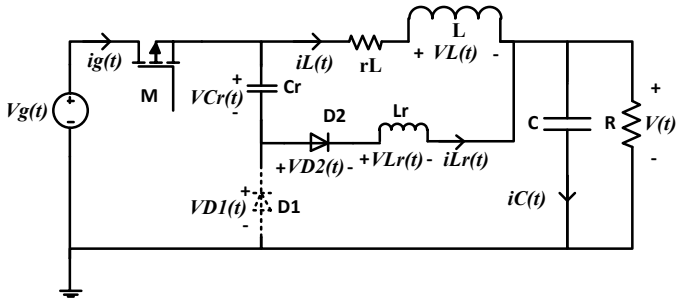

Figure 6 Hybrid Buck Converter including inductor resistance

Only the Volt-Sec balance equation of main inductor is changed and is given below:

$$\langle V_L(t)\rangle_{Ts} = D\times(\mathrm{V_g}-\mathrm{V}-\mathrm{I_L}\times\mathrm{r_L}) + \mathrm{D'}\times(V_{Cr}-V-\mathrm{I_L}\times\mathrm{r_L}) = 0 \quad (27)$$

After simplification we obtain:

$$D\times V_g - V - I_L\times r_L + D'V_{Cr} = 0 \quad (28)$$

Replacing the value of V_{Cr} from (18) and simplifying:

$$V_g - V\times(2-D) - I_L\times r_L = 0 \quad (29)$$

We replace value of IL from (24) and simplify to get final equation:

$$\frac{V}{V_g}=\frac{1}{(2-D)-\frac{r_L}{R\times(2-D)}} \tag{30}$$

This equation shows the effect of inductor dc resistance r_L on DC gain. The DC gain is reduced and thus the converter is able to traverse wider range of output voltage.

3. Small Signal Modeling of HSBC

In this section we derive small signal transfer function of hybrid switching buck converter. We can write the large signal equations

$$\begin{aligned}
&<V_g(t)>_{Ts}=V_g+\hat{v}_g(t),\ <i_g(t)>_{Ts}=I_g+\hat{i}_g(t),\\
&<V_{Cr}(t)>_{Ts}=V_{Cr}+\hat{v}_{cr}(t)\ <V(t)>_{Ts}=V+\hat{v}(t),\\
&<i_L(t)>_{Ts}=I+\hat{i}_L(t),\ <i_{Lr}(t)>_{Ts}=I_{Lr}+\hat{i}_{Lr}(t)\\
&d(t)=D+\hat{d}(t),\ d'(t)=D'-\hat{d}(t)
\end{aligned} \tag{32}$$

Where $\hat{x}(t)$ represents the small signal perturbation in steady state value of variable $x(t)$ .After replacing in (31), we get following equation:

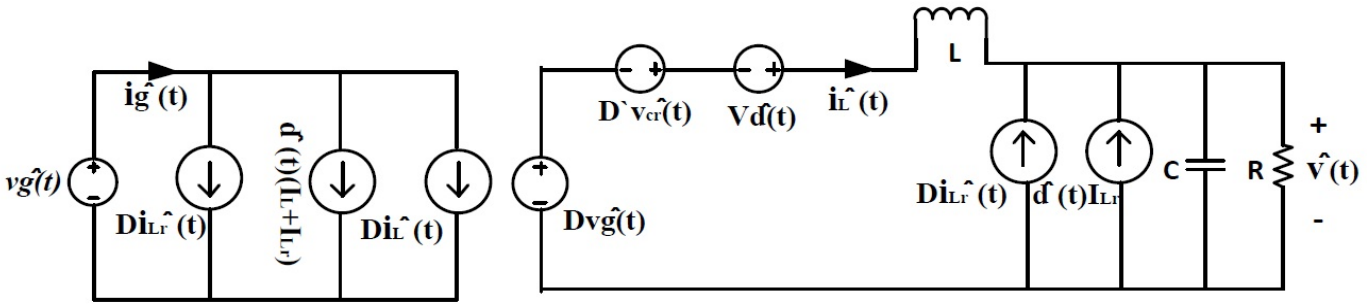

Figure 7 Small Signal Equivalent Circuit for HSBC

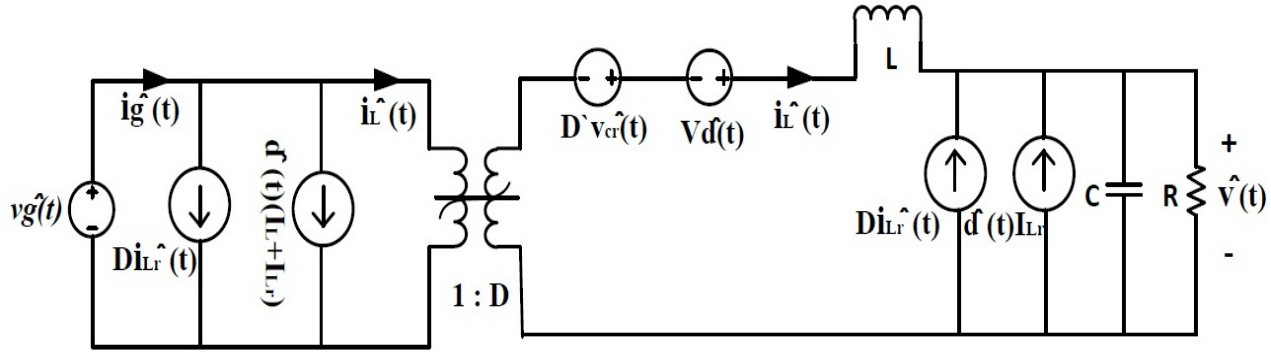

Figure 8 Equivalent Circuit with DC Transformer

for the main filter inductor and capacitor using the approach in [4]. The averaged equation for inductor L is given below:

$$\begin{aligned}
L\frac{\langle di_L(t)\rangle_{Ts}}{dt}&=d(t)[\langle V_g(t)\rangle_{Ts}-\langle V(t)\rangle_{Ts}]\\
&+d'(t)[\langle V_{Cr}(t)\rangle_{Ts}-\langle V(t)\rangle_{Ts}]
\end{aligned} \tag{31}$$

Where $<x(t)>_{Ts}$ denotes the average of x(t) over switching period Ts. We can perturb and linearize this non linear averaged equation by replacing time varying quantities with their steady state values perturbed in small quantities as shown next:

$$\begin{aligned}
L\frac{d[I+\hat{i}_L(t)]}{dt}&=[D+\hat{d}(t)]\times[V_g+\hat{v}_g(t)-V-\hat{v}(t)]\\
&+[D'-\hat{d}(t)]\times[V_{Cr}+\hat{v}_{cr}(t)-V-\hat{v}(t)]
\end{aligned} \tag{33}$$

After simplification, we ignore dc and higher order terms and arrives on following small signal equation for inductor L:

$$L\frac{d\hat{i}_L(t)}{dt}=D\hat{v}_g(t)+D'\hat{v}_{cr}(t)+\hat{d}(t)\,\mathrm{V}-\hat{v}(t) \tag{34}$$

Similarly, the non linear averaged equation can be written for the output capacitor C:

$$C\frac{d<V(t)>_{Ts}}{dt} = d(t)[<i_L(t)>_{Ts} + <i_{Lr}(t)>_{Ts} - \frac{<V(t)>_{Ts}}{R}] + d'(t)[<i_L(t)>_{Ts} - \frac{<V(t)>_{Ts}}{R}] \quad (35)$$

After perturbing and linearizing steps as shown for the inductor, we obtain following small signal equation for capacitor C:

$$C\frac{d\hat{v}(t)}{dt} = \hat{i}_L(t) + D\hat{i}_{Lr}(t) + \hat{d}(t)I_{Lr} - \frac{\hat{v}(t)}{R} \quad (36)$$

Applying the similar procedure for the input current i_g(t), we have:

$$\langle i_g(t)\rangle_{Ts} = d(t)[\langle i_L(t)\rangle_{Ts} + \langle i_{Lr}(t)\rangle_{Ts}] \quad (37)$$

After perturbation and simplification we obtain following equation:

$$\hat{i}_g(t) = \hat{d}(t)[I_L + I_{Lr}] + D[\hat{i}_L(t) + \hat{i}_{Lr}(t)] \quad (38)$$

The (33), (36) and (38) represent the small signal model of the hybrid switching buck converter. We can combine these equations to produce the equivalent small signal model of hybrid switching buck converter.

As can be observed, the small signal ac model of the hybrid switching buck converter is similar to the conventional buck converter with the inclusion of additional voltage and current sources due to the presence of resonant capacitor and inductor. However, this circuit can be solved in the manner similar to the conventional buck converter to obtain desired transfer function such as control to output transfer function [4], [5].

On the primary side of the DC transformer, two additional current sources are present. One current source is due to the effect of the change in resonant inductor current. This is because the resonant inductor current is drawn from the input port of the converter. Any change in this resonant current will be reflected in the input current ig(t). The other two sources combined as one represent the effect of change in control variable i.e. duty cycle d(t). The DC values of both the inductor current and resonant current are responsible for this effect. In case of a conventional buck converter, only DC value of inductor current is present here but in case of HSBC both the main power inductor and resonant inductor are charged by the input port and thus both values are present.

As can be observed on the secondary side, there are two voltage sources as compared to the one in case of a conventional buck converter. Moreover, the voltage source consisting of Vg in conventional buck converter is now replaced with one consisting of output voltage V. This can be attributed to the fact that the HSBC applies different volt-sec to the main power inductor as compared to the conventional buck converter. During the time when the MOSFET switch in OFF, the conventional buck converter applies minus V times the off time interval (-V*D'Ts), where HSBC applies Vcr – V time the off time interval ((Vcr-V)*D'Ts). This difference is reflected in the form of change in voltage source on the secondary side of the transformer.

An additional voltage source is due to the effect of change is resonant capacitor voltage. The resonant capacitor voltage is applied only during the off time interval and hence its small signal component is multiplied by the complement of steady state duty cycle.

One might imagine after looking at small signal equivalent circuits shown above that the HSBC is more difficult to control and that its small signal control to output transfer function will be more complex than a conventional buck converter. However, as will be shown in next sections, the small signal characteristics of HSBC closely mirror those of the conventional buck converter. The control of the HSBC can also be accomplished by the identical computational effort as that of conventional buck converter.

4. Digital Control Implementation

In order to demonstrate the viability of the converter and the potential of simple 8 bit microcontrollers to control this converter, a simple test setup was created in lab around an 8 bit STM microcontroller [5]. The simplified schematic diagram of the implementation is presented below:

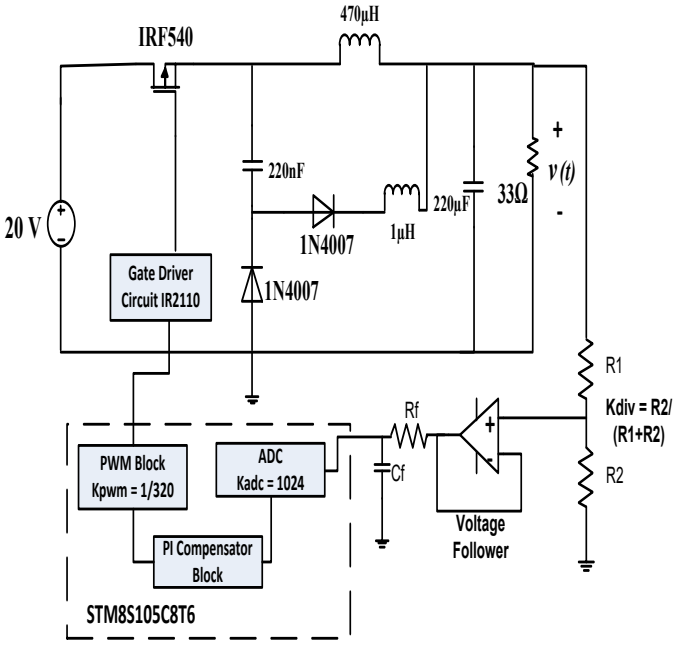

Figure 7 Digital Control Setup

The output of the converter is scaled down by the resistor divider and converted into digital domain by the ADC. The PI compensator block calculates the error and applies compensation to generate the duty cycle for the main switch. The built in PWM block of STM controller is used to generate the duty cycle controlled pulse signal for MOSFET.

The flowchart of the software used to control the converter is shown below:

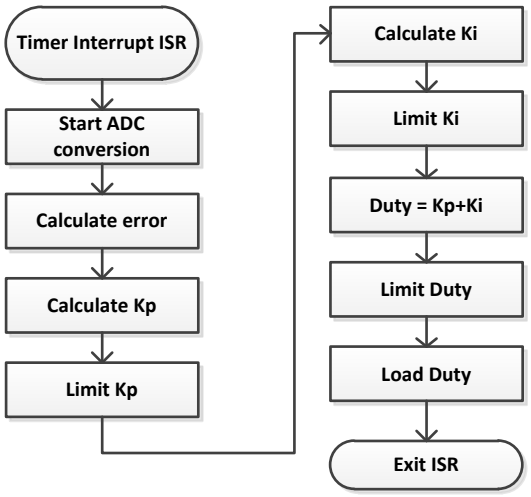

Figure 8 Software Flowchart

It should be noted here that the duty cycle calculated by the PI controller is limited to a certain minimum value to ensure that the duty cycle is always greater than half of resonant period as given by Eq. (2.1). This ensures that the resonant current cycle is completed without any interruption. The concept is illustrated in the next figure.

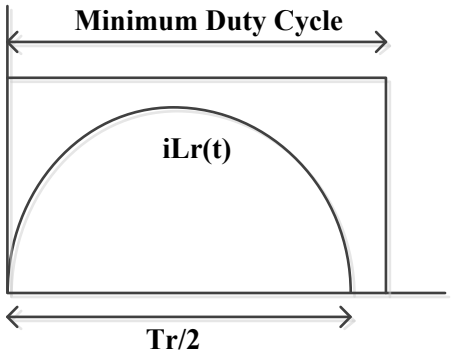

Figure 9 Minimum Duty Cycle

At first glance it would appear that this is negatively restricting duty cycle above a minimum threshold. However, in practical designs, the duty cycle generally oscillates around its designed value in small quantities and very rarely traverses the entire range of its possible values. So, if the converter is designed such that the half resonant period is some small fraction of the duty cycle, say five percent, then this restriction can be met without much problem. In practical setup used for this converter in the lab, the half of resonant period was about five percent of duty cycle and converter operated without problem.

5. Simulation and Practical Results

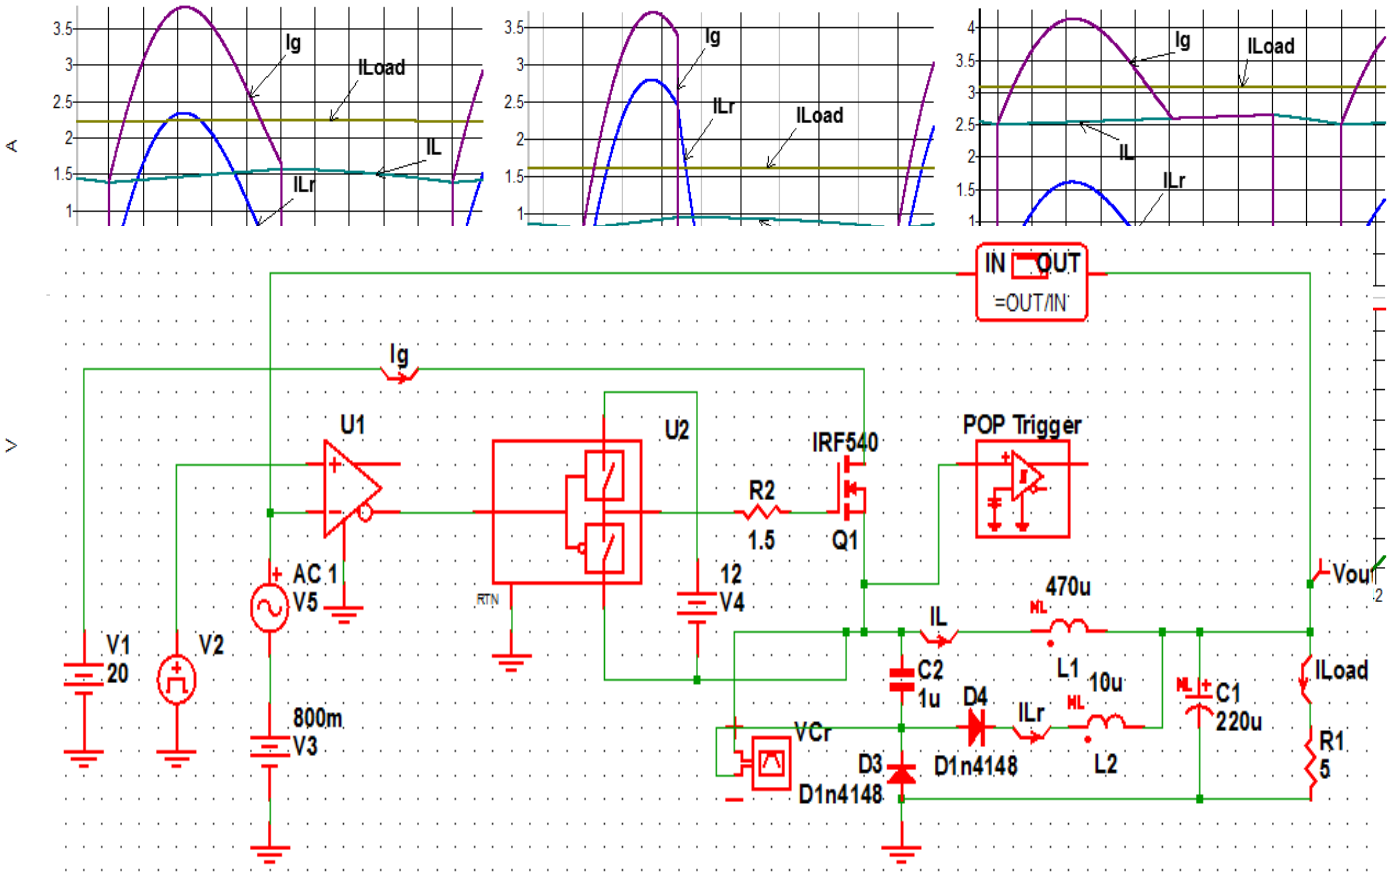

Figure 10 SIMPLIS Simulation of HSBC

The converter is simulated in SIMPLIS simulation software. The screenshot of the SIMPLIS simulation is shown in figure 12.This software provides the ability to simulate the circuit in its steady state form directly, without having to perform lengthy and time consuming transient analysis. This feature of the software is called Periodic Operating Point (POP) analysis.

Moreover, the ac analysis of this converter circuit can be performed in time domain without having to derive equivalent frequency domain models, thereby simulating a real life network analyzer in software [6].

The circuit is simulated for three different values of MOSFET duty cycle, 30%, 50% and 80%. The results of important circuit parameters for these three duty cycles are presented in figure 13.

As we can see from figure 13, the I_{Lr} becomes zero in case of duty cycle being greater than or equal to the half of resonant period. In case duty cycle is less than Tr/2, then the diode D4 will be hard switched and incurs switching losses. Therefore, the converter should be designed such that the duty cycle is limited to the values above the Tr/2.The behavior of the resonant capacitor voltage swing should also be considered here. The case in which duty cycle is less than half of resonant period, the voltage Vcr charges sinusoidally up to the point of switch transition and then discharges linearly. The behavior is consistent with the theory of hybrid switching conversion i.e. resonant charging and linear discharging. Also the case in which duty cycle is greater than half the resonant period, the voltage Vcr rises sinusoidally until the current ILr is flowing. When the current ILr tries to become negative, the diode D2 blocks the flow and the current can flow no further. This results in voltage Vcr becoming constant. This, of course, doesn't affects the converter behavior.

It can be seen that the output voltage can traverse greater range than predicted by the DC gain of (19). This is because of the fact that the simulation software includes the parasitic elements such as MOSFET on resistance and diode forward voltage drops. Such parasitic, like the dc resistance of main power inductor, work to reduce the DC gain predicted by (19), thereby allowing the converter to traverse greater output voltage range.

It was predicted in the previous section that the small signal characteristics of HSBC are very much identical to those of conventional buck converter. In this section, we present the small signal control to output transfer function characteristics simulated in SIMPLIS software. This software has the capability to simulate the circuit in time domain, thereby emulating the behavior of a network analyzer. The bode plots of the simulation are shown next:

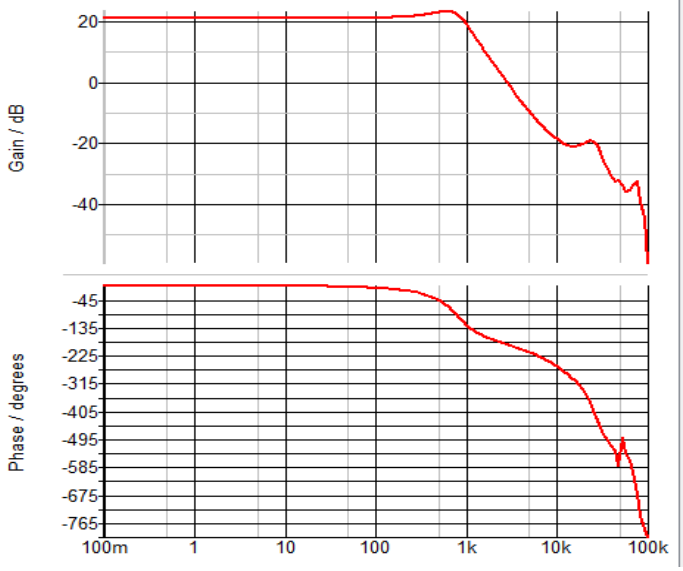

Figure 12 HSBC Bode plot

As we can clearly see, the converter exhibits almost same gain roll off as that of a conventional buck converter [4], [5]. The gain cross over frequency for the simulated circuit comes out to be 2.73 KHz. This shows that HSBC is a stable open loop converter which can be controlled easily using simple control structures.

In order to demonstrate the viability of the converter, a simple prototype was built on breadboard in lab. The setup was arranged according to the figure 9. The following table shows the parameters of this setup:

Table 2 Setup Parameters

Parameter	Value
Input Voltage Vg	20 V
Output Voltage Vout	10 V
Load Resistance	33 Ω
L	470µH
C	220µF
Lr	1 µH
Cr	220nF
MOSFET	IRF540N
Diodes	IN4007
Switching Frequency	50 KHz

The breadboard setup in the lab and the results are presented next:

The breadboard setup consists of a simple assembly of HSBC. The converter is essentially derived from a buck converter presented in [5]. The STM discovery board is used to control the converter using a PI controller. The results of the converter operation are presented next.

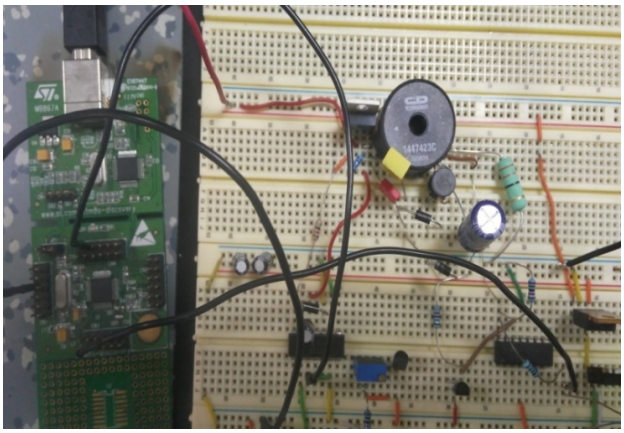

Figure 13 Breadboard Setup

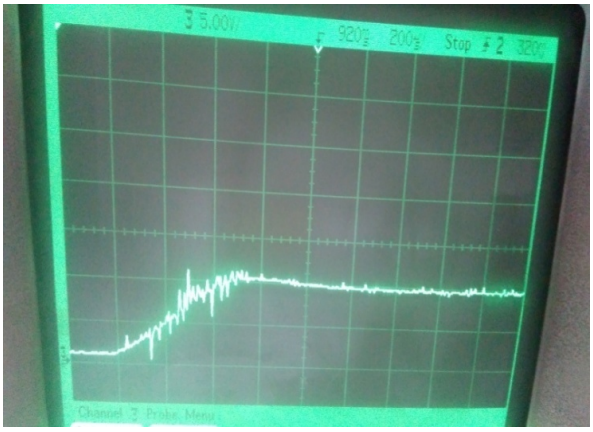

Figure 14 Voltage Startup Response

The output voltage startup response presents good picture with reasonable rise time for an 8 bit controller. The response time should be adequate for general power conversion applications not requiring stringent response constraints.

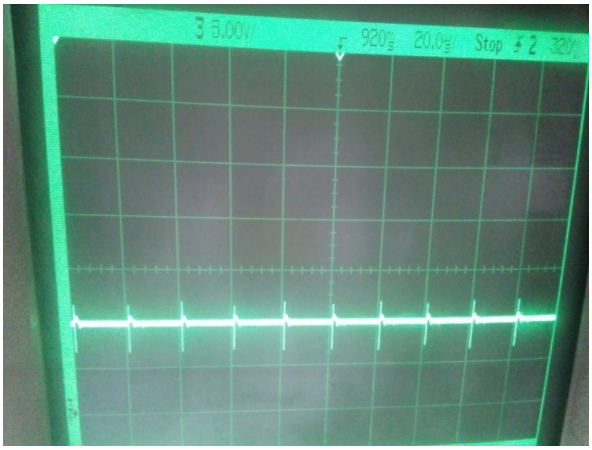

Figure 15 Steady State Output Voltage

As can be observed, over the period of various switching cycles, the converter exhibits no limit cycle oscillations. Therefore, this converter can be controlled using a simple PI

controller. The output voltage can be regulated within reasonable bounds depending on the applications.

6. Potential Applications

The hybrid switching buck converter presented in this paper belongs to a new class of converters and as such is unfamiliar to practicing engineers. Although at first glance it may appear that the part count for this converter is increased when compared to a conventional buck converter, however, the advantages presented by this converter can overcome such issues.

First, if the converter is designed carefully, the diode D2 in series with resonant inductor is soft switched thereby avoiding switching losses. Second, the most significant portion of the PCB is taken up by magnetic in a dc-dc converter. For example, in an MPPT solar battery charger dc-dc converter, the inductor core is the largest component in the power converter. The hybrid switching converter provides the reduction in the size of main power inductor and is therefore suitable for such applications.

Another area of potential application can be the converters that require reduction in size due to space constraints, such as integrated dc-dc converters for military and space applications. Such converters can benefit from this type of hybrid switching buck converter.

7. Conclusion

In this paper, a hybrid switching buck converter was presented. The concept of hybrid switching was introduced. The DC conversion ratio of this HSBC was derived and its dc characteristics were compared to conventional switching buck converter. It was shown that HSBC results in reduced magnetic size without increasing switching frequency of associated switching losses. The small signal analysis was performed on this HSBC and the result was shown to be familiar to the conventional buck converter. The simulation and practical results of digital control using 8 bit microcontroller were presented. The potential application areas of this HSBC were discussed.

ABSTRACT

For human comfort and convenience, appropriate temperature values may not be sufficient enough for the environment that they live in. The moisture content of the air has an important place in this regard. 30% to 65% humidity is desireable for a relaxed and comfortable life. Humidity in the environment is fundamental for the human health, convenience and comfort. Humidity is also valid for therapeutics. The drugs that are used in medicine for diagnosis and therapy must be inhaled with cold or hot water vapor in case drug effectiveness is desired to be increased. For such achievments, cold vaporization method is being preferred to reach the alveoli of the patients, thus, the drug can be used in a more efficient manner without damaging the respiratory tract. In this project, effect of ambient temperaure in ultrasonic nebulizers is investigated. It is proved that as the temperature increases 5°C, the speed of cold vapor increases 10% which refers a decrease in particle diameter. The variations in particle dimension may severely effect the efficiency of therapeutics. Therefore, in this study, it is presented that ultrasonic nebulizers should be designed considering ambient temperature. A design rationale is proposed in this study.

1. Introduction

For the human comfort and convenience, only appropriate temperature values may not be sufficient for the environment that they live in. The moisture content of the air has an important place in this regard [2]. For a relaxed and comfortable life relative humidity is desirable in the range of %30 to %65 in the environment [3]. Humidity in the environment is fundamental for the human health, convenience and comfort [4]. The drugs that used in medicine for diagnosis and therapy must be inhaled with both cold and hot water vapor steam in the patient's body [5]. Cold vaporization method is being preferred to reach the alveoli of the patient, thus, the drug can be used in a more efficient manner without damaging the respiratory tract [6].

Ultrasonic nebulizers utilize water to carry out drugs to the alveols. Ultrasonic nebulizers dissociate water into their smallest particles by sound waves and thus compose cold vapour. Obtained cold vapour and drugs are mixed intoeach other and blown to patient through a mask or directly to the environment. Therefore, respiratory tract is moisturized and the desired drugs are carried out to the alveols of the patients efficiently [7].

Some environments may contain excessive moisture while some of them are over dried. This situation is pretty much common especially among the houses with a radiator during winters and houses with air conditioning in summers. Ideal moisture ratio should be between 30% and 65% for human beings. For humans especially for babies, dry air may cause enfections to spread faster, dehydrate pharyngonasal area, burning in the eyes and cracking in the lips. Dust formation becomes rapid and affects those with allergies. **[8]**. The spread of cold vapor provides accurate humidity in the environment and creates beneficial effects on health. Water droplets have ionizing effect for the air. Negative ions attack pollutant particles in the air, reducing it to a minimum, thereby reducing cigarette smoke, pollens and dust **[9]**. Medical studies have proved that negative ions have a positive effect on people's physical and psychological health with both their stress-relief functions and their direct effects on respiratory devices which makes them much more effective **[10]**.

Simply a nebulizer generates vapour. There are various ways to generate vapour **[11]**. The most convenient method for this is by heating the liquid. On the other hand an ultrasonic nebulizer system evaporates liquids with ultrasonic sound waves. The major problem here is not evaporating water but obtaining cold vapour.

An ultrasonic nebulizer uses a vibrating piezoelectric crystal that vibrates with 1.7 MHz or higher frequency in order to generate vapour **[12]**. The crystal transducer is made of materials like quartz-barium titanate and converts electrical signals into sound waves. The sound beam that focuses on the liquid which is located just above the transducer creates waves. When the frequency and amplitude are strong enough, the wave peak reaches the surface of the fluid as a sprinkler of water particles. Working principle of an ultrasonic nebulizer is illustrated in **Fig. 1**.

Ultrasonic nebulizers are most frequently used in intensive care units. In these units, ultrasonic nebulizers are mainly used for the humidification of the rooms, and also for the evaporation of liquid medicines to assist them to effectively inhaled by respiratory organs. In addition, it is also used to humidify the air for patients who are connected to artificial respiration and oxygen support systems **[13]**.

By the help of this study, effect of ambient temperature on ultrasonic nebulizers is investigated. In order to achieve this, ambient temperature is constantly recorded and particle dimensions of cold vapour are measured. As a result it is understood that, ambient temperature has a serious impact on particle dimension thus affecting the effectiveness of ultrasonic nebulizers therapeutic capability.

In addition, this study aims to further development of national fabrication of ultrasonic nebulizers in Turkey and creates difference in the area of biomedical device fabrication that may not be evaluated as strong **[14-22].**

2. Materials and Method

Ultrasonic nebulizers are based on the princible that disassociating water into its particles with high frequency sound waves that is generated by a vibrating piezoelectric crystal. This piezoelectric crystal that is located under the liquid, generate sound waves with a frequency of 1.7 MHz or more, and disassociating water into its particles.

It is possible to change the particle diameter of of the evaporation by changing the frequency of the piezoelectric crystal. As the frequency of the piezoelectric crystal increases, the particle diameter decreases. As the frequency decreases, the particle diameter increases. As the particle diameter increases, it will be unable for medications or humid air to reach the extreme edges of the alveoli. Same phenomenon is observed when the ambient temperature changes. Particle size decreases as the ambient temperature increases, while particle sizes increase as the ambient temperature decreases.

The quantity of the liquid is important since the piezoelectric crystal is operated inside the liquid. It is important because crystal may deteriorate due to the heat energy that occurs during the formation of the sound waves. For this reason, the quantity of the water is constantly measured and a system is designed that prevents the degradation of the crystal by cutting the energy when there is not enough water left within the device.

Block diagram of the designed ultrasonic nebülizer is illustrated in **Fig. 2**. A picture of the ultrasonic crystal is presented in **Fig. 3**. In addition, a level sensor for water measurement is shown in **Fig 5**.

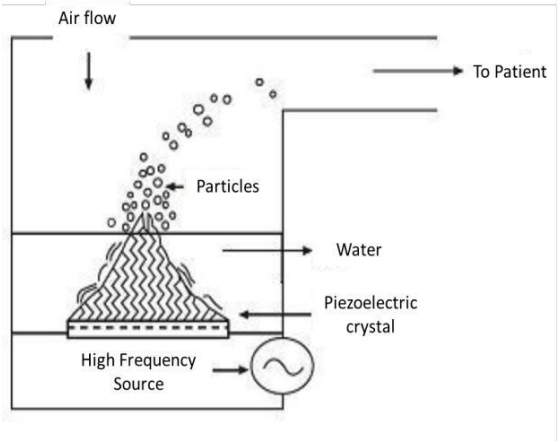

Fig. 1: Working principle of an ultrasonic nebülizer

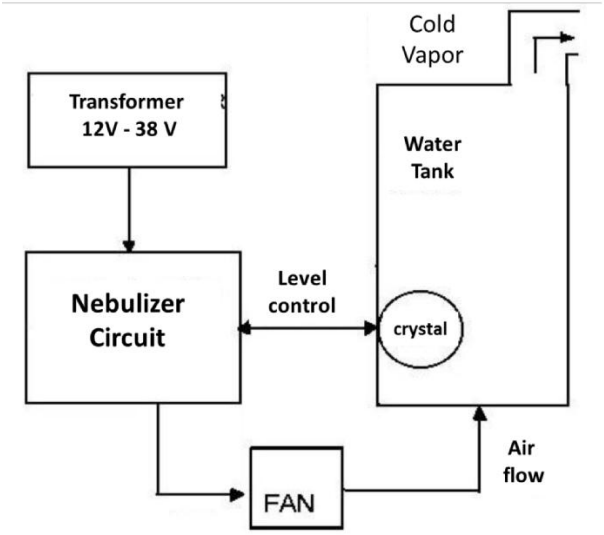

Fig. 2: Block diagram of the designed ultrasonic nebülizer

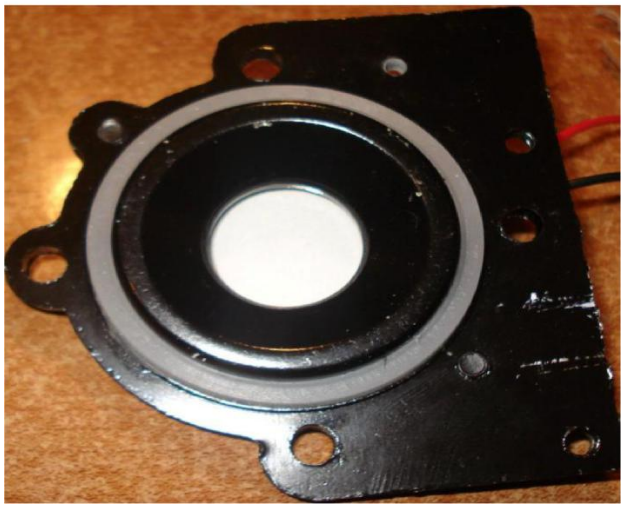

Fig. 3: Ultrasonic crystal

The design and drawing stages of the nebulizer circuit were first completed using the Proteus ISIS program. The design is simulated with the Proteus ISIS program to check the operability of the system. After being confident that the simulation process of the design is completed and the design may work flawlessly, the process of printing circuit board with Proteus ARES program is started. This process is presented in **Fig. 6**.

The design of the boxing process has initiated after the control of the nebulizer circuit and date/clock circuit are implemented and operability of the design is controled. Therefore the circuit and system could be used in maximum confort.

A crystal with a special casting design is placed in the lower part of the water tank. BU 406 power transistor that controls the ultrasonic crystal generates a lot of heat due to the high voltage and fast triggering characteristics. Since this heat may damage the transistor, the special casting that surrounds the crystal is used as a cooler. The water within the water tank cools down the casting and casting cools the crystal and the transistor. This is the reason why water level is critically important for this research. The cold vapor that is generated by the crystal is delivered to the patient by the help of a channel just located on the top of the ultrasonic nebulizer.

Finally, chassis is placed and LCD screen that displays ambient temperature, date/time and control parameters is located on it. Therefore the prototype is finalized. LCD screen and the final design of the ultrasonic nebulizer are shown in **Figs. 7, 8 and 9**.

The experiments are done by changing the ambient temperatures by several radiators that surrounds the ultrasonic nebulizer. At the beginnig the temperature is recorded as 25ºC ±0.3ºC. The process is initiated and the period until the visually detection of cold vapor out from the funnel of the nebulizer is recorded. This period provides the speed of the particles of cold vapor thus giving us the estimations for particle dimensions.

As second step the temperature is increased 5ºC to 30ºC ± 0.3ºC, the process is initiated and the period of visually detection of cold vapour is recorded. As third step the temperature is increased to 35ºC and the entire process is recorded again. As fourth and fifth step, the temperature is reduced to 20ºC ± 0.3ºC and 15ºC ± 0.3ºC, respectively. In those steps, period of visually detection of cold vapor is recorded. All steps are repeated three times to obtain statistically accurate results.

3. Results and Discussion

During the test phase, the ambient temperature is measured in different methods and double checked to ensure that the sensor and system operate properly and consistently. In order to ensure the system has taken correct measurements or not, the measurement stability was controlled with a calibrated thermometer at regular intervals.

Fig.4 presents the relationship between ambient temperature change and period for visually detection of cold vapor. As it is shown as the temperature increases the vapor speed decreases which refers an increase in particle dimensions.

4. Conclusion

The purpose of this project is to prove that it is quite simple to fabricate home made low cost specially designed ultrasonic nebulizers that is mainly imported to Turkey with high prices.

In addition, it is proved that ambient temperature has serious impact on particle dimensions. It is presented that as the ambient temperature increases five celcius, the speed of cold vapour increases around 10% which refers a decrease in particle dimensions. As the temperature decreases five celcius, the speed of cold vapor also decreases 10% which refers an increase in particle dimensions.

As future researches, Particle Image Velocimetry (PIV) might be used to understand the particle dimensions in detail. A PIV may assist us to truly analysis the particle speed and dimensions of the cold vapor as the temperature increases or decreases. Also, in future the sensitivity of the research might be increased, therefore change in particle dimensions and particle speed per one celcius temperature variation might be detected. This may help us to optimize the period for therapeutics.

The most important innovation in this study is to merge a temperature sensor just outside the cover of the ultrasonic nebulizer. This assists users to estimate the particle dimensions and predict the optimum time for therapeutic.

In future, an ultrasonic nebulizer that adjusts the vibration frequency of the ultrasonic crystal based on the change in ambient temperature might be designed. This design may optimize the dimensions of particles and fix the period for therapeutic. This version of an ultrasonic nebulizer will prevent the fluctiations caused by temperature variations of the environment.

This model of an ultrasonic nebulizer is yet haven't fabricated. This should be considered as a future direction.

Variable data extraction
Natural Language Processing

ABSTRACT

Data visualization is an effective tool for communicating the results of opinion surveys, epidemiological studies, statistics on consumer habits, etc. The graphical representation of data usually assists human information processing by reducing demands on attention, working memory, and long-term memory. It allows, among other things, a faster reading of the information (by acting on the forms, directions, colors...), the independence of the language (or culture), a better capture the attention of the audience, etc.

Data that could be graphically represented may be structured or unstructured. The unstructured data, whose volume grows exponentially, often hide important and even vital information for society and companies. It, therefore, takes a lot of work to extract valuable information from unstructured data. If it is easier to understand a message through structured data, such as a table, than through a long narrative text, it is even easier to convey a message through a graphic than a table. In our opinion, it is often very useful to synthesize the unstructured data in the form of graphical representations.

In this paper, we present an approach for processing unstructured data containing statistics in order to represent them graphically. This approach allows transforming the unstructured data into structured one which globally conveys the same countable information. The graphical representation of such a structured data is then obvious. This approach deals with both quantitative and qualitative data. It is based on Natural Language Processing Techniques and Text Mining. An application that implements this process is also presented in this paper.

1. Introduction

The English idiom "A picture is worth a thousand words" expresses an idea implicitly admitted by the human mind and indicates that it is easier to understand a complex idea through an image; But also that an image of a subject conveys its meaning or essence more effectively than a long speech or a textual description does. Data and information visualization is one of the most primitive forms of communication known to man. It meets a very basic need: telling a story. This communication way originated in the drawings found in the prehistoric caves dating back to 30,000 B.C., even before the writing that dates only 3000 B.C.

In our modern world, the visualization of information has evolved and is used to communicate information of all kinds: economic, social, military, health, etc. Graphical representations are the best way to make decisions by facilitating to grasp difficult concepts or to identify new patterns. They help to better process information by reducing the requirements on attention, working memory and long-term memory. In a business environment, visualizations can have two broad goals, which sometimes overlap: Explanatory and Exploratory. Data explanation allows solving specific problems and the exploration of large data sets allows understanding it better. Generally speaking, graphical representations are used to gain better insight of the problem we are studying.

Since the early 1990s, the emergence of the World Wide Web (WWW) [1] has facilitated the access to the information to individuals and companies. It has become the most important vehicle of a tremendous amount of data, allowing the people to share the information from the largest database repositories globally. Almost 80% of the data published on the WWW are unstructured and, despite the computer assistance for data

processing, it remains very difficult to extract valuable knowledge from this large volume of data, when it's about countable data, especially without graphical illustrations.

When unstructured data contain statistics, they may be accompanied by graphical illustrations in the form of static images (GIF, PNG, etc.). These charts and graphics are no longer up-to-date as the data content changes. The graphs should then be reproduced in accordance with the new data.

In our opinion, it would be more appropriate to produce graphical illustrations that correspond exactly to the data processed. This can be made possible by updating the graphical representations, each time the data evolves. However, some data change instantly and reproducing the graphics that are faithful to it makes the process of analyzing it and representing it graphically too complex. The analysis and the graphical representation should, therefore, be on-demand.

The objective of this work is to propose an approach for analyzing data, especially from the WWW in order to extract the relevant countable information, organize it in a way it can be graphically represented and annotate it using the means of the Semantic Web techniques [2]. This allows users to request a graphical representation of this information whenever they want. Indeed, the "on demand graphics" allows taking into account the effective state of the information when such representation is requested.

2. The Graphical Representation of Data

William Playfair (22 September 1759 – 11 February 1823) was the first to devise and publish different types of statistical chart (most notably the time-series line graph, the bar chart, the pie chart, and the circle chart). Modern statistical graphs are almost identical to those published by Playfair and count four basic types of graphs used as well as the graphical representation of stochastic variables: Line graphs/Polygraphs, Bar graphs, Pie graphs and Flow Charts.

Not all data could be graphically represented, and not all graphic representations are of paramount importance. Only data that may vary for effects-related causes can be graphically represented. The objective of these graphical representations is to analyze the causes and predict the effects in order to make the appropriate decisions.

It is usual in the computer science domain to classify data into two well-known categories: structured and unstructured data [3].

Structured data are usually associated with a model or a schema and resides in a fixed field within a record or file such as Relational databases and Spreadsheets. The schema defines the structure of data with data types (string, integers, date, etc.) as well as the way data are stored, accessed and processed. The structured data are easily maintainable and manageable since they are based on Schema-on-write method and managed with most known Structured Query Language (SQL).

Unstructured data do not reside in a field or record, do not have a standard model and do not follow a schema. There's no specific definition of storing, accessing, and processing this kind of data. The unstructured data might follow an internal structure; however, there's no schema, tags, or markers describing the fields of data. Although the unstructured data are difficult to process using traditional computer software modules, their processing is nonetheless very important because of its important volume compared to the structured data. They have remained unidentified or ignored for a long time knowing that important business prospects are hidden in these data as well as social and political trends.

3. Processing the Data

Processing data means processing both structured and unstructured data. In the first case, when data are structured, the variable data are explicitly specified and their different values are well known. The graphical representation of such a data is an easy and very well mastered process. In the second case, when it comes to unstructured data, the amount of text is simply too large to read and analyze efficiently even with assistance of computers. The work is, therefore, more tedious. On the one hand, we must analyze the text to determine the context. On the other hand, it is necessary to extract the statistical data, when it exists, to process it and to carry out calculations in order to transform unstructured data into structured one such as a table.

3.1. Processing Structured Data

The processing of structured data does not pose any significant difficulties. The data are represented in tables, generally easy to understand and interpret. Tables are easy to read, however a visual can communicate more information than a table in a much smaller space and is, therefore more effective than tables for presenting data. For example, notice the Table 1 below, related to the French presidential elections of 2017, and try to spot the candidate with the highest estimated voting rate.

Date	Sample size	Mélenchon	Macron	Fillon	Le Pen
28 Mar 2017	2,231	14%	25.5%	17.5%	25%
24 Mar 2017	2,225	13%	26%	18%	25%
20 Mar 2017	2,245	12.5%	26%	18%	25%
18 Mar 2017	935	11.5%	25%	18%	26%

Table 1. Polls finished since the publication of the official list of candidates

When the data contained in this table are represented graphically (Fig. 1), the information is obtained very quickly. The graphical representation of a structured data set represented in the form of a table presents no particular difficulties. All data processing tools, modern spreadsheets and statistical applications do it very well. The only small problem to be solved in this case is to determine which variable will be represented in the *y-axis* and which will occupy the *x-axis*. This problem is solved from the context of the document that is determined in the same way that the data are structured or not. We will discuss the context of the document and the extraction of variables when processing unstructured data.

The unstructured data that we take into account are texts expressed in natural language. To represent graphically the unstructured data it is necessary that this data contain countable information. These countable data have to be extracted from the text and processed to be transformed into structured data.

Transforming unstructured data into structured data containing the same information requires the specification of a model or a schema for the target structured data. The structure of the countable data in relation to this work is simple and can be specified as a simple association (*variable*, *value*). This association represents what we call the "Main Variable"; e.g. (*candidate*, *voting_rate*). The Main Variable is the one whose values are

represented on the *y-axis*. The value associated with a variable may itself depend on other variable criteria. For example, the *voting_rate* may depend on the *date*, the *region*, the *age* of the voter, etc. A second association necessary is in this case: (*value*, *criterion*).

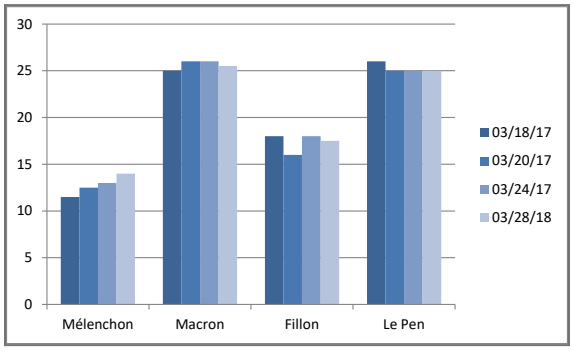

Fig. 1. Data visualization obtained from the Table 1.

3.2. Processing Unstructured Data

The schema of the targeted structured data is modeled as an Ontology that we call "*Ontology of the Context*". Indeed, the different associations specified in this ontology depend on the context. Fig. 2 shows the "*Ontology of the Context*" related to the French Presidential elections of 2017.

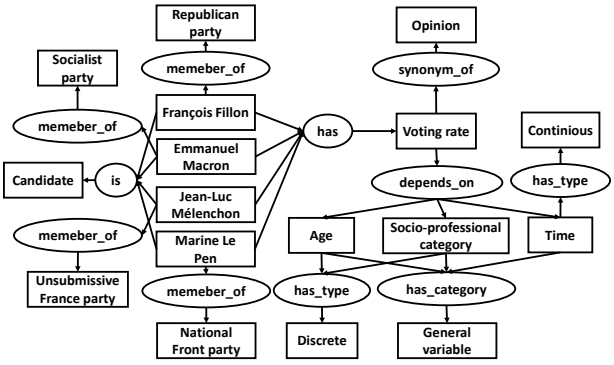

Fig. 2. Ontology of the context

At the present time, the different Ontologies of the Context are modeled manually. The ideal would be that these ontologies be created and updated automatically; this is one of the perspectives of our research works.

The processing of the data is based on two main steps: (i) the identification of variable data and the building of the corresponding structured entity; and (ii) the semantic annotation that avoids reprocessing a set of unstructured data that have already been processed.

4. Transforming unstructured into structured data

Unstructured data that can be subject to statistical calculations may appear in two ways: qualitative data which is when descriptive statements can be made about a subject based on observations, interviews or evaluations, e.g. a political forum (Fig. 3) or numerical values as in the example (*§1*) hereafter:

"*The French Presidential Election of 2017: if you are a French citizen, at least 18 years old, you can participate in the French presidential elections of 2017 and express your opinion. As for most elections in France, presidential elections are conducted in two stages. The first round, which takes place on 23rd April 2017, is open to any candidate who meets the requirements. Assuming, as is virtually certain to happen, that no single candidate acquires no absolute majority of votes in the first round, there is then a second round, a fortnight later, which is a runoff between the two candidates with the highest votes in the first round . The next French President will be whoever gets a simple majority of the votes in the second round.*"

Fig. 3. "French Politics" forum

The processing of unstructured data for the extraction of statistics is a tedious work. On the one hand, we must analyze the text to determine the context. On the other hand, it is necessary to extract the statistical data, when it exists, to process it and to carry out calculations in order to transform unstructured data into structured one such as a table. The overall context in which the data are used allows to build or to update the "Ontology of the Context" [4].

4.1. Identification of the context

The identification of the context requires five main steps as described in [5]:

- The tagging [6] which consists in dividing the text into a sequence of tokens, which roughly correspond to a words and associating to each one of them a label providing certain information (syntactic category, number, verb tense…). This step also allows identifying the different noun phrases and complex nominal groups found in a document. A noun phrase is a word or group of words in a sentence that acts like a noun. A complex nominal group is a simple noun phrase modified by one or two prepositional phrases (preposition followed by a nominal group).
- Named Entity Recognition [7] step which purpose is to label sequences of words in a text (tagged in the first step) which are the names of persons, organizations, locations,

monetary values, etc. The annotation of the different named entities allows identifying variables.

- The coreference resolution [8] occurs when multiple noun phrases refer to the same entity or object in a document. It is an important step in our process, allowing the information extraction, such as the overall context of the document and the significant variable data.
- The Identification of the main topics [9] of a document helps us to identify the most important textual units of a document. These units are formed by key-words that we refer to in this document as "key-terms candidates and are the different noun phrases in a document. The identification of the main topics is basically made thanks to the Text Rank algorithm [10] and the Word Sense Disambiguation process [5].
- The identification of the context is the last step. Once the different main topics are identified, we need to determine only one of them that will be the one representing and defining the context of the document. To do this, first, a similarity rate [11] is computed between each couple of words from the main topics set. The word that has the highest similarity rate with all the other words, is defined as the most important topic of the document. Additional information may be necessary to refine the context. Thus, in a second step, the identification of the different complex nominal groups found in the document is required in order to have a more accurate context. An algorithm allowing the identification of the context has been implemented and experimented [9].

When applying the Context Identification Process on the following paragraph (*§1*), the text raking allows selecting the different main topics found in the data: "*French presidential election*", "*round*", "*president*", "*votes*", "*candidates*", etc. The similarity between all pairs of main topics is calculated and given in Table 2.

	Round	Votes	Candidates	France	President
French Presidential Elections	0,0635	18,7456	0,0616	0,0592	0,0715
Round	×	0,0575	0,0625	0,0585	0,046
Votes	×	×	0,0618	0,0592	0,0715
Candidates	×	×	×	0,0629	0,0487
France	×	×	×	×	0,0471

Table 2. Measurement of similarity rates between all pairs of main topics

The topic that has the highest similarity rate with all the others is: "*French presidential election*". However important information is missing: the date. The algorithm presented in [9] determines the different complex nominal groups and identifies the final context: "*The French presidential election of 2017*".

The similarity rate between the topics "*French presidential election*" and "*votes*" is very high. This represents a very good indication of the variable data to be extracted from the text. Referring to the "Ontology of the Context", we see that the vote is associated with a candidate. The pair (*Variable*, *Value*) of the "Main Variable" is thus identified. Other information is easily identified in this paragraph which is the relationship between the vote and the city which represents the pair (*value*, *criterion*).

4.2. Identification of the countable information

The identification and retrieval of countable data depend on the nature of the data sources. The processing of such a data differs according to the variable data being represented by numerical values or qualitative data.

Case 1: *Data containing numeric values*

The extraction of the variables consists first of all in identifying the key words characterizing each of the identified countable data. This work is still in progress and is mainly based on the Natural Language Processing (NLP) [12] and the Text Mining [13, 14]. At the present time, it uses a controlled vocabulary and is not completely automated. The purpose of this process is to determine the identifiers of each countable data. An identifier of a variable datum is a token obtained from unstructured text and standardized according to the well-known methods used in NLP and indexing, namely stemming and lemmatization [15]. This process occurs simultaneously with the identification of the context. It uses the different named entities extracted in the data processing stage in order to group the ones that belong to the same category (the names of persons, organizations, etc.) in a "class of category". The identifier of the Main Variable is obtained from the keyword which has the highest similarity rate with the identified context, after resolving the coreferences.

The process of identification of significant variable data takes place in three main steps [9]: (*i.*) the grouping of the named entities in classes of categories, (*ii.*) the Classification of named entities of the same class of category, and (*iii.*) the variables' identification. We take the following example (*§2*) to illustrate this three-step process:

(*§2*) "*The French presidential election will be held on April 2017. The election will occur in different French cities to allow the winning candidate to access the presidency. Until now, the candidate with the estimated highest scores of votes is Marine Le Pen. She is credited with 35% of voting intentions in Paris. Polls give her 32% of voting intentions in Toulouse. However, she is ranked third in other cities such as Marseille with 18% of voting intentions and Lyon with 16.5% of voting intentions according to the most recent surveys. We asked the question "who would you vote for?" for the two childhood friends Fabien Martin and Marcel Laurent. Although they lived in the same neighborhood and in the same conditions of life, the two friends vote for two different candidates. Fabien says he will vote for François Fillon while Marcel is in favor of Marine Le Pen*"

i. Processing the named entities, this consists in grouping the named entities belonging to the same "Class of Category" such as the names of persons, organizations, etc. In the (*§2*), a Class of Category "PERSON" gathers four names (Fig.4)

ii. Processing the named entities of the same class of category. Named entities within a same category may belong to different concepts. A concept is a general idea about some distinct entities or classes of entities. Let's consider a class of category that contains different names of candidates and voters (Fig. 4), the process must be able to differentiate between both concepts "*candidate*" and "*voter*". The named entities that belong to the same class of category are classified according to their concept. The Class of Categories PERSON includes candidates for the presidential election (*François Fillon* and *Marine Le Pen*) and other names that can be considered as voters (*Fabien Martin* and *Marcel Laurent*) (Fig. 4). Two classes of concepts have been identified: "*CANDIDATE*" and "*UNKNOWN*" (Fig. 5)

Fig. 4. Building the Classes of Categories

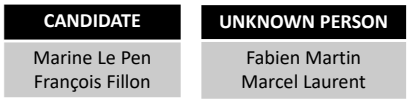

Fig. 5. Building the classes of concepts

iii. Identification of countable data. The last step consists in identifying the variable data: the "Main Variable" that depends on the context and the others according to which the Main Variable varies. We have developed an algorithm [9] allowing to extract the different variables and to "format" them in a structure such as a table. The algorithm builds a matrix *M* with *n* rows (*n* is the number of sentences in the document) and three columns containing respectively *nouns*, *verbs* and *complements*, which are obtained from each sentence. The algorithm splits up the matrix *M* into several sub-matrices (M_k). The cutting of the matrix is based on the verbs. Each row of each sub-matrix contains the triplets (*name*, *verb*, *complement*) extracted from each sentence. The rows of each sub-matrix are formed of all triplets containing the same verb or one of its synonyms.

The processing of (*§2*) using the algorithm [9] results in the following sub-matrices:

$$M_1 = \begin{pmatrix} \text{Noun} & \text{Verb} & \text{Complement} \\ \text{Marine Le Pen} & \text{is credited} & \text{with 35\% of voting intention in Paris} \\ \text{Polls} & \text{give} & \text{Marine Le Pen 32\% of voting intentions in Toulouse} \\ \text{Marine Le Pen} & \text{is ranked} & \text{third in other cities such as Marseille with 18\% of voting intentions and lyon with 16.5\% of voting intentions according to the most recent surveys} \end{pmatrix}$$

$$M_2 = \begin{pmatrix} \text{Noun} & \text{Verb} & \text{Complement} \\ \text{The French presidential election} & \text{will be held} & \text{on April 2017} \end{pmatrix}$$

$$M_3 = \begin{pmatrix} \text{Noun} & \text{Verb} & \text{Complement} \\ \text{The candidate with the highest scores of vote} & \text{is} & \text{Marine Le Pen} \end{pmatrix}$$

Among all the sub-matrices obtained from the splitting up of the matrix *M*, we keep only those with the noun and complement columns corresponding to the parameters of the main variable. In the considered example, only the sub-matrix M_1 contains the name of a candidate in the noun column or complement column. While processing the nouns or the complements one can identifies voting rates (numerical values) as well as the names of some French cities. The pair (*voting_rate*, *city*) is therefore identified. Table 3 is the result of this process:

Candidate	Votes	City
Marine Le Pen	35%	Paris
Marine Le Pen	32%	Toulouse
Marine Le Pen	18%	Marseille
Marine Le Pen	16,5%	Lyon

Table 3. Identification of countable data

Case 2: Qualitative data

The political forum contains only expressions of voting intentions and no numerical data (Fig. 3). Each row of it is an expression of opinion in which the "*speaker*" supports the *candidate* he has chosen.

In an unstructured text where people express their opinions, it is important to determine the author of the text of an opinion as well as the content of that opinion. The Opinion generally expresses a positive or negative feeling towards a particular context or situation. The recognition of the "*speaker*" prevents counting the same opinion several times.

Several works have been carried out for the recognition of the "*speaker*" in a text. K. Glass and S. Bangay [16] propose "a naïve, salience-based method for speaker identification in fiction books". They have shown that it is possible to identify different speakers from a text without using a complex machine learning or logic-based techniques. D. K. Elson et al. [17] proposed a method for extracting social networks from literary fiction. This method allows identifying all the characters in a story and determining which characters have relationships with each other. The method also allows determining whether the sentiment in each relationship is positive or negative. Other research works [18, 19] have addressed the same subject and demonstrated the feasibility of recognizing the speaker in the texts. Some of the "speaker recognition" methods have been implemented.

The sentiment analysis [20, 21], also known as opinion mining, seeks to recognize and characterize aspects of an author's opinion or appreciation on a topic from information in natural language written texts. An opinion can be expressed by a person or an organization about a product, a service, a topic, an event, etc. We use the word "*entity*" to qualify the topic that is evaluated by an expression of feeling. For example, the entity in a political forum is a candidate.

The sentiment analysis focuses today on attributing of a polarity to subjective expressions (words and phrases that express opinions, emotions, feelings, etc.) in order to decide the orientation of an opinion [22] or the positive / negative / neutral value of it in a document [23][24][25]. Most of the techniques used for the classification of sentiment in texts in natural languages are based on supervised learning, e.g. naive Bayesian classification, support vector machines (SVM), or any other supervised learning method.

In our experiments, we have used the implementation of the speaker recognition as well as the sentiment analysis in the Stanford CoreNLP framework [26].

The object that is evaluated by a sentiment in a text depends on the context. At the present time, it is determined as the Main Variable by the Ontology of the Context. The value associated with the Main Variable is calculated by summing the positive opinions expressed. Negative or neutral opinions are not taken into account. For example, in political forum (Fig. 3), voting intentions are calculated by adding together the speakers who express an opinion favorable to a given candidate. When a speaker changes his mind, only his last expression is taken into account.

5. Application

The results of our research works have been implemented as an application allowing transforming unstructured data into structured data that could be represented graphically. The architecture of the application is presented in Fig. 6.

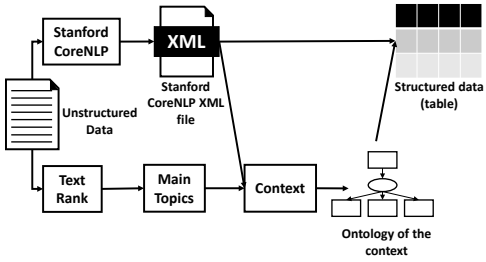

Fig. 6. Architecture of the application

The application has been developed with the help of the following open source frameworks:

- *Stanford CoreNLP* [26], a Java open source framework created by Stanford University, that implements most of the common core natural language processing (NLP) steps needed in our approach, from tokenization through to coreference resolution.
- *TextRank* [27]: a Java implementation of the TextRank algorithm allowing the identification of the most important keywords in a document.
- *WordNet* Similarity *for Java* (WS4J) [28]: a module that implements a variety of semantic similarity and relatedness measures based on information found in the lexical database WordNet.

The application has been tested on several types of data. In this paper, we present the case of the French presidential elections of 2017. The recognition of the context is precise however, we had some problems for the recognition of the "speaker". We have modified the source code, but we have not yet got the expected precision and a research work is underway to address this issue.

The forum contains only expressions of voting intentions and no numerical data (Fig. 3). Each row of it is an expression of opinion in which the "*speaker*" supports the *candidate* he has chosen. Fig. 7, Fig. 8, Fig. 9 and Fig. 10 represent the output of the application:

6. Conclusion

Visualization provides a simple, easy-to-interpret idea of a data volume that may be too large. The graphically representable data generally contain relationships between causes and effects that may change according to different criteria (date, region, climate, etc.). Data linked by cause-and-effect relationships can be either quantitative or qualitative and may also be in the form of structured or unstructured data. When it comes to unstructured data, it is easy for a human mind to extract relationships and make the graphical representation if the volume of data provided is reasonable. Since this is a very large volume of data, computer assistance is essential. For structured data, this is hardly a problem, but when it comes to unstructured data, the work is more tedious.

In this paper, we present a method allowing the graphical representation of statistical data presented in the form of unstructured data. The first consists of transforming the unstructured data into structured data and then graphically represent this latter, which is an obvious task. We also present a framework developed from the results obtained from our research. The method is based on NLP and text mining for the analysis and identification of statistical data. An algorithm has been developed for the transformation of unstructured statistical data into structured data easily represented graphically.

The work presented in this paper is only the first step. Currently, it leaves an important number of research perspectives. Indeed, this work concerns only a single document. In our future work, we will exploit the results of a Web search query to make a graphical representation of common significant variable data. Similarly, we will intend to improve our process using the Text mining. This technique concerns the classification of multiple documents in order to enrich the "Ontology of the Context". Besides, it will allow the analyses of the documents in order to extract the variable data.

Sparse Neugebauer Model

ABSTRACT

This paper proposes a method for estimating the spectral reflectance of Neugebauer primaries or eight basic colors when the spectral reflectance data of several colors are given. The proposed method is based on Neugebauer model, which expresses an arbitrary color as a weighted average of Neugebauer primaries, and its sparse version called sparse Neugebauer model. We also reproduce the colors from the estimated reflectance spectra, and show experimental results of spectral reflectance estimation and color reproduction from the estimated spectral data. It is experimentally demonstrated that the sparse Neugebauer model outperforms the conventional Neugebauer model in both spectral reflectance estimation and color reproduction.

1. Introduction

The reflectance properties of object surfaces are determined by the spectral reflectance factors that are normally measured at regular intervals in the visible spectrum of radiation by reflectance spectrophotometers [1]. The integrals of the products of the spectral reflectance, the relative spectral power distribution of an illuminant and color matching functions produce the tristimulus values. On the other hand, the inverse computation from tristimulus values or colorimetric data to the spectral reflectance is a difficult problem because the computation of tristimulus values from spectral reflectance involves the dimensionality reduction of data, i.e., the spectral reflectance estimation is an ill-posed problem.

Recently, Sharma and Wang proposed a neural network-based spectrum recovery method, and evaluated the accuracy of the spectrum recovery by the spectral mean-squared error [2]. Harifi et al. presented a principal component analysis (PCA)-based method which employed six principal components [3]. Amiri and Amirshahi proposed a step by step progressive method for recovery of spectral data from the corresponding colorimetric information, where the spatial dimensions are decreased from 6D to 3D in a step-by-step manner to decrease the number of samples used for color gamut interpolation [4]. Wu et al. presented an approach that uses a new sample selection criterion based on color feature match to select a series of suitable samples for creating the adapted transformation matrix to reconstruct spectral reflectance [5]. Inoue et al. proposed two methods for recovering the reflectance spectra of colorimetric data by using the non-negative constraints in reflectance spectra, where the problem of reflectance spectra recovery is formulated as a nonnegative least squares problem [6] into which the Neugebauer model [7] is incorporated [8]. These methods can be used to estimate the spectral reflectance from general colorimetric data including CIE tristimulus values and CMYK-printed samples.

The Neugebauer model can be used to infer the gamut boundaries of printed colorants on paper [7] by printers such as conventional CMYK printers. If three inks, such as cyan, magenta and yellow, are utilized, then the paper may be covered by one ink, two inks, three inks, or may be left blank. As a result, eight combinations of overlap of inks can occur, and they correspond to eight basic colors, such as red, green, blue, black, cyan, magenta, yellow and white, which are referred to as the Neugebauer primaries [7]. Although the Neugebauer model was originally developed for modeling the printed colorants on paper, it can be used for general colorimetric data as we will prove in Subsection 2.1 that the equation of the Neugebauer model holds for any color in RGB color space.

In this paper, we propose sparse Neugebauer model for estimating spectral reflectance of Neugebauer primaries or basic eight colors when reflectance spectra of several colors are given. Experimental results show that the proposed method achieves

Email: k-inoue@design.kyushu-u.ac.jp

lower estimation error than the previous method with the conventional Neugebauer model. We also reproduce the Neugebauer primaries and the colors of given reflectance spectra from the estimated reflectance spectra. The effectiveness of the sparse Neugebauer model in color reproduction is also demonstrated in comparison with the conventional Neugebauer model.

The rest of this paper is organized as follows. Section 2 summarizes the Neugebauer model, and then proposes the sparse Neugebauer model. Section 3 proposes a method for estimating the spectral reflectance based on the Neugebauer models, and a convergence property of the proposed estimation algorithm is proved. Section 4 describes the procedure for reproducing the colors from the estimated spectral data. Section 5 shows experimental results. Finally, Section 6 concludes this paper.

2. Neugebauer Models

In this section, we first summarize the Neugebauer model, and then propose sparse Neugebauer model to improve the performance of spectral reflectance estimation and color reproduction.

2.1. Neugebauer Model

Let $\boldsymbol{v} = [r, g, b]$ be a color vector in RGB color space (bold italic lowercase letters denote vectors), where r, g and b denote the red, green and blue components of the color, and satisfy $0 \le r \le 1, 0 \le g \le 1$ and $0 \le b \le 1$, respectively. Then $\boldsymbol{v}$ have another expression as follows:

$$\boldsymbol{v} = a_1\boldsymbol{r} + a_2\boldsymbol{g} + a_3\boldsymbol{b} + a_4\boldsymbol{k} + a_5\boldsymbol{c} + a_6\boldsymbol{m} + a_7\boldsymbol{y} + a_8\boldsymbol{w}, \quad (1)$$

where $\boldsymbol{r} = [1,0,0], \boldsymbol{g} = [0,1,0], \boldsymbol{b} = [0,0,1], \boldsymbol{k} = [0,0,0], \boldsymbol{c} = \boldsymbol{w} - \boldsymbol{r}, \boldsymbol{m} = \boldsymbol{w} - \boldsymbol{g}, \boldsymbol{y} = \boldsymbol{w} - \boldsymbol{b}$ and $\boldsymbol{w} = [1,1,1]$ denote the Neugebauer primaries [7]: red, green, blue, black, cyan, magenta, yellow and white, respectively. The coefficients in (1) are given by

$$\begin{aligned} a_1 &= r(1-g)(1-b), \quad a_5 = (1-r)gb, \\ a_2 &= (1-r)g(1-b), \quad a_6 = r(1-g)b, \\ a_3 &= (1-r)(1-g)b, \quad a_7 = rg(1-b), \\ a_4 &= (1-r)(1-g)(1-b), \quad a_8 = rgb, \end{aligned} \quad (2)$$

which are called the Demichel equations, and (1) is called the Neugebauer equation [7]. The coefficients in (2) are nonnegative and satisfy $\sum_{k=1}^{K} a_k = 1$ where $K = 8$. The equality in (1) with the coefficients in (2) can be confirmed for each element as follows: for example, the first element in (1) satisfies

$$\begin{aligned} &r(1-g)(1-b) + r(1-g)b + rg(1-b) + rgb \\ &= r[(1-g)(1-b) + (1-g)b + g(1-b) + gb] \\ &= r[(1-g)\{(1-b) + b\} + g\{(1-b) + b\}] \\ &= r[(1-g) + g][(1-b) + b] = r. \end{aligned}$$

The similar equations hold for the second and third elements in (1).

We simply call (1) with (2) the Neugebauer model, which is valid for both tristimulus values and spectral reflectance, and use it for spectral reflectance estimation.

2.2. Sparse Neugebauer Model

Let $S = \{\boldsymbol{r}, \boldsymbol{g}, \boldsymbol{b}, \boldsymbol{k}, \boldsymbol{c}, \boldsymbol{m}, \boldsymbol{y}, \boldsymbol{w}\}$ be a set of the Neugebauer primaries. Then the Neugebauer equation in (1) states that an arbitrary color vector $\boldsymbol{v}$ can be expressed as a weighted average of the eight color vectors in S. We can also express a color vector in RGB color space as a linear combination of four colors which are in general position in RGB color space because four points being in general position in a three-dimensional color span a three-dimensional linear space, and form a tetrahedron. If a color is just on a plane spanned by three vertices of RGB color cube or a line connecting two vertices of RGB color cube, then the color is expressed as the linear combinations of three or two vertices, respectively. We describe the most general four-color case as follows (in the other degenerated cases, the description can be simplified): Let $\tilde{S} = \{\boldsymbol{s}_1, \boldsymbol{s}_2, \boldsymbol{s}_3, \boldsymbol{s}_4\}$ be a subset of S the elements of which are in general position. Then, for a color vector $\boldsymbol{v}$, we have

$$\begin{aligned} \boldsymbol{v} - \boldsymbol{s}_1 &= \alpha_2(\boldsymbol{s}_2 - \boldsymbol{s}_1) + \alpha_3(\boldsymbol{s}_3 - \boldsymbol{s}_1) + \alpha_4(\boldsymbol{s}_4 - \boldsymbol{s}_1) \\ &= [\alpha_2, \alpha_3, \alpha_4]\begin{bmatrix} \boldsymbol{s}_2 - \boldsymbol{s}_1 \\ \boldsymbol{s}_3 - \boldsymbol{s}_1 \\ \boldsymbol{s}_4 - \boldsymbol{s}_1 \end{bmatrix}, \end{aligned}$$

from which the coefficients $\alpha_2, \alpha_3, \alpha_4$ are given by

$$[\alpha_2, \alpha_3, \alpha_4] = (\boldsymbol{v} - \boldsymbol{s}_1)\begin{bmatrix} \boldsymbol{s}_2 - \boldsymbol{s}_1 \\ \boldsymbol{s}_3 - \boldsymbol{s}_1 \\ \boldsymbol{s}_4 - \boldsymbol{s}_1 \end{bmatrix}^{-1},$$

where $\boldsymbol{s}_1$ is selected as a basic point. As a result, we have

$$\boldsymbol{v} = \alpha_1\boldsymbol{s}_1 + \alpha_2\boldsymbol{s}_2 + \alpha_3\boldsymbol{s}_3 + \alpha_4\boldsymbol{s}_4, \quad (3)$$

where $\alpha_1 = 1 - \alpha_2 - \alpha_3 - \alpha_4$, and the four coefficients are nonnegative if $\boldsymbol{v}$ is in the tetrahedron with the four vertices in $\tilde{S}$. We call (3) the sparse Neugebauer model since four coefficients among eight ones in (1) are zero in (3).

We adapt the minimal brightness variation criterion (MBVQ) proposed by Shaked et al. [9] for selecting four Neugebauer primaries $\boldsymbol{s}_1, \boldsymbol{s}_2, \boldsymbol{s}_3, \boldsymbol{s}_4$, which are called the minimal brightness variation quadruple (MBVQ) [9], and given by $\{\boldsymbol{r}, \boldsymbol{g}, \boldsymbol{b}, \boldsymbol{k}\}, \{\boldsymbol{w}, \boldsymbol{c}, \boldsymbol{m}, \boldsymbol{y}\}, \{\boldsymbol{m}, \boldsymbol{y}, \boldsymbol{g}, \boldsymbol{c}\}, \{\boldsymbol{r}, \boldsymbol{g}, \boldsymbol{m}, \boldsymbol{y}\}, \{\boldsymbol{r}, \boldsymbol{g}, \boldsymbol{b}, \boldsymbol{m}\}$ or $\{\boldsymbol{c}, \boldsymbol{m}, \boldsymbol{g}, \boldsymbol{b}\}$.

3. Spectral Reflectance Estimation

Assume that the reflectance spectra of m colors $\boldsymbol{v}_i = [r_i, g_i, b_i]$ for $i = 1, \dots, m$ are given and stored in $Q = [q_{ij}]$, where q_{ij} denotes the reflectance of the jth wavelength λ_j for $j = 1, \dots, n$ in the ith color $\boldsymbol{v}_i$. Then, by the above nonsparse or sparse Neugebauer model, we have

$$Q \approx AP,$$

where $A = [a_{ik}]$ denotes an $m \times K$ coefficient matrix whose elements are given by

$$a_{i,1} = r_i(1-g_i)(1-b_i),\ \ a_{i,5} = (1-r_i)g_ib_i,$$

$$a_{i,2} = (1-r_i)g_i(1-b_i),\ \ a_{i,6} = r_i(1-g_i)b_i,$$

$$a_{i,3} = (1-r_i)(1-g_i)b_i,\ \ a_{i,7} = r_ig_i(1-b_i),$$

$$a_{i,4} = (1-r_i)(1-g_i)(1-b_i),\ \ a_{i,8} = r_ig_ib_i, \qquad (4)$$

when the Neugebauer model is used, and these are the Demichel equations [7] for the ith color $\boldsymbol{v}_i$, and the number of columns in A is the number of the Neugebauer primaries, i.e., $K = 8$. For the sparse Neugebauer model, four coefficients out of the eight ones in (4) become zero. $P = [p_{kj}]$ denotes a $K \times n$ matrix whose (k, j) element p_{kj} is the reflectance of the k th Neugebauer primary at the jth wavelength λ_j. Then we formulate the problem for estimating the spectral reflectance of the Neugebauer primaries as follows:

$$\min_P \|Q - AP\|_F^2, \qquad (5)$$

$$\text{subj. to}\ \ p_{kj} \geq 0, \qquad (6)$$

where $\|\cdot\|_F$ denotes the Frobenius norm, and the constraint (6) is for $k = 1, \dots, K$ and $j = 1, \dots, n$. Let $E(P)$ be the objective function in (5), then we have

$$E(P) = \sum_{i=1}^m \sum_{j=1}^n \left(q_{ij} - \sum_{k=1}^K a_{ik}p_{kj}\right)^2$$

$$= \sum_{i=1}^m \sum_{j=1}^n \left[q_{ij}^2 - 2q_{ij}\sum_{k=1}^K a_{ik}p_{kj} + \left(\sum_{k=1}^K a_{ik}p_{kj}\right)^2\right].$$

Since $\sum_{i=1}^m \sum_{j=1}^n q_{ij}^2$ is a constant independent of p_{kj}, the minimization of $E(P)$ is equivalent to the maximization of

$$F(P) = \sum_{i=1}^m \sum_{j=1}^n \left[q_{ij}\sum_{k=1}^K a_{ik}p_{kj} - \frac{1}{2}\left(\sum_{k=1}^K a_{ik}p_{kj}\right)^2\right]. \qquad (7)$$

Applying Jensen's inequality [10] to the second term of the right side in (7), we have

$$\left(\sum_{k=1}^K a_{ik}p_{kj}\right)^2 = \left(\sum_{k=1}^K u_{ijk}\frac{a_{ik}p_{kj}}{u_{ijk}}\right)^2$$

$$\leq \sum_{k=1}^K u_{ijk}\left(\frac{a_{ik}p_{kj}}{u_{ijk}}\right)^2 = \sum_{k=1}^K \frac{(a_{ik}p_{kj})^2}{u_{ijk}}, \qquad (8)$$

where u_{ijk} are positive constants satisfying $\sum_{k=1}^K u_{ijk} = 1$. Substituting the rightmost term in (8) into (7), we have a lower bound of $F(P)$ as

$$F_{LB}(P, U) = \sum_{i=1}^m \sum_{j=1}^n \left[q_{ij}\sum_{k=1}^K a_{ik}p_{kj} - \frac{1}{2}\sum_{k=1}^K \frac{(a_{ik}p_{kj})^2}{u_{ijk}}\right], \qquad (9)$$

where $U = [u_{ijk}]$ denotes a three-dimensional array having u_{ijk} as its (i, j, k) element.

Replacing F with F_{LB}, we formulate the problem of spectral reflectance estimation as follows:

$$\max_{P,U} F_{LB}(P, U) \qquad (10)$$

$$\text{subj. to}\ \ \sum_{k=1}^K u_{ijk} = 1,\ \ u_{ijk} > 0,\ \ p_{kj} \geq 0. \qquad (11)$$

Let $L = F_{LB} - \sum_{i=1}^m \sum_{j=1}^n \mu_{ij}(\sum_{k=1}^K u_{ijk} - 1)$ be the Lagrange function for the constrained maximization problem (10) with (11), where μ_{ij} for $i = 1, \dots, m$ and $j = 1, \dots, n$ are the Lagrange multipliers. Then we have the following condition for optimality:

$$\frac{\partial L}{\partial u_{ijk}} = \frac{1}{2}\frac{(a_{ik}p_{kj})^2}{u_{ijk}^2} - \mu_{ij} = 0,$$

from which we have

$$u_{ijk} = \frac{a_{ik}p_{kj}}{\sqrt{2\mu_{ij}}}, \qquad (12)$$

which is substituted into

$$\frac{\partial L}{\partial \mu_{ij}} = \sum_{k=1}^K u_{ijk} - 1 = 0$$

to obtain

$$\sqrt{2\mu_{ij}} = \sum_{k=1}^K a_{ik}p_{kj}. \qquad (13)$$

Substitution of (13) into (12) gives

$$u_{ijk} = \frac{a_{ik}p_{kj}}{\sum_{l=1}^K a_{il}p_{lj}}. \qquad (14)$$

Next, we solve the following optimality condition for p_{kj}:

$$\frac{\partial L}{\partial p_{kj}} = \frac{\partial F_{LB}}{\partial p_{kj}} = \sum_{i=1}^m \left(a_{ik}q_{ij} - \frac{a_{ik}^2 p_{kj}}{u_{ijk}}\right) = 0,$$

and have

$$p_{kj} = \frac{\sum_{i=1}^m a_{ik}q_{ij}}{\sum_{i=1}^m \frac{a_{ik}^2}{u_{ijk}}},$$

into which we substitute (14) to have

$$p_{kj} = \frac{\sum_{i=1}^m a_{ik}q_{ij}}{\sum_{i=1}^m a_{ik}^2 \frac{\sum_{l=1}^K a_{il}p_{lj}}{a_{ik}p_{kj}}} = p_{kj}\frac{\sum_{i=1}^m a_{ik}q_{ij}}{\sum_{i=1}^m \sum_{l=1}^K a_{ik}a_{il}p_{lj}},$$

from which we have an iterative formula for p_{kj} as follows:

$$p_{kj}^{(t+1)} = p_{kj}^{(t)}\frac{\sum_{i=1}^m a_{ik}q_{ij}}{\sum_{i=1}^m \sum_{l=1}^K a_{ik}a_{il}p_{lk}^{(t)}}, \qquad (15)$$

where t denotes the number of iterations for $t = 0, 1, \dots, T$ with the maximum iteration number T. The above formula (15) can be written in a matrix form as

$$P^{(t+1)} = P^{(t)} \odot (A^T Q) \oslash \left(A^T A P^{(t)}\right), \qquad (16)$$

where $\odot$ and $\oslash$ denote the element-wise multiplication and division, respectively, because $p_{kj}^{(t)}$, $\sum_{i=1}^{m} a_{ik}q_{ij}$ and $\sum_{i=1}^{m}\sum_{l=1}^{K} a_{ik}a_{il}p_{lk}^{(t)}$ in (15) are the (k,j) elements of matrices $P^{(t)}$, A^TQ and $A^TAP^{(t)}$ in (16), respectively.

Proposition 1 *The sequence* $\{E(P^{(t)})\}_{t=0,1,\ldots}$ *converges.*

Proof. Let

$$u_{ijk}^{(t+1)} = \frac{a_{ik}p_{kj}^{(t)}}{\sum_{l=1}^{K} a_{il}p_{lj}^{(t)}} \tag{17}$$

be an instance of u_{ijk} substituted $p_{kj}^{(t)}$ for p_{kj} in (14). Then (15) can be written as

$$p_{kj}^{(t+1)} = \frac{\sum_{i=1}^{m} a_{ik}q_{ij}}{\sum_{i=1}^{m} \frac{a_{ik}^2}{u_{ijk}^{(t+1)}}}. \tag{18}$$

Since (17) is the solution to $\partial L/\partial u_{ijk} = 0$ and $\partial L/\partial \mu_{ij} = 0$ with $P = P^{(t)}$, we find that $F_{LB}(P^{(t)}, U^{(t+1)}) \geq F_{LB}(P^{(t)}, U^{(t)})$. Similarly, since (18) is the solution to $\partial L/\partial p_{kj} = 0$ with $U = U^{(t+1)}$, we find that $F_{LB}(P^{(t+1)}, U^{(t+1)}) \geq F_{LB}(P^{(t)}, U^{(t+1)})$, i.e.,

$$F_{LB}\left(P^{(t+1)}, U^{(t+1)}\right) \geq F_{LB}\left(P^{(t)}, U^{(t)}\right). \tag{19}$$

Next, substituting (14) into (9), we have

$$F_{LB}(P,U) = \sum_{i=1}^{m}\sum_{j=1}^{n}\left[q_{ij}\sum_{k=1}^{K} a_{ik}p_{kj} - \frac{1}{2}\sum_{k=1}^{K}\frac{\left(a_{ik}p_{kj}\right)^2}{a_{ik}p_{kj}}\sum_{l=1}^{K} a_{il}p_{lj}\right]$$

$$= \sum_{i=1}^{m}\sum_{j=1}^{n}\left[q_{ij}\sum_{k=1}^{K} a_{ik}p_{kj} - \frac{1}{2}\left(\sum_{k=1}^{K} a_{ik}p_{kj}\right)^2\right] = F(P),$$

from which and (19) we have

$$F\left(P^{(t+1)}\right) \geq F\left(P^{(t)}\right). \tag{20}$$

Considering the relationship between $E(P)$ and $F(P)$ given by $E(P) = \sum_{i=1}^{m}\sum_{j=1}^{n} q_{ij}^2 - 2F(P)$, we have the following inequality from (20):

$$E\left(P^{(t+1)}\right) \leq E\left(P^{(t)}\right),$$

that is, the sequence $\{E(P^{(t)})\}_{t=0,1,\ldots}$ is monotonically nonincreasing, and is also bounded below by 0, i.e., $E(P) \geq 0$ by definition. Consequently, the sequence $\{E(P^{(t)})\}_{t=0,1,\ldots}$ converges to a number greater than or equal to 0. ■

4. Color Reproduction

Let $\bar{x}(\lambda)$, $\bar{y}(\lambda)$ and $\bar{z}(\lambda)$ be the color matching functions for the 1931 2° CIE standard colorimetric observer [], where λ denotes a wavelength, and let $\bar{s}(\lambda)$ be the relative spectral power distribution of an illuminant. Then the CIE XYZ tristimulus values of a spectral reflectance $\bar{p}(\lambda)$ are given by

$$\bar{X} = \bar{k}\int \bar{s}(\lambda)\bar{p}(\lambda)\bar{x}(\lambda)d\lambda, \tag{21}$$

$$\bar{Y} = \bar{k}\int \bar{s}(\lambda)\bar{p}(\lambda)\bar{y}(\lambda)d\lambda, \tag{22}$$

$$\bar{Z} = \bar{k}\int \bar{s}(\lambda)\bar{p}(\lambda)\bar{z}(\lambda)d\lambda, \tag{23}$$

where $\bar{k}$ is a normalizing factor given by $\bar{k} = \int \bar{s}(\lambda)\bar{y}(\lambda)d\lambda$. We use the trapezoidal rule for computing the above integrals. The transformation from the CIE XYZ tristimulus values into the standard RGB (sRGB) is as follows. First, we compute the linear transformation

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} 3.2406 & -1.5372 & -0.4986 \\ -0.9689 & 1.8758 & 0.0415 \\ 0.0557 & -0.2040 & 1.0570 \end{bmatrix}\begin{bmatrix} \bar{X} \\ \bar{Y} \\ \bar{Z} \end{bmatrix},$$

where note that similar but slightly different transformation matrices are also proposed and used in practice.

Next, a nonlinear luminance encoding, which is also known as gamma encoding, is calculated to obtain sRGB values as follows:

$$R_{\mathrm{sRGB}} = \begin{cases} 1.055R^{\frac{1}{2.4}} - 0.055, & \text{if } R > 0.0031308, \\ 12.92R, & \text{if } R \leq 0.0031308; \end{cases}$$

$$G_{\mathrm{sRGB}} = \begin{cases} 1.055G^{\frac{1}{2.4}} - 0.055, & \text{if } G > 0.0031308, \\ 12.92G, & \text{if } G \leq 0.0031308; \end{cases}$$

$$B_{\mathrm{sRGB}} = \begin{cases} 1.055B^{\frac{1}{2.4}} - 0.055, & \text{if } B > 0.0031308, \\ 12.92B, & \text{if } B \leq 0.0031308. \end{cases}$$

Consequently, we obtain the sRGB values $(R_{\mathrm{sRGB}}, G_{\mathrm{sRGB}}, B_{\mathrm{sRGB}})$ transformed from the CIE XYZ tristimulus values $(\bar{X}, \bar{Y}, \bar{Z})$.

5. Experimental Results

In this section, we show experimental results of spectral reflectance estimation and color reproduction. Figure 1 shows the Macbeth ColorChecker (MCC), of which the manufacturer's sRGB D65 color values are also given on the Internet (ColorChecker, Wikipedia. URL: https://en.wikipedia.org/wiki/ColorChecker). Although the 24 squares of painted samples in MCC are not materials but colorants, the proposed method can handle both of them equally because the Neugebauer model is valid for general colorimetric data as shown in Subsection 2.1.

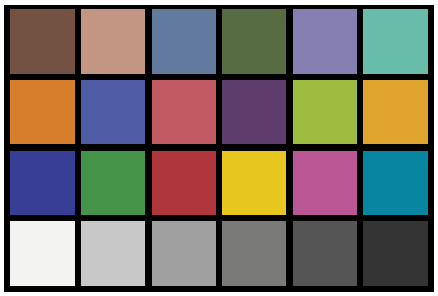

Figure 1 Macbeth ColorChecker.

The spectral reflectance data of the 24 colors in MCC are shown in Figure 2, where the line colors correspond to the MCC colors. These data are provided by the Munsell Color Science Laboratory (URL: http://www.cis.rit.edu/research/mcsl2/online/cie.php).

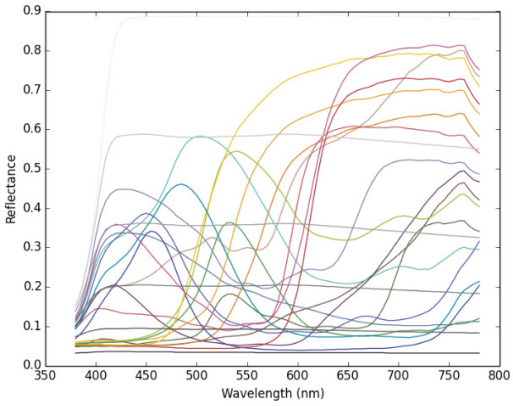

Figure 2 Reflectance spectra of Macbeth ColorChecker colors.

In the following experiments, we store the above data in a matrix $Q \in \mathbb{R}^{m \times n}$ where m denotes the number of colors in MCC, i.e., $m = 24$, and n denotes the number of spectral data in which the wavelengths between 380 nm (nanometer) and 780 nm are sampled at 5 nm intervals, i.e., $n = 81$.

Figure 3 shows the change in the value of the objective function $E(P)$ of the proposed method with the Neugebauer model described in Section 2.1, where the vertical and horizontal axes denote the objective function value and the number of iterations t with the maximum iteration number $T = 50$, respectively. The objective function value monotonically decreases with the increase in the number of iterations, that supports the claim in Proposition 1 experimentally.

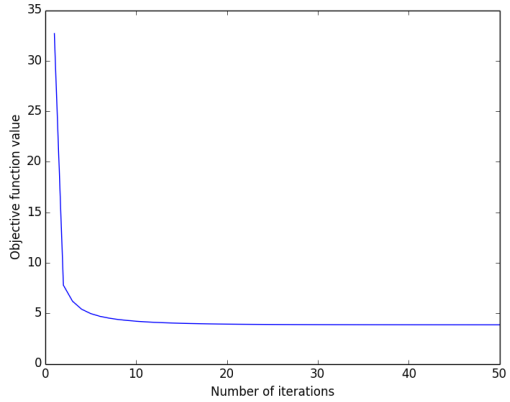

Figure 3 Change in objective function value.

Figure 4 shows the estimated spectral reflectance of the Neugebauer primaries by the sequential coordinate-wise algorithm (SCA) [6,8], where the vertical and horizontal axes denote the reflectance and wavelength, respectively, and the colors of solid lines correspond to the primary colors, and the broken line denotes white color. On the other hand, Figure 5 shows the estimated spectral reflectance by the proposed method with the Neugebauer model, and is similar to Figure 4, although the algorithms are different from each other. We measured CPU time for estimating the spectral reflectance on an Intel Core-i3-equipped PC using Portable Python 2.7.6.1. Then SCA and the proposed method required 1.12 and 0.028 seconds, respectively, from which we conclude that the proposed method is computationally more efficient than SCA.

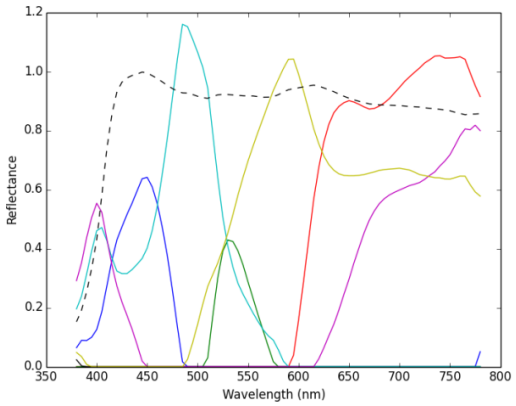

Figure 4 Estimated spectral reflectance by SCA [6,8].

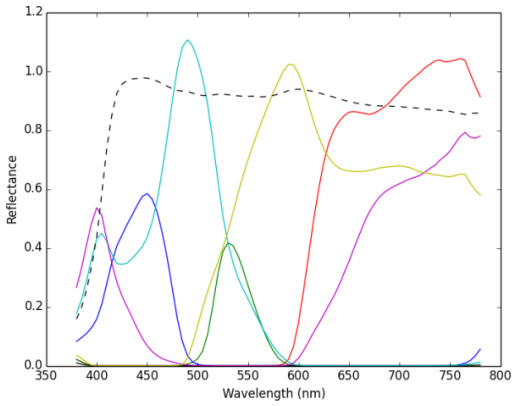

Figure 5 Estimated spectral reflectance by the proposed method with Neugebauer model.

Next, we compare sparse Neugebauer model with nonsparse or conventional Neugebauer model in the proposed method. Figure 6 shows the coefficients in two Neugebauer models for the upper left color in MCC in Figure 1, where the vertical and horizontal axes denote the value of each coefficient and the Neugebauer primaries, respectively. the blue and red bars denote conventional (nonsparse) and sparse Neugebauer models, respectively. In the conventional model (blue bars), all Neugebauer primaries have positive values. On the other hand, in sparse one (red bars), only four colors (R, G, B and M) have positive values, and the other coefficients are strictly zero.

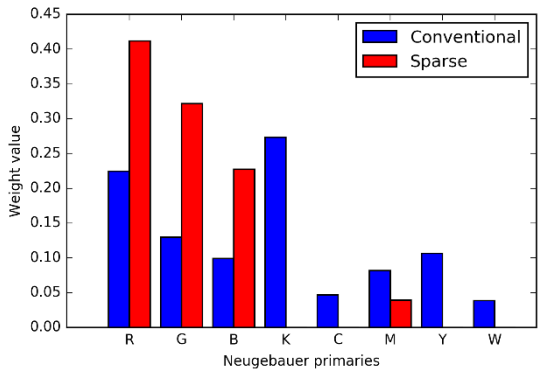

Figure 6 Coefficients in Neugebauer models.

Figure 7 shows the estimated spectral reflectance of the Neugebauer primaries by the proposed method with the sparse Neugebauer model. Each curve in Figure 7 has greater variance than that in Figure 5 or 4.

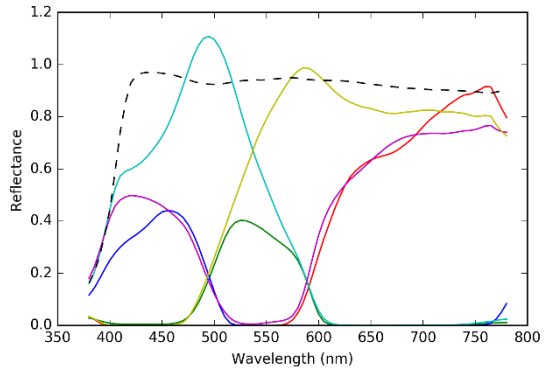

Figure 7 Estimated spectral reflectance by the proposed method with sparse Neugebauer model.

From Figure 8 to Figure 11, we show the reflectance spectra of the colors in MCC from the first to fourth rows, respectively (here we divide the 24 MCC colors into 4 figures each of which includes the spectral reflectance curves of 6 colors for visibility), where solid lines show the original reflectance spectra, and broken lines show their estimated ones by the proposed method with the Neugebauer model.

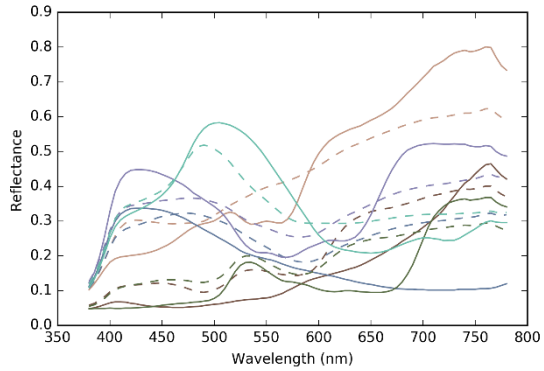

Figure 8 The original reflectance spectra of the colors in the first row of MCC (solid lines) and their estimated ones by the proposed method with Neugebauer model (broken lines).

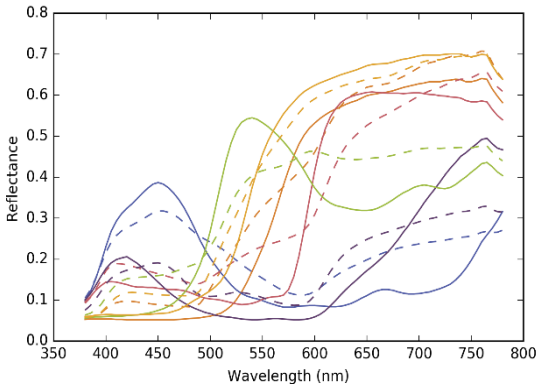

Figure 9 The original reflectance spectra of the colors in the second row of MCC (solid lines) and their estimated ones by the proposed method with Neugebauer model (broken lines).

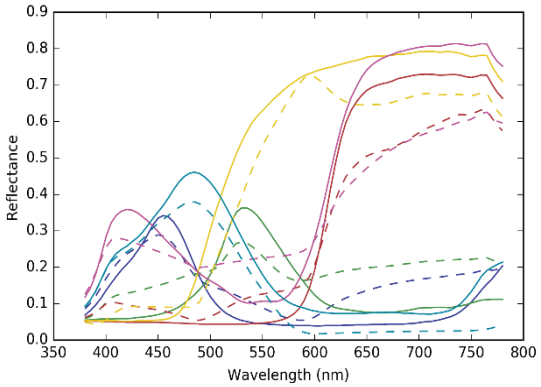

Figure 10 The original reflectance spectra of the colors in the third row of MCC (solid lines) and their estimated ones by the proposed method with Neugebauer model (broken lines).

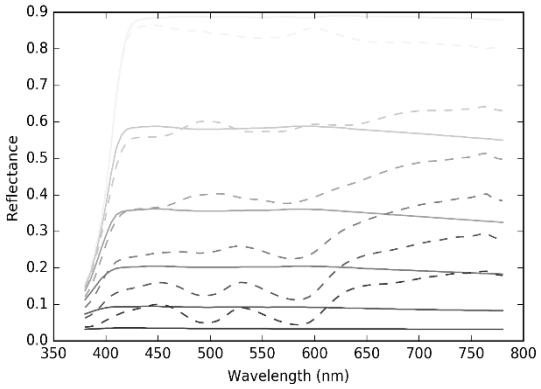

Figure 11 The original reflectance spectra of the colors in the fourth row of MCC (solid lines) and their estimated ones by the proposed method with Neugebauer model (broken lines).

On the other hand, from Figure 12 to Figure 15, we show the estimated reflectance spectra by the proposed method with sparse Neugebauer model, as well as Figures 8-11 with the Neugebauer model.

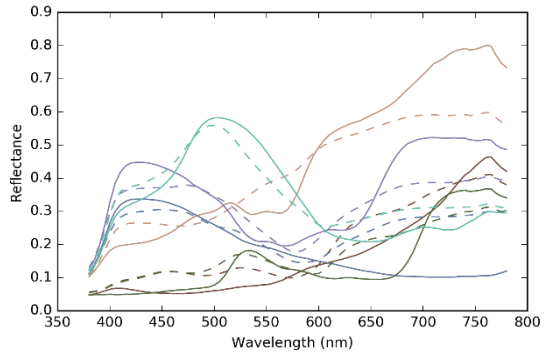

Figure 12 The original reflectance spectra of the colors in the first row of MCC (solid lines) and their estimated ones by the proposed method with sparse Neugebauer model (broken lines).

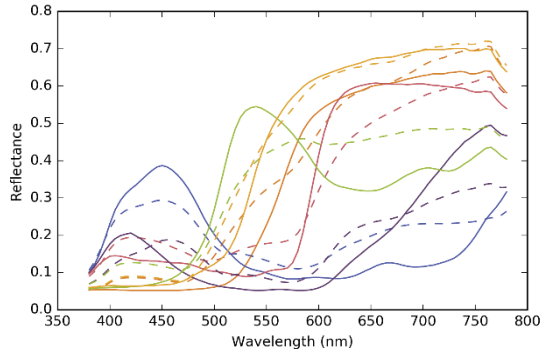

Figure 13 The original reflectance spectra of the colors in the second row of MCC (solid lines) and their estimated ones by the proposed method with sparse Neugebauer model (broken lines).

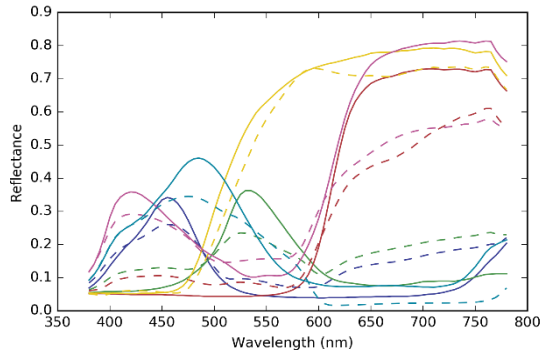

Figure 14 The original reflectance spectra of the colors in the third row of MCC (solid lines) and their estimated ones by the proposed method with sparse Neugebauer model (broken lines).

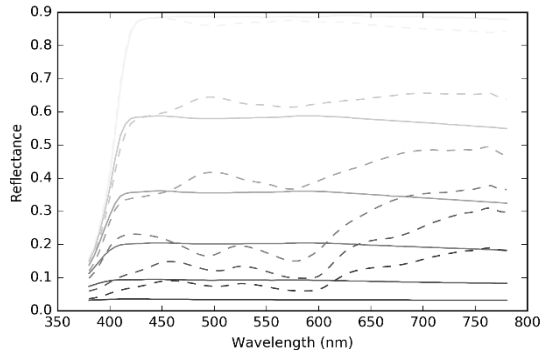

Figure 15 The original reflectance spectra of the colors in the fourth row of MCC (solid lines) and their estimated ones by the proposed method with sparse Neugebauer model (broken lines).

We evaluate the mean squared error between the original and estimated reflectance spectra given by

$$\mathrm{MSE}_i = \frac{1}{n}\sum_{j=1}^{n}\left(q_{ij} - \sum_{k=1}^{K} a_{ik}p_{kj}\right)^2$$

for the ith color in MCC. Figure 16 shows the result where the vertical and horizontal axes denote the mean squared error and the identification number of MCC colors, respectively, and the blue and red bars denote the conventional nonsparse and the sparse Neugebauer models, respectively. In 18 colors among all 24 colors, the sparse Neugebauer model achieved smaller MSE_i than the conventional one. The average of MSE_i for $i = 1, \ldots, m$ given by

$$\mathrm{MSE} = \frac{1}{m}\sum_{i=1}^{m}\mathrm{MSE}_i$$

are 7.66×10^{-3} for the conventional Neugebauer model and 6.83×10^{-3} for the sparse one.

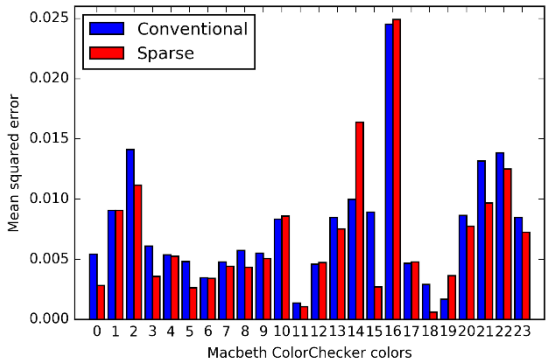

Figure 16 Mean squared error of estimated reflectance spectra.

Next, we also evaluate the same measure using the leave-one-out cross-validation [11], where the spectral reflectance of the ith color in MCC is removed from Q to evaluate MSE_i. Figure 17 shows the result, where the sparse Neugebauer model (red bars) achieved smaller MSE_i in 15 colors among all 24 colors than the conventional Neugebauer model (blue bars). The values of MSE are 1.37×10^{-2} for the conventional Neugebauer model and 1.15×10^{-2} for the sparse one.

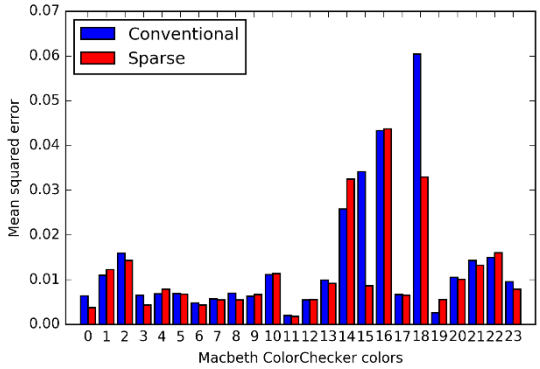

Figure 17 Mean squared error of estimated reflectance spectra evaluated by the leave-one-out cross-validation.

Finally, we show the results of color reproduction from the estimated reflectance spectra. Figure 18 shows the original Neugebauer primaries: red, green, blue, black, cyan, magenta, yellow and white.

Figure 18 Neugebauer primaries.

Figure 19 shows the reproduced Neugebauer primaries with the conventional Neugebauer model, in which blue is wrongly transformed into magenta.

Figure 19 Reproduced Neugebauer primaries from the estimated reflectance spectra with Neugebauer model.

On the other hand, the reproduced Neugebauer primaries with the sparse Neugebauer model is shown in Figure 20, where blue is correctly reproduced as well as the other colors.

Figure 20 Reproduced Neugebauer primaries from the estimated reflectance spectra with sparse Neugebauer model.

Figures 21 and 22 show the reproduced MCC colors with the conventional and sparse Neugebauer models, respectively. The reproduced colors are similar to the original ones in Figure 1. Additionally, note that the proposed method can be applied to not only the CMYK-printed colors like MCC but also more general tristimulus values including material colors.

Figure 21 Reproduced MCC colors with Neugebauer model.

Figure 22 Reproduced MCC colors with sparse Neugebauer model.

We evaluate the mean absolute error between the original and reproduced MCC colors given by

$$\mathrm{MAE}_i = \frac{|r_i - \tilde{r}_i| + |g_i - \tilde{g}_i| + |b_i - \tilde{b}_i|}{3}$$

for the ith color in MCC, where $\tilde{r}_i$, $\tilde{g}_i$ and $\tilde{b}_i$ denote the reproduced sRGB values from the estimated reflectance spectra. Figure 23 shows the result, where the sparse Neugebauer model (red bars) achieved smaller MAE_i in 20 colors among all 24 colors than the conventional Neugebauer model. The average of MAE_i for $i = 1, \ldots, m$ given by

$$\mathrm{MAE} = \frac{1}{m}\sum_{i=1}^{m} \mathrm{MAE}_i$$

are 17.65 for the conventional Neugebauer model and 13.81 for the sparse one.

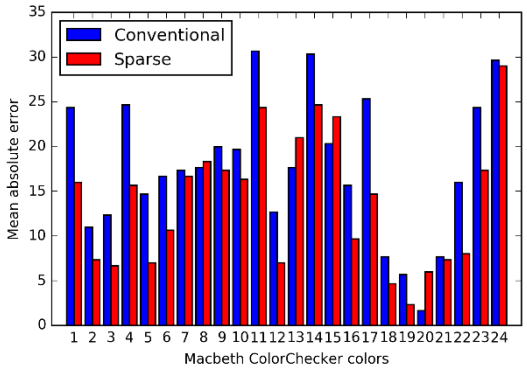

Figure 23 Mean absolute error of reproduced MCC colors.

Consequently, the sparse Neugebauer model improved the performance of both spectral reflectance estimation and color reproduction from the estimated spectral reflectance compared with the conventional Neugebauer model.

6. Conclusion

In this paper, we proposed a method for estimating spectral reflectance based on the Neugebauer model and its sparse version. The sparse Neugebauer model improved the estimation performance compared with the conventional Neugebauer model. We also proved the convergence property of the proposed algorithm for spectral reflectance estimation. Additionally, we reproduced the colors from the estimated spectral reflectance, in which the sparse Neugebauer model also improved the performance compared with the conventional one.

For future work we would like to improve the performance of both spectral reflectance estimation and color reproduction by robustifying the proposed method, and compare the proposed method with other related methods including learning-based methods. We are also planning an application of the proposed method to the design of spectral reflectance for controlled color reproduction under various illuminations.

Conflict of Interest

The authors declare no conflict of interest.

Kinect
Processing Software

ABSTRACT

The discussed system in this paper uses the Kinect's 3D input (acquired through IR projector and Camera) to detect gestures and then based on these gestures perform certain tasks, and display certain results on an output screen. The programming language used here is the Processing open source software and a database was implemented to manage the data required within the system. The deigned system was created for a library but the system's design is broad enough to allow its utilization in many more domains. Implementation, system screenshots, simulation and results are discussed along with testing the system in different condition of light and distance. Some simple additions have been added to this version of the program to facilitate the interaction between the user and the system further.

1. Introduction

The advancement of control systems that has taken large leaps in the past decade has raised human-machine interfaces to a whole new level where they became more and more remote from the user's body like voice control, eye control and body and hand gesture control which have changed the concept of human-machine interface from the typical and complex concept to become more natural and human-like, also known as Natural User Interfaces or NUI . Most of the new systems are trying to enhance the user interface further more so that a larger number of people can be able to use the new technology with less effort and time consumption. These types of interfaces allow users to bypass the limits of age, education and sometimes physical disabilities to have a better control over technological systems which have become an undisputable need for us on daily basis.

The system to be discussed implements gesture recognition to control the system where users interface with it remotely using simple gestures to navigate the system. With all the possibilities available for gesture detection, the most reliable method is 3D imaging, where the gesture is no longer dependent on the 2D properties of the hands, like color, shape etc. to determine and recognize the gestures of the user, which is very expensive in terms of processing and may lead to delays within the system when the user is expecting real time feedback.

Although the system was designed for a library however its possible implementations can go way beyond the walls of libraries into museums, hospitals, malls and many more applications, it can also aid elderly or people with special needs control many things from electrical appliances to electrical doors, applications etc... . It will follow the hand gestures of the user to allow him to explore different books with different genres and authors available within the library, where the books will be classified into topics, and within each topic related books available will be displayed. Further information about each book (including author's name, ISBN, a short summary about the contents of the book and its location within the library) can be displayed to the user. This paper demonstrates the design and implementation of a 3D gesture-based control system that was previously discussed in 2016 2nd International Conference on Open Source Software Computing (OSSCOM) [1].

2. Similar Systems

2.1. Maintaining the Integrity of the Specifications (Heading 2)

Similar control systems were created using different techniques. A "Wireless Gesture Controlled Robotic Arm with Vision" was presented in [2] using accelerometers that allowed the user to control the robotic arm wirelessly, by using 3-axis DOF's (Degree of Freedom) accelerometers controlled via RF signals. The robotic arm is mounted on a movable platform to signify the hand and leg of the user, where the robotic arm correspond to the user's arm and the platform corresponds to the user's leg. Accelerometers are fixed on the user's hand and leg to capture their gestures and movements allowing the robotic arm and platform to move accordingly.

Another gesture controlled user interface called "Open Gesture" was proposed in [3]. A web cam is used with an open source program to implement the system in smart TVs for almost all users. Although the system can be used by most people, still it faces some drawbacks; the main tool for capturing gestures is a web cam, meaning that to identify gestures, image processing is required, and that is computationally expensive and will not allow the system to receive the same quality of information obtained by 3D scanning. Another drawback is the fact that the web cam is light-dependent and will not work in all lighting conditions, where dim lit and unlit places create a challenge for the system to identify the gestures performed. The system also assumes that all users are of a certain educational background, and that is not true, so the system is limited to these people only. Even though the system we propose in this paper is for a library, however the gesture control can be performed over anything and almost everywhere we want with some small changes.

Another approach was presented in [4], which uses the WiiMote from Nintendo to control smart homes (appliances, lights, windows…), where the 3D accelerometer will be used to detect the gestures and a classification framework composed of machine-learning algorithms like Neural Networks and Support Vector Machine (SVM) will be used for gesture recognition classification and training. Although this system has a high level of accuracy for gesture recognition due to the use of the classification framework, a setback lies in the use of the WiiMote, where it restricts the gesture recognition for the user to only the time when the controller is held by hand, which after long periods may result in inconveniences for the users especially the elderly.

Yet another gesture controlled system was presented by [5], where Kinect's depth imaging was combined with traditional Camshift tracking algorithm along with HMM (Hidden Markov Models) for dynamic gesture classification to control the motion of a bi-handed Cyton 14D-2G. A Client/Server structured robot tele-operation application system is developed, which provides a favorable function of remotely controlling a dual-arm robot by gestural commands.

3. Proposed System

3.1. Design Specifications

From the many choices of NUI we chose to utilize hand gestures because they are familiar and universal to all users where even small children learn to use gestures before they even learn to talk, and so this supports the fact that this system can be compatible with all backgrounds and ages of users.

Gesture recognition was accomplished with the help of the Kinect, which is a line of motion sensing input devices that includes a 2D camera along with a 3D scanner system called Light Coding which employs a variant of image-based 3D reconstruction that requires the work of an IR projector and IR camera.

Some of the great advantages of using the Kinect sensor are the fact that its price is affordable and that it can catch great depth images in different lighting conditions like dim lit or unlit places as well as places with good lighting. This is a property not available in any of the other 2D image capturing sensors. Another important factors is the fact that Kinect uses 3D imaging instead of 2D imaging, which is independent of the light (as previously mentioned) and thus does not require image processing and resolves the issue of computationally expensive algorithm we would have been forced to use, making the system more robust and increasing gesture detection therefore increasing the speed and dependability of the system's response to the gestures.

The Kinect will be connected to a computer with a Processing program designed to detect gestures and respond accordingly to them. Since we only needed the 3D imaging of the Kinect, 2D images were not used and thus the real time streaming of the surrounding environment was done in grey scale images of the Kinect sensor.

The system design targets the majority of people, meaning that users' age, physical abilities and educational backgrounds will vary, so we had to take into consideration the controlling gestures since they had to be performable and known to all users with ease and without resorting to difficult physical actions that on the long term may strain the users. The system was only programmed to respond to two types of gestures: hand wave and hand click, where the wave gesture was used to initiate the program and then when inside the program it was used to go back to the previous screen/menu while the click gesture was used as a selection gesture.

The programming language used was Processing, which is a free open source programming language and runs on Mac, Windows, and GNU/Linux platforms. Processing has many libraries related to Kinect, and because it was easy to learn and because it is an object oriented programming language, it allowed us to have more flexibility when dealing with Kinect input and manipulating information and output.

Data were stored in a database that can be updated according to the needs of the system where the program fetches required information from the database depending on the type of gesture detected. If the gesture is a click for example, then the system will fetch all the information related to the object clicked on by the user. And so for that purpose MySQL database was used to store the information about the books and the other information to be displayed within the program.

The following figure (Fig.1) represents the interaction between hardware components of the system designed:

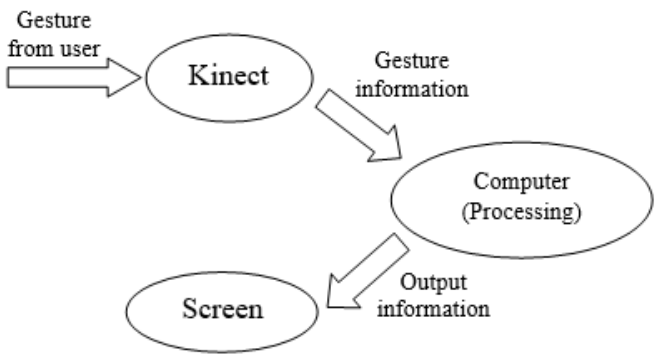

Figure 1 Hardware components of the system

4. Implementation

The system developed is an event-response application, where the user's gestures are the events that change the state of the system (the displayed information and the navigation through the system) to trigger the response to these events allowing him/her to control the system.

To allow the system to understand gestures we needed a gesture recognition algorithm to start with. So we decided to use a pre-made gesture recognition program that was available to save time and effort and to focus on the main idea of the project.

Although two approaches were available for us to control the system, one was 2 dimensional (2D) and the other was 3 dimensional (3D) depending on the algorithm used for the detection of gestures, however the 2D approach proved to have poor reliability due to the delays it showed within the system and the program's inability to follow the users hand and fingertips proficiently, thus it was halted and the 3D approach was adopted due to its good response to the users hand movements and gestures adding to the reliability of the system.

4.1. 2D Approach

The Finger Tracker library was our first alternate for gesture detection where it detects the tips of the fingers of the user. It does that through slicing the space detected by the Kinect into layers of 2D surfaces and then determining the fingertips through scanning each 2D surface and finding "inflections in the curvature of the contour" then drawing red ellipses in their positions, as seen in Figure 2.

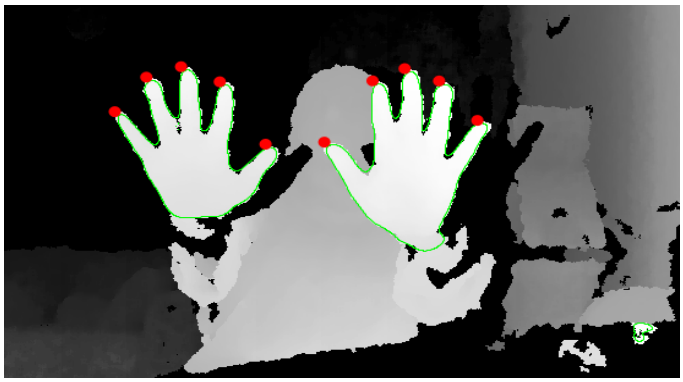

Figure 2 Fingers tracked using FingeTracker library

Finger's gestures and movements were used as the events that control the system. So we first eliminated the depth image (the grey-scaled 3D-image captured by the Kinect seen in Figure 2) and only drew the contour of the hand along with the fingertips (fingertips displayed in red and contour in green in Figure 2) with a rate approximate to 30 fps (frames per second), which is the frame rate of the Kinect, on a black background, and like that we were able to observe the real-time motion of our fingertips on screen. Next, fingertips previously drawn as 2d images were replaced by special 2D graphics known as "Sprites" as displayed in Figure 3. Sprites are 2D images that have special properties with boundaries and libraries that allow us to detect the collision between one sprite and the other, set their properties, motion, speeds and so much more. The library used here is called Sprites library, and allows us to control all the previously mentioned properties of sprites.

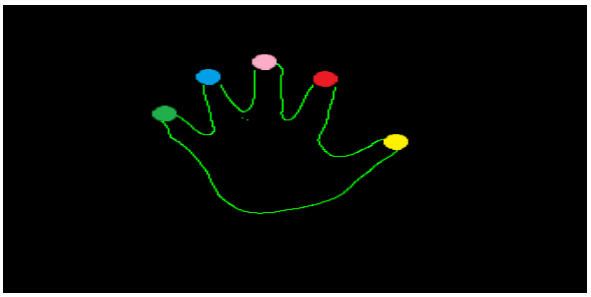

Figure 3 Sprites inserted on the fingertips

Images of books were inserted as sprites as well (see Fig.4), so to be able to detect collision between them and the fingertips sprites and the books sprites, an algorithm was created so that certain actions can be executed upon detection.

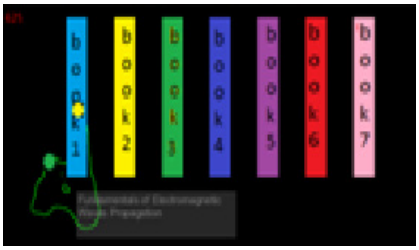

Figure 4 Book information displayed upon the detection of collision between a fingertip sprite and a book sprite

Two events were defined to control the system and change its states, a pointing gesture and a pinching gesture.A loop was used to iterate over the seven pictures given, then a condition checks for any collision between any book and a predefined fingertip (detected when the user is pointing at the book) which is shown using the yellow sprite in Figure 2. If the condition is satisfied, the name of the book that the finger sprite collided with will be printed on screen (see Figure3). Then the loop iterates over the books again to check for collisions. To select the required book two fingertips were used, such that if a pinching gesture was performed and the distance between the boundaries of the finger sprites was smaller than a certain threshold and the collision between these sprites and the book sprite was detected information about the selected book will be displayed, thus the system would transit from the initial state where the books are displayed to either state depending on the detected event; a pointing gesture results in displaying the name and a pinching gesture results in displaying the information. The following state chart displays how the system transits between states based on the events created by the user. (Figure 5)

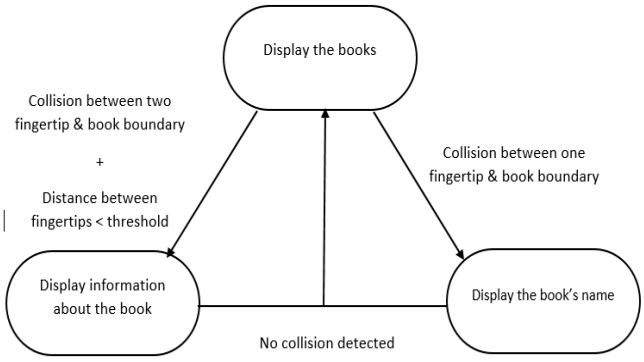

Figure 5State chart that shows the transition of the system between states based on events created by user

Figure 6 displays how the software components in this approach work with each other:

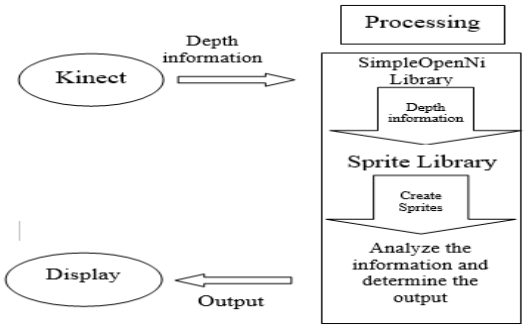

Figure 3 Software components of 2D approach

4.2. 3D Approach

The other available option for gesture implementation and detection was within the SimpleOpenNi library which is the "Hands" sample code that allows us to detect three hand gestures: Wave, Click, and Hand Raise which will be used as attributes for events to change the state of the system (and therefore change the displayed output). Upon detecting any of the three gestures, the detected hand is given an ID number between 1 and 7 and a unique colour is assigned to it where a circle of that colour is drawn in the upper middle part of the user's palm and displayed on the screen, as can be seen in Figure 7.

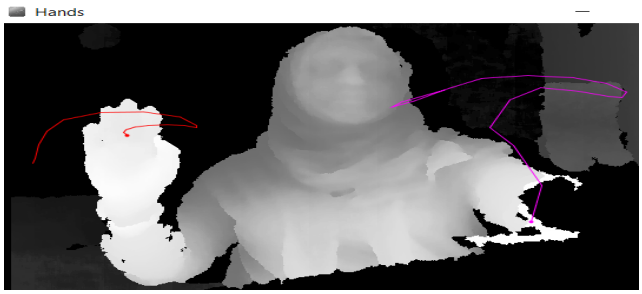

Figure 4 How hand code displays detected hands after gestures

Each gesture is assigned an integer number from 1 to 3, where Wave = 0, Click = 1, and Hand_Riase = 2. Because our system only needed the presence of two gestures (one for selection and another to go back to the previous menu) the click gesture was used for selection and the wave gesture was used for going back. Notice that the system focuses on detection of hands only, thus the user's profile, age, physical abilities and educational background are of no importance, as long as the user can use his/her hands effectively in front of the Kinect.

Then the system was programmed to respond to a certain gesture in a certain position where the position is the other attribute of the events that allow us to change the state of the system and therefore navigate forth and back through them, so that if the user wanted to select a certain topic or book all he had to do was to click on the image of that topic or book and after getting the required information, a simple wave of the hand allows the user to go back to the topics menu or to the collection of displayed books, allowing him to navigate back and forth within the system.

Meaning that the events here have two attributes; one is the gesture type and the other is the position where the gesture is performed, so upon the completion of the event when satisfying the conditions, the system transits to another state where the information matching the completed event are displayed.

A small description of the system along with some screenshots will be displayed for better understanding of how the system works.

The user faces a Kinect sensor and a Screen that will display to him the program he will interact with. The screen displays the user's depth image, this shows that the program still isn't functional till the user waves his/her hand, then a "START" button will be displayed in the middle of the screen (as seen in Figure 8) announcing that the program is ready and waiting for the click of the user.

Figure 5 After a wave of the hand the start button is displayed

Next the user will "click" within the boundaries of the start button opening the main page of the system where empty shelves and the topics of the available books are displayed on the screen. Figure 9 displays the state chart of the system, where each event allows the user to go back or forth within the system, changing the state and therefore the displayed output of the system.

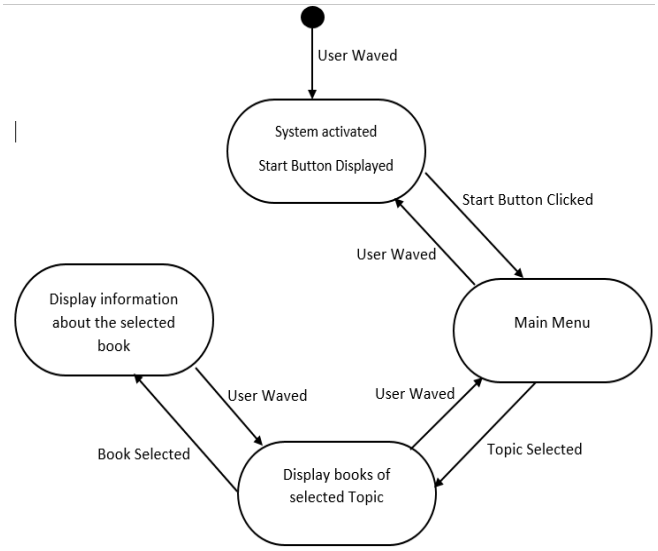

Figure 6 State chart displaying the overall states of the system and how they changed based on the user's events (click and wave)

As the user clicks the start button, a new screen will appear with the topics of the available books displayed on the left side of the screen, and empty shelves in the middle of the screen, as seen in Figure 10. Here the condition was to perform the click gesture within the boundary range of the start button.

Figure 7 Main screen displayed after clicking the start button

Next the user can select any of the displayed topics he/she is interested in through a click gesture on the required topic.

As a response to this gesture pictures of the available books concerning this topic will be displayed on the empty shelves as seen in Fig. 11.

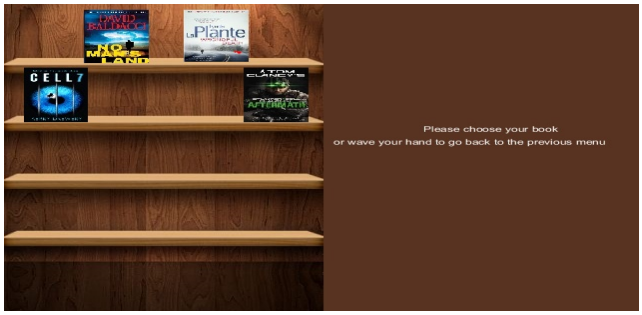

Figure 8 Books displayed on the shelves

With a simple click on the book a larger image of it is displayed along with information about it (author, ISBN, summary, position within the library…) on the right hand side of the screen as seen in Figure 12.

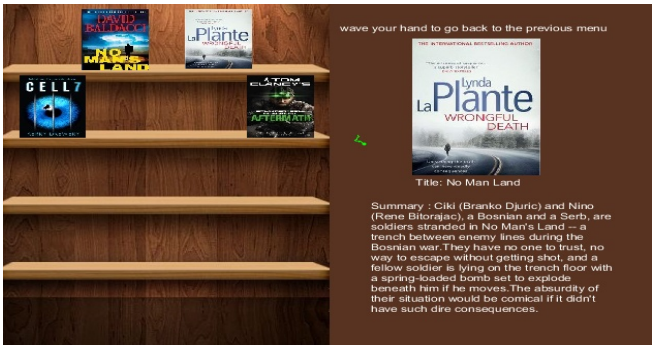

Figure 9Information displayed about the selected book

Going back to the previous menu can be done with a simple wave of the hand. The same gesture can take us back one step wherever we are within the program, as seen in Figure 11.

Figure 13 displays the software components of the 3D approach of the system.

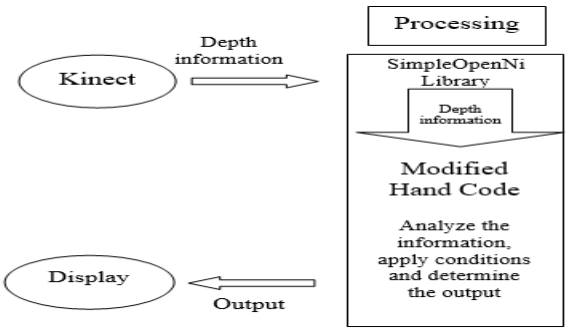

Figure 10 Software components of the 3D approach

4.3. Database Implementation

MySQL database was created to store the attributes and information and picture paths of the books to be displayed on screen, and information were retrieved from the database, using queries triggered by events created by the user.

For the system to retrieve the data a function was created which returned the desired information as a string array. The function then

- Performs a query: Selects all rows from the specified table
- Iterates over all of the selected rows
- Gets the "attribute" value of each entry
- Increments the loop to hop to the next position in the array thus retrieving the paths of pictures and books' information (summary, author…)

This implementation makes this control system quite broad where if we wanted to change the application field of the system from a library management system to another different domain, then the users must only supply the database with the new information to update the tables, so the system can then perform different actions (display images, control devices etc…) thus extending the range of the system's application field.

5. Simulations and Results

5.1. Test Cases and Acceptance Criteria

To consider the system as acceptable for interfacing it should satisfy the following criteria:

- Be able to detect gestures without too much effort from the user, and without any delays.
- Be well organized so that the user wouldn't be confused about the information or about how to select items.
- Use gestures that are easy and familiar to people so that all users would be able to perform them without effort.
- Limit the range of gesture performance such that it wouldn't be too wide, so that the hand movements wouldn't strain the user, and they must be swift and not involve too much movement.
- Have a high percentage of accuracy and fidelity.

The tests were performed on both approaches mentioned before, the 2D and 3D approaches.

5.2. Simulation Results

Although the 2D approach involved finger gestures that have become quite common among most people due to their use in touch interface (smartphones and tablets etc..), the continuous flickering of the fingertip sprites and the fact that the detected IDs of the finger sprites were inconsistent made collision detection much harder reducing the accuracy of the system significantly, leading to considering the approach as invalid.

The 3D approach underwent many tests to validate its efficiency, fidelity, real time response to users' gestures and the response of users towards the used gestures. The results proved the system to be well compatible with the criteria mentioned above. The range of gesture performance has also been detected to be good and reachable by the majority of the users who have performed this test which included users of different ages and different educational levels. The gestures used, namely the waving and clicking were very well detected and responded to, on condition that the user faces the Kinect head on without any tilting and without any obstacles and that the Kinect would remain stationary after calibration. The accuracy has increased significantly from the first prototype, and fidelity was very good, where users were able to go forth and back while navigating within the system.

The figures previously displayed were screenshots captured during the simulation of both approaches, where each of them displays exactly how the system responds to the actions of the user.

Statistics were made based on new review from test users of the system, where two surveys was conducted concerning the concept of the system as a gesture based control system, whether users had previously used similar system and if they would buy such a system themselves (see Figure 14). The survey was done on social media and on field with test users.

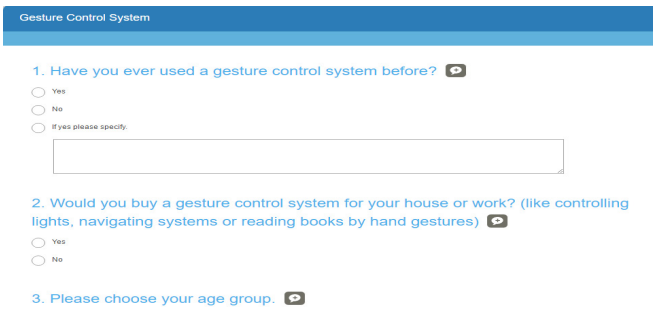

Figure 11 Online survey

The results of the survey were as follows:
64% of the users stated that this was their first time using a gesture controlled system while 36% stated that they have a similar previous experience (Xbox, telephone), 72% of them stated that they would buy such a system to use in their daily life while 28% declared that they would not. (Figure 15)

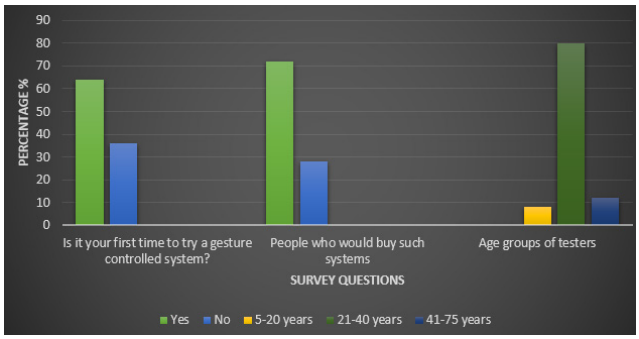

Figure 12 Statistics of Surveys

Although the feedback of users varied about buying such a system or not, but all agreed that the system was easy to use and learn, and that the gestures were fairly simple to perform. While the wave gesture was the easiest to perform with a 100% on its performance and real time response, the click gesture was more challenging where the response to the gesture was at 50% before making the Kinect stationary, but rose to 90% after fixing it to a specific location, making the gesture detection easier and the system response to users better, where the optimal distance for the user to be at is between 2 and 2,5 meters away from the Kinect with the Kinect stationed at 1.5 to 1.65 meters high.

The system was also tested for other gestures that are not defined within the program, but there was no reaction from the system whatsoever, so the system only responds to predefined gestures (the ones mentioned before).

The size of the population was increased from the previous paper, where about 20 people previously tested the system, and now the test subjects were doubled so the responses were more various and the feedback was more accurate.

The ground truth for the gestures used for us as programmers was obtained through tests, and then when the system is presented to the users, a tutorial is given to make sure the gestures and how the system works are both clear to the users, and after the tutorial, users adapted immediately to the system and the feedback was very satisfactory. These are some of the users' feedbacks on the system: "Gestures are easy to learn and perform", "The wave gesture is like saying hello and goodbye", some noted that the tutorial is very important for controlling the system properly, and so within each display window instructions were included to help first time users understand what to do while navigating the system. (See Figure 16)

Figure 13 Directions displayed to help users

A better step would be to include a video tutorial about the gestures to make sure that even people who can't read can still understand and use the system.

To test the performance of the system under different conditions we decided to perform the test with a single user but on different distances, and in different lighting conditions.

The evaluation of the response was classified as Excellent (100%), Very Good (85%), Good (70%) and Bad (0), and the distance started from 1.5 m from the Kinect to make sure that the user's hand wouldn't extend to its blind spot, where the range of detection starts from 1 m and extends to almost 6m away from the Kinect.

As for lighting conditions, the tester performed the gestures outdoors during daytime in an open space, where there was a lot of sunlight, then indoors but with sunlight as well, then the amount of sunlight was decreased and instead electric lighting was used mostly, then the lights were 85% dimmed and finally the lights were completely turned off and the sunlight was blocked to get the darkest possible environment.

Figure 17 displays the response of the system under the previously mentioned conditions. As we can see in the figure, the response of the system is optimal between 1.5 and 3 m and precisely at 2.5m which is the optimal distance for the user in all lighting conditions, however when the distance increases outdoors the response becomes very bad due to the large amounts of IR light present in sunlight which can affect the performance of the sensor and decrease its range of response. The performance gets better as the amount of sunlight decreases, however in the remaining lighting conditions it proved to have a good response till about 4m from the Kinect, then the response decreases and stops after 5m. But when all lights were blocked, the response was much better and the range increased to 6m which is the range of "vision" of the Kinect.

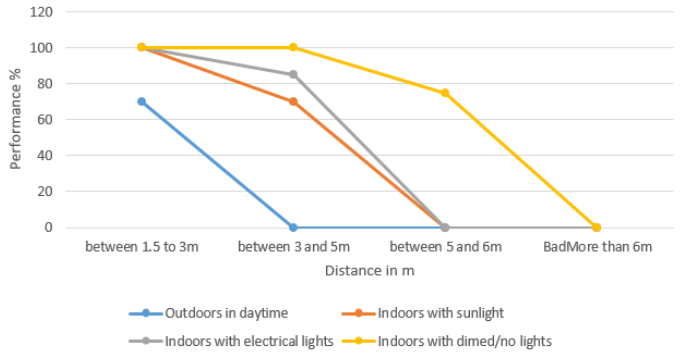

Figure 14 System response under different lighting conditions and distances

Another problem we faced in this implementation which was the calibration of the sensor distance from the user, where any change in the distance between the user and the sensor had greatly affected the system. This can be resolved by keeping the sensor stationary. Since the control system created was implemented in a library, then the educational background of the user is limited to a certain level, and age has its limits as well, however this type of control system is gesture dependent, meaning that if implemented in other domains to control things, like hardware, then it will no longer limit the educational background or age of users and it can be used by the majority of people.

The accuracy of the system was very good, however for better results new algorithms can be created specifically for the purpose of this system, which would enhance the accuracy and hence the overall system response.

6. Conclusion

The simulations of the system and the user feedback about the system have reflected a good response, as long as the Kinect remains stationary after calibration to ensure the best results. The simplicity of the system can allow it to go into various domains for control over software or hardware and so it can be implemented anywhere to control systems easier, however it can be improved through further studies and more specialized hand detection algorithms.

Detection
S-transform

ABSTRACT

A new method to detect heart sound that does not require machine learning is proposed. The heart sound is a time series event which is generated by the heart mechanical system. From the analysis of heart sound S-transform and the understanding of how heart works, it can be deducted that each heart sound component has unique properties in terms of timing, frequency, and amplitude. Based on these facts, a deterministic method can be designed to identify each heart sound components. The recorded heart sound then can be printed with each component correctly labeled. This greatly help the physician to diagnose the heart problem. The result shows that most known heart sounds were successfully detected. There are some murmur cases where the detection failed. This can be improved by adding more heuristics including setting some initial parameters such as noise threshold accurately, taking into account the recording equipment and also the environmental condition. It is expected that this method can be integrated into an electronic stethoscope biomedical system

1 Introduction

Auscultation is an act of medical diagnosis by listening to sounds from the heart, lungs or other organs with a stethoscope. Stethoscope has been a popular tool to early diagnose a patient since its development on 1800's [1], due to its simplicity and wide availability. The outcome from a diagnose using this stethoscope could vary according to physician's hearing sensitivity and experiences [2]. The introduction of digital stethoscopes reduce the hearing sensitivity problem because the heart sound can be amplified to suit the examiner's need and furthermore noise can also be reduced. However, the digital stethoscopes still have not solved the skill and experience required to be able to diagnose heart problems accurately.

Our research group is working to develop an easy to use digital stethoscope that has some capabilities to detect various type of heart sound.To do this, we need to design a device that can detect components of heart sound such as primary heart sound; S1, S2, S3, S4, as well as murmurs and clicks. The intention is to develop a tool that can provide some suggestion to help medical practitioners in performing a quick diagnose of patient's problem. This tools should be small and simple enough so that it will be easily accepted because it is not very different than the ordinary stethoscope.

The first challenge towards this goal is to design a simple and yet effective heart sound detection technique. Most of heart sound classification techniques are based on machine learning methods such as clustering and artificial neural networks [3, 4], SVM and MCSearch [5]. They need a large amount of data to learn from and also they require a lot of computation. To overcome those problems, this study investigated a simple detection method without machine learning or statistical approach using only the time series features of heart sound.

The next section takes a deeper look at heart sound signals to discover the deterministic features of each component. These features will be used in the core of the proposed detection method described in section III. Section IV presents the result and discussion of our experiment. The conclusion of this paper is written in section V.

2 Heart Sound as Time Series

Heart sound is acoustic signal produced by the mechanical activities of the heart as a result of the vibration of the valves, heart muscle tissues, and great

(a) (b)

Figure 1: (a) Illustration of heart sound signal with S1, S2, S3 and S4 component, (b) S-transform diagram.

vessels . The closure of mitral tricuspid valves produce S1, and the second heart sound (S2) caused by the sudden closure of aortic and pulmonary valves. S1 has lower frequency with longer duration and higher intensity, while S2 has higher frequency with shorter duration. Under pathological conditions and abnormalities, additional components of the third heart sound (S3) and/or the fourth heart sound (S4) may be present. S3 occurs in the rapid filling period of early diastole after S2 due to the vibration of blood inside the ventricles, which may indicate the systolic dysfunction. S4 appears before S1 and it is caused by altered physical properties of ventricle or increase in the rate and volume of blood flow in the late diastolic interval, which may indicate the presence of acute myocardial infarction or ischemia diseases [6] . S3 and S4 are usually low amplitude and low frequency that make them difficult to be detected. These four heart sound components lie in the frequency range of 20-200 Hz [7].

A normal cardiac cycle comprises of four main segments which are S1, systolic period, S2 and diastolic period, as shown in 1. Single cardiac cycle can also be defined by the interval between the beginning of S1 and the beginning of the next S1. Systolic period is the interval between the end of S1 and the beginning of S2, while diastolic period is defined as the interval between the end of S2 and the beginning of S1 in the next cycle. The systolic period is usually shorter than the diastolic period. Figure 1 illustrates two cycles of quadruple gallop heart sound consisting of S1, S2, S3, and S4 components (each sound has been labeled by red text). By analyzing the pattern of heart sound features, the heart malfunction symptoms leading to CVD can be identified. The first and most important step towards automatic heart sound diagnosis and analysis is segmentation and detection.

According to the process how a heart sound is generated, it can be considered as a time-series events which generate a series of amplitudes values that follow a certain pattern. Hence methods commonly used in time series analysis such as Fourier Transform (FFT, DFT, STFT), wavelet, and S-transform can also be used to analyze heart sound. To further understand the heart sound behavior, S-transform analysis is applied on denoised heart sound signal to examine its time and frequency characteristics.

S-transform is introduced by Stockwell et.al and defined as:

$$S(t,f) = \int_b^a s(t) \frac{|f|}{\sqrt{2\pi}} e^{\frac{-t-\tau^2 f^2}{2}} e^{-i2\pi f\tau} d\tau \qquad (1)$$

Figure 1(a) depicts a heart sound signal in time domain, while Figure 1(b) shows its S-transform representation. From these two figures it can be deducted that each component of heart sound occupies separate area in time domain. Since there is no overlapping region we can use time as the main feature to deterministically distinguish each component (S1, S2, S3, and S4).

3 Detection Method

The steps of the proposed method are depicted in Figure 2. Description of each step is as follows:

3.1 Preprocessing

These are processes that should be done before heart sound detection can be performed:

3.1.1 Down Sampling

Normally a phonocardiogram or a heart sound record duration is at least 15 seconds. The recording can be performed using digital stethoscope. With sample rate at 44.1 kHz the amount of data generated is too large for our purpose, so this signal should be downsampled to 2000 Hz. The reason to choose this downsampling frequency is to make sure that all the heart sound which occurred in this frequency is properly represented [8].

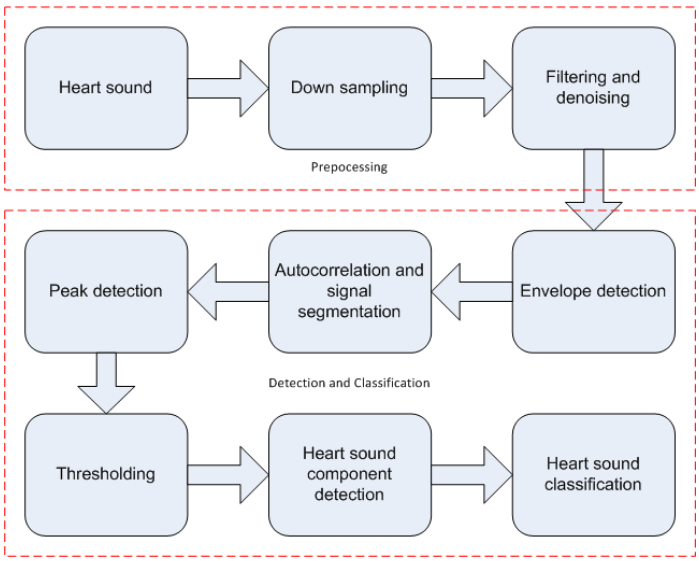

Figure 2: Heart sounds detection's steps.

3.1.2 Filtering and Denoising

To reduce high-frequency noise, the down-sampled signal $x(n)$ is filtered using low passed filter with 400 Hz cut-off frequency. To extract the remaining artifacts, signal $x(n)$ was pass through denoising process using Empirical Mode Decomposition (EMD) [9] method which produced signal $x_d(n)$. This method is chosen because it gave better results compared to other denoising technique [10].

3.2 Detection and classification

3.2.1 Envelope Extraction and Smoothing

Shannon Energy theorem was used in the envelope extraction process of denoised signal [11, 12]. Based on these envelopes heart sound components will be determined.

$$x_{env}(n) = -x_d^2(n) log x_d^2(n) \tag{2}$$

Our experiment shows that the produced envelope was not smooth. It has some ripples that might falsely be detected as peaks during peak detection process. To overcome this problem, the Finite Impulse Response (FIR) filter was used to remove the ripples. The cut-off frequency of this filter is 25 HZ.

3.2.2 Autocorrelation and Signal Segmentation

To compute cardiac cycle and cardiac number, autocorrelation method was applied to the envelopes. Cardiac cycle period was determined by calculating the average distance between highest peaks and its neighboring peaks. To calculate the number of cardiac cycle, sum of the number of highest peaks and one was divided by two. Based on our experiment, to calculate more accurate a cardiac cycle time, it was needed at least three cycles. Therefore it needs at least three seconds recording time. In order to shorten the calculation process, the calculation process, envelope signal that has been smoothed was divided into four cardiac cycle segment.

3.2.3 Peak Detection and Threshold Calculation

A peak is defined as the highest point (local maxima) between two local valley points. The formula for local maxima is:

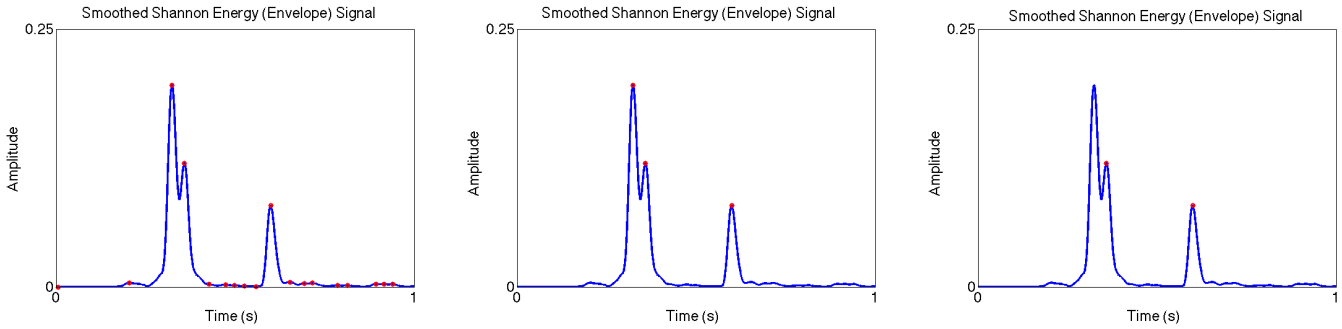
$$\frac{d(x_{env}(n))}{dn} > 0 \text{ and } \frac{d(x_{env}(n+1))}{dn} < 0 \tag{3}$$

while valley point (minima) defines as

$$\frac{d(x_{env}(n))}{dn} < 0 \text{ and } \frac{d(x_{env}(n+1))}{dn} > 0 \tag{4}$$

Some extra peaks might be detected by the program due to left over noise and artifacts. For example, a normal heart sound must have two peaks per cardiac cycle. Due to the noise, the program might detect some small peaks as shown by red dot in Figure 3a. To overcome this problem the Heron's formula was applied to calculate the threshold of the peak. With this formula the area of triangle formed by a local maximum and its two neighbor local minima was calculated. The area that is less than average of all triangles will be ignored. The results of implemented this formula is shown in Figure 3b. This procedure will not ignore the peak caused by a split.

It shows that after applying this formula, the program detects three peaks instead of two. After calculating peak's threshold, the adjustment of peak is needed. In this adjustment the difference between the peak's two minima amplitudes were checked. If the difference is greater than 0.01 mv the adjustment will ignore (not remove) the peak and its second minima. Then the new peak is produced from a combination of first peak's minima, second peak, and second peak's minima. The results of the adjustment is shown in



(a) Before using Heron's formula (b) After using Heron's formula (c) After peak adjustment

Figure 3: Graphical outcome for peak detection method.

Figure 3c.

3.2.4 Heart Sound Component Detection

to distinguish primary heart sound, extra heart sound, murmur, and other abnormalities, five features were extracted from the signal; peak frequency, peak interval, peak duration, total power, and amplitude. On the peak adjustment process, peak frequency is used to calculate each peak frequency that was detected.

The distance between two heart sound components (peaks) is determined by peak interval. The peak interval is measured from the first peak's second minima to the second peak's first minima, while the peak duration is measured from the first minima to the second minima of the peak. To calculate the power on systolic and diastolic region we use to the total power formula. Finally, the amplitude is used to differentiate heart sound abnormalities in systolic and diastolic region.

The following are the detection steps starting with wide split detection, followed by heart sound component detection, split detection, and murmur, click, and ejection click detection. Figure 4 shows the whole detection process, while the descriptions of each step is as follows:

Firstly, Wide Split Detection. Wide split is occured if S1 or S2 has more than one peaks. Wide split detection is used to distinguish whether the second peak of the closest is extra heart sound (S3 or S4) or the split sound. In this process, peak frequency feature is used. If the frequency peaks are similar, thus the peaks must be considered as a wide split sound and the number of peaks in the cycle will be reduced by one. If the frequency of peaks are quite different, it means the second peak is either S3 or S4.

Secondly, Heart Sounds Component Detection. The number of peak per cycle and the heart sounds' characteristics (TABLE 1 [13, 14, 15]) are used in this detection process as the bases to detect the heart sounds components. There are four possible number of peaks per cycle as explained below.

No	Sounds	Duration (ms)	Frequency (Hz)
1	S1	100 – 160	10 – 140
2	S2	80 – 140	10 – 400
3	S3	40 – 80	15 – 60
4	S4	30 – 60	15 – 45

Table 1: Heart sounds characteristics

- Case 1: Only one peak in a cardiac cycle is detected. It means that the peak is S1, and S2 is covered by murmur, either its continuous murmur or to-and-fro murmur.
- Case 2: There are two peaks in a cycle. It means that those peaks are S1 and S2. To determine which peak corresponds to S1 or S2, peak interval features is used. If the distance of second minima of first peak to first minima of second peak is less than the distance of second minima of second peak to first minima of first peak, it means that the first peak is S1 and the second peak is S2, vice versa.
- Case 3: There are three peaks in a cycle. It means there is an extra sound component which either S3 or S4. Before determining S3 or S4, S1 and S2 need to be decided. To distinguish extra sound from primary sound, the distinctive feature of heart sound, peak duration, is used. S3 or S4 has shorter duration than S1 or S2. Therefore, S1 and S2 can be decided by using the same method that explain before. If the distance between the third peak and S1 is shorter than the distance between this peak and S2, thus this peak is S4, otherwise this peak is S3.
- Case 4: There are four peaks in a cycle. It means that S1, S2, S4, and S4 are present in the cycle. The same procedure using peak duration and peak interval will be applied to determine each peak to corresponding heart sound.

Thirdly, Split Detection. Split only occurs on either S1 or S2. Split can be heard when the separation exceeds 20 ms [16]. It means that if there is more than one peak in either S1 or S2 and they are more than 20 ms apart, then it is considered a split Example of S1

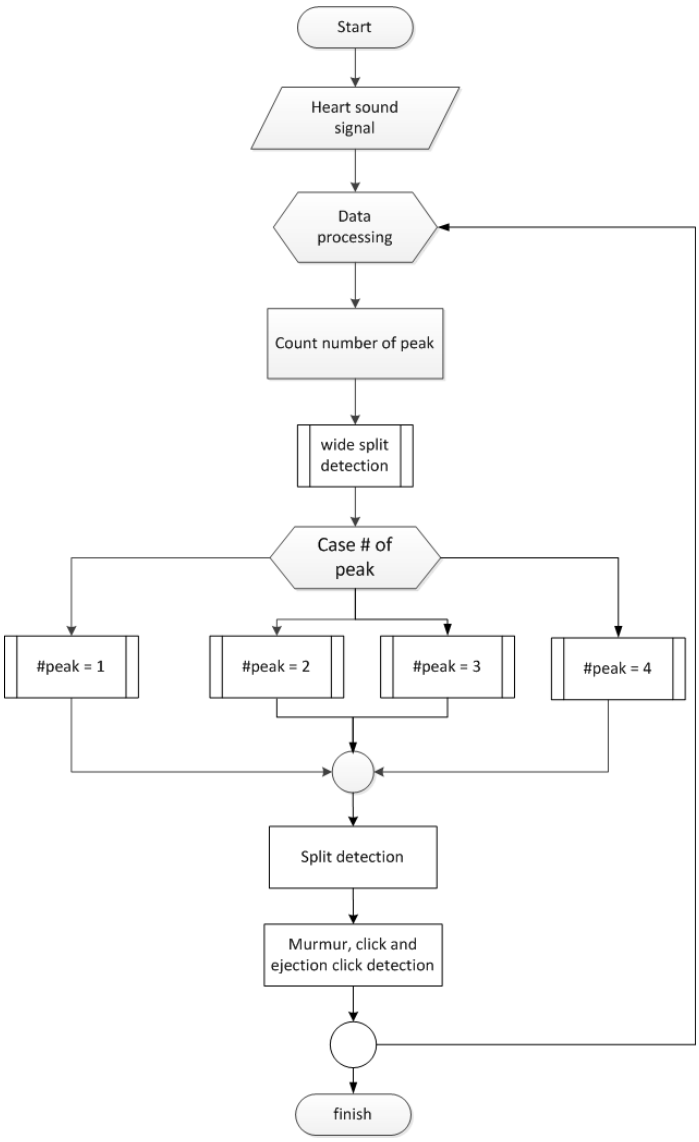


Figure 4: Flowchart of detection process.

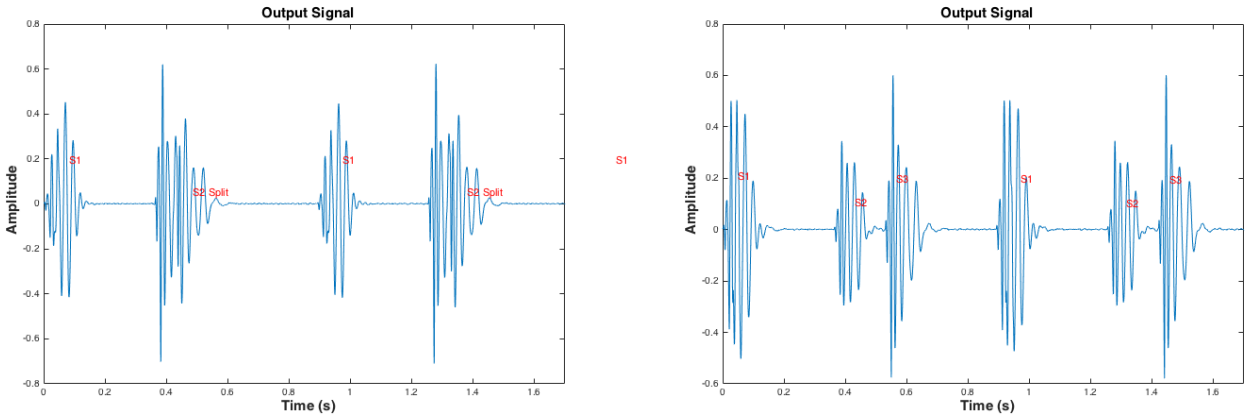

(a) S2 Split

(b) S3

Figure 5: Graphical outcome for peak detection method.

split can be seen in Figure 3, which shows envelope signal of split S1.

Finally, Murmur, Click, and Ejection Click Detection. The avarge power feature is used to indicate whether there is murmur or click in either systolic or diastolic area. If the average power in systolic or

diastloic area greater than the average power in that area for a normal heart sound it indicates there is abnormal sound such as murmur, click or ejection click in the area [17]. In this case, the envelope signals in systolic or diastolic area are examined further to determine which abnormal sound these signals belong to. If there are several peaks that are higher than the threshold then these can be an indication of murmur. Based on our experience, the threshold for murmur should be set to half of the average amplitude of the known signal. The type of murmur is classified based on the location where the murmur occurs and its amplitude. If the peak is greater than four times of murmur's threshold then it is a Click. These threshold are obtained purely heuristically form our observations. If there is a click that followed by murmur then it is an Ejection Click.

It is expected that the above process will be able to produce information related to following heart problems [18], such as:

- The presence of systolic murmur can indicate AV valve regurgitation, while diastolic is murmur related with the problem on semilunar valves
- To-and-fro murmur indicates the problem with all valves
- Wide split of S1 and/or S2 is a symptom of right brand bundle block (RBBB)
- Fixed split on S2 indicate an atrial septal defect
- Paradoxical splitting on S2 means LBBB problem
- Ejection click is a symptom of aortic or pulmonary stenosis
- Mid systolic click indicates mitral or tricuspid prolapse
- Opening snap shows the presence of artificial valve or rheumatic mitral stenosis
- The presence of S3 or S4 indicates ventricle stiffness, the summation gallop indicates the heart failure

However the decision regarding the real heart problems of a patient is entirely left to the physician.

4 Results and Discussion

The heart sounds samples were taken form the ones that available in the internet [19, 20, 21], which signals were noiseless. To make them imitate the real sound, an artificial noise was added to the signal. In our experiment, the input signals were designed to have a 13.98 dB signal-to-noise ratio. This noise addition is intended to demonstrate the effect of filtering and denoising process.

The simulation is run on OS X El Capitan with processor 2.5 GHz intel core i5 and 8 GB RAM using MATLAB 2014a software.

There are more than 20 heart sounds recording that are used to test the detection program. The list of distinctive sounds that are successfully detected and classified are shown in Table 2. The goal of the program is to identify and produced a label on the printed heart sound signal to mark which type of sounds occur. Figure 5 shows two of the simulation results, which are Figure 5a S2 Split and Figure 5b S3

There are cases where the program does not give correct results. This is happen if and only if murmur or the abnormal sounds amplitude and frequency are similar with the heart sounds'. If this happen, the whole heart sounds will be covered by the abnormal sounds or murmur. The example of this case is continuous murmur, where S2 is covered by murmur.

Tabel 2 shows the different signals that can be identified

5 Conclusion

This study proposes a deterministic approach to detect heart sound and its regularity. The preprocessing apply EMD denoising and low pass filter to cancel noise and remove unwanted artifact. To extract signal's envelope Shannon Energy method is used, and follow by using FIR filter to smoothen the jagged envelope. Our main source to classify heart sound is the signal's envelope. To detect the number of peak per cardiac cycle, Heron's formula and peak adjustment were then applied. These peaks and their extracted features were the keys to detect and classify the heart sounds.

Our experiment shows that quite a few of distinctive heart sounds can be successfully detected by this proposed method. Still, some more heuristics can be added to improve accuracy. This method will be further improved so that it can be embedded as part of a digital stethoscope.

Conflict of Interest We have read and understood the policy on declaration of interests and declare that we have no competing interests.

F-OFDM
Maximum-likelihood (ML) detector
Spectral efficiency and Spectrum utilization

ABSTRACT

In this paper, a spatial modulation (SM) which provides no synchronization between the transmitting antennas and avoids inter-channel interference (ICI) at the receiver input while maintaining high spectral efficiency is applied to filtered-orthogonal frequency division multiplexing (F-OFDM) transmission. The SM technique maps a block of information bits into two information carrying units, namely, a symbol chosen from a signal constellation diagram and a unique antenna number selected from the set of transmit antennas. Therefore, for F-OFDM wireless transmission, each subcarrier within the subband is mapped to one of the transmitting antennas. During wireless data transmission, there is only one active antenna transmitting power on that subcarrier at an instant of time and the rest of the antennas remains silent (zero power). At the receiver, a maximum-likelihood (ML) detector recovers the transmitted block of information bits by estimating the transmitted signal and the respective transmit antenna number. The effectiveness of the proposed method is verified using numerical results.

1 Introduction

The unprecedented increase of mobile communications, wireless Internet access and multi-media applications has been driven by telecommunications companies and researchers to conceive new transmission technologies, protocols, and network infrastructure solutions in order to maximize both throughput and spectral efficiency [1]. For the next generation of wireless communication, it has become necessary to provide higher data rate and improve spectral efficiency. Employing multi–antennas at transmitter and receiver has shown to be an effective technique to achieve spectral efficiency over the past few years. The use of spatial multiplexing using multiple input multiple output (MIMO) was first proposed in [2]. MIMO technology is one of the techniques employed to attain high spectral efficiency by transmitting multiple data streams from multiple antennas [3]. However, the MIMO transmission is dependent on transmit and receive antenna spacing [4, 5], synchronization of the transmit antenna [6], as well as the algorithm needed for inter-channel interference (ICI) reduction at the receiver input. The Bell Labs Layered Space-Time Architecture (BLAST) in [7] proposed MIMO detection algorithms, named vertical BLAST (V-BLAST) [8]. In V-BLAST, multiple data streams are transmitted separately and detected successively by employing both an array processing (nulling) and interference cancelation techniques.

OFDM is another promising technique proposed for transmitting high speed data over wireless channels in future mobile communication systems [9]. OFDM has been useful in several wireless standards, for example, digital audio and video broadcasting (DAB) and (DVB-T), IEEE 802.11a [10], the IEEE 802.16a metropolitan area network (MAN), and the local area standard (LAN) [11]. Although, OFDM features seems attractive, there is still technical challenges that needs to be addressed for future wireless transmission [12, 13].

Recently, a new extension to OFDM has been proposed, namely, F-OFDM in [12, 13]. The most significant difference of F-OFDM, as opposed to the conventional OFDM, is that the former total bandwidth has been divided into multiple subband. In addition, each subband have a distinct subcarrier spacing with its own cyclic prefix (CP) and filter. On the other, in conventional OFDM, total bandwidth consists of a single block and has the same subcarrier spacing between the individual subcarriers. Note that, there is de-

[*] Shaddrack Yaw Nusenu, UESTC and KTU, Ghana, Email: nusenu2012gh@yahoo.com

https://dx.doi.org/10.25046/aj0203124

gree of flexibility in F-OFDM than its counterpart OFDM. The details can be found in [12, 13].

Therefore, in this paper, SM is applied to F-OFDM, namely, spatial modulation F-OFDM (SM F-OFDM), which provides higher spectral efficiency as a result of both SM and F-OFDM advantages. The main contributions of this work can be summarized as follows: (i) Analogue to [9], SM F-OFDM is designed for wireless transmission. (ii) Binary phase shift keying (BPSK) and quadrature amplitude modulation (QAM) modulation schemes were adopted for SM mapping rule.

The remaining sections are organized as follows: In Section II, the system model of SM-F-OFDM is presented. Simulation results are provided in Section III and concluding summaries are drawn in Section IV.

Throughout the paper, the following notations are used. Bold lowercase and bold uppercase letters denote vectors and matrices, respectively. We use $[.]^T$ and $\|.\|_F$ to denote transpose and Frobenius norm of a matrix or a vector, respectively. $\hat{i}(k)$ is the estimated transmit antenna index (number) and $\hat{x}_{\hat{i}}(k)$ is the estimated transmitted symbol. F-OFDM modulator-1 contains data belong to first antenna and so forth and $\otimes$ denotes time convolution.

2 System Model of SM F-OFDM

In this section, SM is discussed briefly. Suppose the total number of transmit and receive antennas is denoted by N_t and N_r respectively, M being the cardinality of the signal constellation. Hence, the rate of SM (bits per channel use - (bpcu)) for arbitrary N_t and M respectively, can be given by [14],[15]

$$R_{SM} = \log_2(N_t) + \log_2(M) \tag{1}$$

where $\log_2(N_t)$ defines the single active transmit antenna and $\log_2(M)$ is the transmitted QAM/BPSK modulation symbols. Note that the N_t, N_r and M, respectively, can be chosen independently [16]. The basic principle of SM is that, it maps multiple information bits into one information symbol with respect to their corresponding transmit antenna number. The number of information bits that can be transmitted in SM technique depends on the signal constellation diagram employed as well as the given number of transmit antennas. It is important to note that the SM utilizes the distinctiveness and random nature of the wireless channel for communication. The following summarized SM characteristics [14]:

1) At any signaling time instance, only one transmit antenna is active for data transmission while the other antennas remains silent.

2) The spatial position of each transmit antenna of the set is employed as an information source.

The proposed architecture of SM F-OFDM system is depicted in Figure 1, with the F-OFDM transmitter showing in Figure 2, while F-OFDM receiver is illustrated in Figure 3. Suppose the input $\mathbf{Q}(k)$ is $m \times n$ matrix which represents the transmitted symbols, where m is the total number of bits per symbol per subcarrier and n denotes the total number of subcarriers of the multiple subband of F-OFDM system. By using the SM mapping rule as listed in Table I, this matrix is mapped into $\mathbf{X}(k)$ of size $N_t \times n$.

From Table I, the SM mapping rule, maps each column in $\mathbf{Q}(k)$ into 4QAM and BPSK signal constellations respectively. In addition, one transmit antenna from a set of two (QPSK) and four (BPSK) antennas is assumed. Herein, 4QAM and BPSK modulation schemes were adopted in this work. As can be seen in Table I, the encoding mechanism are $N_t = 2$ and $M = 4$ when QAM is adopted. Note that, three information bits can be mapped onto 4-QAM with two transmit antennas selected. Similarly, for BPSK, the same spectral efficiency can be achieved with $N_t = 4$ and $M = 4$. Thus the F-OFDM system can convey three bits in each time slots. The number of information bits that can be transmitted on each F-OFDM subcarriers is given in (1). According to the SM mapping rule, the matrix $\mathbf{Q}(k)$ has one nonzero element in each column at the position of the mapped transmit antenna number. All the other elements in that column are defined as zero. It is worth mentioning that, when $N_t = 1$ simplifies SM F-OFDM to conventional single antenna communications.

Supposing in Figure 1, an input bit sequence of $[0 \;\; 0 \;\; 1]^T$ (column vector in $\mathbf{Q}(k)$) from Table I, is mapped to the QAM symbol - 1 + j and the first transmit antenna by using SM mapping. Thus only the first antenna transmits this symbol on the first F-OFDM subcarrier, whereas other antenna remains silent (zero power). As a result, the first column vector in $\mathbf{X}(k)$ is $[-1+j \quad 0]^T$. The second bit sequence is $[1 \;\; 1 \;\; 0]^T$ and is mapped to $[0 \quad -1-\mathrm{j}]^T$, and so on. Similarly, the same approach is adopted for BPSK symbols. The resultant symbols in each row vector $\mathbf{x}_v(k)$ are the data that will be transmitted on all subcarriers from transmit antenna v. And F-OFDM modulator will be used to modulate each row vector $\mathbf{x}_v(k)$.

At the F-OFDM modulator output, $\mathbf{s}_v(t)$ vector is generated. Each $\mathbf{s}_v(t)$ vector generated has a unique and disjoint set of F-OFDM subcarriers. The resulting output vectors at the F-OFDM modulator will be transmitted simultaneously from the N_t over the channel $\mathbf{H}(t)$. At the receiver, the received matrix $\mathbf{Y}(t)$ can be expressed as

$$\mathbf{Y}(t) = \mathbf{H}(t) \otimes \mathbf{S}(t) + \mathbf{G}(t) \tag{2}$$

where $\mathbf{S}(t)$ is a matrix that has all F-OFDM symbols that are transmitted from all transmit antennas. $\mathbf{G}(t)$ is the additive noise matrix, in which each element is assumed to be an independent and identically distributed (iid) zero mean complex Gaussian random variable with variance σ_N^2. $\mathbf{H}(t)$ is the $N_r \times N_t$ channel matrix between transmit antennas v and receive antennas k, respectively and can be expressed as (3)

$$\mathbf{H}(t) = \begin{pmatrix} h_{1,1}(t) & h_{1,2}(t) & \cdots & h_{1,N_r}(t) \\ h_{2,1}(t) & h_{2,2}(t) & \cdots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ h_{N_r,1}(t) & h_{N_r,2}(t) & \cdots & h_{N_r,N_t}(t) \end{pmatrix} \tag{3}$$

where $\mathbf{h}_{k,v}$ is a complex fading coefficient between the v^{th} transmit antenna and k^{th} the receive antenna. $\mathbf{h}_{k,v}$ is as-

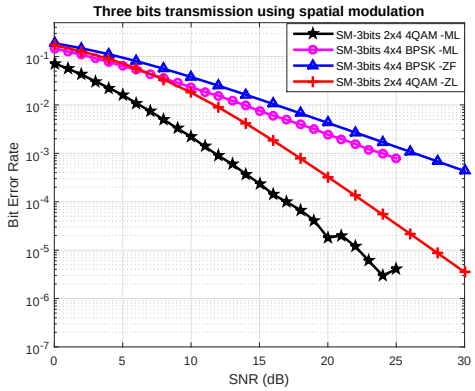

Figure 5: Illustration of BER performance for 3 bits per subcarrier employing ML and ZF detectors.

sumed to be iid complex zero mean Gaussian with variance one.

The receiver uses maximum likelihood detector to estimate the index, $\hat{i}(k)$ and the transmitted symbol, $\hat{x}_{\hat{i}}(k)$ can be expressed as

$$\begin{aligned}\left[\hat{i}^{\partial},\hat{\mathrm{x}}^{\partial}\right] &= \arg\max_{i,\mathrm{x}} \Pr\left(\mathrm{Y}_{\partial}\left|\mathrm{H}(t),\hat{\mathrm{x}}_{\hat{i}}\right.\right) \\ &= \arg\min_{i,x}\left(\left\|\mathrm{Y}_{\partial}-H(t),\hat{x}_{\hat{i}}\right\|_F^2\right)\end{aligned} \tag{4}$$

where $\mathbf{Y}_{\partial}$ is the output matrix from the ML for the subcarrier ∂, i.e. $(\partial : 1,2,...,n)$ and

$$\Pr\left(\mathbf{Y}_{\partial}\left|\mathbf{H}(t),\hat{x}_{\hat{i}}\right.\right) = \frac{1}{\pi^{N_r}\sigma_N^{2N_r}}\exp\left[\frac{\left\|\mathbf{Y}_{\partial}-\mathbf{H}(t),\hat{x}_{\hat{i}}\right\|_F^2}{\sigma_N^2}\right] \tag{5}$$

is the conditional probability density function (PDF) of $\mathbf{Y}_{\partial}$ given $\mathbf{H}(t)$ and $\mathbf{x}_{\hat{i}}$. Equation (4) estimates both the transmit antenna number and the transmitted symbols jointly. The SM demodulator, then used these two estimates to extract the transmitted information bits on this subcarrier by taking an inverse mapping process adopted by the same mapping table used at the transmitter.

Similarly, the zero forcing (ZF) detector can be written as

$$\left[\widehat{i}^{\partial},\widehat{\mathrm{x}}^{\partial}\right] = \left(\left(\mathbf{H}^T(t)\mathbf{H}(t)\right)^{-1}\mathbf{H}(t)\right) * \mathbf{x} \tag{6}$$

where $\mathbf{x}$ denotes the transmitted symbol vector, $\mathbf{H}^T(t)$ is the transpose of the channel matrix in (3) and $*$ denotes the convolution.

3 Simulation Results and Discussions

In this section, simulation results for the proposed SM F-OFDM transmission is shown. Monte Carlo simulations is used to evaluate bit error rate (BER) performance utilizing maximum likelihood (ML) detector at the receiver. In addition, zero forcing (ZF) detector was employed for comparison. Herein, it was considered that the receiver have full channel knowledge and the receive antennas are separated wide enough to avoid correlation. Flat Rayleigh fading channel was also assumed.

3.1 Three Bits Transmission

By using different configurations, a three bits per subcarrier transmission can be achieved. For SM, a 4×4 BPSK and 2×4 4QAM configuration convey three bits per subcarrier. In Figure 4, SM 4×4 BPSK shows performance degradation as compared to SM 2×4 4QAM when ML detector is used. A similar trend can be observed for ZF detector as the same degradation performance is seen with the same configurations. The results in Figure 4 shows that the ML detector estimation outperforms ZL detector estimation.

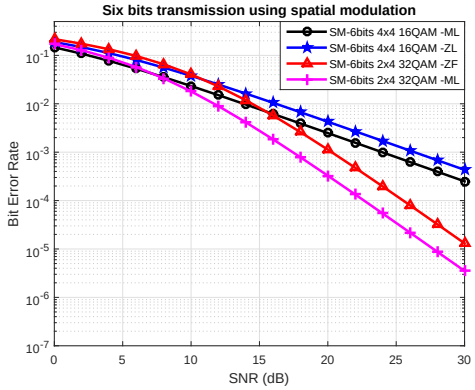

Figure 6: Illustration of BER performance for 6 bits per subcarrier employing ML and ZF detectors.

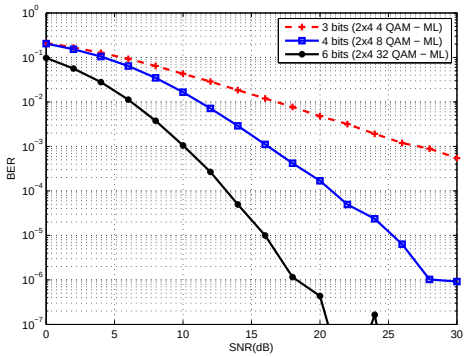

Figure 7: BER comparison performance for SM bits transmission, namely, 3, 4 and 6 bits, respectively when ML is adopted.

3.2 Four Bits Transmission

Four bits transmission can be achieved by the employment of SM 4×4 4QAM or 2×4 8QAM configuration. The comparison BER results in Figure 5 shows that the ZF demonstrates the worst performance as compared to ML detector.

3.3 Six Bits Transmission

Figure 6 results extended the simulation to a spectral efficiency of 6 bpcu for SM 4×4 16QAM or 2×4 32QAM transmissions. Again, ML detection outperforms ZF detection. It can be observed that the likelihood of errors for antenna detection increases with an increase in the number of transmit antennas. Therefore, the 2×4 SM system outperforms 4×4 system at high SNR. An interesting feature of SM can be noticed in Figure 6, where the 2×4 32QAM for ZF detector BER curve crosses the 4×4 16QAM ML detector at around 16 dB. This effect is a result of two estimation processes which is performed in SM, thus antenna number and transmitted symbol. Note that, the error level is dominated by the estimation of the transmitted symbol for low SNR, while the error level is dominated by the estimation of the transmit antenna number for a relatively high SNR. Hence, the scenario shown in Figure 6, for $SNR < 16dB$, lower constellation size and higher number of transmit antenna array is better for improved performance. On the other hand, for $SNR > 16dB$, higher constellation size and lower number of transmit antenna array is better. So there is a flexible tradeoff in this regard.

Figure 7 illustrates the BER comparison for distinct SM bits transmission, namely, 3 bits, 4 bits and 6 bits, respectively, for QAM modulation scheme. It can be observed that the 6 bits SM transmission performs better than the 3 bits and 4 bits. Thus $6bits > 4bits > 3bits$. This is because higher data rate can be achieved in the SM 6 bits transmission leading to a higher spectral efficiency.

4 Conclusion

In this paper, spectral efficient multiple antenna transmission technique, namely, spatial modulation (SM) is applied to F-OFDM for wireless transmission. The antenna pattern is considered as a spatial constellation in an innovative fashion by using SM technique to increase the spectral efficiency. By computer simulation, BER performance for the proposed scheme was evaluated for uncorrelated Rayleigh fading channel and compared with ZF detector. The proposed SM F-OFDM achieves a constant spectral efficiency in bits per subcarrier. Another significant merit of employing SM is the possibility of interchanging the constellation size and number of transmit antenna array to achieve better performance with respect to the operating SNR. In a follows up work, this feature will be further exploited. Furthermore, the performance improvement of the system increases as the transmission rate increases, which makes it a potential candidate for high data rate transmission systems. In addi-

tion, due to the estimation processes in SM approach, it is worth investigating further new algorithms for detection to improve the performance.

Conflict of Interest The author declare no conflict of interest.

ABSTRACT

Diffusion MRI-based tractography, which is built by connecting the principal components of the estimated water diffusion pattern, is used to elucidate neuronal connectivity. However, the anatomical accuracy of the method is affected by factors such as noise and imaging misalignments. In this manuscript, we present a method to clean diffusion datasets by rotating the diffusion patterns according to a transformation matrix, that is in turn obtained in the fractional anisotropy domain. We demonstrated the accuracy and feasibility of our method by improving brain images of a mouse and also by creating a diffusion template in a neonates framework.

1 Introduction

The diffusion-based methods of magnetic resonance imaging (dMRI) are capable of elucidating microstructural insights by estimating the water patterns of displacement into the tissue under study [1, 2]. Briefly, if there are not boundaries hindering the free movement caused by Brownian motion, the water diffuses isotropically. On the contrary, when there are restrictions, the water displacement occurs along the open spaces tracing a preference proper of the anisotropic diffusion. Thus, the images produced with dMRI are particularly useful for lighting neuronal state and trending, which has been vastly explored [3, 4, 5] and to study the integrity of muscle fiber [6, 7]. In the brain, dMRI is an outstanding tool that allows the follow up in horizontal research; this property together with the non-intrusiveness nature of magnetic resonance imaging (MRI), have lead to several studies of neurodegenerative assessments including Parkinson [8, 9], Multiple sclerosis [10, 11], Schizophrenia [12, 13] among others. However, dMRI is a time-consuming technique and image quality as any other MRI procedure deteriorates rapidly if the scanning time is reduced. The timing issue has restricted the dMRI to be fully implemented in the clinics, and currently, it is only used to diagnose stroke in ultra rapid sequences where the whole head volume is scanned three times to covering the orthogonal axes and once more to produce the reference signal (B0) needed to compute diffusion [14, 15]. Despite this clinical acquisition scheme yields images with a bad Signal-to-Noise ratio, it is enough to localize the swelling processes depictive of stroke. As for other applications in the clinics regarding dMRI, it is mandatory to use a higher angular resolution like in diffusion tensor imaging (DTI) [1, 16] or high angular resolution diffusion imaging (HARDI) [17, 18]. The required time to implement these high angular resolution techniques renders it use prohibited in the clinics. Researchers in their side, have the flexibility to plan the scans and recruit the patients. They can also apply standard methods to all samples and care for repeatability. Thanks to this flexibility humanity has faced in detail, important aspects and the core of neurodegenerative diseases. However, a full understanding requires close monitoring of the dynamic apoptotic events which calls the attention over the small animal modeling field. Here, scaning time is a concern only for ethical reasons but, spatial resolution is so exigent that the quality gained by the wider scanning periods is lost in the little spin recruitment induced when reducing the voxels' size. Additionally, at grids of cents of micrometers as used in the small animal MRI field, a slight movement in the physical setup is traduced in huge displacements or rotations in the image. In this document, we present a method that enhances the quality of dMRI datasets. Here, we turn deteriorated diffusion images into meaningful ones. More importantly, the quality is improved with every new session which is of utmost relevance in horizontal studies. The method was developed and

https://dx.doi.org/10.25046/aj0203125

thoroughly tested on programmatically created diffusion phantoms and translated to both, the small animals and the clinics.

2 Materials and Methods

The **Fig. 1** depicts the common dMRI pipeline under the DTI modeling.

Our driving hypothesis focuses on DTI and states that a diffusion study is more cost and time effective if an averaging is done in the tensor space rather than in the Diffusion Weighted Imaging (DWI) domain. Often, quality enhancement in dMRI is achieved by incrementing the number of machine averages which increments the acquisition time. We instead propose to use several images acquired in the low SNR regime and perform the average-enhancing strategy in the tensor domain. The averaging proposed here is not an obvious one. Recall that tensors are 3 by 3 matrices representing a diffusion geometry –all forms ellipsoids including the sphere– and consequently, a corrective action is not as simple as performing a linear operation over the axes of the images. To elaborate on this aspect, we summarize a theoretical framework that illustrates our rationale on a toy example using numerical phantoms.

2.1 Creating synthetic diffusion phantoms

Synthetic DWI signals can be created and manipulated to reproduce rotational structural misalignments in noise-free situations and with added Rician noise using the framework mentioned above. For demonstrative purposes, a synthetic-diffusion phantom is created from which, one diffusion voxel or a group of them (V) are selected. The V contains several diffusion patterns as shown in **Fig.** 2. Each of them is restricted to a cylinder of $\rho = 5\mu$ and length $L = 5mm$, where the particles diffuse at $1/1500\ mm^2/s$ as in [19]. This cylindrical model for diffusion mimics the preferential direction of water motion in the free space between cells, voxel by voxel. We define an initial reference signal resting along the x-axis (D_{ref}), see **Fig.** 2-**AI**, which is a compendium of diffusion patterns in each voxel that together create a preferred global diffusion as it would do a brain tract under dMRI. Then, using this model, we create other synthetic diffusion patterns that are rotated creating the desired misalignments, as in frames AII and AIII of **Fig.** 2.

Assume then that each diffusion pattern comes from a single fiber, like in fiber tracking [20]. Each fiber orientation is then governed by **Equation. 1**.

$$fib_i = \left[cos(\alpha * \frac{pi}{180}), sin(\alpha * \frac{pi}{180}), 0\right]. \quad (1)$$

Where the parameter α will be zero in the synthetic D_{ref} signal, and will receive any value in the range [0,90] whenever non-overlapping diffusion signals are simulated among acquisitions. Here, fib_i represents the i simulated pattern. **Fig.** 2-**Panel A** illustrates this procedure.

The diffusion coefficents in the V are derived by taking the log on both sides of the Sketjal-Tanner equation as in [21]:

$$\log(\hat{S}_i) = \log(S_o) - bg_i' D g_i \quad (2)$$

Where S_o is the non-sensitized signal, b is the b-value, g_i is the gradient direction, D is the diffusion factor, and $\hat{S}_i$ is the DWI signal for the g_i direction. The $\hat{S}_i$ factor can be decomposed into the ideal signal S_i and a Rician noise component, represented as two independent Gaussians N_1 and N_2 with a variance σ:

$$\hat{S}_i = \sqrt{[S_i + N_1(0,\sigma) + N_2(0,\sigma)}} \quad (3)$$

The diffusion tensors D_t are estimated in the Log-euclidean (LE) domain (where they are represented by the parameter L) using the D contributions from all gradient directions:

$$L = \log(D) \leftrightarrow \check{D} = \exp(\check{L}) \quad (4)$$

The operations in the LE domain are computationally inexpensive when compared with other manifold-based methods such as [22, 23, 24]. To see details of how the LE outperforms other common tensor estimation strategies; please refer to the document [21]. Tensors in the LE domain can be moved back to the original tensor space through **Equation 4**.

For the framework described in this section, rotations are forced to be in the x-y plane (about the z-axis). Hence, rotational corrections under ideal conditions are generated using $T_{rot} = RTR'$, where R can be represented as:

$$R = \begin{bmatrix} \cos\frac{\alpha*pi}{180} & -\sin\frac{\alpha*pi}{180} & 0 \\ \sin\frac{\alpha*pi}{180} & \cos\frac{\alpha*pi}{180} & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (5)$$

In the presence of noise, the diffusion pattern rotates randomly in any direction; thus, the correction matrices may have rotational components along the Z axis as well. Conveniently, R in **Equation 5** is dynamically created through registration in the Fractional Anistropy (FA) domain; hence, projections in Z-axis, in the case they are present, are also accounted.

The **Fig.** 2 illustrates the synthetic data that we generated to test our method.

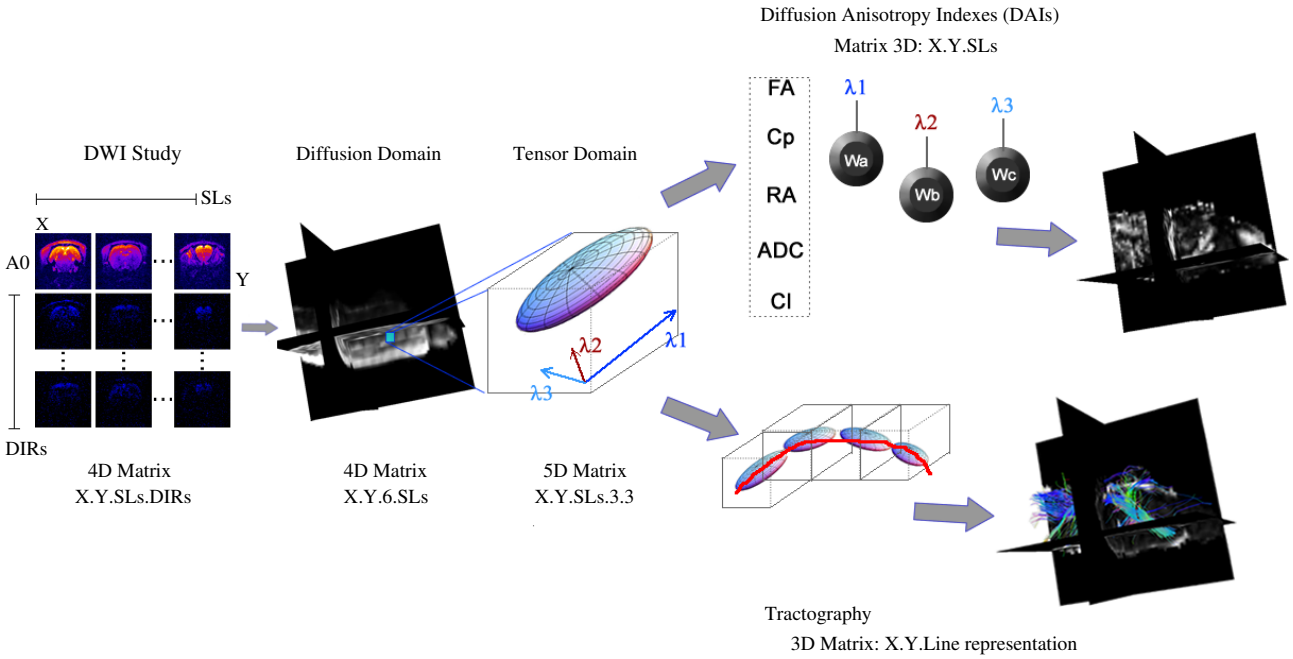

Figure 1: **Standard DTI pipeline**. In the dimensions of the data, SLs stands for slices and DIRs for gradient directions. Note how the data produces complex matrix formats along the whole path and only in the DAIs the outputs are scalars. From here the convinience to using a registration on the FA index fro correction purposes.

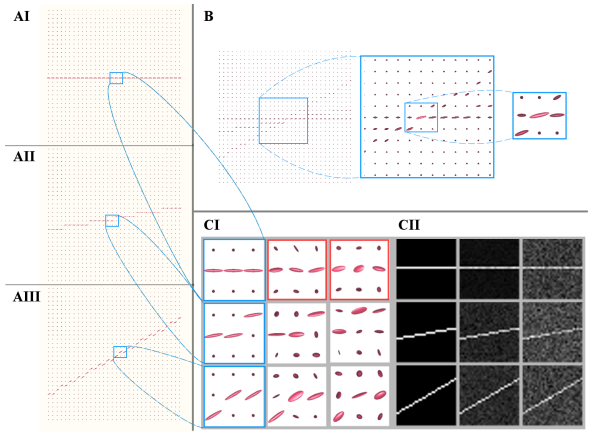

Figure 2: **Proof of concept synthetic data**

The panel A of **Fig. 2** shows ideal-synthetic-tensor fields: AI is the reference, AII and AIII are tensor fields simulating acquisition rotated 10 and 30 degrees with respect to the reference (AI). Panel B shows the tensor field that is generated when the three acquisitions (AI,AII, and AIII) are averaged in the DWI-domain. Panel C shows the same information in the tensor and FA domains. Some tensors of Panel A are zoomed-in and shown in the first column of CI. In Panel C, the columns simulate acquisitions with different levels of noise. In CI, the parameters of the tensors are as follows: rows 1, 2, and 3 represent tensors with 0, 10, and 30 degree rotations, respectively; columns 1, 2, and 3 represent tensors with 0, 0.1, and 0.2 sigma noise, respectively, with the exception of the tensors in the red boxes, in which the noise levels are 0.05 and 0.15 (left and right, respectively). Each panel of CI is the tensor field from which the FA is generated in the corresponding panel in CII.

In this proof of concept, a field of 32x32 pixels with a horizontal diffusion pattern is used as a reference. Its tensor field is extracted as shown in Panel AI. A set of rotations is induced in the tensor fields (see Panels AII and AIII) and Rician noise with different levels is added (as displayed in Panel CI). For our theoretical experiment, we generated six different datasets using a combination of angular rotations respect to the x-axis as well as various noise levels. The details of these datasets are shown in Table 1. The variance in the Rician noise of the noisy reference signals (Panel C, row 1, columns 2,3) is decreased by 0.5 to simulate the model acquisitions. The tensor fields are also used to generate FA maps for registration purposes, which generates the transformation matrices used to correct the misalignments in the tensor field. Hence, in summary, with this procedure, synthetic signals in the DWI domain, tensor fields, and FA maps are generated. The outcomes of these set of experiments will serve to demonstrate how the proposed method not only de-noises the images, but also correct structural misalignments at the tensor stage, enhancing general quality with each acquisition and, therefore, improving the results in every subsequent step.

2.2 Tensor averaging on small animal data

Small animals are often used to recreate pathogenic models. The idea of monitoring these models in time

Table 1: Angles of rotation and noise levels of 5 different datasets of synthesized signals. Sets 0 and 3 represent the ideal sets with no noise. Abbreviations: AoR (angles of rotation), σ (variance of Rician noise).

Set	Reference	1st additional acquistion	2nd additional Acquisition
Set 0	$AoR = 0°$, $\sigma = 0.00$	$AoR = 10°$, $\sigma = 0.00$	$AoR = 30°$, $\sigma = 0.00$
Set 1	$AoR = 0°$, $\sigma = 0.05$	$AoR = 10°$, $\sigma = 0.10$	$AoR = 30°$, $\sigma = 0.10$
Set 2	$AoR = 0°$, $\sigma = 0.15$	$AoR = 10°$, $\sigma = 0.20$	$AoR = 30°$, $\sigma = 0.20$
Set 3	$AoR = 0°$, $\sigma = 0.00$	$AoR = 0°$, $\sigma = 0.00$	$AoR = 0°$, $\sigma = 0.00$
Set 4	$AoR = 0°$, $\sigma = 0.05$	$AoR = 0°$, $\sigma = 0.10$	$AoR = 0°$, $\sigma = 0.10$
Set 5	$AoR = 0°$, $\sigma = 0.15$	$AoR = 0°$, $\sigma = 0.20$	$AoR = 0°$, $\sigma = 0.20$

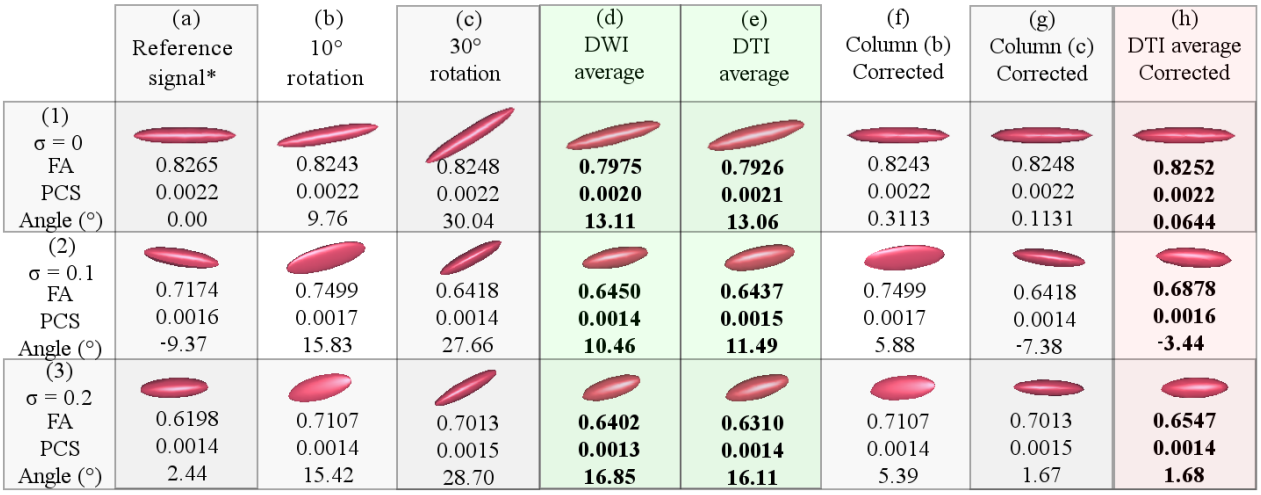

Figure 3: **Results of the theoretical experiment using the new pipeline on synthetic data with rotation induction.**

using non-intrusive means such as the MRI vanish in spite of the quality of images. Here we present a case of quality enhancement on the diffusion data of an animal model.

A mouse imaged with a 9.4 Tesla Bruker BioSpin MRI GmbH using the diffusion EPI sequence. The acquisition produced a matrix size of $106x160x88$ where each voxel has isometric side lengths of 0.08 mm, yielding a field of view of $8.5x12.8x7.0mm^3$. The diffusion parameters were set in 6 gradient directions with sensitizer b-value of $3000s/mm^2$ and one reference image without sensitizer (B0).

The mouse was scanned twice using the same protocol and once more using the DWI averaging strategy that comes built-in with scanners set in two. The added acquisition time of the two initial experiments equals the one utilized in the two DWI averaging acquisition creating a fair comparison scheme.

2.3 Templates on human neonates data

Templates are vastly used in human frameworks as references for structural assessments. Either T1 or T2 images are aligned and averaged to produce smooth models [25, 26, 27]. Recall that T1 and T2 images are 3D stacks while diffusion images are 4D stacks, from here the difficulty to apply the same aligning and averaging techniques in this kind of data. For this proof of concept, five brain DTI scans of term neonates with regular -not pathological- MRI scans images were acquired with a 1.5T GE scanner. The images are captured in a matrix of $256x256x22$ where each voxel represents a space of $0.70x0.70x4.99mm^3$; therefore, the field of view is of $180x180x110mm^3$. The diffusion parameters were set in 25 gradient directions with sensitizer b-value of $700s/mm^2$ and one reference image without sensitizer (B0). The images were acquired without DWI averaging.

2.4 Tracts extraction in Neonates

As a proof of implementation, in this section, we use the previously created template to map a limbic, some association and commissural fiber tracts in a neonate of 42 weeks conceptional age. Recall that these structures are undergoing the process of myelination at this

age according to [28, 29, 30, 31]. In this conditions, structural visualization under diffusion MRI methods is not only hardened by factors such as size and neuronal hyper-connectivity, but also by the lack of natural barriers that restrict the water displacement which is provided by the myelin sheets in adult brains. The structures shown in **Fig. 7** correspond to one of the subjects utilized to create the template.

3 Results

3.1 Synthetic data

With the synthetic material generated in **Section 2**, the analysis focuses on the behaviour of the center pixel, in which all the created signals converge (see Panel B in **Figure 2**). The eigenvalues and eigenvectors that describe the diffusion geometry are dependent on the accuracy of the overlays of concomitant diffusion patterns. The results of these experiments are shown in **Figures 3** and **4**. Recall that the transformations induced in the central voxel are also applied to the other voxels in the field of view; therefore, the outcomes of this exercise should be extrapolated to the whole image space.

All the references to columns in this paragraph belong to the **Fig. 3**. Column (a) contains the tensor of the reference DWI signal. Columns (b) and (c) hold tensors of the DWI signals that have been rotated 10°and 30°respectively, respect to the x-axis. Column (d) represents the tensor of the DWI signal that has been averaged using (a),(b) and (c) in the DWI domain without any prior rotation correction. Column (e) shows the same information as in (d), but all done in the tensor field. Column (f) and (g) contain the corrected tensors of Columns (b) and (c), respectively. Column (h) displays the result of averaging the tensors in Columns (a), (f) and (g).

All the references to columns in this paragraph belong to the **Fig. 4**. Column (a) contains the tensor of the reference DWI signal. Column (i) and (j) hold tensors of the two additional DWI signals that have been randomly generated. Column (d) represents the tensor of the DWI signal that has been averaged using (a),(i) and (j) in the DWI domain without any prior rotation correction. Column (e) is the same as (d) but all done in the tensor field. Column (k) and (l) hold the corrected tensors of Columns (i) and (j), respectively. Column (h) displays the tensor that has been averaged from the tensors in Columns (a),(k) and (l).

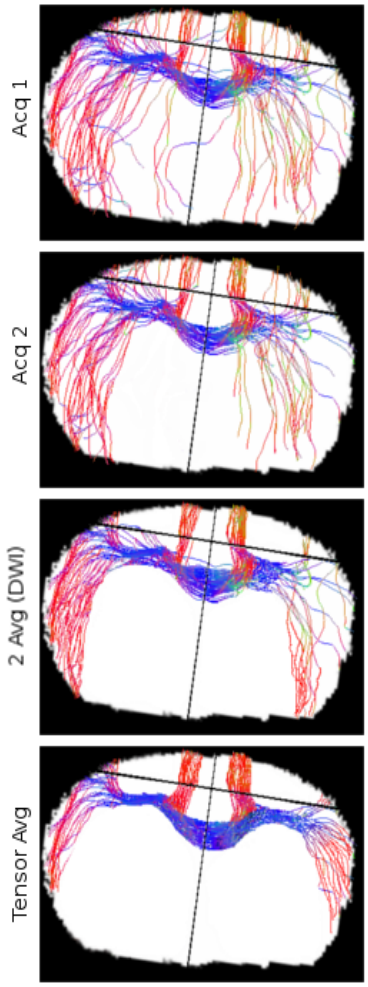

Figure 5: Diffusion image enhancement in small animal data. Tractography of the corpus callosum (CC) using a single region of interest that fully covers the structure in coronal view.

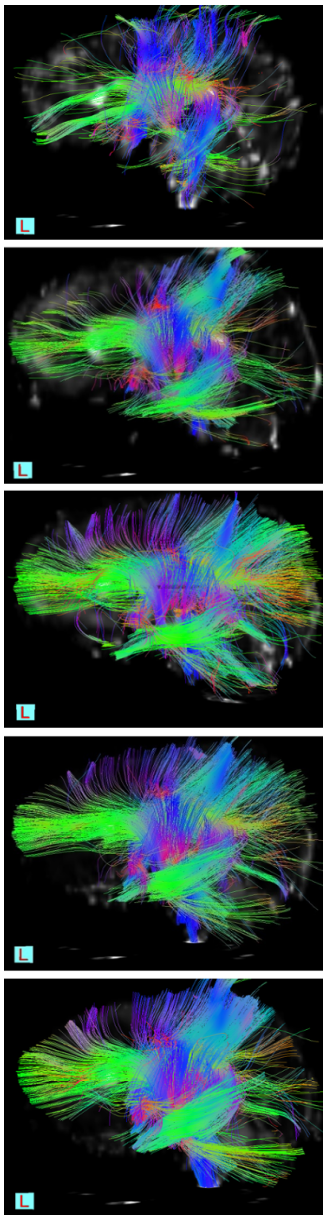

Figure 6: **Dynamic diffusion template for neonates** The tractography of the commissural and associating tracts. Using a single subject -on top- and adding one subject each time to end in a template of 5 subject at the bottom

For both Figures 3 and 4: Row (1) displays the dataset with ideal conditions (no noise), row (2) the one with $\sigma = 0.1$, and row (3) that with $\sigma = 0.2$. The provided Angle (°) is the nearest angle (in degrees) of the principle eigenvector with respect to the x-axis. Abbreviations: FA (fractional anisotropy); PCS (principal component); σ (variance of Rician noise). Also note that in sets marked with * the σ is 0.5 lower in the reference signals of the noisy datasets (row (2) and (3)). The columns with bold entries correspond to definitive results and should be use to focus the comparisons.

In the experiments with synthetic data, the proposed method always aligned the additional acquisitions to the model dataset, thus improving the overlap between structures and consequently cleaning the images while retaining the essential information. This statement remains true even in the data affected by noise. Note also how all the factors that affect the tractography are favorably adjusted.

3.2 Small animal data

The dMRI studies depicted in **Fig. 5** corresponds to only one animal scanned several times, replicating what it would happen in horizontal research.

The averaging is performed using the Acq 1 and Acq2. Note how the corpus callosum (CC) fiber are shown in blue, this is due to the position of the animal in the scanner. Recall that in humans, the coordinates are rotated 180° in the YZ plane; thus, fibers in the CC that connect the two brain hemisphere are usually shown in red.

3.3 Neonatal data

The infant data has been processed with the tensor averaging method after a rigorous re-sampling process to enable the standard space and the registration as well. The **Fig. 6** shows the progressive improvement with each newly added subject.

3.4 Tractography in neonatal datasets

With a clean template such as the one shown in **Fig. 6**, it is possible to map the tracts of a subject with highly compromised quality, as it is often the case in clinics and hospitals where the medical necessity and the comfort of the patient is prioritized over image clarity. Through non-linear registration in the factional anisotropy domain and by applying the obtained deformation fields to the tracts in the template, the tracts in the subject appear respecting the anatomy, see **Fig. 7**.

4 Dicussion

The Diffusion methods in the brain are meaningful if the extracted structures follow the neuronal trending that has been estimated through histology in postmorten samples. The tractography is an unbeatable mechanism to elucidate the structures created by neuron connectivity and thus, a visualizing method of utmost relevance for our purposes and those of any study based in dMRI. Once, the tractography is found consistent with the previous knowledge of the structure, one can start analyzing the DAIs under the tracts or out of them to enlight contrast. The results section is presented with evidence of tractography and improvement in this domain due to the relevance of this visualization mechanism in dMRI.

The proof of concept of **Section 2.1** consists of two stages. The first one is intended to demonstrate that set-up associated rotations can be dynamically corrected. In a second run, the same pipeline is used in a testing-set where no rotations are added; thus working solely with the random and unavoidable geometry modifiers introduced by noise. In both groups of experiments, ideal situations and two levels of noise are evaluated. With our method, the tractography, FA, principal components and angles are all kept within acceptable ranges of the ground truth. Tensor patterns are also closest to the original in (a), as it is evidenced if comparing columns (e),(f) and (h). Refer to **Figures 3** and **4**. Note also how the rotations do not greatly affect the diffusion geometry; the major contribution of our new pipeline consists in correcting the angle of the main principal components, therefore enabling the tractography in these datasets [32]. Also, note in **Figure 2 - Panel B**, how the averaging of tensor fields that are rotated about each other results in shrunk tensors. In contrast, our method obtains acceptable orientations and tensor sizes in spite of noise in the signal. When these specifications are moved to real data, the tractography is better defined with each new intake.

Regading the small animal data, rats and mice are preferably used for tracking pathologies associated with motor deficiencies. One big field of study is the ictus, which researchers induce in these animals. Cell swelling and apoptosis happen in the first 24 hours and diffusion normalizing processes happen along the week after the inducement. Also, consider that an adult rodent is used for these sort of experiments; thus, growing factors are not crucial. Neuron state and neuron connectivity changes, those are the ones that we need to capture. If the structures are aligned, as we proposed within our method, we do not only clean the images while averaging. Recall that as noise, any non-correlated data will be diminished. Analogously, all correlated data will be sustained. In this way neurodegenerative processes will become non-correlated information through acquisitions and thus will be manifested as disappearing structures while averaging. In a similar manner, proliferation processes will be non-correlated data along scannings, but this time, it will be displayed as appearing structures while averaging.

The above is a hypothesis and despite its veracity can be inferred from the simulations in **Section 2-A**, has not been demonstrated in the current work, overall because we do not have real data to support such as statements. What we have shown is that our method is more time-efficient that the machine averaging often used to produce better image quality. The message that we would like to transmit is stated as follows:

Using our tensor FA-based rotation strategy in n separated acquisitions that spend m minutes would yield better image quality than doing one acquisition lasting the same m minutes. This is very convenient also regarding scanning setup, recall that the animals should not be anesthetized more than 2 hours for ethical reasons. Our strategy presents a way out to this limitation which is a major drawback when working with alive subjects at such as exigent spatial resolution. This claim remains true also for the neonates field where the patient is priority and the scanning times are fastened to avoid displacement artifacts.

The procedure that we are performing does not modify the diffusion pattern (the lamdas are the same), it just re-accommodate the orientation and displacement in case present. As the diffusion anisotropy indexes (such as FA, Aparent Diffusion Coeficiente, Mean Diffusivity and so on) are rotationally independent, and we keep the lamdas unmodified, our procedure does not modify these values. Additionally, we would like to emphasize the importance of the tractography because all our efforts are focused on generating a good one. Once the structure of interest is well located and even when the rotations do not affect the DAIs – because of the facts given above –, you can always run the DAIs analysis on the voxels overlapped by the extracted tractography in the original data.

The method exposed in this manuscript has been successfully tested in a controlled environment be-

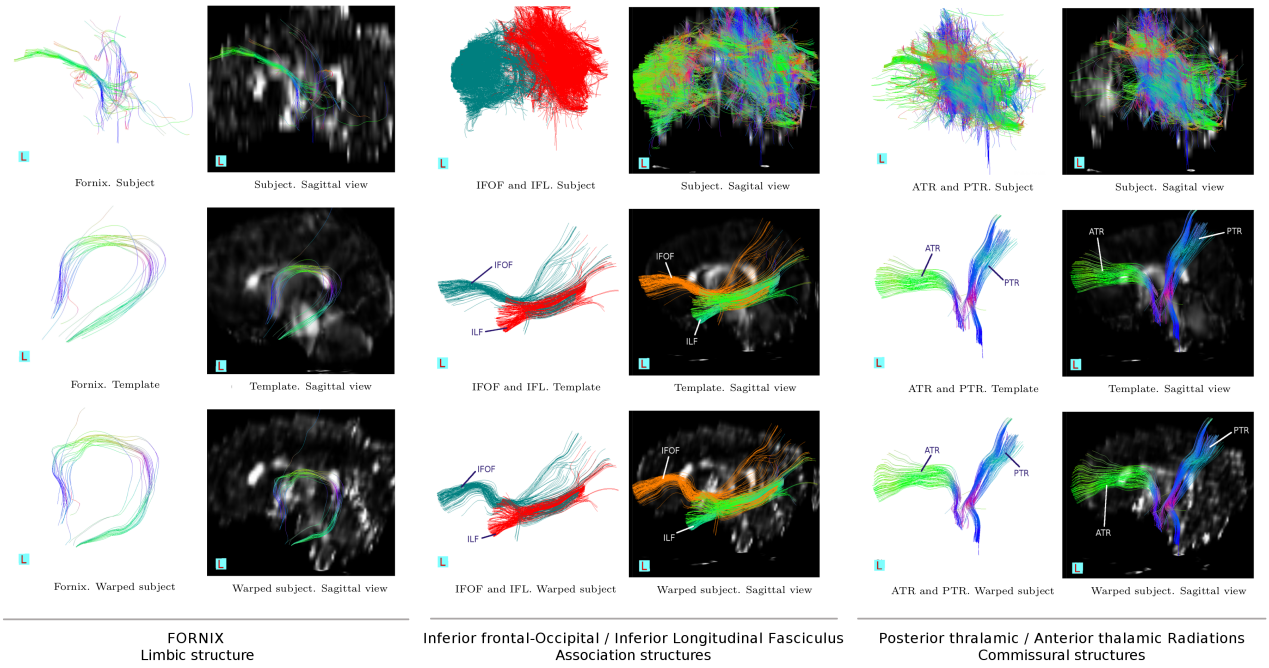

Figure 7: **Tractography in clinical datasets.** Limbic, association and commissural structures (left,center and right respectively) by standard methods (top row), in the template (center row) and in the studied clinical subject (bottom row). Each structure is presented in stand alone fashion and overlapped with its respective FA map of the brain. Top and bottom rows show, graphically, the significance of the proposed method.

fore being tested on the animal and also on clinical data. The biological variability that authors try to diminish by increasing the sample size is not an issue here because the noise and the misalignments are not produced by any metabolic or physiological reason. We are dealing with setup-related factors that are difficult to overcome due to the high resolution used in the case of the animals and also to procedimental disparities in the clinics. On the noise side, recall that making smaller voxels reduces the rate of spin recruitment while Brownian motion keeps the noise in constant levels. On the displacement side, note that we are trying to sharply locate the animal in our macro world when the scanning system is capturing the changes between 200 and 400 micrometers. As for the neonates, the diversity in the acqusition protocols and spatial resolutions is the reason for the lack of structural coherence among subjects.

In both sets of real data, the enhancement consists in better definition of structures and elimination of doubtful fibers. The better definition of paths is achieved when the diffusion information is highly correlated among acquisitions or subjects, not only reinforcing the correlated information but also weakening non-correlated one like noise. Another important aspect demonstrated in the procedure with synthetic data is the angle recovering of the tensor averaging method. The angle in which principal components of diffusion –the longest axis– coexists in neighboring voxels can create or eliminate fibers depending if this angle is smaller or bigger than 10°. The last statement applies if the fiber tracking is performed with the TensorLine algorithm [33] which is the case of the current implementation.

5 Conclusions

Diffusion MRI is a powerful tool that has not yet been implemented in full extend at the clinics due to the long lasting sessions required to achieve a good image quality. Regarding the small animal field, dMRI opens a myriad of possibilities but the spatial resolution is too exigent, and the quality of the images ends by discouraging the realization. If carefully observed, in both fields of application the quality is a concern and in MRI, quality is a matter of time. Here, we have introduced a post-scanning method that makes the inter-acquisition time to become a valued asset for image enhancing purposes. The method has been thoroughly tested in synthetic toys and successfully translated to real case scenarios. With all compelling evidence exposed in this document, we confirm that time in dMRI can be more efficiently utilized in the tensor space than in the DWI domain.

ABSTRACT

Classification of EEG signals in self-paced Brain Computer Interfaces (BCI) is an extremely challenging task. The main difficulty stems from the fact that start time of a control task is not defined. Therefore it is imperative to exploit the characteristics of the EEG data to the extent possible. In sensory motor self-paced BCIs, while performing the mental task, the user's brain goes through several well-defined internal state changes. Applying appropriate classifiers that can capture these state changes and exploit the temporal correlation in EEG data can enhance the performance of the BCI. In this paper, we propose an ensemble learning approach for self-paced BCIs. We use Bayesian optimization to train several different classifiers on different parts of the BCI hyper-parameter space. We call each of these classifiers Neural Network Conditional Random Field (NNCRF). NNCRF is a combination of a neural network and conditional random field (CRF). As in the standard CRF, NNCRF is able to model the correlation between adjacent EEG samples. However, NNCRF can also model the nonlinear dependencies between the input and the output, which makes it more powerful than the standard CRF. We compare the performance of our algorithm to those of three popular sequence labeling algorithms (Hidden Markov Models, Hidden Markov Support Vector Machines and CRF), and to two classical classifiers (Logistic Regression and Support Vector Machines). The classifiers are compared for the two cases: when the ensemble learning approach is not used and when it is. The data used in our studies are those from the BCI competition IV and the SM2 dataset. We show that our algorithm is considerably superior to the other approaches in terms of the Area Under the Curve (AUC) of the BCI system.

1 Introduction

A brain computer interface (BCI) aims at detecting the presence of specific patterns in a person's brain activity. These patterns relate to the user's intention to control a device [1]. If such patterns are detected in the brain waves, then the BCI issues specific signals to control the device.

BCI systems can be classified into two categories: synchronous and self-paced [2]. In synchronous BCIs, the user controls the BCI output during specific short periods. Therefore, the user can only issue a control command when he/she is prompted to operate the system. Users of self-paced BCIs, on the other hand, can control the system whenever they wish. The periods during which a user is issuing a signal to control the system are called Control states, and those during which the user is not controlling the system are called No-Control (NC) states. During the NC states, the BCI system should be designed so it does not issue any control signal; otherwise a false positive output is produced.

Despite the much progress made in self-paced BCIs, they remain extremely challenging to design, compared with synchronous BCI systems. This is because (unlike the case of synchronous BCIs), a user of a self-paced BCI should be able to control the system at any time, but the BCI system does not have any

https://dx.doi.org/10.25046/aj0203126

knowledge about the onset of any control command.

To address this property of self-paced BCIs (i.e. the onset detection of intentional control), one of the following two approaches can be used. The first approach exploits the properties of the electroencephalogram (EEG) data to design more advanced classification and/or feature extraction techniques (the focus of this paper). For instance in [3] and [4] the authors have used more advanced classifiers to design self-paced BCI. The second approach takes advantage of other cognitive tasks to detect the onset of the intentional control. For instance in [5] the authors have used high pitch and siren-like sounds to facilitate distinguishing control tasks from no-control states. In [6] the authors have used a combination of motor imagery and P300 potential to design self-paced BCIs.

The task of classifying brain signals in a self-paced BCI has been formulated as a sequential supervised learning problem [7]. In sequential learning, a sequence of observations and their corresponding labels are known, and the goal is to construct a classifier that predicts the sequence of the labels of a new sequence of observations.

The most popular way to obtain observation sequences for sequential supervised learning is to use a sliding window over the signal (these windows might overlap). This approach takes consecutive input windows of the brain signal (each of length w milliseconds), extracts features from each window and assigns a label to each window. The labels correspond to whether or not the user is issuing a command to operate the device. The sequence of the extracted feature vectors and their corresponding labels are used to train a classifier. For a new sequence, the trained classifier estimates the label of each window (i.e. the intention of the user).

The advantage of using the sliding window approach is that it converts the sequential supervised learning problem into a standard classification problem. Thus any classical supervised learning method can be used to solve the problem. The majority of the publications in the field have used this method to build different self-paced BCIs [8], [9], [10]. The disadvantage of the sliding window approach is that the sequential correlation of the labels of consecutive EEG windows is not exploited. Yet, the observations and the labels of nearby windows are usually related to each other. Thus there is a sequential correlation between adjacent EEG windows, and this knowledge could be used to improve the performance of the system.

In [11] the authors show that the brain goes through several well-defined internal state changes while the subject is carrying out a motor imagery mental task. Employing an algorithm that can model/exploit these state transitions can enhance the performance of the BCI. The class of sequence labeling algorithms are able to exploit the temporal structure of the EEG data. Among these algorithms, the most popular is the Hidden Markov Model (HMM) [12], which is a generative classifier. A generative classifier models the joint probability of observations and label sequences. Although the HMM classifier has been successful in synchronous BCIs, in [13] the authors concluded that the sliding window approach (i.e. using classical classifiers) is superior to HMM in self-paced BCIs. Due to intractability issues, HMMs assume the observations are independent given the states. This makes it difficult to incorporate knowledge about the structure of the EEG data into the model by extracting informative overlapping observations (the problem of over-counting evidence).

Another type of sequence labeling classifiers (besides HMM) are the discriminative ones. These classifiers directly maximize the conditional likelihood of the label sequence given the observations. These algorithms have yielded very promising results in the fields of natural language processing [14], and activity recognition [15] which are very similar in nature to the task of self-paced classification of BCI. The advantage of these models is that they give the user the freedom to extract many informative and overlapping features from the observation sequence [1]. These features might be extracted from previous windows in the brain signal and can be correlated.

In [16], [17] and [18], the authors applied discriminative sequence labeling algorithms to self-paced BCIs, to classify different motor imagery tasks. In this paper, we use a discriminative sequence labeling algorithms to discriminate between NC and control states. The challenge here is that during the control states, i.e. while the subject is performing the mental task, a set of well-defined state changes occur. However, during the NC states, the subject can be in any mental state, therefore finding specific patterns in the EEG signal during NC states is extremely difficult. In other words, discriminating between two predetermined mental tasks (e.g. right hand versus left hand movement) is much easier than discriminating a predetermined mental task (e.g. left hand movement) from NC states.

Our contributions in this paper are two-fold. The first is a new discriminative sequence labeling classifier for self-paced BCIs. Our approach combines the power of one of the most popular discriminative sequence labeling classifiers (Conditional Random Field) to exploit the correlation in consecutive EEG windows. It also utilizes a neural network to extract high-level features from the observations. We call our classifier Neural Network Conditional Random Field (NNCRF). We compare its performance to those of Hidden Markov Models (HMM), and two of the most popular discriminative sequence labeling classifiers i.e. Conditional Random Field (CRF) [19] and Structural Support Vector Machines (SSVM) [20]. We also compare the performance of these discriminative sequence labeling classifiers with two popu-

[1] These observations correspond to the features extracted from the raw EEG signal.

lar classical classifiers i.e. Support Vector Machines (SVM) [21] and Logistic Regression classifiers [22]. Our second contribution is discussed in the latter part of the paper, where we propose an ensemble learning approach to further improve the accuracy of the BCI system. We use Bayesian optimization [23] to train several diverse classifiers on different parts of the BCI hyper-parameter space. We evaluate the performance of different algorithms using the data from the BCI competition IV [24] and SM2 [25] dataset, and show that our algorithm is considerably superior to the existing approaches in terms of the Area Under the Curve (AUC) of the BCI system.

In the rest of this paper, in section 2, we describe the feature function in discriminative sequence labeling classifiers. In section 3, we introduce our proposed sequence labeling classifier i.e. NNCRF. In section 4 we describe our ensemble classification approach. In section 5, we explain the datasets, and in sections 6 and 7, the results of different algorithms are compared.

2 Feature Function in Discriminative Sequence Labeling

For sequence labeling algorithms, we assume that each data sample in the training set consists of a sequence of observations, [2] and its corresponding label sequence. Assuming the training set is $\{x_i, y_i\}_{i=1}^{N}$ where N is the number of training samples. x_i is the sequence of observations from K consecutive windows and y_i is the corresponding sequence of K labels. Every w milliseconds of the EEG creates a window. x_i is created by concatenating the observations from each of K consecutive windows i.e. $x_i = [x_{i1},...,x_{ik},...,x_{iK}]$ and x_{ik} corresponds to the observations from the k^{th} window in the sequence number i [3]. Likewise, y_i is created by concatenating the labels of each of these K consecutive windows i.e. $y_i = [y_{i1},...,y_{ik},...,y_{iK}]$ and y_{ik} corresponds to the label of the k^{th} window in the sequence number i.

The discriminative sequence labeling algorithms have the advantage of enabling a set of features to be designed based on the structure of the data. Each feature is a function of the joint observations and their labels i.e. $\Phi : X \times Y -> R$, where X is the observation space, Y is the label space and R is the real space. In classical classification the feature vector is built based on the observations (X) only. However, here the idea is to extract features from the joint observations (X) and label (Y) spaces. In this way, a feature function Φ measures the joint compatibility of x (x_i) and y (y_i) [4]. Although more complex types of features can be used, the feature functions we use here are inspired from first order HMMs.

The first feature function we used, is defined as

$$\phi_0^{\sigma} = I(y_k = \sigma),\ \sigma \in \Sigma, \tag{1}$$

where I represents the indicator function, and Σ corresponds to the set of possible label values (i.e. NC states and movement states). The above feature function is based on Y only.

The second set of features forms a vector $\phi_{k,1:L}$ with L dimensions that captures the relation between the observation vector and the k^{th} label in the sequence. We are assuming the observation vector is of dimension L. Each element $\phi_{k,l}^{\sigma}$ of the vector $\phi_{k,1:L}^{\sigma}$ is defined as

$$\phi_{k,l}^{\sigma} = x_{k,l} I(y_k = \sigma),\ \sigma \in \Sigma, \tag{2}$$

where $x_{k,l}$ is the l^{th} dimension of the observation vector.

The third type of features is defined as

$$\phi_{k(k-1)}^{\sigma_1,\sigma_2} = I(y_k = \sigma_1 \wedge y_{k-1} = \sigma_2),\ \sigma_1, \sigma_2 \in \Sigma, \tag{3}$$

where $\phi_{k(k-1)}^{\sigma_1,\sigma_2}$ captures the relation between the k^{th} and $(k-1)^{th}$ labels in the sequence.

3 Neural Network Conditional Random Fields

In this section we first describe the standard Conditional Random Field (CRF), then we describe Neural Network CRF. CRF is one of the most popular discriminative sequence labeling classifiers. In general the linear chain Conditional Random Field (CRF) classifier models the posterior distribution of the form

$$\Pr(Y|X) = \frac{\exp(\sum_{j=1}^{J} \lambda_j \sum_{k=1}^{K} \Phi_j(y_{k-1}, y_k, x, k))}{Z(X)}, \tag{4}$$

where K is the sequence length, J is the number of features extracted from the joint observation labels pair, and Φ_j is the feature function. λ_js are the parameters of the model which are learned based on the training data. $Z(x)$ is the normalization factor (partition function):

$$Z(X) = \sum_{y'_1} \sum_{y'_2} ... \sum_{y'_K} \exp(\sum_{j=1}^{J} \lambda_j \sum_{k=1}^{K} \Phi_j(y'_{k-1}, y'_k, x, k)). \tag{5}$$

To calculate the partition function we use forward-backward algorithm which is a dynamic programming algorithm.

Using the above mentioned set of features (equations 1, 2 and 3) the posterior function will be of the

[2] These observations correspond to the features extracted from the raw EEG signal.

[3] In our case, x_{ik} corresponds to the band-power of the window in a specific frequency band.

[4] For the sake of clarity, we drop the index i in the remainder of the text

form

$$\Pr(y_{1:K}|x_{1:K}) = \frac{\exp\Big(\sum_{k=1}^{K}(b_{y_k} + W_{y_k,1:L}^T x_k) + \sum_{k=2}^{K} V_{y_{k-1},y_k}\Big)}{Z(X)}, \quad (6)$$

where b_{y_k}, $W_{y_k,1:L}$ and V_{y_{k-1},y_k} are the parameters of the posterior distribution and should be learned using the training dataset. The set of parameters b_{y_k}, $W_{y_k,1:L}$ and $V_{y_k,y_{k-1}}$ capture the importance of the first, second and third type of features respectively.

To learn the optimal values of the parameters, we minimize the L_2 regularized negative log likelihood

$$\min_{\lambda} \sum_{i=1}^{N} -Log\Pr(y_i|x_i) + C\lambda^T\lambda, \quad (7)$$

where the vector λ consists of the parameters of the model (i.e. b_{y_k}, $W_{y_k,1:L}$ and V_{y_{k-1},y_k}), and C is the regularization coefficient. To find the optimal value of the parameters, we use stochastic gradient descent algorithm. As the loss function is convex, the gradient descent algorithm converges to the global optimum of the loss function.

For the inference i.e. assigning a sequence of labels to x_{N+1}, we assign the most probable sequence as the predicted labels i.e.

$$y_{predicted} = \arg\max_{y} P(y|x_{N+1}). \quad (8)$$

A Viterbi [12] like algorithm is used to find the most probable sequence of labels.

The linearity of the exponent term in CRF makes this classifier to have less expressive power compared to the classifiers that exploit kernels. A good approach that makes these algorithms more powerful is to pass the data through a feed-forward neural network before applying the CRF part. Neural networks transform the observation vector into high level features which are then used as the input to the CRF. As a result, the exponent term in CRF (i.e. the exponent term in equation 6) becomes non-linear because of the several layers of non-linear activation functions that have been applied on the observation vector [26] [27]. This combination of a neural network followed by a CRF forms our proposed classifier which we denote by NNCRF (Neural Network Conditional Random Field).

The NNCRF can be viewed as a standard linear chain CRF that uses a high level representation of the observations. Therefore, the posterior function of NNCRF has the same form as in equation 6 except that the x_k terms are replaced with the $h^M(x_k)$ term which represents the output of a feed-forward neural networks with M layers.

$$\Pr(Y|X) = \frac{\exp(\sum_{k=1}^{K}(b_{y_k} + W_{y_k,1:L}^T h^{(M)}(x_k)_{y_k}) + \sum_{k=2}^{K} V_{y_{k-1},y_k})}{Z(X)}. \quad (9)$$

The output of the $(M)_{th}$ layer ($h^{(M)}$) is

$$h^{(M)}(x_k) = tanh(b^{(M-1)} + W^{(M-1)}h^{M-1}(x_k)), \quad (10)$$

where $b^{(M-1)}$ and $W^{(M-1)}$ are the weights of the $(M-1)^{th}$ layer, $h^{M-1}(x_k)$ is the output of the $(M-1)_{th}$ layer of the neural network, and $h^0(x_k) = x_k$. To avoid overfitting, the weights of the neural networks are the same for all observations x_k in a sequence i.e. the values of the weights do not depend on k.

Initialization of a neural networks is very crucial for this algorithm to converge to a good local optima. For initialization of the neural network, the value of each parameter is a sample taken from a uniform distribution $U[-\gamma, +\gamma]$ where

$$\gamma = \frac{\sqrt{6}}{\sqrt{size(M) + size(M-1)}}, \quad (11)$$

where $size(M)$ is the number of hidden units in the M^{th} layer of the neural networks.

The loss function is the same as the loss function of the standard CRF (Equation 7). The values of the parameters of the neural networks and of the CRF are jointly optimized using the back propagation algorithm. The learning rate of the stochastic gradient descent algorithm is adjusted using the bold driver approach. For inference the same algorithm as in standard linear chain CRF is used.

4 Ensemble of classifiers

In [28], the authors proposed an algorithm to customize the synchronous BCI based on the brain characteristics of each subject. Here, we adopt a similar approach to build an ensemble of classifiers for self-paced BCIs based on the brain characteristics of each subject.

The brain characteristics of each subject are captured in the form of some hyper-parameters of the BCI system. Hyper-parameters are the parameters of the BCI system which are selected before feature extraction and classification. We use Bayesian optimization which is an iterative algorithm to propose the values of the hyper-parameters. The proposed values of the hyper-parameters are used to train different classifiers on different parts of the input space. Then, we combine the results of the trained classifiers, using averaging, to form the output of the ensemble classifier.

Bayesian optimization [23] [29] optimizes an objective function g(x) over some bounded set X. The objective function does not have a closed form expression and its derivative is unknown. A Bayesian optimization algorithm sequentially constructs a probabilistic model for g(x) and then uses this model to select a candidate for the optimization task. In our case, the objective function is the cross-validation accuracy of the classifier. The input to the Bayesian optimization algorithm consists of the values of the hyper-parameters of the BCI system. Therefore the set X is the hyper-parameter space of the BCI system.

In this study, the hyper-parameter space of every classifier consists of the frequency ranges to filter the EEG signal, the selected channels (from which features are extracted), and the window length. For our proposed NNCRF, we have an additional hyper-parameter which is the number of neurons in the hidden layer of the neural networks. In our experiments, we use NNCRF with one hidden layer NN.

The first set of hyper-parameters are the frequency ranges to filter the EEG signal. In motor imagery BCIs, the event-related desynchronization (ERD) and the event-related synchronization (ERS) occur in the upper alpha and the lower beta rhythms of the brain [11]. Generally the range of the alpha and beta brain waves are $[8-12]Hz$ and $[16-24]Hz$ respectively. A popular approach for extracting features (i.e. building the observation vector) is to find these frequency ranges for each subject, then calculate the band-power of the brain signal in the given frequency ranges. Another approach is to apply a filter with a large bandwidth in the approximate range $\approx [4-35]Hz$ that includes both the alpha and the beta brain waves of each channel, then extract the band-power of the brain signal. But even when we apply the second approach it is better to customize the frequency range for each subject. Therefore, for frequency filtering, in each iteration of the Bayesian optimization, our algorithm chooses one of the two above-mentioned options. The first option is to apply a filter-bank with two blocks corresponding to alpha and beta frequencies of the brain on each channel. The second option is to apply a filter with a large bandwidth (in the range $[4-35]Hz$) that includes both alpha and beta brain waves of each channel.

The second hyper-parameter is the set of the channels used to extract features from. For channel selection, our algorithm selects the number of Common Spatial Pattern (CSP) [30] filters (N = 2, 4, 6). It also has the option of not applying CSP (i.e. uses all the channels without applying any spatial filtering).

The third hyper-parameter is the length w (milliseconds) of the window that we extract band-power features from. For all of the sequence labeling classifiers, we have only used the past two seconds of the EEG signal to build the observation vector. For sequence labeling classifiers, we build a chain of consecutive windows as our observation vector. The length of the chain is therefore $\frac{2}{|w|} \times 1000$. For classical classifiers we only look at the past w milliseconds of the data. As discussed above, for the NNCRF classifier we have a fourth hyper-parameter which is the number of neurons in the hidden layer of the neural networks.

The pseudo code of the ensemble of classifiers is given in Algorithm 1. At each iteration (t) of our algorithm, the optimizer suggests a new set of values (h_t) of the hyper-parameters, then a new classifier (L_t) is built based on these values. Based on the cross-validation accuracy of L_t at iteration t, another set of values of the hyper-parameters is suggested for iteration $(t+1)$ and this process continues for at most MAX iterations or when the cross-validation accuracy plateaus. After running the optimization, we have T classifiers, each trained on a different subset of the hyper-parameter space.

The outputs of the classifiers are combined into a single prediction rule which is much more accurate than the individual classifiers. We use averaging to create the output of the ensemble of classifiers. In general, we seek a model with low bias and high variance as our final classifier. When the training data is small and the classifier has high variance, and by averaging we reduce the variance of the final classifier while preserving the low bias of a single model. Especially in the case of neural networks which can get stuck in a local optimum and has a high variance, creating an ensemble of classifiers i.e. neural networks which are trained on different parts of the hyper-parameter space, may result in a better approximation of the best possible classifier.

1. t := 1;
repeat
   2. Increment t;
   3. Find candidate (h_t) from the hyper-parameter space using Bayesian optimization;
   4. Create an observation matrix X_t from the brain signals using h_t;
   5. Train a new Classifier (L_t) using observation matrix X_t;
until *t reaches maximum number of iterations (MAX) or until convergence*;
6. Combine $L_1 ... L_T$ using averaging to build an ensemble classifier;

Algorithm 1: The pseudo-code of the proposed algorithm

5 Datasets

To perform the experiments two self-paced sensory motor BCI datasets have been used. The first dataset, SM2 [25], was collected from 4 subjects attempting to activate a switch by performing a right index finger movement. At random intervals, a cue was displayed for the subjects. The subjects attempted to activate a switch by moving their right index finger after the cue appeared. The EEG was recorded from 10 channels positioned over the supplementary motor area and the primary motor cortex (i.e. FC1-4, FCz, C1-4, Cz).

The second dataset, BCICIV2a, is the dataset IIa from the BCI competition IV which is recorded from 9 subjects performing 4-class motor imagery (left hand and right hand, both feet and tongue imagery movements) tasks. The data consists of 19 channels along the scalp and recorded in a synchronous paradigm. We have treated this dataset as a self-paced BCI dataset. In other words, to evaluate the performance of the classifiers on this dataset the time of transition from previous mental task to the new one (the time cue was displayed) has not been used. We have also converted the problem into a binary classi-

fication task i.e. separating movement imagery from NC states. All 4-classes of motor-imagery are considered as movement and the periods in which the subject did not control the system are considered as the No-Control class.

6 Results and Discussion

In our experiments, we first compared the performance of our proposed NNCRF with the standard CRF classifier, Hidden Markov Support Vector Machines (HMSVM), Hidden Markov Models (HMM) and two popular classical classifiers i.e. Logistic Regression and Support Vector Machines (SVM).

A Hidden Markov Support Vector Machine [31] is a special case of Structural Support Vector Machines in which the features are designed to capture the sequential nature of the data. The set of feature vectors we used, capture the dependency between consecutive labels in a sequence (y_k and y_{k-1}), and measure the relation between the observation in the k^{th} window (x_k) and its corresponding label y_k in a sequence.

To apply HMMs on self-paced BCIs, we trained different HMMs for different mental tasks. We trained two different HMMs, one was trained using NC data and the other one using the samples of movement (intentional control) task. Then the likelihood of a new given sequence is calculated using the forward-back algorithm, and the classification is performed by comparing the likelihoods of different HMMs. In this case, each HMM focuses on learning the structure of the mental task that it is trained on, rather than learning to discriminate between different tasks.

The emission function used for HMM is a mixture of Gaussian distributions. The parameters of the HMM include the transition probabilities, and the parameters of the mixture of Gaussian distributions. The parameters are learned by maximizing the likelihood of the training dataset. The Baum-Weltch algorithm is used to learn the parameters of the HMM model.

To select the value of the hyper-parameters for the first part of our experiments, we searched through a manually specified set of values for the hyper-parameters (default values). For frequency filtering, we applied a filter-bank with two blocks in ranges [8-12]Hz and [16-24]Hz corresponding to the typical alpha and beta frequencies of the brain. For spatial filtering, we tried CSP with two, four and six filters. The values of these hyper-parameters along with each classifier's parameters are adjusted jointly using five-fold cross-validation. The parameters with the best mean cross-validation accuracy were used to train a classifier on the training set. We used Area Under the Curve (AUC) to evaluate the performance of the classifiers on the test dataset.

In our experiments, the band power of the EEG signal is used as the extracted features (observations) for the classification phase. The window length was equal to the sampling rate of the dataset and we used the last two seconds of the data to perform the classification in the test phase.

In the second set of experiments, we used the approach explained in section 4 to create an ensemble of classifiers. For all classifiers except NNCRF, we have created the ensemble using different values of the BCI hyper-parameters as explained in section 4. For NNCRF, along with the BCI hyper-parameters, we have also used different values of the number of neurons in the hidden layer of the NNCRF algorithm to create the ensemble. The Bayesian optimization algorithm ran for at most 50 iterations or until cross-validation accuracy plateaued. We repeated our experiments five times to reduce the effect of random seed. The average number of iterations of the Bayesian optimization algorithm for all different classifiers was 27.

Table 1 shows the results of comparing different classifiers when we used an ensemble of classifiers. The columns with the label "Default" correspond to the results of not using the ensemble approach. In Table 1, the columns with the "Ensemble" label correspond to the results of using an ensemble of each of the classifiers. The results shown in Table 1 are obtained by evaluating the classifiers on the independent test dataset of each subject. Figure 1 (which is a summary of Table 1) shows the average AUC of different algorithms when we used Bayesian optimization compared to using the default value of the hyper-parameters.

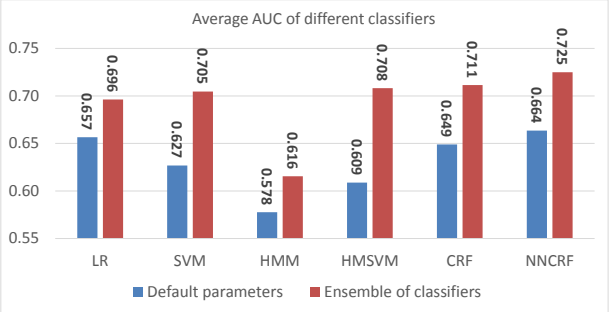

Figure 1: Average AUC of different classifiers across all subjects. The blue bars correspond to the average AUC when the default value of the hyper-parameters have been used. The red bars correspond to the average AUC after using our ensemble learning algorithm. The numbers on top of each bar correspond to the AUC of each algorithm.

Qualitative comparison of different algorithms in Tables 1 suggests the following: 1) our proposed ensemble learning approach considerably improves the performance of any classifier for almost all subjects, 2) HMM is the worst performing classifier, 3) NNCRF outperforms other algorithms in terms of average AUC across all subjects on the test dataset, and 4) interestingly, for some subjects none of the discriminative sequence labeling classifiers had a good performance - this means that these classifiers are not able to capture the temporal structure of the signal in these subjects.

Table 1: The results of comparing different algorithms on the test dataset. Default is the results of using the default values of the hyper-parameters. Ensemble corresponds to the results of the ensemble learning approach. Highlighted cells show the algorithm for which the performance is the best.

To statistically compare the performance of the different classification methods, the Friedman statistical test was performed. The Friedman test [32] is a non-parametric statistical test, which ranks different classifiers for each subject separately. It then averages the ranks over all subjects. The algorithm with the lowest rank is the best performing one. Figure 2 shows the average rank of different classifiers. The best performing classifier is the ensemble of NNCRFs. In all classification algorithms, using the ensemble approach considerably improves the average rank.

In the Friedman test, the null hypothesis assumes that all algorithms have the same performance (thus, they have the same rank). After performing the Friedman test, the p-value was 4.34E-11. α was chosen to be 0.05. This p-value is low enough to reject the null hypothesis, therefore we conclude that the difference between algorithms is not random. Another set of statistical tests are performed to identify which algorithms are the source of difference. We conduct the Holm's [32] test as the post-hoc statistical test. In the post-hoc test, we perform pairwise comparison of all the other classifiers versus the best classifier (i.e. ensemble of NNCRFs) in terms of the average rank.

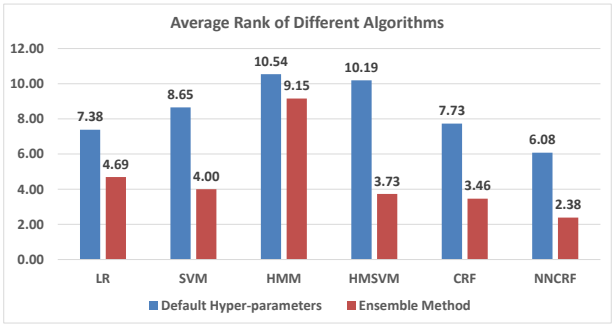

Figure 2: Average rank of different classifiers across all subjects. The blue bars correspond to the average rank when the default value of the hyper-parameters have been used. The red bars correspond to the average rank after using our ensemble learning algorithm.

	Hypothesis	P-value
11	HMM vs. NNCRF(ensemble)	8.13E-09
10	HMSVM vs. NNCRF(ensemble)	3.37E-08
9	HMM(Ensemble) vs. NNCRF(ensemble)	1.70E-06
8	SVM vs. NNCRF(ensemble)	9.29E-06
7	CRF vs. NNCRF(ensemble)	1.57E-04
6	LR vs. NNCRF(ensemble)	4.07E-04
5	NNCRF vs. NNCRF(ensemble)	9.03E-03
4	LR(Ensemble) vs. NNCRF(ensemble)	1.03E-01
3	SVM(Ensemble) vs. NNCRF(ensemble)	2.53E-01
2	HMSVM(Ensemble) vs. NNCRF(ensemble)	3.41E-01
1	CRF(Ensemble) vs. NNCRF(ensemble)	4.46E-01

Table 2: P-values corresponding to pairwise comparison of different classifiers versus the best performing classifier. α is chosen to be 0.05. All hypothesis with p-value less than 0.001 are rejected.

In this statistical test, each null hypothesis states that the best classifier and the other classifier have the same mean rank. The p-values corresponding to pairwise comparison of classifiers are shown in Table **??**. According to the Holms test results, the null hypothesis 1 through 5 are not rejected. This means that the difference between the ensemble of NNCRFs and other ensemble algorithms is not significant. However, the statistical tests show that the ensemble of NNCRFs is significantly better than non-ensemble methods.

7 Conclusion

In this study, we proposed a discriminative sequence labeling algorithm (classifier), to capture the dynamics of the EEG signal. We evaluated the performance of our algorithm (which we denote as NNCRF) on two self-paced BCI datasets and showed that it is superior, compared to classical classifiers and sequence labeling classifiers. NNCRF is a combination of a neural network and a CRF classifier. We demonstrated that CRF and NNCRF can capture the temporal properties of the EEG signal and improve the accuracy of the BCI in most of the subjects. In some subjects however, the temporal structure of the EEG data is difficult to capture by these classifiers. The neural network part of NNCRF converts the original observation vector into a new representation which is then fed to the CRF part. The non-linear transformation (by the neural network) of the observation vector helps the CRF part to easily discriminate between the different control and NC.

Overall, the reason for the poor performance of classical approaches is that they do not exploit the dynamics of the EEG signal. As for the HMM, although this algorithm models the temporal correlations in an EEG signal, its poor performance stems from the fact that it focuses on learning each mental task separately (i.e. without learning to discriminate between them). On the other hand, discriminative sequence labeling classifiers do not only model the temporal properties of each mental task, they also model the transition from one metal task to another (e.g. transition from movement to NC state).

We also showed that using an ensemble of classifiers that have been trained on different parts of the BCI hyper-parameter space can further improve the performance. We used Bayesian optimization to find the different values of the BCI hyper-parameters. Selecting different values for the hyper-parameters exposes each individual classifier to different parts of the BCI hyper-parameter space. We believe that this diversification is the key to the superiority of using the ensemble of classifiers. The performance of each individual classifier is very sensitive to the choice of the hyper-parameters of the BCI and using an ensemble of classifiers can decrease the variance of the final classifier.

The best performing algorithm was the ensemble of NNCRF classifiers both in terms of the aver-

age rank and average AUC of the final classifier. We statistically compared the performance of different classifiers to the ensemble of NNCRFs. The results showed, for SVM, LR, HMSVM and CRF, the ensemble learning approach results in significantly better performance compared to the single classifier with default value of the hyper-parameters. For NNCRF, the Holm's statistical test showed that the difference between NNCRF and the ensemble of NNCRF was not significant. However, the performance of the ensemble of NNCRFs was considerably better than the single NNCRF with default values of the hyper-parameters.

In this study, we used linear chain discriminative sequence labeling classifiers, i.e. the type of the feature functions used in this study were all inspired by Hidden Markov Models. So they are all local in nature, with each feature function only depending on the current or the previous label in the sequence. It is possible to use global features such as the ones that capture higher orders of dependency of the transition between consecutive labels, or feature functions that capture dependency between the EEG signal and labels of the EEG signal from distant past. These types of feature functions have the ability to capture more complex structures in the data and increase the power of each individual classifier.

Appendix

A. Block Diagram of the Learning

Figure 3 shows a simple block diagram of one iteration of our ensemble learning algorithm (which is explained in Section 4). In our approach the BCI is like a self-regulating system which improves itself based on the feedback that it receives from the classification block. The cross-validation accuracy of the classifier is given to the Bayesian optimization block, and this block proposes new values for the hyper-parameters for next iteration of the algorithm. The hyper-parameter values are used to extract features from the EEG signal, and a new classifier is trained using the features extracted from the training data. The extracted features are the power values in the frequency bands proposed by the Bayesian optimization block.

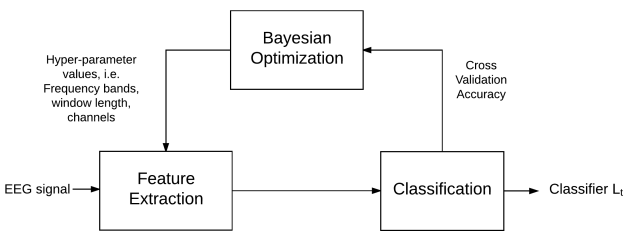

Figure 3: A simple block diagram of one iteration of our proposed ensemble learning algorithm.

Each iteration of our ensemble learning approach generates a classifier (L_t). After running the algorithm for T iterations, we will have T different classifiers which are trained on different parts of the BCI hyper-parameter space. Eventually, the classifiers $(L_1, L_2, ..., L_T)$ are combined (using averaging) to build a final classifier which is evaluated on the unseen test dataset.

ABSTRACT

Greenhouse cultivation is easy to keep up and control important factors such as light, temperature, and humidity. Using of sensors and actuators in the greenhouse to capture different values allows for the control of the equipment, it can also be optimized for growth at optimal temperature and humidity of various crops planted. We use wireless sensor networks' system by sending results to the cloud service, monitoring values, and devices's controlling via smart phone. The results of this study are useful for growing crops not only in technical parts, but also in physical part; it was evaluated by questionnaire using technology acceptance model.

1 Introduction

Technology can link everything to the Internet called the Internet of Things (IoTs). This means that the human beings control any object using a wireless sensor network (WSN) which makes convenience to everyday life. Technology can be applied in many fields such as home, city, wearable, industrial, health, retail, farming, etc. IoTs refer to the network of objects, vehicles, buildings, and other electronic detectors, as well as software for connecting networks to exchange data from sensors or actuators. IoTs can also make people aware of the environment and remote control over the existing network infrastructure. We can integrate the physical world into the computer system and virtual resources available on the internet to provide both value-added data and functionality for users. The trend of 2020 IoTs usage will increase by 50 billion object were expected to be connected in the IoT [1].

IoTs' devices include RFID, sensors, and computer nodes. The system must have an internet connection that the devices can send data and receive results to communicate with each other. If there is no connection to the Internet but there are also some models that can be connected to other IoTs' devices. Bluetooth is also an option in many ways to connect devices to physical phenomena on networks [2].

At present, farmers need access to the existence of agricultural information and they have relevant knowledge in making decision and respond to information needs. In the agricultural sector, through the development of knowledge management systems and farmers' information inquiries, they can be answered with the helpfulness of accessible multimedia as the application of technology. Agriculture was interested in improving access to technology. Promoting agriculture on several aspects in developing countries, technology had crossed handles using wireless technology and networking to utilize energy and power consumption by equipment, which is helpful in the agricultural development. The development of technology in various domains had driven substantial interest according to rising investments by private sectors towards the growth of technology [3].

In this research, The greenhouse is the best experimental place of our study with the IoTs system as well as a closed viewing area. It was equipped with sensors and internal devices for easy operation to analyze [4].

2 Related Work

Greenhouses can control easily the environment inside their houses and disease outbreak in plants. It can reduce energy consumption for the growth of the plant fully. The benefits of greenhouses are high, but the investment is also high. The original purpose of the greenhouse is able to grow crops that cannot normally grow in the climate of that area. If a good greenhouse system was managed, the greenhouse system can grow all kinds of crops in the right habitat.

Hydroponics is a plant that does not use soil, but that uses water with nutrients dissolved or planted in nutrient solution. This is a new way to grow crops especially growing vegetables and plants used as food. Because of saving space and non-contaminated with chemicals in the soil, we get clean and fresh vegetables. Nowadays, hydroponics has two main benefits; first, it allows for a more controlled environment for planting growth instead of using the same soil eliminating many unknown variables out of many experiments. Second, many plants produce much less time and sometimes better quality in a certain economic environment and condition. Hydroponics will bring more profit to farmers, have no disease in the soil, and it can grow crops very close together. For this reason, the plants produce more volume while using limited space. There is also very little water use because of the use of containers or closed loop water system to circulate water compared with traditional agriculture.

Hydroponics technology uses it gently such as measuring ions, pH, and temperature in water. By adopting sensors with the microcontroller, we get the bills in the greenhouse and analyze the information to control the water supply from this paper. Making WSNs work helps us saving costs in many areas, such as energy, labor costs, and chemical costs. And it can make long-term value.

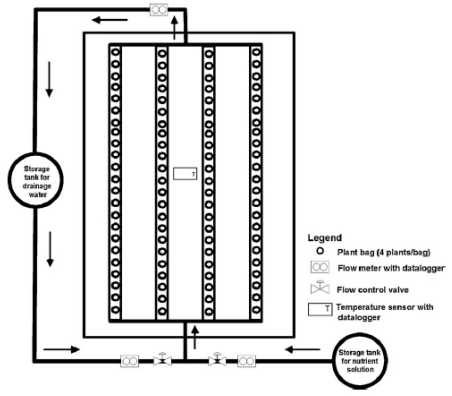

Figure 1: Schematic of the hydroponic greenhouse system used in this study [6]

From the beginning step of our research, we build a greenhouse and take the sensor to control the crops of Hydroponics freely as automation [5] which requires modeling as we want to fit the environmental management by placing the sensors in order to provide humidity control in relation to the ambient air temperature. The conditions were met by installing a color bulb to feed the plants LED representing of red (R) and blue (B) in emission either warm (4700K+2700K) or cool white in parenting [6] and managing water to save water as shown in Figure 1.

The development of today agriculture brings more and more applied technology have a reference and understanding of the environment that is important in the economic production. The yield is sometimes uncertain because of lack of environmental planting's understanding. It creates the WSNs' technology for environmental monitoring and theft detection; simple, cheap, and easy to use the system the detect the data of temperature and humidity in the air covered on the greenhouse properly.

Since we do not want to control by our own, we have to look for the way that technology can control itself automatically. The technology that we mentioned above called Message Queuing Telemetry Transport (MQTT). This is communication technology between sensors as M2M (machine-to-machine) connected with the lightweight protocol. MQTT is designed for the small electronics, small traffic data, and low-bandwidth networks. It can be not only linked to devices simultaneously but also changed the information together. This means that we can make your devices into the bigger network allowing it to control the device where it was needed to turn on-off the devices [5] as shown in Figure 2.

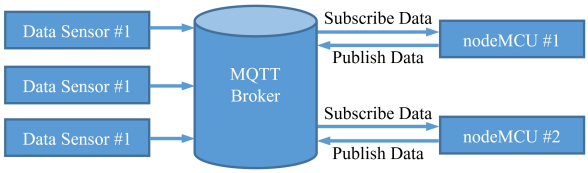

Figure 2: Flow Diagram of MQTT with nodeMCU

Nevertheless, there are many types of protocols, such as HTTP and XMPP. MQTT on IoTs will have an MQTT Broker to manage the storage that can send information to hardware. MQTT clients and servers handle complex messages for mobile applications and reduce network management costs. MQTT applications run on mobile devices, such as smartphones and tablets. MQTT was used for sensor and remote control data reception.

3 System Design and Realization

Adaptation of agriculture is difficult. We have to invite an agency to improve agriculture and make the agricultural sector more productive. Therefore, we make one more comfortable and efficient technology provided that farmers understand for controlling the greenhouse. We can use one of the mobile application called Blynk. It can be used the control system via API from the application into the operation of various devices and also tracked the data via mobile without

technology knowledge. It is easy for people who do not have the ability for using technology. Moreover, the Blynk's user interface system is very easy to use. This following is the devices in details used in this work as shown in Table 1.

Parameter	Value	Voltage
Temperature & Humidity	DHT-11	2.5mA
Ultrasonic Sensor	HC-SR04	15mA
Relay Board	4 Channel	10mA
Grow light	-	1.7mA
Solenoid	Plastic 1/4	1.3mA
Architecture	Greenhouse	-

Table 1: Deployment parameters

3.1 Monitoring Interface

This work was divided into two major topics: hardware and software requirements. The first topic shows in details such sensors, actuators, and components in the system. The second topic deals with software that was used for connecting hardware controls such as turning on-and-off grow light and water pump.

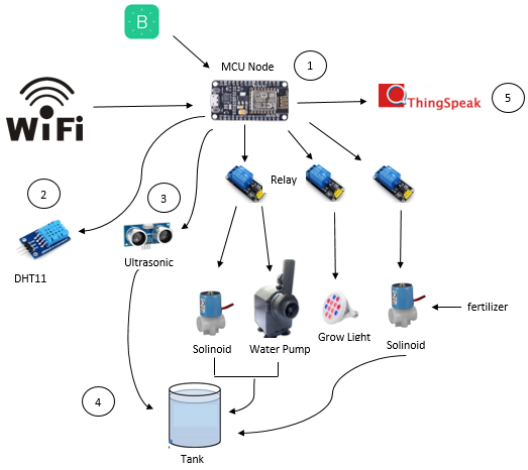

Figure 3: Phototype of system

Hardware Requirements: The main components of the prototype as shown in the Figure 3. The details of each section are as follows:

- NodeMCU is use to implement the monitoring modules. The following sensors and other peripherals were used to collect real time data from the field.
- DHT11 is a relatively cheap sensor for measuring temperature and humidity values.
- Four Channel Relay Board (5V) for switching AC/DC is used to high level trigger with AC motor (220V) to operate the electricity devices.
- Ultrasonic Sensor Module (HC-SR04) includes an ultrasonic transmitter, receiver, and circuit. There are four pins measuring 5-700 cm. used to detect the water level in tank.
- Grow light is an artificial light source used to keep plant growth at night by emitting an electromagnetic.
- Solenoid is the device controls the opening and closing of the water flow.
- Water pump is water pushers move forward from the tank to the pipe hydroponics.

Sensor data was connected to the ThingSpeak™as API to store all results to the cloud results to the database as shown in Figure 4. In order to analyze the future information, we retrieve the information on the smart phone device control which can be controlled by grow light and water pumps.

Software Requirements: Sending data from hardware to smart phone by using the Arduino IDE as a communication medium. Here, the smart phone application was called Blynk.

Blynk is an open-source electronics prototyping platform which is a modified version of Wiring/Arduino IDE with iOS and Android apps to control Arduino board using the Internet as shown in Figure 4.

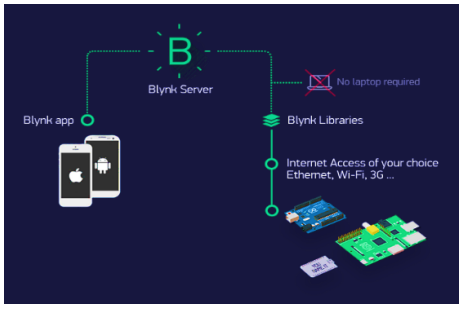

Figure 4: Blynk platform

Blynk platform with iOS and Android apps to control Arduino, Raspberry Pi, and the likes over the Internet. It is a digital dashboard where you can build a graphic user interface for your research by simply dragging and dropping widgets.

3.2 Greenhouse Specification

- *Area:* The greenhouse is mounted on the roof of the building with the size of 2.4 * 5.3 * 2.0 (length * width * height: m).
- *Plants:* The plants used in this study is Cantonese that season pale green succulent stems, petioles 25-40 cm. wide, 5-15 cm. long. Vegetable consumption grows rapidly; it can be harvested just 35-45 days. We acknowledged the seeds coming from Mae Jo University as an organic grain.

4 Results

4.1 Productivity receive

First generation's Productivity: Due to the high temperature of the plant, 48 plants dying in the first week since maximum temperature is 44°C measured from the sensor via the IoT. The DHT11 sensor was used to measure in the survival rate 0% as shown in Figure 5.

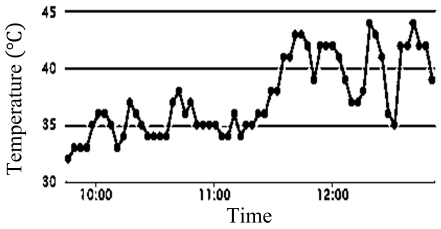

Figure 5: Temperature in the first week

Next step, we created a 50% black SLAN UV filter mesh filter under the roof. Then the heat in the greenhouse is noticeably reduced, as shown in Figure 6.

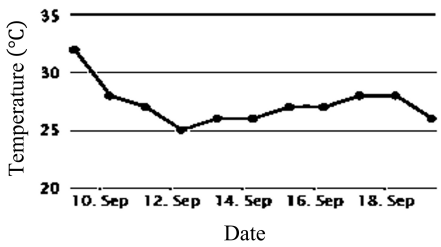

Figure 6: Temperature after installing filter UV 50%

Second generation's productivity: After reducing temperature by UV filtration inside a greenhouse, 48 plants can be survived 22 plants. This means that the survival rate is 45.83%. It can be seen that from the lower temperatures, the plants were more survived. Hence, this is better productivity for growing as well. The ultrasonic sensor monitors the amount of water in the tank if it is lower than normal as we set up for the suitable value of water level in the tank. After instant processing, the solenoid valve was working to add water until full of water. Both devices work reliably Ultrasonic sensor sends the up-to-date data which we can desire the duration time for collecting data into ThingSpeak™. The simulation of the water level can be represented by graph plotted by the relationship between water usage and time as shown in Figure 7.

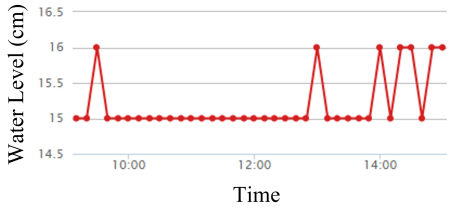

Figure 7: Water usage represented to ThingSpeak™

Electronic devices, such as the solenoid and UV light, were controlled by nodeMCU which makes the connection with the sensor and sends data to ThinkSpeak™for processing devices work of vegetables growth as well as shown in Figure 8.

Figure 8: Vegetables growth in the greenhouse

The greenhouses can work automatically and control via the applications controlled by the mobile device. The connections were able to control by NodeMCU. Freely, no matter where we are around the world, you can control via Blynk, the top and middle part displays the current temperature and the status of the device, respectively, as shown in Figure 9. Remark that it is really simple to set up everything and start customizing. Blynk is one application instead of supports hardware of your choices whether your Arduino was linked to the Internet over Wi-Fi, Ethernet, or this new ESP8266 chip.

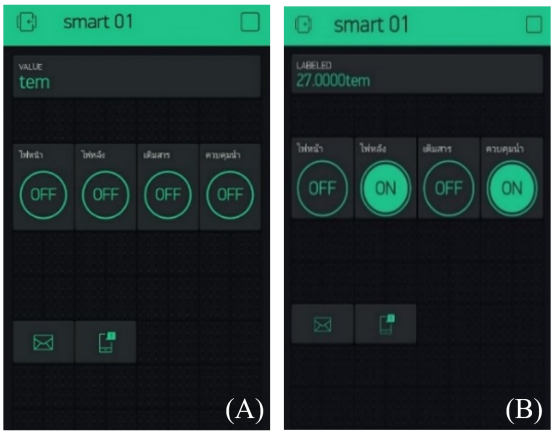

Figure 9: Blnk Applications: (A) Draft display screen (B) Display screen after processing

The sensor data including temperature and relative humidity were recorded to the ThingSpeak™every 3 minutes frequently. Not only all data from sensors were processed in a reasonable manner for the next plotted graph, but also the location of this study from Google API service of ThingSpeak was represented from all tasks can get the appropriate information of the survival plant. It can be seen that the temperature and humidity in the air inverse variation as shown in Figures 10 by analyzing with principal component analysis.

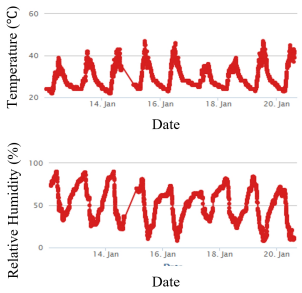

Figure 10: All data of temperature and relative humidity

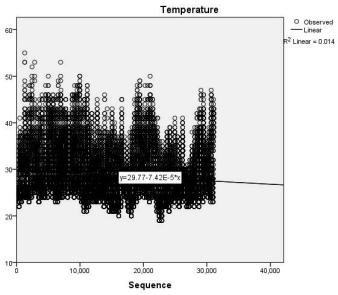

Figure 11: Relationship between temperature and time

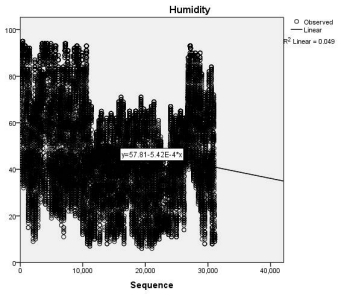

Figure 12: Relationship between relative humidity and time

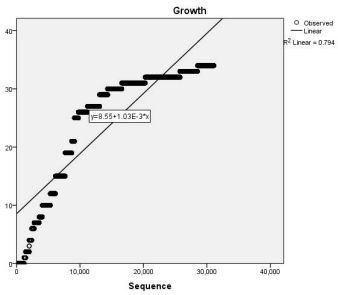

Figure 13: Relationship between plant growth and time

We brought all the data to create the chart for finding the appropriate value through the SPSS program. We plotted the graph for finding the correlation between temperature, humidity, growth with time as shown in Figures 11-13, respectively. We can arrange the correlations observation by linear regression represented by

$$\frac{\nabla y - 96.13}{0.4128E^{-}3} = x; \quad \nabla y = \sum_{i=1}^{n} y_i,$$

where $y_i, i = 1,2,3$ denotes temperature, humidity, and growth variables, respectively.

Since we analyze from principal component analysis, we can consider the communalities and total variance explained as initial eigenvalues as shown in Tables 2-3.

Component	Initial Extraction	Time
Time	1.000	0.730
Temperature	1.000	0.858
Humidity	1.000	0.857
Growth	1.000	0.971

Table 2: Factors Processed by Principal component analysis

Component	Total	Variance %	Cumulative %
Time	2.301	57.531	57.531
Temperature	1.115	27.871	85.402
Humidity	0.404	10.089	95.491
Growth	0.180	4.509	100.000

Table 3: Total variance explained with initial eigenvalues

Notice that the temperature reverse variation with humidity. From the total variance explained the acceptance of correlation's observation with 70%, we can see the humidity was adapted growth extremely as well. However, the temperature is one of factor reacted with growth as necessary condition.

4.2 Control Testing

In our evaluation, we tested 10 times for checking the efficiency of delay controlling. The Statistical tool is mean or average (AVG). Hence, the result is not significant as shown in Tables 4-5. This means that both testing control inside and outside the LAN Delay were equated.

NO.	Inside the LAN Delay(s)

Table 5: Moblie Control Testing via Blynk in case of outside the LAN delay

Remark the 0* that the sensor stops the water to overflow the tank makes Solenoid stop working.

4.3 Evaluation Method

Technology Acceptance Model (TAM) was a recognized and well-known theory as a measure of success. Using TRA technology to develop a TAM model and use it to study in the context of the adoption of information systems. Without adopting the norms of the surrounding people. Behavioral display it was used as a factor in forecasting actual usage behavior.

Evaluation methods in how we will test our prototype show control over let the enthusiasts play mobile apps users will need more time 5-10 minutes per person. The rating 5 points 4 scale questionnaires based in TAM provides the theory by being one, there are external variables, how the influence Attitude and willingness to use in the research, the model was designed as follows:

- Study on the use of TAM as the principle to create a 4-D combination of forms 4 main factors of TAM 16 articles,
- Satisfaction and meaning 5 agree that Strongly agree 4 means Agree , 3 means 'Neutral,2 means 'Disagree', and 1 means to ' Strongly disagree',
- Those interested in the quiz after our presentation Android application,
- Collect results Assessment, and
- Analysis of Cronbach (performance by processing using the SPSS program standard the achievement of Cronbach) must be 0.7 or higher.

We consider four factor of TAM as follows:

- Perceived Usefulness (PU) is a perception of the technology use. The technology will make the job better. Make more revenue.
- Perceived Ease of Use (PEU) is a perception that the technology is easy to use. Users are more comfortable than ever.
- Online Cognitions (OC) is a perception data on the Internet through online for helping people recognize information through social media, and viable online communities.
- Behavior Intention (BI) is behavior in technology that influences the intended and actual use of technology.

Our questionnaire used all factors of TAM such as Perceived Usefulness, Perceived Ease of Use, Online Cognitions and Behavioral Intention to Use in Figure 14.

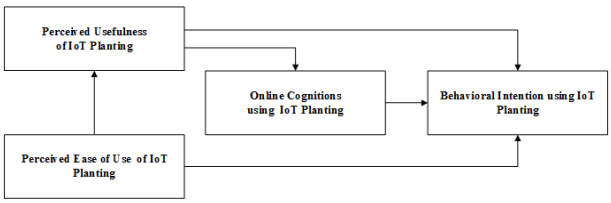

Figure 14: TAM for system Smart Farm Hydropronics Style

4.4 Sample Storage

The sample size for this study was 30, totaling 30 Thai persons in the age range of 20-40 years living in Suratthani as shown in Table 7.

Attrinute	Value	N	Percentage
Gender	Male	11	36.3%
	Female	19	63.6%
Age (years)	20-24	10	33.3%
	25-29	10	33.3%
	30-34	7	23.3%
	35-39	3	33.5%
IT usage ability	Nothing	0	0.0%
	Moderate	18	60.0%
	High	12	40.0%

Table 6: Details of Samples

4.5 User Satisfaction

Analyzing the data using SPSS22. The Cronbach's alpha Coefficient and Pearson Correlation of evaluation as shown in Tables 8-11.

Factors	Cronbach's α Coefficient
PU	0.744
PEU	0.763
OC	0.816
BI	0.721

Table 7: Reliability Coefficient of Constructs

From the result in Table 8, the value of all factors is greater than 0.7, which was considered reliable and accepted average satisfaction of each factor the result

and analyze the average of evaluation satisfaction of each factor as shown in Table 9.

Factors	Average	S.D.
PU	3.6754	0.51003
PEU	3.8653	0.57487
OC	3.8667	0.54756
BI	3.5671	0.63521

Table 8: Average Satisfaction of Each Factor

After that, we find the relationship between two weighted variables in the level measurement section as Independent or dependent factors. Correlation coefficient is a measure of dependence between two factors to interpret the TAM by using Pearson Correlation as shown in Table 10.

Factors Relationship		P.C.	R^2(%)
Independence	Dependence		
PEU	PU	0.731	0.559
PEU	BI	0.724	0.603
PU	OC	0.873	0.758
PU	BI	0.746	0.724
OC	BI	0.623	0.454

Table 9: Factors Correlation

Suggest that the correlation of PEU and OC is the most related together. For another correlation, almost factors have relation closer as shown in Figure 15.

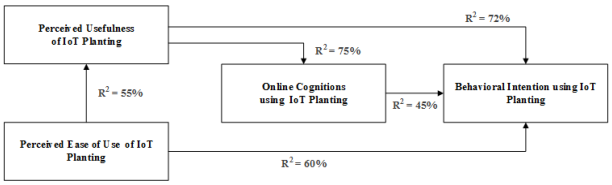

Figure 15: Relational Model of Factors Relationship

5 Conclusion and Future Work

Sensor technology was intended for the automatic control devices via mobile accurate correctly. This technology will save time to look for vegetables which people can eat healthily. Farmers need some helps in the different stages of crop growth and the guidance should be given at the right time. Farmers are suffering a lot of problem; economy, social, and politics. Various challenges in the agricultural domain were identified. The architecture of the challenges mentioned above, knowledge-based structure have various details about agriculture, flow, various input such as market availability, geospatial information and weather prediction. Monitoring system contains modules like remainder, monitoring plant growth in various stages, irrigation planner, and the water need of a plant per day with devised algorithms help

The future work of this study will be developed the sensor for using in public actually. We will study the process of using machinery or machinery to determine the growth of crops and harvest the crops in order to save time and labor. Each vegetable was calculated to get the right temperature for the vegetable.

Acknowledgment This research was financially supported by Prince of Songkla University, Surat Thani Campus, 2015. Furthermore, the present author would like to deeply express thanks to Intelligence and Intelligent Informatics (AI3) Laboratory, Sirindhorn International Institute of Technology, Thammasat University for making the experiment and giving him various comments.

ABSTRACT

In this paper a novel approach to extract 2D skeleton information (skeletonization) from natural image is proposed. The work presented here is the extension of our previous paper presented at the International Sympsosium on Multimedia 2016. In the past work, a threshold based method is utilized. Here the algorithm is further improved by using a better edge points detection and skeleton extraction. Furthermore the proposed method is compared with the Skeleton Strength Map (SSM) and shows better result visually and numerically (F-measure comparison).

1 Introduction

This paper is an extension of the work [1] originally presented at International Symposium on Multimedia 2016 (ISM'16). In this paper we provide a more detail and some improvement from the previous paper presented at ISM 2016.

Skeletonization is a process to extract the simplest, the most compact form of an object (skeleton) from 2D or 3D objects. Although mostly used in animation[2], skeleton information has also been used in symmetry detection [3], shape analysis [4], etc. Based on the input to the skeletonization, we can classify it into two types; 2D skeletonization and 3D skeletonization. In this paper, we are dealing with the first type, i.e. the 2D skeletonization or skeletonization from an image.

Corneat et al.[5] classify skeletonization into 4 classes, i.e. thinning and boundary propagation, distance field-based, geometric and general-field functions. While most of these approach works well, it only applies to the binary image. In order to get the binary image, of course one can use a foreground-background separation, but unfortunately foreground-background separation is still an open problem in image processing field. Another way to see the problem is that conventional approaches need a closed boundary information to extract the skeleton information. It holds when the object and the background information has a high contrast, but does not hold for object with a low contrast value with the background (such as similar color and texture).

When the input image is not a binary image, the skeletonization is often referred as grey-scale skeletonization. Grey-scale skeletonization can be regarded as a relaxation of the conventional skeletonization. Instead of a binary image, the input to grey-scale skeletonization is usually the brightness image (grey-scale image) or the color images. Skeleton is related closely to the symmetry information, therefore several authors are utilizing the symmetricity. You and Tang[6] proposed a method to detect the skeleton of characters using the wavelet. Widynski et al.[3] proposed a method based on particle filter approach. Levinshtein et al.[7] proposed a method based on superpixel segmentation and learned affinity function. In the last two methods, a supervised learning step is incorporated.

Du et al.[8] proposed a method based on a structure adaptive anisotropic filtering. The method is extracting the skeleton by updating the scale orientation and kernel of every pixel. The process is done iteratively including the update step therefore requiring a high computational cost. Another method is proposed by Li et al.[9] using a distance transform method [10]. By first extracting the edge information using Canny edge extraction algorithm and then calculating the inverted of the distance transform, this method can extract the skeleton of the object and its surrounding. To further increase the performance, a learned context model is utilized. Since this method relies on the distance transform, connected edge pixel is needed to

[*] Vicky Sintunata, vicky@riec.tohoku.ac.jp

https://dx.doi.org/10.25046/aj0203128

some extend. It is important to note again here that while the connected edge pixel can be retrieved or extracted in an image where the object has high contrast, the opposite is not true. This condition results in a sparse or unconnected edge pixels in the image.

Most of the papers mentioned above has high computational cost or need a learning step in one of their method. In this paper we tried to solve the grey-scale skeletonization without a learning step. Furthermore the proposal can be used to relax the unconnected (sparse) boundary pixel condition. The rest of the paper is as follows: in section 2 the more detail explanation of the proposed method is presented. In section 3 some examples of the result and discussion will be presented. Finally section 4 will conclude this paper.

2 Proposed Method

The general framework for the proposed method can be seen in Figure 1. There are three major steps in the method: boundary points extraction, skeleton extraction and pruning step.

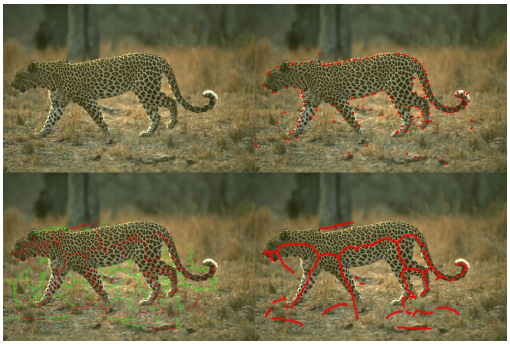

Figure 1: Proposed Method Framework. Upper-left: input; Upper-right: edge points extraction; Lower-left: skeleton extraction; Lower-right: pruning

2.1 Boundary Points Extraction

The method starts by making a grid of the input image and finding the edge points inside each grid. This edge points are selected by choosing the highest intensity among the pixels inside the grid. The question is then how are we suppose to find these edge points. It is very common to get the edge information from the gradient of the image. The higher the intensity of the gradient image is, the higher the probability it is considered to be the boundary object. Instead of using Canny edge detection which relies on the brightness image only, we calculate the edge (or gradient) information from both the brightness image and the color images.

First, the input image is converted into CIE color space and then split to each corresponding channels (i.e. brightness or luminance (L*) and two color channels (u* and v*)). Let $e_c(i,j)$ denotes the value of the gradient image at channel c ($c \in$ L*, u*, v*) at (i,j) position. The value of $e_c(i,j)$ is calculated from the standard deviation of a pixel at (i,j) with its surrounding ($n \times n$ patch) at its respective channels (1). The benefit of calculating the standard deviation is that textured object will have a higher deviation which results in an easier way to locate the boundary pixel between two different objects. Finally we can combine them by averaging the values of these edge images (2) at each pixel.

$$e_c(i,j) = \sigma_{i,j,n} = \sqrt{\frac{\sum_{a,b=-\frac{n-1}{2}}^{\frac{n-1}{2}} (x_c(i+a,j+b) - \bar{x})^2}{n^2}} \quad (1)$$

$$e(i,j) = \frac{e_{L*}(i,j) + e_{u*}(i,j) + e_{v*}(i,j)}{3} \quad (2)$$

Since we are only interested on the boundary of the object, we can further reduce the texture effect by redoing the previous step onto the combined image (generated from 2). This will reduce the texture inside the object, but will also make the boundary of the object to lies inside a "valley". This can be avoided by applying the resulting image with the Laplacian operator. Let $I_{\mathcal{L}}$ be the image after applying the Laplacian operator. $I_{\mathcal{L}}$ will then be convoluted with the standard deviation image of the combined image, to construct the final edge image. Figure 2 shows the example of this approach.

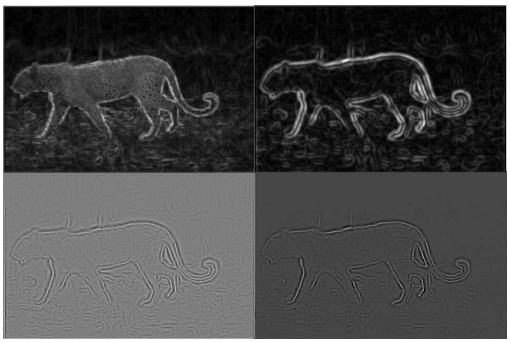

Figure 2: Edge Image Generation. Upper-left: combined image, Upper-right: Standard deviation image; Lower-left: Laplacian image; Lower-right: Final Edge image.

The edge points are then extracted from this edge image. Since we are selecting the edge points from the grid, there will be points which lie in the non-edge position. Filtering these points (candidate points) is done by using a method similar to a method proposed in [11,12]. The idea is very intuitive: at each pixel in the image, generate a patch and divide it into two halves along an orientation. At each section calculate its histogram (intensity, colors, etc.) and compare both of the sections. The higher the distance between the histograms (χ^2 distance) the more likely the examined pixel to be an edge pixels.

Notice that we need to have an orientation at each candidate point. To approximate the orientation at each candidate point, the phase calculated from the difference of horizontal and vertical neighboring pixels of the edge image is used (Sobel operator). Let $d_x(i,j)$ and $d_y(i,j)$ denote the gradient in x and y direction respectively and $\theta(i,j)$ defined in (3), denotes the

phase at position (*i,j*). Let $p_\theta(i,j)$ be the approximation of orientation in a candidate point with coordinate (*i,j*) and is defined by (4). Equation 4 means that the angle approximation is determined by the average of the phase surrounding the point. Finally the filtering is done by using the k-means (k = 2) algorithm with the histograms' difference as features along with the intensity value at the corresponding pixel in the edge image.

$$\theta(i,j) = \frac{d_y(i,j)}{d_x(i,j)} \tag{3}$$

$$p_\theta(i,j) = \frac{1}{n^2} \sum_{a,b=-\frac{n-1}{2}}^{\frac{n-1}{2}} \theta(i+a, j+b) \tag{4}$$

Some of the points will lie very near with each other and it will affect the triangulation in the next step. Therefore a merging step is also applied to the filtered points, i.e. merging the points which lie near each other. The merged new position is calculated based on the average position of the merge points.

2.2 Skeleton Extraction

Skeleton extraction is done by first applying the Delaunay Triangulation to the edge points acquired in previous step. In order to do the skeleton extraction, a triangle grouping should be done. In [13,14] the authors classify triangles into 3 types: terminal triangle, junction triangle and sleeve triangle. The terminal triangle is defined as a triangle which has two outer contour as its edges. Junction triangle is defined as a triangle which does not have outer contour as its edges. Sleeve triangle is defined as a triangle which has only one outer contour as one of its edges. Note that in their application, which can be classified as the binary image skeletonization, the information regarding the outer edge is readily available. In our approach, we do not have that kind of information.

Note that in the previous step during clustering using k-means, we do have the idea to determine a point whether it belongs to the boundary points or non-boundary points based on its histogram distance feature. Therefore, we used this information to cluster the edge as follows. Let point m_i be the middle point of the *i*-th edge. By applying the same approach as in section 2, i.e. orientation approximation and histogram calculation, we can determine point m_i to be an edge point based on its (feature-) vector distance to the center points of each cluster. Another way to see this is, we are not recalculating the cluster centers since the cluster centers (which will determine whether a point is a boundary or non-boundary point) has already been calculated in the previous step, the evaluation of these edge points (*m*) can be done just by calculating the distance to the cluster centers. If $dist(m_i, C_k)$ is defined as the L2 distance between point m_i and the *k*-th center, then point m_i belongs to the the *k*-th cluster if it has the minimum distance compared to another cluster's center.

In this case we can similarly define the triangles as in [13,14]. In sleeve triangle, two of its non-boundary *m* points will be connected together and no connection will be established in terminal triangle. Two types of junction triangles are defined: obtuse triangle and acute triangle. In case of acute triangle, an additional point (the center of triangle) will be added and every *m* points will be connected to this additional point. In obtuse triangle type, instead of generating an additional point, we connect the points on two of the edges of the largest angle to the point lying in front of the angle. See Figure 3 for visualization. Note that the yellow point (e.g. m_1 in Figure 3.a) represents *m* belonging to the boundary cluster.

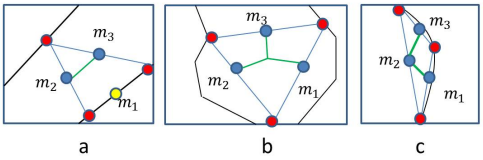

Figure 3: Three types of triangles: a. Sleeve; b. Acute Junction; c. Obtuse Junction .

Given an initial skeleton (point to point connection) from the previous step, the problem now is to determine which of the connection belongs to the same object. Let *T* denotes the set of pixels traversed by the skeleton's edge (Figure 4). By calculating the mean pixel value of T we can get a set of feature vector (f) to represent the skeleton for the clustering algorithm (5). The subscript l denotes the type of image the pixel belongs to, i.e. color images, brightness image, etc. Figure 5 shows the result of the clustering algorithm. Note that since the contrast of the color images might be low for some images and resulting in a non-discriminative cluster, a contrast limited adaptive histogram equalization (CLAHE) is applied to the color images.

$$f_l = \frac{1}{n} \sum_{i=1}^{n} T_i, \qquad T_i \in T_l \tag{5}$$

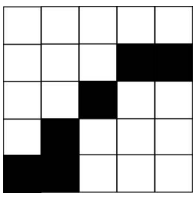

Figure 4: Pixels' value traversed by the skeleton (black tile) will be included in the mean value calculation (5)

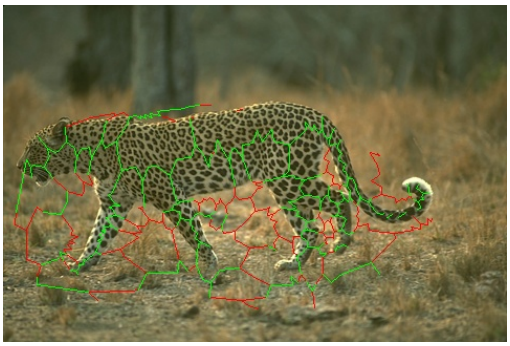

Figure 5: Example result of skeleton grouping

There is a possibility that the generated skeleton has a loop. In order to prevent such condition, loop removal step is applied. This is done by merging all the points of the loop into a point c, where c is the mean position of the points belonging to that loop (Figure 6). If a loop consists of a smaller loop, only the largest loop is considered (Figure 7).

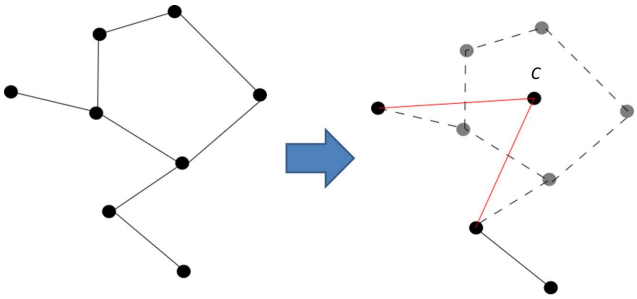

Figure 6: Loop removal step example. A new connection between the generated middle point c and remaining points are constructed.

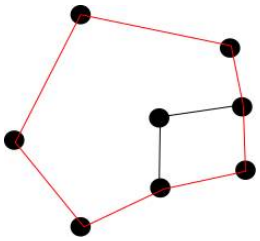

Figure 7: When there is a smaller loop inside a greater loop, only the outer loop will be considered (red lines)

2.3 Skeleton Pruning

Some might notice some redundant skeleton branches from Figure 5. Skeleton pruning is the step required to remove these branches. Borrowing the triangle types term, depending on the number of connection it has, skeleton points can be classified into three types: terminal, sleeve, and junction point. Terminal point means that the point only has one connection with another skeleton point. Sleeve point means that it has two connections with two other skeleton points. Junction point defines a point with more than two connections with other points. In this paper, skeleton branches are defined as the terminal points which connect to junction point. If there are such connection, then the connection will be deleted (Figure 8).

Finally, a bezier smoothing is applied to the skeleton. A curve skeleton is defined as the set of points starting from the terminal point until a junction point, therefore taking Figure 8 as an example, there are two curve skeletons in Figure 8. The sleeve points will be used as the control points for the bezier curve generation.

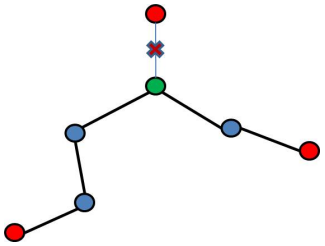

Figure 8: Colored points represent types of skeleton point. Red: terminal; Blue: sleeve: Green: junction

3 Experimental Result and Discussion

All experiments were done using a C++ language and OpenCV 2.4.9 library. There are several parameters which are fixed in this paper, i.e. the number of histogram bins is set to 16 and the size of the grid is set to 5 (refer to section 2.1). CIE Luv is used in this paper. Five images taken from the Berkeley dataset [15] were used for the experiment.

The results of the proposed method are then compared with a method based on [9]. Figure 9 shows the comparison, including the ground truth image generated by human observer. The first column is the ground truth skeleton image, the second column is the proposed method and the third column is skeleton generated based on [9]. Notice that although the proposed method did not generate the skeleton perfectly, it still represents the object in the image better than the method based on [9].

In order to further assess the result, F-measure of the ground truth and the methods were calculated (6). The precision and recall is calculated following (7) and (8). The number of true positive (tp) is calculated by counting the number of pixel where both the ground truth (GT) image (with a $\sigma = 1$ allowance) and the generated skeleton image have the same value. σ here means that if the generated skeleton differs only slightly, i.e. still inside the allowance σ then it is still considered to be true positive and hence counted. Notice again that when comparing both the image to calculate the F-measure, skeleton image generated has binary color where the pixels will have a 1 (white colored) value if the pixel is not traversed by the skeleton edge and 0 (black colored) if it is traversed by the skeleton edge. For the false negative (fn), it is calculated as the number of pixel where it has a value of 1 in the ground truth image, but 0 in the skeleton im-

age. Vice versa, for false positive (fp), we are counting the number of pixel where it has value of 0 in the ground truth but 1 in the skeleton image. Table 1 shows the result of the F-measure calculation.

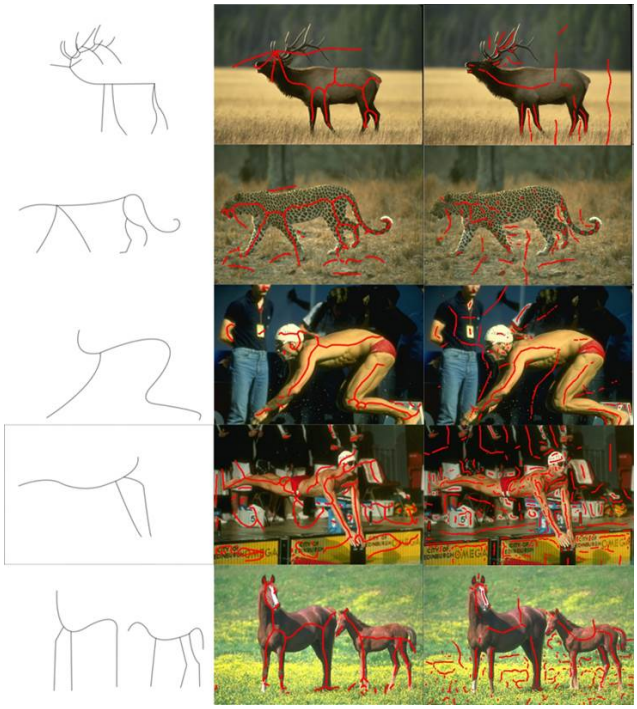

Figure 9: The skeleton is overlaid on top of the input image. For visualization purpose, the skeleton is colored red.

$$F = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{6}$$

$$Precision = \frac{tp}{tp + fp} \tag{7}$$

$$Recall = \frac{tp}{tp + fn} \tag{8}$$

Table 1: F-measure Results

Image	Proposed	SSM[9]
Deer	**0.250**	0.180
Cheetah	**0.345**	0.104
Swimmer1	**0.299**	0.154
Swimmer2	**0.175**	0.092
Horse	**0.359**	0.215

Although every image has its own best parameters, for general purpose, we try to find the parameter values which gave the best average F-measure from the test images. Four window sizes, which is used for histogram calculation, were tested (n = 7, 9, 11, and 15) along with the CLAHE limit parameter (l = 2 and 4). The result is shown in Figure 10. The x-axis is the combination parameters, i.e. (n,l). As shown in Figure 10 the combination of n = 9 and l = 4 has higher average F-measure among the other combinations.

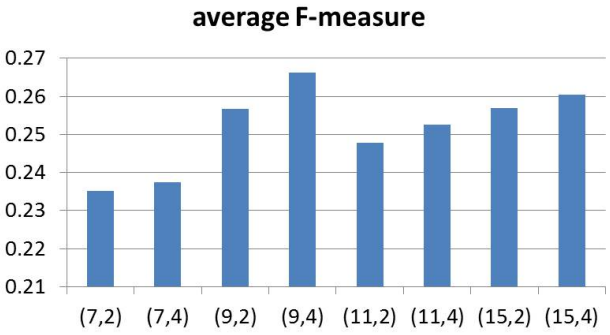

Figure 10: Average F-measure of parameters combination

4 Conclusion

In this paper a novel method to extract 2D skeleton information from a natural image is proposed. Based on the results shown in section 3, the proposed method shows a higher performance compared to the SSM method. Not only compared visually, in order to have a better comparison, the proposed method and SSM method is also compared by calculating their F-measures, which is shown to outperform the SSM method. There are several limitations for the proposed method, e.g. some images still have redundant skeleton branches and user interference (manually select) when choosing the final skeleton cluster (subsection 2.2). Therefore for our future work, we are going to solve these problems.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

This paper presents a full wave active rectifier for biomedical implanted devices using a new comparator in order to reduce the rectifier transistors reverse current. The rectifier was designed in 0.13µm CMOS process and it can deliver 1.2Vdc for a minimum signal of 1.3Vac. It achieves a power conversion efficiency of 92% at the 13.56MHz Scientific and Medical (ISM) band.

1 Introduction

This paper is an extension of work originally presented in The 15th International Symposium on Integrated Circuits, Sigapure, 2016 [1]. It presents some details not described in the original paper. This paper also brings new results obtained after a new calibration of the system that improved the circuit efficiency.

Implanted medical device is a technology that offers several possibilities to improve medicine and it can change the paradigm of how doctors and patients deal with treatments and drugs. In order to be implanted, a medical devices need a source of power that will provide energy to the circuit. As used in RFID technology, one of the ways to supply power to implanted medical device is by using an inductive link [2] that can power up a circuit through the skin without to use transcutaneous wires, which could expose the patient to bacterias and viruses [3]. The other solution is by using batteries that have limited life and can cause heavy metal contamination in case of leakage.

Although this work is focused on inductive links, there are other ways to transfer energy. There are some applications that use ultrasound waves to excite a piezoelectric device to generate a current. Another way to provide power to medical implants is by using a thermoelectric generator that makes use of the temperature gradient between inside and outside of body to create energy by Seebeck Effect.

An inductive link requires an AC-DC rectifier that is responsible to transform the signal wave into a power supply. Rectifiers are usually designed to use conventional diodes that have a built drop voltage of 0.7V, which is suitable for conventional applications but it is unusable for circuits running on power supplies of 1V or less. Alternatively to the conventional diodes, Schottky diodes can be used, but the manufacturing process of low forward drop voltage can be more expensive than the traditional processes [4] because they might not be present in some regular processes and require extra fabrication steps [5]. An alternative is the use of diode connected MOS transistors to replace the conventional diodes in a bridge connection. CMOS transistors connected as diodes can work at high frequencies, such as the Scientific and Medical - ISM band (13.56MHZ) that has been widely used [4, 5, 6]. One problem of this solutions is that diode connected MOS transistors in a bridge connection offers low ON-OFF switching speed which in turn creates an undesirable reverse current. A cross-coupled connected structure (Figure 1) can make the operation more efficient and minimizes the reverse current, but in the ideal case the ON-OFF switch of the CMOS transistors would be controlled by another circuit that can speed up the operation and can create a dynamic rectifier to make the operation more efficient, thus minimizing the reverse current. Some dynamic rectifiers have been reported in the last few years [6, 7, 8] as solutions for powering medical devices under low power.

One important characteristic of power supply is the power conversion efficiency (PCE), equation 1, which is defined as the rate of the energy dissipated by the load by the power consumed by the entire circuit [10], where η_{pa}, η_{link}, $\eta_{rectifier}$, $\eta_{regulator}$ represents the power amplifier, inductive link, rectifier, and regulator efficiency respectively. The $\eta_{rectifier}$ represents the amount of power provided to the output divided by the amount of power that enters in the rectifier (equa-

https://dx.doi.org/10.25046/aj0203129

tion 2). For a PCE of 30% it is expected to have around 80% of efficiency of the AC-DC converter [6].

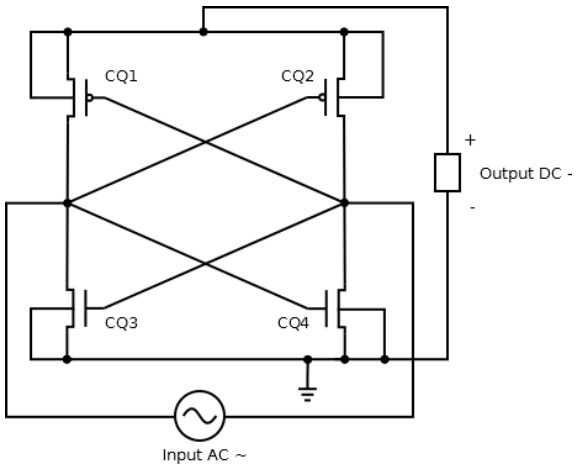

Figure 1: Cross-Coupled Rectifier [9].

$$PCE = \eta_{pa} * \eta_{link} * \eta_{rectifier} * \eta_{regulator} \quad (1)$$

$$\eta_{rectifier} = \frac{Pout_DC}{Pout_AC} \quad (2)$$

This paper presents one active rectifier using diode connected CMOS transistors, in 0.13μm process, controlled by two original comparators that are responsible for turning ON-OFF the circuit and minimize the reverse current. This work was intended to provide an output voltage of at least 1V.

2 Cross Couple Structure

The cross-coupled structure shown in Figure 1 connects the transistors gates in a cross mode. That configuration puts the gates of transistors CQ1 and CQ2 biased at a positive signal when their drain are biased by the negative signal. On the other hand, when the circle change, the drains are biased by the positive signal and the gates by the negative signal. The transistors are made to turn ON at different voltage levels in their gates. NMOS needs to have high voltage and PMOS needs to have low voltage. At the same time the cross coupled circuit is designed so that the PMOS transistors provide higher voltage to the load while NMOS provide the lower voltage or GND voltage.

3 Active Rectifier

As mentioned in the introduction section, the desirable rectifier should have a minimal reverse current, and one widely used way to achieve it is by using a comparator that can turn the rectifier ON-OFF faster enough. The Figure 2 shows the schematic of the rectifier [6].

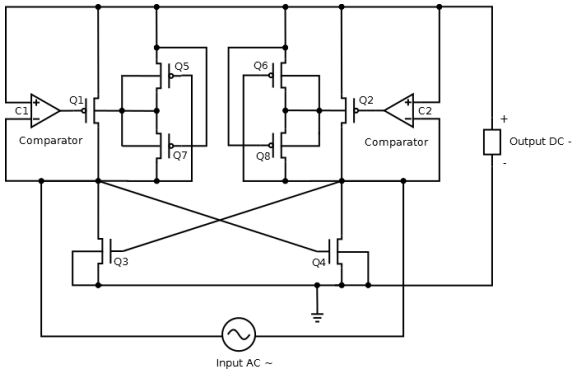

Figure 2: Active Rectifier Circuit [6].

The rectifier of Figure 2 is comprised of PMOS transistors Q1 and Q2, and NMOS transistors Q3 and Q4. Transistors Q5, Q6, Q7, and Q8 work in order to tie the PMOS base transistor always at the higher voltage [11]. Transistors Q3 and Q4 are connected as a cross-coupled gate structure while Q1 and Q2 are driven by comparators C1 and C2.

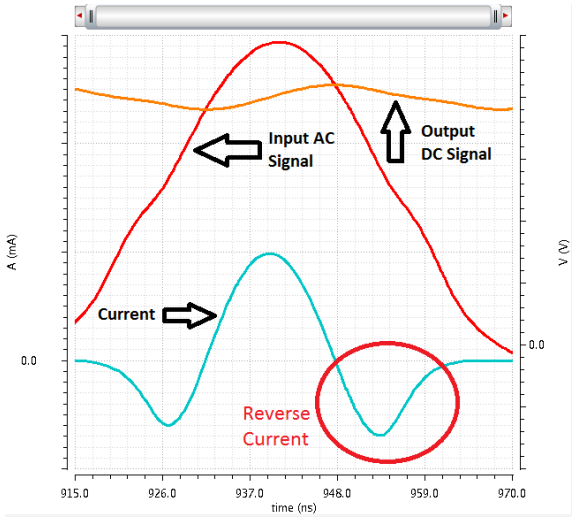

Figure 3: Cross-Coupled Rectifier wave form.

While the cross-coupled rectifier has a considerable reverse current (Figure 3) the two comparators shown in Figure 2 allow the active rectifier to switch faster and minimize it. The challenge faced by this technology is to make the comparators work fast enough. Figure 4 shows the waveform signals and highlights the comparator signal delay by circles C and B, as well as the reverse current, by circle A.

In the ideal case, a perfect comparator would start its output signal a moment before the AC signal became larger than DC signal and would finish the pulse in the exactly moment the AC signal becames smaller than the DC signal. It is possible to see in the Figure 4 the delay showed inside of circle B which creates the reverse current in circle A.

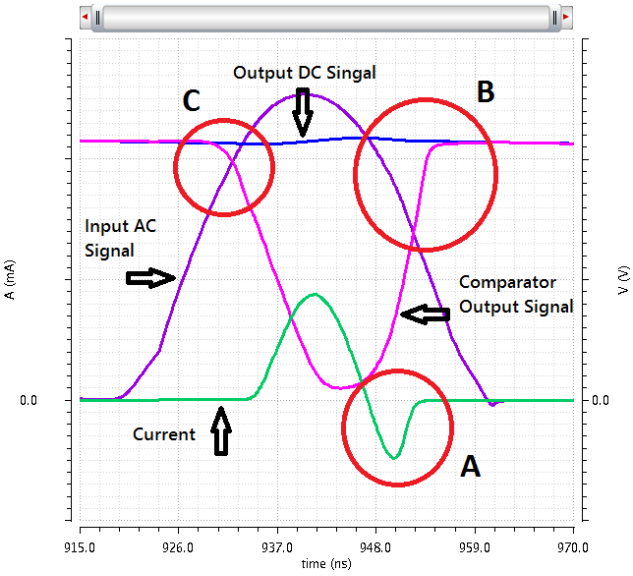

Figure 4: Active Rectifier waveform - (A) reverse current, (B) output delay, (C) entry delay.

4 Two Input Common Gate

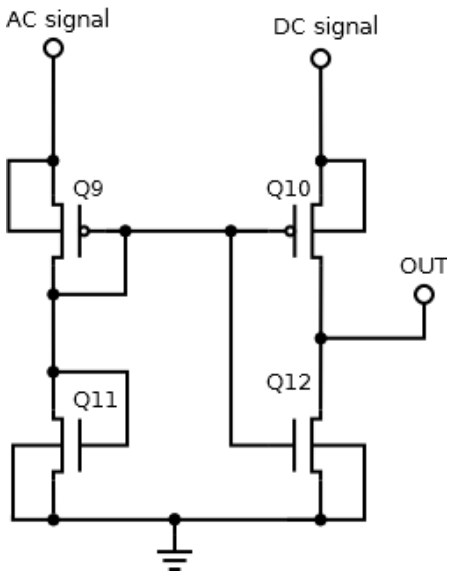

Figure 5: Two input common gate.

Figure 5 shows the Two Input Common Gate Comparator, which is the comparator used to develop the proposed comparator. This comparator is used in order to monitor AC and DC signals, and to switch ON and OFF the rectifier transistors always when the AC signal becomes larger or smaller than the DC signal. The Two Input Common Gate uses only four transistors, Q10 and Q12 that form an inverter, and Q9 and Q11 that form a voltage divider responsible by create an (AC signal)/2. That comparator has been used since it is small and simple, it does not require external power source, it consumes low power and provides faster switch for the rectifier transistors than a cross couple structure. Although that comparator is relatively fast, we propose a new comparator based on the Two Input Common Gate, with some modifications that speeds up the operation of the switching transistors.

5 Proposed Comparator

The proposed comparator shown in Figure 6 is a modified version of the two-input common gate, with an extra capacitor and an extra voltage divider that are responsible for speeding up the comparator.

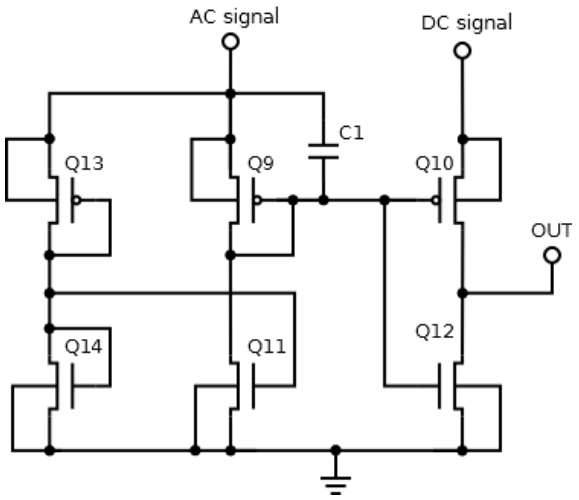

Figure 6: Proposed Comparator.

Transistors Q9, Q10, Q11, and Q12 form a modified common gate structure. The gate of transistor Q11 is connected to Q13 and Q14. Transistors Q10 and Q12 compose an inverter that can bring the OUT pin to low or high level (DC signal). The transition between high and low level happens when the voltage, at Q10 and Q12 gates, is larger than half of DC signal. Our comparator aims to detect when AC signal is larger than DC signal. In order to accomplish it, transistors Q9 and Q11 form a voltage divider designed to put the gates of Q10 and Q12 at a voltage larger than DC/2 in the moment that AC signal is larger than the DC signal.

In the proposed comparator, capacitor C1 works in order to improve the rise time of the signal provided by the voltage divider formed by Q9-Q11. While C1 is not charged, it works as a short circuit and allows the AC signal to drive the Q10-Q12 inverter. When C1 is charged, it becomes an open circuit, and the voltage between Q9 and Q11 starts to drive the inverter. Figure 7 Q10-Q12 gates voltage waveform inside of the circle. A lump appears when C1 gets full and disconnects the AC signal from driving the inverter. The lump can occur above or below in the signal according to the value of capacitor C1. If C1 is larger than a certain value it will stop decreasing the reverse current and will start increasing it. Figure 8 (a) shows a waveform with an acceptable capacitor and (b) with a capacitor larger than the optimum point. Figure 8

(b) does not have a lump since its capacitor C1 is so big that it never gets fully charged, and the AC signal drives the inverter the whole time.

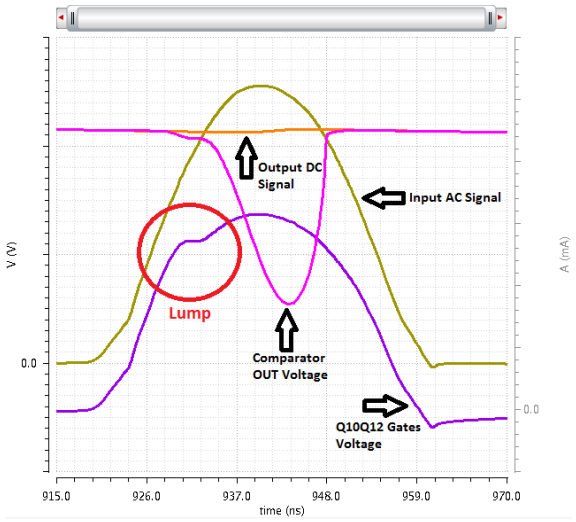

Figure 7: Proposed Comparator waveform. Lump's highlight.

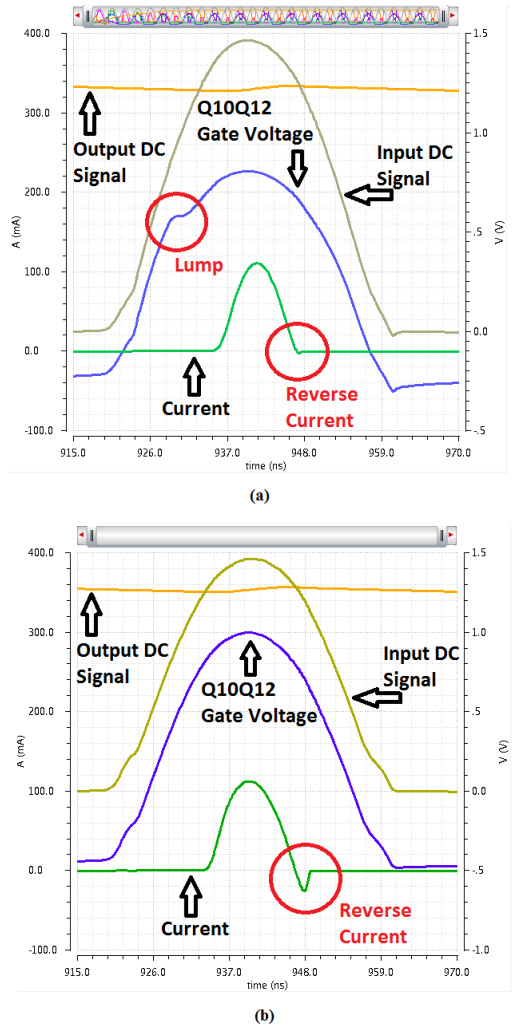

Figure 8: Comparative between waveforms using an acceptable capacitor size (a) and an over sized capacitor (b).

Capacitor C1 helps the circuit to work faster but the use of integrated capacitor can be a problem since it may take a lot of silicon area. In order to avoid it, a second voltage divider is used. The voltage between transistors Q13 and Q14 is designed to be just a little higher than the voltage between transistors Q9 and Q11. It allows transistor Q11 to turn ON a little earlier and to provide the delay shown in Figure 4 circle B to be a little shorter. Just as a comparison, if capacitor C1 is 10pF at 1.3Vac input signal voltage, the maximum reverse current, without the voltage divider, is almost 2 times larger than the use of a voltage divider. In order to have the same result without to use the voltage divider, capacitor C1 would need to be 97pF.

6 Details About the Capacitor

In order to choose an ideal size of capacitor, some considerations taken into account. The capacitor size depends on the resistance and on the frequency operation, which defines the time the capacitor needs to get fully charged. Since the circuit resistance changes during the circuit operation, the maximum capacitance will be calculated, and later a smaller capacitance value needs to be calibrated through simulations. The τ constant shown in equation 3 relates capacitor load time to the circuit resistance and capacitance

$$\tau = RC \tag{3}$$

During the time given by the RC constant, a capacitor gets 63% charged/discharged [12]. For a 99.3% load, it takes 5τ [13]. If a charge time of $T = 5\tau$ replace τ at equation 3 then the equation 4 will provide capacitance that can be used in the circuit.

$$C = \frac{T}{5R} \tag{4}$$

In order to obtain the time T on equation 4, the circuit frequency needs to be analyzed. The time for the capacitor be fully charged needs to be less than the time to signal AC changes from zero to the maximum voltage value. That time is exactly 1/4 of the cycle time. For 13.56MHz, it is 0.0184μs.

In order to determine the resistance R, the Thevenin method for equivalent resistance can be used. The R resistance applied to equation 4 results in a reference capacitance that needs to be calibrated by simulations. Its occurs because the R resistance is not constant in this circuit.

7 Type of Transistor

In this work halo implanted transistors of small channel were used. Although this kind of transistor has some problems such as threshold voltage mismatch, caused by the halo implant, [14] they offer the advantage of having less internal resistance [14]. This smaller internal resistance helps the circuit to waste less energy on its own operation.

8 Transistors Sizing

The transistors sizing takes 4 steps. The first step is used to obtain the current to be provided by the rectifier transistors. This amount of current sets the minimum size of the four rectifier transistors according to the technology used. After selecting the size of the four rectifier transistors, the others three steps are related with the comparator.

In the second step 2, transistors Q10 and Q12, which form the inverter are chosen. Those transistors need to be large enough to supply current to the rectifier. Besides that, Q10 and Q12 need to be designed to switch the inverter exactly at half of the DC signal voltage.

The next step would be the design of transistors Q9 and Q11 that form the main voltage divider and provide voltage to the inverter. Nevertheless, since the gate of Q11 is controlled by Q13 and Q14, the auxiliary voltage divider, therefore the voltage divider Q13Q14 needs to be designed first.

While the main voltage divider needs to provide a voltage of (AC signal)/2 to the inverter, the auxiliary voltage divider needs to provide a voltage larger than (AC signal)/2 to the gate of Q11 in order to turn it on a little earlier. Thus, in step 3 the voltage divider Q13Q14 needs to be designed to provide voltage ((AC signal)/2 + δ). In our work we have chosen $\delta = 100$mV, but a different voltage is acceptable.

The fourth step, after designing the inverted and the auxiliary voltage divisor, the main divisor needs to be designed to provide (AC signal)/2 voltage. Since the auxiliary voltage divider controls the gate of Q11 it can be a little difficult to obtain the Q9 and Q11 sizes. A simulation tool can help this task.

After the 4 steps, the capacitor needs to be calculated, as described in section 6.

Figure 9 summarizes all the steps described in this section.

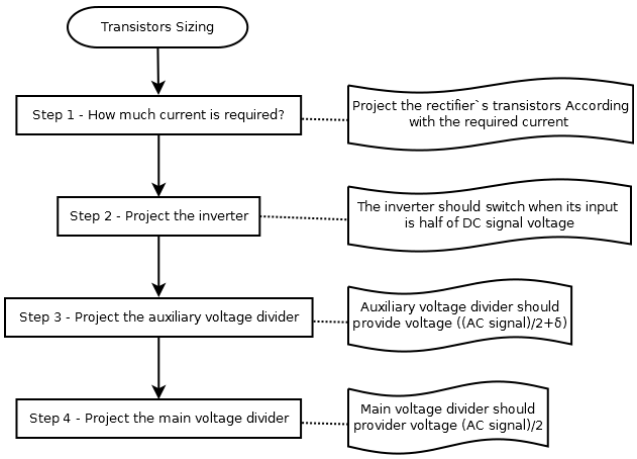

Figure 9: Transistors Sizing Flowchart.

9 Results

In order to simulate an input sine-wave at 13.56MHz, of 1.3V peak was used.

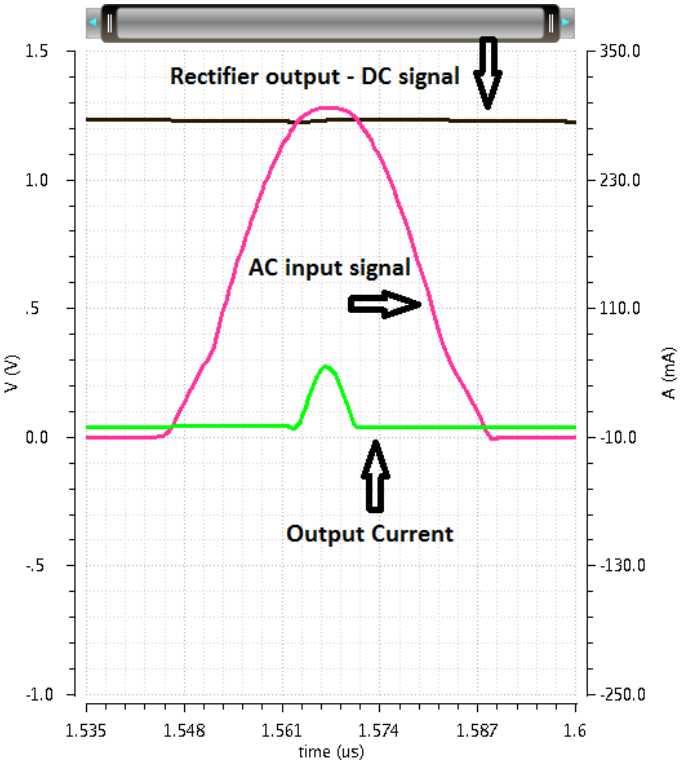

Figure 10: Output of wave form using the proposed comparator.

Figure 10 shows the output waveform. The output DC voltage is 1.2V and the output peak current is 55.55mA under a reverse current of -1.47mA. In order to trace this curve, a capacitor of 20nF and a resistor of 193 ohms were connected in parallel as load [6].

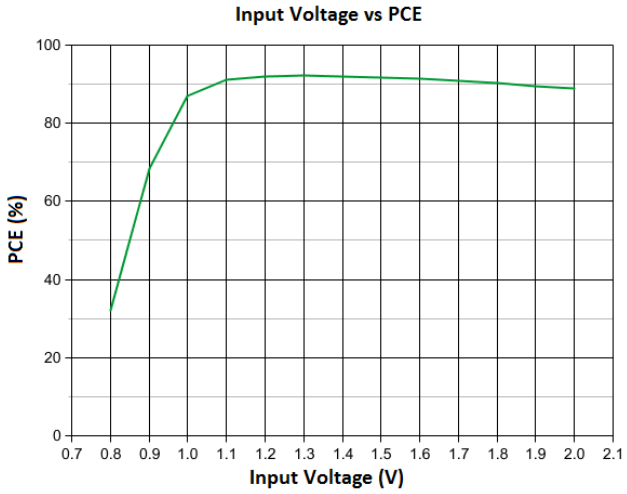

Figure 11: Relationship between input voltage and PCE.

The maximum $\eta_{rectifier}$ obtained is 0.92 and it was

Parameter	This Work	[11]	[5]	[4]
Input Frequency (MHz)	13.56	13.56	13.56	13.56
Input Amplitude (|Vac|)	1.3	1.5	3.8	3.5
Output Voltage (V)	1.2	1.33	3.1	3.2
R Load (KΩ)	0.193	1	0.1	1.8
Output Power (mW)	44.93	1.8	96	5.7
PCE (%)	92	81.9	80.2	87
Process Technology (μm)	0.13	0.18	0.5	0.35

Table 1: Comparison with previous works.

computed using the same method described in [6] that can be obtained from equation 2. The curve of input voltage vs PCE is shown in Figure 11.

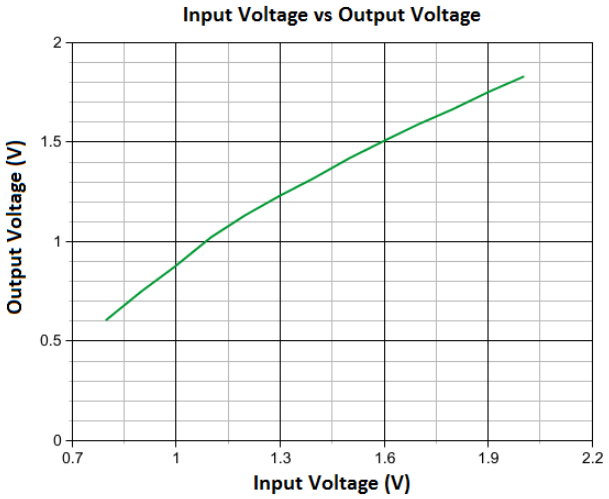

Figure 12: Relationship between input and output voltage.

Figure 12 shows the relationship between input and output voltage.

Table 1 shows a comparison to other works. It is possible to verify the PCE achieved was compatible with other reported rectifiers and that the output voltage is compatible with implantable devices.

10 Conclusion

In this extended version it is presented a low power rectifier, on a new operating condition, using a proposed comparator. The comparator is intended to reduce the switching delay of the rectifier transistors, in order to decrease the reverse current. It was accomplished by using an extra capacitor and an extra voltage divider as compared to the original two-input common gate comparator. Those comparator and rectifier were designed and simulated on 0.13μm CMOS process. The circuit was designed to work at 13.56MHz with an input signal of at least 1.3Vac. The rectifier efficiency increased by 10% when compared to the original paper and it can achieve a 92% of maximum efficiency at 1.2V.

ABSTRACT

The research in Neuro-Prosthetics is gaining more significance and popularity as the advancement in prosthetics control allows amputees to perform even more tasks. Indeed, the improvement of classification accuracy is a challenge in prosthetics control. In this research, a system is developed in order to improve the multiclass classification rate. Two classifiers namely Artificial Neural Network(ANN) and Support Vector Machine(SVM) are trained to recognize five different myoelectric motions of hand fingers. The Electromyography(EMG) signals are acquired using surface electrodes placed on the forearm at specific nodes. The signal conditioning is performed using two stage filtering and amplification followed by digitization process. The final version of EMG signals is correlated in joint time and frequency domain for best feature vectors done via Discrete Wavelet Transform (DWT). The feature vectors are used to train the ANN and SVM. The classification results show an exceptional performance of ANN with classification accuracy of 98.7%. over the SVM, which is 96.7%.

1. Introduction

A lot of work is done in the field of bionics and kinematics. The purpose is to identify the finger movements. Electromyography is a procedure commonly used to assess the muscular activity created by skeletal muscles when fired by neurons. These signals can be used to detect muscular diseases and disorders etc. Some of the applications are found in prosthetics control where EMG signals are used for the robotic control of hands, arms and fingers. The most frequently used approaches for acquiring EMG signals are surface and intramuscular methods. In first case, surface electrodes are placed on specific nodes on forearm in pair form. A reference or a neutral point is defined usually taken as bone and a single electrode is placed on it. The EMG signal picked up from nodes have a small amplitude usually in millivolts and contains noise of line and skin impedance. Signal conditioning of these EMGs is needed to further processing. Feature extraction is a significant step following signal acquisition. It helps to identify and extract useful information present in signals. These feature vectors are used for training, validation and testing of the classifier used for classification. Thus, the pattern recognition method has an important role.

A technique used for multi-channel classification of surface EMG using support vector machine (SVM) and signal based wavelet is reported in [1]. The algorithm is trained to classify EMG signals of six hand movement. The technique showed an overall classification accuracy of 95%.

There are some works which describe the use of SVM either in medical findings [2] or related to myoelectric prosthetics control. Crawford *et al.* [3] described the use of SVM for Myoelectric classification. The purpose is to control a robotic arm with 4 degrees of freedom. A set of seven single electrodes placed on the forearm were employed to distinguish eight hand gestures. The results showed a classification rate was over 90%,

The hand gesture EMG recognition based on ANN technique has been reported in [4,5]. A back-propagation ANN classifier with Levenberg-Marquardt training algorithm was used. The network used features in time and frequency domain. The results

[*]Corresponding Author: Jawad Ahmad, Chongqing University, Contact: +86-157-36123585, Email: Jawad.ahmad@cqu.edu.cn

showed that ANN can classify six different hand movements (left, right, up and down) with an error rate of 11.6 %.

Similarly, Bitzer and Smagt have also used SVMs to identify six different finger actions with ten double differential electrodes placed near to the wrist [6]. The accuracy was between 90-94% for relax and pronation postures of arm. Another work reported by Lucas *et al.* [7], shows a multi-channel classification problem where Myoelectric identification was performed in order to distinguish six different movements of the hand based on SVM and wavelet coefficients. Final results show that the optimal wavelet selection favors the performance of classifier, giving an average error rate of 5%.

Some work related to the five fingers motion identification has been reported in [8]. The two-layered feed forward neural network was trained to identify 16 features from five fingers motion. The ANN was able to classify the features with the maximum classification rate of 96.7%.

The main aim of this research is to improve the classification rate by designing a hardware and software based system. A hardware module consists of filters and amplifiers is designed for capturing an optimum EMG signal in meaningful frequency range. Firstly, the EMGs are acquired using electrodes placed on nodes and are conditioned by filters and amplifiers. The conditioned signals are digitized and read in MATLAB which are then subjected to transformation in joint time and frequency domain by Discrete Wavelet Transform (DWT). The features returned by DWT are availed to trained the ANN used to classify five finger movements. A total of 500 utilized feature vectors will be fed up to the input of neural network for training, validation and testing. To compare the performance results, SVM is also trained. Furthermore, the classification performance of ANN and SVM is compared when classifiers are subjected to testing data. Finally, the efficiency and robustness of SVM and ANN is also discussed.

The classification results of ANN show an improved classification rate of 98.7% achieved in five fingers classification. The performance results of ANN showed an edge over the performance of SVM which is 96.7%. The network robustness is depicted by the superb performance plots of the neural network.

2. Material and Method

This research is carried out in flow stated in Figure 1 below. The block diagram shows the phases for EMGs processing.

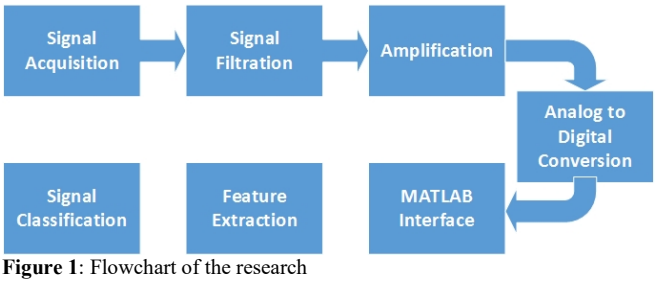

Figure 1: Flowchart of the research

2.1. Electrode Placement

Signals are acquired from five fingers using surface EMG Electrodes. Gelled Ag/AgCl electrodes are used as it helps in creating good contact between skin and electrode thus mitigating skin impedance. To avoid crosstalk and distortion suitable size and distance of electrodes is chosen. The size of electrode is chosen 10mm as suggested by SENIAM [9] and European inventory. For each finger two electrodes are used in pair configuration. These electrodes are placed between motor units and tendon insertion of muscles with the inter-electrode distance of 20mm between them. For each finger, the electrodes are placed on forearm on specific nodes as shown in Figure 2. The reference electrode is placed at back side of hand on bone giving a reference signal to differential amplifier used for filtration in next step.

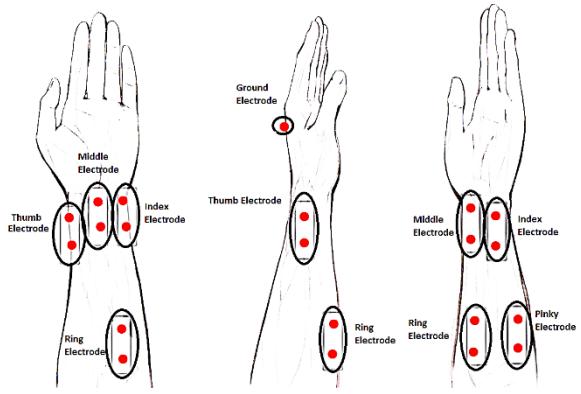

Figure 2: Electrode placement on forearm for signal acquisition

A stereo cable is used to connect electrode and the signal conditioning circuit. One end of the cable has a dual-channel stereo jack and other end consists of alligator clips.

2.2. Signal Conditioning Circuit

In order to remove noise from EMGs, a signal conditioning circuit is implemented as shown in Figure 3. It consists of five channels for five fingers respectively. Stereo jack sockets are utilized to connect the connecting wires.

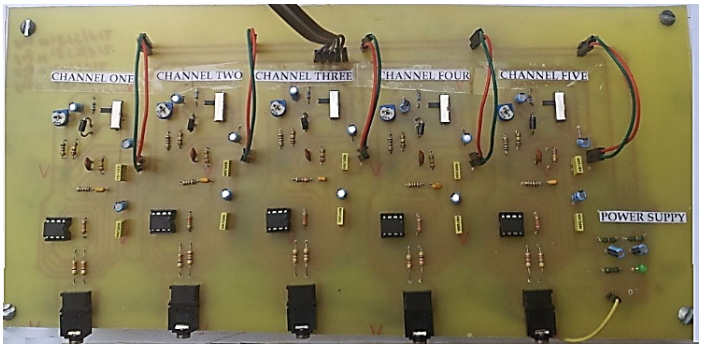

Figure 3: Hardware module used for signal conditioning

2.3. Differential Filtration

Signals acquired from electrodes contain noise due to skin Impedance and connecting leads. An instrumentation amplifier AD623 is used to remove noise. The signals are read with respect to reference electrode and their difference is amplified as shown in (1). The common mode rejection capability of the amplifier removes noise from signals. The read signals are free of noises such as power lines noise. Indeed, the CMMR is an important factor for any differential amplifier as it eliminates any correlated signals that come from power sources or electromagnetic devices.

The CMMR determines how well the input signals have subtracted. AD623 provides better CMRR, high input impedance and strong DC voltage suppression, therefore, keeping the error to a minimum. The CMRR for amplifier remains constant up to 200 Hz. Figure 4 shows the schematic of the instrumentation amplifier used for differential filtration.

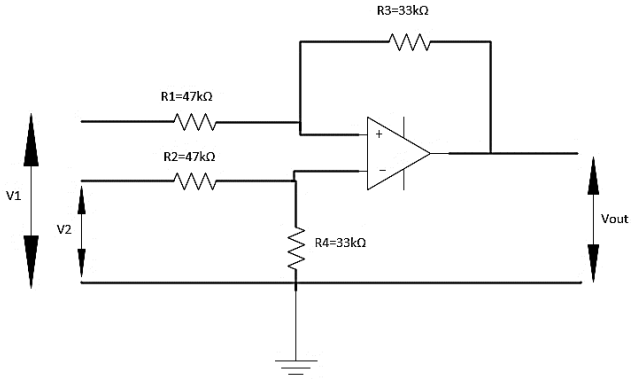

Figure 4: Circuit diagram for differential amplifier

$$V_{out} = \frac{R_3}{R_1}(V_2 - V_1) \quad (1)$$

Where R1=R2=47 kΩ and R3=R4=33 kΩ

2.4. Bandpass Filtration and Amplification

To select the useful range of frequencies and amplification, a low voltage operational amplifier LMV358 having voltage range between 2.7 V and 5.5 V is used. LMV358 is dual low voltage amplifier. First op-amp is used as frequency selective bandpass filtering and amplification. The frequency range is selected between 100-500 Hz. Figure 5 shows the schematics of the bandpass filter and amplifier.

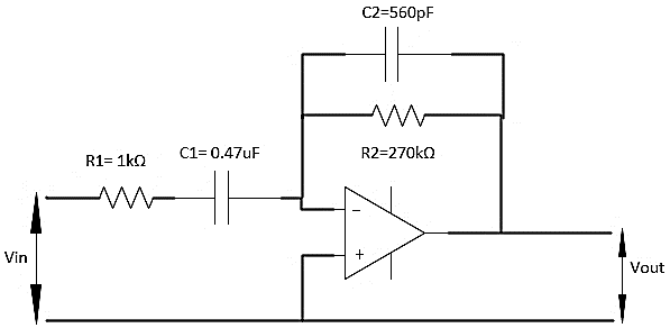

Figure 5: Circuit diagram for bandpass filter

In figure given above R1 = 1 k, C1 = 0.47uf, R2 = 270 k, C2 = 560pf. The equations for bandpass filter are given as follows:

$$Gain(Av) = -\frac{R_2}{R_1}, f_{c1} = \frac{1}{2\pi R_1 C_1}, f_{c2} = \frac{1}{2\pi R_2 C_2} \quad (2)$$

To enhance the resolution of recoded signals, amplification is also required. Amplifier of high quality having adjustable gains is used. The second operational amplifier in LMV358 is used as inverting amplifier with adjustable gain. The values of resistors are selected such that the op-amp provides negative gain of 250, therefore, during each acquisition of EMG signal the signal to noise ratio gets maximized and EMG signals are amplified to appropriate levels. Figure 6 shows the schematic of an inverting amplifier used for amplification.

$$Gain(Av) = \frac{V_{out}}{V_{in}} = -\frac{R_f}{R_{in}} \quad (3)$$

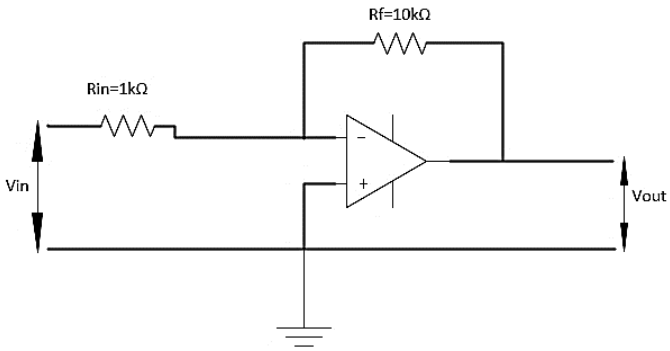

Figure 6: Circuit diagram for an inverting amplifier

After amplification, EMG signals are subjected to a peak detector circuit. It consists of diode which renders only positive deflections of the signal. The random nature in amplitude of EMG signals exists even after rectification. To extract amplitude related information, the concept of smoothing is adopted by using the RC combination as a low pass filter to suppress high frequency fluctuations in the EMG signal. The deflections in EMG signal appear smooth and the peak value of EMG signal is easily captured by RC combination.

After passing the EMG signals through various steps of signal conditioning, filtration, amplification and rectification, the final signal is obtained as shown in Figure 7. This is the positive signal with average amplitude lies in range of 0-5V as ensured through previous amplification.

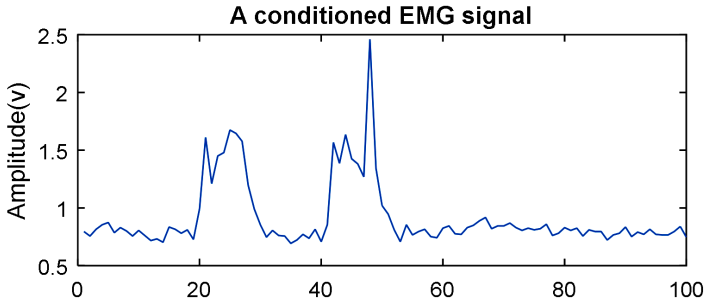

Figure 7: The final waveform of a conditioned EMG signal

2.5. Analogue to Digital Conversion

Signal conditioning steps remove noise and amplify the signals to appropriate levels. These signals then need to be used in Matlab for further processing. An Arduino Uno board based on ATmega328P is used for analog to digital conversion. It uses a built-in 10-bit ADC at a sampling rate of 8.6 kHz according to the Nyquist criteria. The analog voltages are mapped between 0 and 3 V with resolution of 1024.

Digital signals from the Arduino are read in Matlab through serial interface of Arduino. 9600 baud rate is used. For ease of coding a hardware support package of Arduino is used in Matlab.

2.6. Feature Extraction

Feature extraction is important step for any classification problem as it helps to extract important information from the signals. The features acquired in this step are used as training data to classifier. Wavelet transform transforms the stochastic EMG signals into time and frequency based information which is helpful in finding the harmonic contents and better diagnostic possibilities as compared to the conventional Fourier transform. The rapid variations within a signal can be accurately studied and analyzed using wavelet transform. As can be seen in the Figure 9, the Fourier transform forms a constant frequency resolution as the signal is divided into constant time window. However, in the case of wavelet transform the signals are divided into different time windows with different range of frequencies which provides better allocation for high frequency components in the signal. Another advantage of wavelet transform is simple computation and less complexity as compared to the Fourier transform.

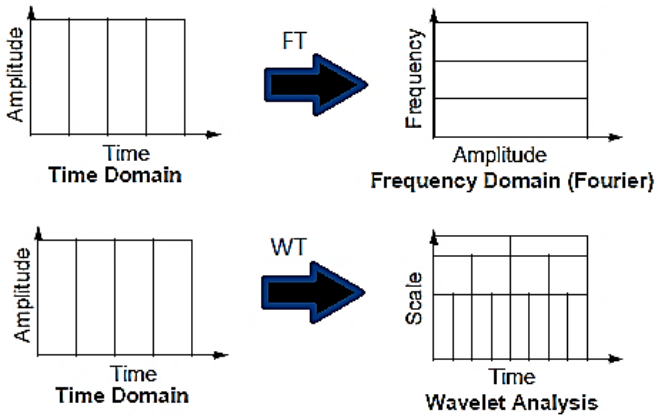

Figure 9: Comparison between Fourier and wavelet transform

Since, the DWT exhibits good frequency resolution at low frequencies and good time resolution at high frequencies [10], therefore, the DWT is chosen as a feature extraction technique for surface EMG signal. The DWT coefficients of a signal *x(n)* may be obtained as:

$$C(a,b)=\sum_{n=z} x[n]\Psi_{a,b}[n] \tag{4}$$

$$\Psi_{a,b}[n]=\frac{1}{\sqrt{a}}\Psi\left\{\frac{n-b}{n}\right\} \tag{5}$$

Where *a* is scale, *b* is translation and ψ(n) is a discrete wavelet. The Daubechies 4 or db4 wavelet window is used as it provides best correlation with the EMGs, therefore, giving best feature vectors for training the classifiers. The DWT is achieved by passing the signal *x[n]* through two complementary filters, a low pass filter having impulse response *g[n]* and a high pass filter having impulse response *h[n]* as shown below:

$$y_g[n]=\sum_{k=-\infty}^{\infty} x[k]g[2n-k] \tag{6}$$

$$y_h[n]=\sum_{k=-\infty}^{\infty} x[k]h[2n-k] \tag{7}$$

The application of two filters gives the approximation and detailed coefficients containing information about the shape and sharp variations of the signal respectively. For capturing sharp variations in the five fingers EMG signals, the detailed coefficients are used as features for training the classifiers.

Hence, the DWT helps to analyze the EMG signals at different frequency band with different resolution which is helpful to extract best feature vectors for training ANN and SVM.

2.7. Feature Classification

The features extracted from EMGs are utilized to train ANN and SVM.

2.8. Support Vector Machine (SVM)

Support Vector Machine (SVM) was first introduced by Vapnik and Chervonenkis at 1965. SVM is a supervised learning technique used in the field of machine learning. In SVM, the training is reformulated in such a way to achieve a quadratic programming problem whose solution is unique and global. The detailed information regarding the SVM can be found in [11]. SVM is a binary classifier whose output is estimated by the given empirical data:

$$(x_1,y_1),....,(x_m,y_m)\in R^N\times\{\pm 1\} \tag{8}$$

The problems related to non-linear problems are solved by mapping the original data into a feature space. The mapping data is linearly separable in feature space. Function $\varphi(x)$, which maps the training vector x_i into a higher dimensional space, requires to belong to a dot product space. The dot product of mapping function is termed as kernel:

$$k(x_i,x_j)=\varphi(x_i)^T\varphi(x_j) \tag{9}$$

The group of data that is mapped in high dimensional linear space is divided in two labeled classes by a hyperplane. The labeled classes are shown as:

$$w^T\varphi(x)+b=0 \tag{10}$$

$$w\in R^N, b\in R$$

To ensure maximum margin between separating classes, the selection of a suitable hyperplane is necessary. To construct this hyperplane, we need to solve the following quadratic problem:

$$\min\frac{1}{2}\|w\|^2+C\sum_{i=1}^{m}\xi_i \tag{11}$$

$$y_i(w^T\theta(x_i)+b)\geq 1-\xi_i,\xi_i\geq 0, i=1,2.....m$$

where ξ is called the slack variable, which takes values for each x_i. It is related to the concept of soft margin, whereas, C is the tuning parameter used to tolerate errors and balance the training data. Equation (11) can be solved by the introduction of a Lagrange multipliers α_i through next expression as:

$$\max \sum_{i=1}^{m} \alpha_i - \frac{1}{2} \sum_{j=1}^{m} \alpha_i \alpha_j y_i y_j k(x_i, x_j) \tag{12}$$

$$\sum_{i=1}^{m} \alpha_i y_i = 0, 0 \le \alpha_i \le C, \forall i \tag{13}$$

Solving (12) leads to an optimal decision function as:

$$f(x) = \operatorname{sgn}\{\sum_{i=1}^{m} \alpha_i y_i k(x_i, x) + b\} \tag{14}$$

The decision function shown in (14) depicts that the classifier has an extension in terms of a subset of the training data. Those patterns whose α_i is non-zero, are termed as support vectors. The non-linear classification can be achieved by introducing different kernel functions, which computes the inner product of vectors $\varphi_{(x_i)}$ and $\varphi_{(x_j)}$. These typical kernels functions include lineal, quadratic and radial functions. The SVM inherently is a binary classifier and performs classifications on two class problems. To solve multiclass problems, like in our case for five fingers motion classification, we need to extend the capabilities of SVM to multiclass approach. Therefore, for multiclass SVM, (8) can be represented as:

$$(x_1, y_1)_1, ..., (x_m, y_m)_k \in R^N \times \{1, ...k\} \tag{15}$$

The theme is to train *5* independent binary classifiers so that each one is trained to discriminate the training samples in only one class against all the remaining classes. For classifying a new sample, *5* classifiers work separately, the one giving largest output is chosen as an estimated class. This scheme is referred to as the *one-against-all*. It is simple, fast and accurate method to implement. The kernel function used for separating patterns is a quadratic function having box constraint level equal to 1.

2.9. Artificial Neural Network

In this paper, the pattern recognition of the features is done using the ANN as shown in Figure 10.

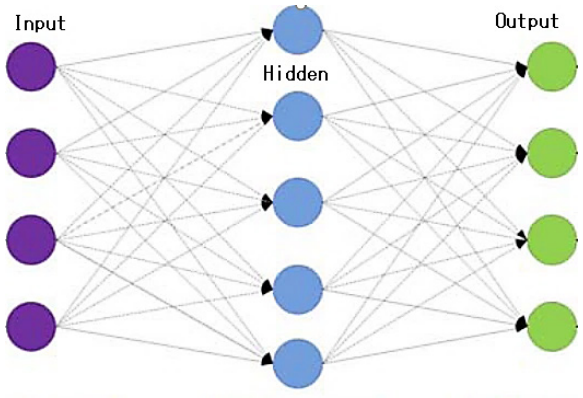

Figure 10: The structure of Neural Network

The first output neuron in the hidden layer is given by (16).

$$a^1 = f^1(IWp + b^1) \tag{16}$$

Whereas a^1 is the output vector from the input layer, *IW* is the weight matrix of input, f^1 is the hidden layer transfer function and b^1 is the hidden layer bias function. Similarly, the first output neuron of the output layer can be expressed as:

$$a^2 = f^2(LW(f^1(IWp + b^1)) + b^2) \tag{17}$$

Whereas a^2 is the output vector of output layer, LW is the weight matrix of output, f^2 is the output layer transfer function and b^2 is the bias vector of output layer. The network is a two-layered feed forward network having with a sigmoid transfer function in hidden layer and a SoftMax transfer function in the output layer as depicted in (18) and (19) respectively.

$$f(n) = \frac{1}{1 + e^{-n}} \tag{18}$$

$$h_\theta(x) = \frac{1}{1 + \exp(-\theta^T x)} \tag{19}$$

The network has 10 neurons in the hidden layer. The network is trained using scaled conjugate gradient backpropagation. The backpropagation is performed on the whole feedforward network in order to improve the results of ANN. This technique is referred to as fine tuning of a whole ANN. The theme is to retrain the whole network in a supervised fashion. In backpropagation training, the goal of training is to mitigate $\lambda(w)$ which is the square error taken over all n vectors.

$$\lambda(w) = \sum_{p=1}^{n} \sum_{k=1}^{k} (d_{kp} - o_{kp})^2 \tag{20}$$

Where d_{kp} and o_{kp} is the desired output and network output for node k and p respectively During training, the backpropagation algorithm fine-tunes the weights that are randomized initially respective to the steepest gradient along the surface of error. Weights are set as per their influence to the output which is done by the method of reusing the squared error signal through weights layers. Training is proceeded by the presentation of each normalized input vector z and its equivalent output target vector d, until each $\lambda(w)$ becomes smaller than the maximum allowable error $\lambda(w)_{max}$. The presentation of complete set of training data to the network is called an epoch.

The performance of ANN is evaluated based on cross entropy. During the learning process, the ANN goes through various stages in which the reduction rate of error is very slow which can influence the learning process. For solution, the mean square error (MSE) is replaced by cross entropy error function. The results of

error function show a better performance having a shorter stagnation period. The original MSE function for all training patterns is given by

$$E_m = \frac{1}{m}\{\sum_{k=1}^{m}\left(t_k - y_k\right)^2\} \quad (21)$$

where t_k represents the target value and t_y is the actual value of network. In the backpropagation technique, the error through the iterative updates of weights is minimized for all training patterns. In practice, this approach allows the network to have a good performance but convergence rate is slow. Therefore, in order to accelerate the backpropagation, we propose the following cross entropy error function to be minimized:

$$E_m = \frac{1}{m}\{\sum_{k=1}^{m}[t_k \ln y_k + (1-t_k)\ln(1-y_k)]\} \quad (22)$$

To minimize the error E_m, each weight w_{jk} is updated proportional to the partial derivative of E_m, with respect to weight. Using the mean square error, the partial derivative of E_m with respect to w_{jk} is

$$\frac{\partial E_m}{\partial w_{jk}} = \sigma.(y_k - t_k)y_k(1-y_k).z_j \quad (23)$$

By using the cross-entropy error function, (20) becomes:

$$\frac{\partial E_m}{\partial w_{jk}} = \sigma.(y_k - t_k).z_j \quad (24)$$

Hence, the error signal that propagates back from each output unit becomes proportional to the difference between target value and actual value. This leads to a better network performance along with shorter stagnation period. A total of 350 samples are used to trained the ANN. The network performance is tested using 150 samples of EMG data.

3. Experiments

3.1. Simulation of Signal Conditioning Circuit

Schematics and simulations of the circuit are carried out using Proteus Software. The differential filter removes the noise by amplifying difference of two signals. This removes the noise due to the skin impedance and terminals of the connecting wires. The bandpass filter selects the frequency range of 100-500 Hz and provides 250x gain, thereby, removing the power line noise and giving an optimum signal in meaningful frequency range. The millivolt signal is amplified to more than 2 volts which is appropriate level for further processing. The impedance of wires interfacing the electrodes and the circuit board is matched to, that of the board mainly, the input of differential amplifier for ensuring the maximum power transfer.

The circuit's performance shows that this configuration of hardware components is suitable for EMG signal acquisition. The fingers movement is depicted in Figure 11. The EMG signal is recorded as a result of individual finger movement. A total of 500 samples are taken from finger patterns which is then used for feature extraction followed by the training, validation and testing of the classifier (ANN).

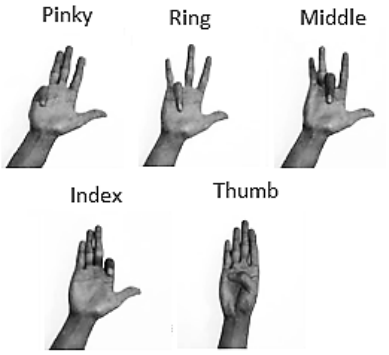

Figure 11: The five fingers movement pattern for EMG signal acquisition

The EMG data acquired from five fingers are sent via serial interface to the Matlab workspace. Shown in Figure 12 are signals for five fingers read through serial port of Arduino in Matlab. The Arduino Hardware support package is used in Matlab for having simplicity in serial interface. This package allows to import the libraries of Arduino in Matlab, therefore, giving a sophisticated way to program the controller in Matlab and to read serial data from its serial interface. The data read in Matlab is stored in an array form in the workspace of Matlab.

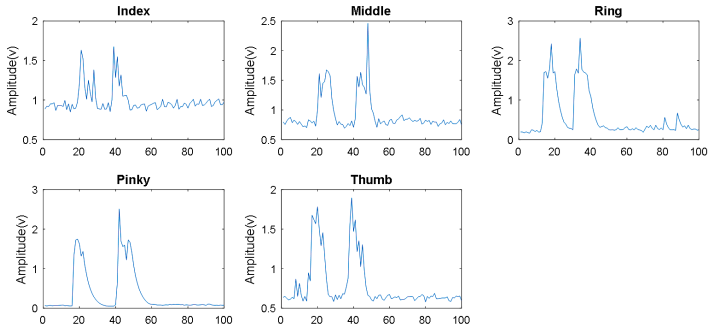

Figure 12: The five fingers EMG signals read in Matlab

3.2. Feature Extraction and Classification

The feature extraction and classification was performed in Matlab 2017a software. Discrete Wavelet Transform (DWT) was used for feature extraction from EMG signals. The Daubechies 4 or db4 wavelet window is used for best correlation with EMGs as discussed previously. It provides approximation and detailed coefficients containing information related to shape of signal and sharp variations in the signal respectively. The detailed coefficients or high frequency components as shown in Figure 13 are used as feature vectors for training of the classifier.

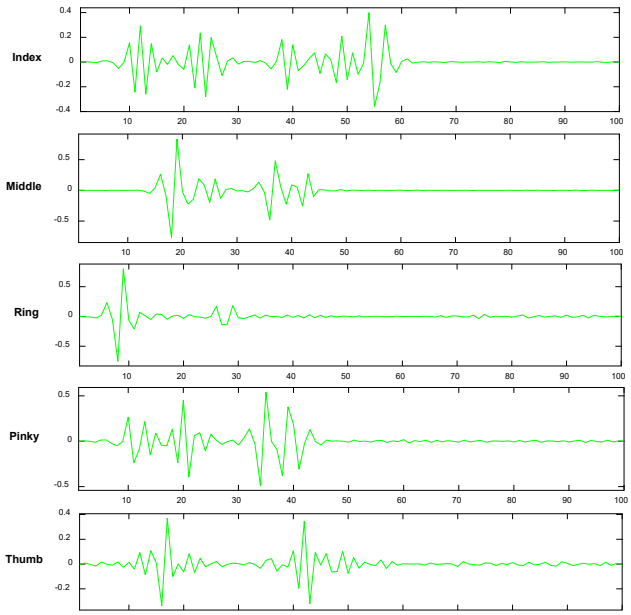

Figure 13: The DWT detailed coefficients of five fingers respectively.

3.3. Cross Entropy

During training the ANN, there is a measure of error between computed outputs and the desired target outputs of the training data. The most common measure of error is called mean squared error. The performance of ANN based on cross entropy is shown in Figure 14(A). The results show best performance of 0.024758 at epoch 27. The steep fall of training curve shows best performance of ANN achieved during training. The performance of ANN is tested by 150 samples of data which is depicted in the curve of testing. The ANN converges to output in a very small stagnation time as can be seen in Figure 14(A).

3.4. The Confusion Matrix

The confusion matrix is used to estimate the quality of the output of a classifier on the specified data set, providing an insight of the errors and specially the types of errors made during the classification. The diagonal elements characterize the number of samples correctly classified by the classifier, while non-diagonal elements are those that are misclassified by the classifier. The higher values in diagonal depicts the better accuracy of the classifier. The theme is to divide the correct predictions by total no of predictions made by the classifier to output the percentage accuracy as given below.

$$Accuracy = \frac{\sum_{p=1}^{n}(y_p)}{n} * 100 \quad (25)$$

Whereas y_p corresponds to correct classification taken over n patterns. The confusion matrix showing the results of ANN classification using 10 hidden neurons are shown in Figure 14(B). The confusion matrix of SVM is shown in Figure 15.

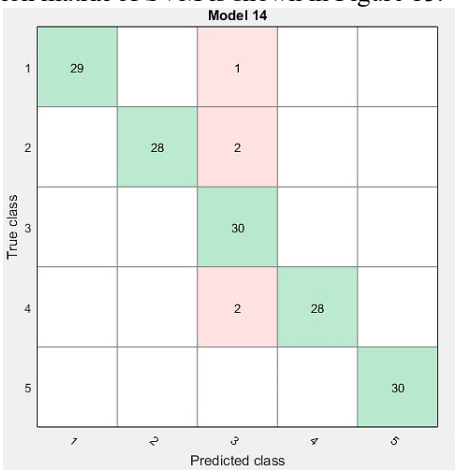

Figure 15: The confusion matrix of SVM

The overall accuracy of classification is calculated to be 96.7%. The ANN matrix shows an excellent classification accuracy of 98.7% which is an edge over the accuracy of SVM. The classification accuracies using SVM for each finger are given in Table 1 whereas the classification results of ANN are listed in Table 2.

3.5. The Receiver Operating Characteristics

Receiver Operating Characteristic (ROC) curve is also used to assess the classifier output performance. ROC curve plots the True Positive Rate (TPR) on Y axis, and False Positive Rate (FPR) on X axis. This characterizes an ideal point, a false positive rate, to lie on the top left corner of the plot, giving a FPR of zero, and a TPR of one. This type of characteristic gives a greater area under the curve (AUC) for achieving best performance. The Figure 14(C) shows the ROC of ANN output. Figure 16 shows the ROC of

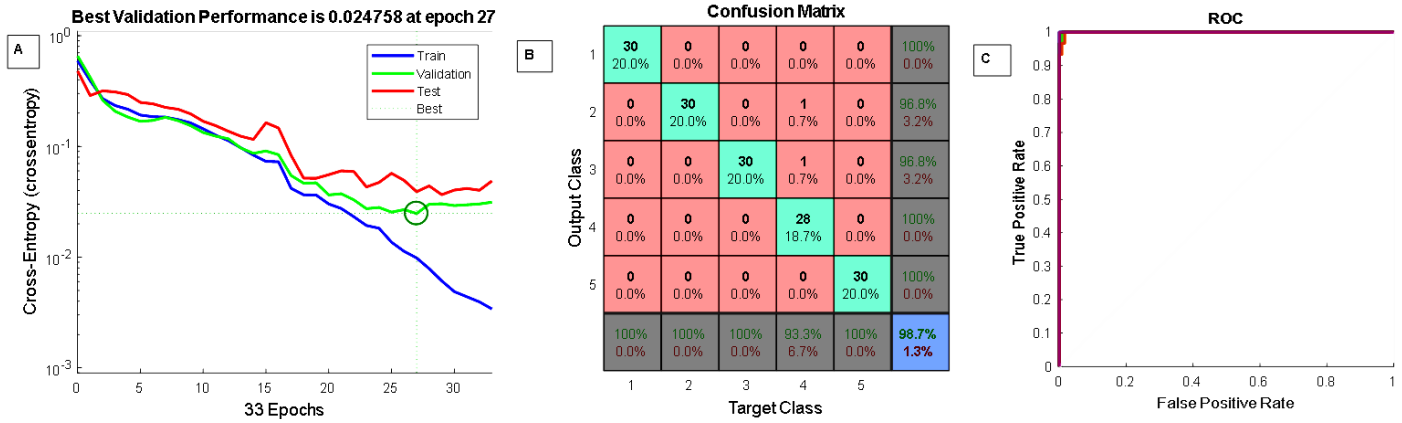

Figure 14: The plots showing the performance of ANN. (A) shows the performance of ANN training, validation and testing respectively. (B) shows the confusion matrix classification results of ANN obtained using 10 hidden neurons. (C) shows the ROC for five classes respectively.

SVM. The ROC curve of ANN is the representation of an excellent performance, giving AUC = 0.983, whereas, the ROC for SVM is 0.978. The steepness observed in curves of both ANN and SVM is also very significant, thereby, maximizing the TPR while minimizing the FPR.

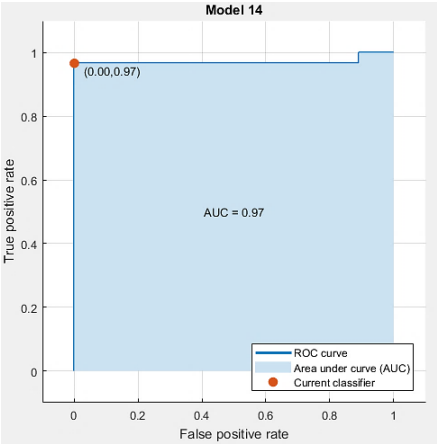

Figure 16: The ROC of SVM

Table 1 Classification accuracy of five fingers using SVM

Finger Name	Total Samples	Classified samples	Accuracy	Error
Index	30	29	96.67%	3.33%
Middle	30	28	93.3%	6.7%
Ring	30	30	100%	0%
Pinky	30	28	93.3%	6.7%
Thumb	30	30	100%	0%
Overall Accuracy & Error			96.7%	3.3%

Table 2 Classification accuracy of five fingers using ANN

Finger Name	Total Samples	Classified samples	Accuracy	Error
Index	30	30	100%	0%
Middle	30	30	100%	0%
Ring	30	30	100%	0%
Pinky	30	28	93.3%	6.7%
Thumb	30	30	100%	0%
Overall Accuracy & Error			98.7%	1.3%

4. Conclusion

A noise free and an optimum EMG signal is captured by the signal conditioning circuit. The feature vectors obtained through DWT is best for feeding the classifier as it provides maximum correlation with EMGs. The binary SVM is made capable of solving five class finger recognition problem via multiclass approach. The SVM showed an overall accuracy of 96.7% with an average error rate of 3.3%. The two-layered feed forward network showed an excellent performance over the SVM in the classification of EMG signals showing a minimum error of 1.3%. The accuracy is improved to 98.7% with 10 neurons being used in hidden layer. The network is converged in a small stagnation time. In future work, the two-layered feed forward network can be extended to multilayered deep networks, for improving the classification accuracy. Moreover, the multiclass SVM and ANN network proposed can be used to recognize several hand gestures at certain degrees of freedom proving more robustness in the prosthetics control specially for amputees.

Conflict of Interest

No any.

ABSTRACT

In this paper considered the movement of multi-agent system that consists of several UAVs that carry out monitoring ground surface. The multi-agent system includes a lead agent and several agents-members of the group. The motion of this system occurs along a trajectory, which is determined by the initial conditions, its mathematical model and obstacles on the route. Only the leader of the group knows the ultimate goal of the movement. The motion of this structure is considered in the potential field, which determined the forces of attraction and repulsion and created control signals by measuring the distances to the nearest neighbors. This allows the UAV group to consider an aggregate that has some size and to describe its motion the system of differential equations of second-order. As UAV selected Quadrotor. In this investigation, the stability conditions of such motion are considered, and simulation of approach is proposed.

1. Introduction

UAV is a popular air reconnaissance platform due to developed technologies that it were allowed to use a large number of constructive elements and motion control components for its creation. Now developers of unmanned vehicles pay attention to air platforms with the possibility of vertical launch and landing and existence a programmable control such as a Quadrotors that were developed recently.

Compared with other types of UAVs the Quadrotor differs accuracy of positioning, fly stability, allowable flight time, payload, and reliability. Such platforms can not only carry a payload, but also fly a flexible program. Their main tasks can be ground surveillance, execution of search and rescue operations, fire detection, cargo operations and military tasks. The advantage of the UAV is a low cost operation, no pilot that rules out the risk of loss of human life, existence software for performance of variety problems.

Intuitively, we can assume that application of the group of UAVs is more effective than the application of one aircraft. As parameters of evaluation of the effectiveness of the group except for accuracy and time performance can be the number of assignments, objectivity and reliability of its performance. However, group behavior is more difficult than the behavior of one UAV.

An important task, as in the case of one UAV, is path planning of a group. This task complicated the flight safety requirement. The distance between UAVs should be neither small, nor very large in order to keep the integrity of the group. Usually minimum distance between elements of group must not less than 2-3 maximal length of aircraft. The requirement of flight safety is achieved by increasing the distance between the UAVs. Maximum distance must to accord stable communication between elements of group. Thus for maintaining the integrity of the group distance between agents should not be too large.

Group's elements should know how to interact in order to achieve mission goal. To solve it, we consider methods that are based on behavior of herds of animals, birds and insects. Unfortunately, not all of them are suitable for application in technical means because it needs definition the man-operator role, group of UAVs should not be too large otherwise it technical and calculated complexity realization of this system will lead to expensive of managing system. Flight control of big UAVs team is need transmission the significant data flow and increasing time on decisions making.

*Corresponding Author: Dmytro Pavlovich Kucherov, National Aviation University, Educational and Scientific Institute of Computer Information Technologies, 03680, Ukraine, Email: d_kucherov@ukr.net

For solving main problems, the behavior of group used agent-based approach as usually. Tasks performance also should be provided by mechanisms and procedures of interaction for achieving common goal. The classic approach to solving this problem is the use in scientific works of methods based on the analogies with sociality in animals and especially in insect societies. However, not all of these methods are suitable for use in technical means, as a group of technical agents usually manages by human operator, the group consists of a limited number of UAVs, and it must operate in a real environment where there is interference and obstacles movement. Considering these properties increases the flow of data in the system, leads to an increase computational and technical complexity of a system.

In some cases, the performance of tasks limited interference of artificial or natural origin. Impact of power interference on the group flight leads to restructure of a group or change the route in order to achieve flight objectives. Thus, the interference signals should be known for synthesis of a control law.

The problem formulation involves the traditional description of group behavior as a dynamic system with restrictions on the intervals and the distance between the individual elements of the group. The group performs the movement on a route. There are fixed obstacles that located on the path of its movement. The mission of a group is to reach the goal and to avoid collision on the route.

In this paper considered movement of Quadrotors group that carry out monitoring of ground surface. Main problem of this task we consider the maintenance the group size for following of the route. Group consists of an agent-leader and agent-members that are fulfil their task in some closed region, where located an obstacles. One of problems that should be solved is to overcome an obstacles type of «bottleneck» on a route of UAVs.

The structure of this paper is organized as follows: in the next section, related work on the behavior of UAVs group is reviewed. Section 3 gives the system model and problem formulation. Section 4 provides movement stability study in different condition. The control laws for movement with and without obstacles are also proposed. Analysis of a Quadrotor model as a group element conducts in Section 5. Simulations conducts in Section 6. Section 7 concludes the paper.

2. Related work

This paper is an extension of work originally presented in International Conference “Methods and Systems of Navigation and Motion Control (MSNMC)” [1], which considered a description of group dynamics UAV in the presence of fixed obstacles.

Despite the fact, that currently drawn a lot of reviews and publications on multi-agent systems, the most common questions about this type of systems given in [2]. This monograph introduces the concept of autonomous agents capable of performing independent activities. Generalized architecture of agent system has three levels of management that are answer for the planning, conduct and interaction of the system.

The results of the use of multi-agent systems when performing practical tasks is given in [3-6]. In [3], for example, using the principles of ant colony for wireless sensor networks and new routing functions is considered. The proposed algorithm of optimization synthesized by on a probabilistic procedure, whereby authors cannot reduce the amount of computational operations that occur during the delivery of information packets. The positive results obtained by the authors using known approaches based on search algorithms, evaporation and aggregation.

In [4] proposed algorithms coordination and optimization of multi-agent system RobotCup to perform rescue operations. Coordination of agents carried out on protocol that provided by some agreements and optimization by the way modified A* algorithm and search Nilsson’s algorithm. The work demonstrates the advantages of decentralized management for these tasks.

The authors [5] consider UAV swarm consisting of Quadrotors whose actions modeled by algorithms of behavior of animals and insects swarm. Conducted experiments revealed that quality of multi-agent system depends on the number of agents, but increases the number of links in the group, making it difficult to manage the system.

The problem of robot control and dynamic goal on surface coordinates is represented in [6]. Robot movement occurs in additive potential field of attractive and repulsive forces. These functions depend on mutual positions, velocities, and accelerators between robot and goal. If deviation of position, velocity and acceleration of the robot from the corresponding goal coordinates is equal to zero, robot is stopped.

Tracking the robots of a moving goal are presented in [6], [7]. The movement of vehicles [6] and UAVs swarm [7] occurs in the additive potential field forces of attraction and repulsion. The resulting force depends on the relative position, speed and acceleration, developed between robot and objective. Stopping robots is performed on speed and acceleration coordinates.

In [7] considered movement of swarm of UAVs for target tracking. The UAVs swarm moving to the target in artificial potential attractive and repulsive field. Attractive field will lead any free agent to the swarm. Repulsive field helps to avoid collisions and to save constant distance between the systems. Authors propose main ideas with respect to analytical relations for description of potential field.

The authors [8] introduced the concept of aggregation for movement and control operations of units with kinematic links. Agents described by integrators and transition to another positions performer in sliding mode. The main goal this movement lies in the avoidance of "unfavorable" positions on the way. Motion carried in potential field, which is a closed area some size. The disadvantage of this presentation is to use a large amplitude control signals which cause the sliding mode of agents, leading to at least to delay the process control.

The authors [9, 10] offer a description of the actions the group of agents for computer network. Agents’ actions are based on the protocol of negotiations between neighbors, according to them the agent network is created on principles of self-organization. To support cooperation agents and avoid delays in the process of organizing the authors suggest a mechanism of mutual concessions and the management on algorithm Q-learning.

In solving practical problems the most interesting is route planning. Recent results on the topic presented in [11-13]. The combination of advanced heuristic search algorithm A^* and stochastic dynamic programming approach in planning the trajectory of an unmanned ground vehicle is proposed in [11]. To

avoid the pits, ditches and congestion on the route, the unmanned vehicle uses information from optoelectronic sensors, which it is equipped, to optimize the route in real time.

Planning of the route with fixed wing of UAVs by using differential geometry solved in [12]. For carrying out the maneuver type of slew for a minimum time with constant velocity authors propose to build a route on well known Dubins path, arcs curves submitted semi-circles and segments of straight lines, but the lateral acceleration becomes intermittent. Continuousness of acceleration achieved using Pythagorean hodograph. In [13] authors solve a similar problem by Bezier curves.

For a stable and reliable work group is responsible communication subsystem. In [14, 15] addresses the problem of providing subsystem reliability data. Common approaches to the design of the subsystem presented in [14], especially that arising in data and algorithms for their consideration could be found in [15]. Planning methods trajectory shown in graph theory [16]. The motion work is carried out within the given trajectories. In this paper, movement is viewed as completely determined task at a constant speed and without interference.

Mission of path planning can be solved by methods of graph theory as shown in [16]. Robots are moving between spots of interest. Authors assume robot movement to determinate the order with the constant velocity and without obstacles.

An approach of tracking UAVs for the moving target is presented in [17]. The movement of a UAVs swarm occurs in attractive and repulsive fields that created regarding robot-leader by state feedback controller. However, Lyapunov criterion that is applied in the work, assumes stability only in the asymptotic behavior at large time interval, and it may not be applicable in the presence of obstacles.

The problem of surveillance by swarm of UAV of moving target given in [17]. Movement of swarm occurs in a potential field created robot's controllers relatively leader by feedback. Proposed the Lyapunov criterion for evaluating the stability of motion has effect only on a large interval of a time, and it cannot used in presence of interference. Practical realization where robot follow to target with radio interference was given in [18]. Unfortunately, the proposed method is not suitable for controlling the UAV.

Compared to [1], in this work is developed synthesis UAV traffic control for a limited size group, which is not fixed and it can increase with rounding maneuvers and obstacles.

Compared to previous work, are proposed in this paper the algorithms of explicitly solution of the task moving in bounded conditions. The main algorithm creates two tasks. First task is to save dimension of the group when naturals or imitation obstacles of increase its dimension. Second task is to guarantee performance of the main task of group. To solve these tasks, much used potential field between robot-members within group and feedback control for following for robot-leader of group. Correctness of the proposed algorithm is proved. The details of the algorithms are presented in Section IV.

3. Problem formulation

Let a swarm of N UAVs (further agents) that are indicated as $A_1, \ldots, A_n$, which carry out some task in Euclidean space (x, y, z), for example monitoring or reconnaissance areas of the earth's surface. For this purpose, agents can use known tactics such as "bearing", "wedge" or other, or perform autonomous flight. On Figure 1 we can see the flight by "wedge" the group of UAVS, N=4.

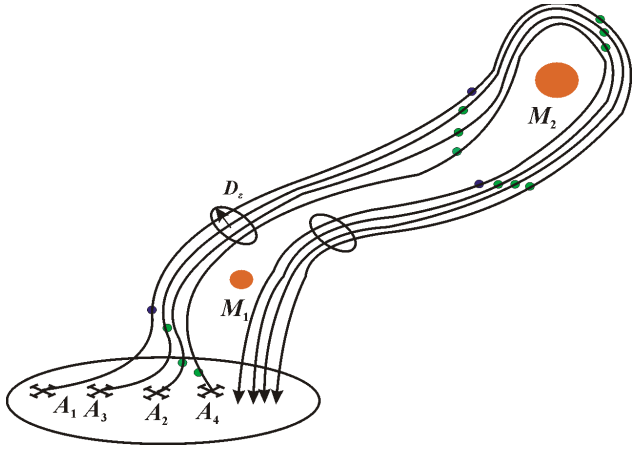

Figure 1. Group of UAVs, N =4

Figure 1 shows the trajectory of UAVs group that forms multi-agent system from the 4-agents and performs the task of monitoring a predetermined route; where there are obstacles M_1, M_2 with known coordinates (x_M, y_M, z_M). To avoid collisions and saving group configuration when performing motion is assumed approximately equal velocity agents $v_i \approx v_j, \ i \neq j$.

Such formation of the agents' behavior we can describe as aggregation with some centroid. In order to perform the task of group, each agent of aggregation is provided with means of communication and motion control. If members act in a limited size, additional members may be joined to this formation. Such formation is a swarm.

Let imagine structure swarm of UAVs as some formation of limited size. Using the terminology of [8], this is formation called aggregate with a center. We assume that each agent provided of communications and control means to carry themselves mission.

Each agent is moving in a three-dimensional Euclidean space. On its rout it can meet obstacles. The agent has vertical takeoff and landing (VTOL) and it therefore is can to bypass obstacles. Thus, agent i-th dynamic is described in space position as p_i with coordinates $p_i = (x_i, y_i, z_i)$ and it has control signal u_i. We will describe the dynamic model of agent's motion as an integrator of the second order in form [1, 5, 7]

Agents move in three-dimensional Euclidean space, in which can presented obstacles. Existing controls allow them to make the maneuver and get around obstacles. Let p_i is a position of i-th agent and u_i is a control signal in space, $p_i = (x_i, y_i, z_i)$. Then the dynamic model of movement of i-th agent can be described by differential equations of the second order as [1, 5, 7]

$$\ddot{p}_i = k_i u_i. \tag{1}$$

In (1) p_i, u_i are functions of a time t. As in [8] we enter parameter $D_\varepsilon > 0$, which characterizes the size of aggregate that for $\forall t \to \infty$ maintained control signals u_i

$$p_i \to D_\varepsilon(p_c), \tag{2}$$

where position of central agent (leader) in aggregator

$$p_c(t) = \frac{1}{n}\sum_{i=1}^{n} p_i(t), \tag{3}$$

and

$$D_\varepsilon(p_c) = \{p \in \Re^3 : d = \| p - p_c \| < \varepsilon\}. \tag{4}$$

In (4) ε is a constructive parameter, which is determined by the system developer. Equation (4) is a criterion to ensure the integrity of the group.

If on the route of UAVs is obstacles, group configuration is change, it selects a new type of configuration, which ensures their overcoming, in general, it slightly increases the parameter $D(p_c)$ so as to ensure inequality $D(p_c) \le D_\varepsilon(p_c)$. This assume reconfiguring the formation in "a small" and does not change the overall objective of the group.

This paper concerns and solves the problem of the synthesis of the control of group from n UAV, which moves along the route, where there are natural obstacles fixed type, to ensure the fairness of condition $D(p_c) \le D_\varepsilon(p_c)$.

4. Method of potential field

As in [6-8, 17], we submit multi-agent system a field of agents, which is formed by forces of attractive and repulsion. Attractive energy supports the chosen configuration, and the repulsion energy keeps agents from collisions among themselves and with obstacles.

As known [19], the energy of a potential attractive field is described by

$$E_{att}(\Delta p) = \frac{1}{2}\mu(\Delta p)^2, \tag{5}$$

where $\mu > 0$ is scaling factor, and $\Delta p_i = \| p_i - p_c \|$ is the Euclidian distance between the i-th agent and the agent centric. The view of relation to centric agent A_c in uniform attractive field is show on Figure 2. This field is weaker in the center and stronger on edges.

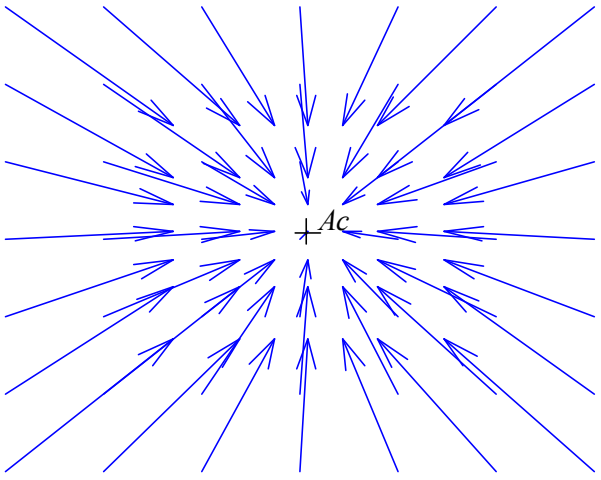

Figure 2. Attractive field acting on agent A_c

Forces of attractive field is constructed as [20]

$$u_{att}(\Delta p) = -grad\ E_{att}(\Delta p) = -\ \mu(\Delta p). \tag{6}$$

The repulsive energy is calculated as [19]

$$E_{rep}(\Delta p_i) = \begin{cases} \frac{1}{2}\nu\left(\frac{1}{\Delta p_i} - \frac{1}{d_0}\right)^2, & if\ \Delta p_i \le d_0, \\ 0, & if\ \Delta p_i > d_0, \end{cases} \tag{7}$$

where $\nu > 0$ is scaling factor, $d_0 > 0$ is constant, which determines the maximum distance of action on the closest agent. Veiw of repulsive field built in accordance to (7) shown on Figure 3. This field is stronger in the center unlike attractive field.

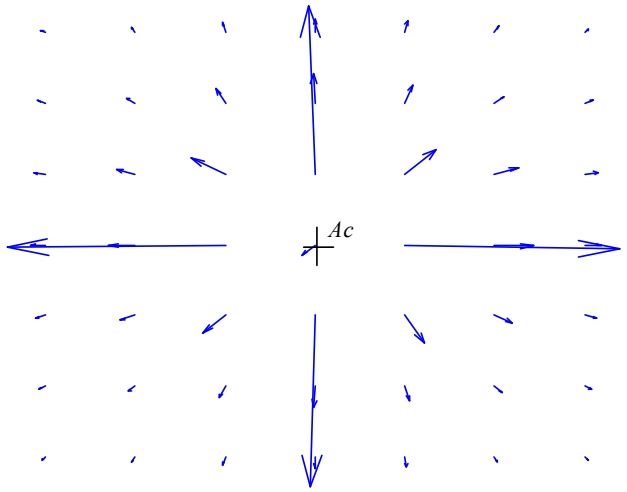

Figure 3. Repulsive field acting on agent A_c

Repulsive forces similarly (6) we can represent as

$$u_{rep}(\Delta p_i) = -grad\ E_{rep}(\Delta p_i) = \begin{cases} \nu\left(\frac{1}{\Delta p_i} - \frac{1}{d_0}\right)\frac{1}{(\Delta p_i)^2}\frac{p_i - p_0}{d_0}, & if\ \Delta p_i \le d_0, \\ 0, & if\ \Delta p_i > d_0. \end{cases} \tag{8}$$

In (8) p_0 is the coordinates to closest agent p_i or obstacle p_M, and

$$d_0 = \max_{1 \le i \le N} \| p_i - p_0 \|,$$

is constant equal of maximum from all of their Euclidean distances.

Then, the general control law, which allows agents to achieve the objectives is the sum of components

$$u_i^g = u^i + u_i^{att} + u_i^{rep}, \tag{9}$$

where u_i is law of motion of i-th agent in the aggregation, and u_i^{att}, u_i^{rep} components, which are determined by formulas (6), (8).

If the i-th agent is the leader of the group, then $u^i = u^l$. Trajectory of leader determined the dynamics of its motion and described by equations, like (1)

$$\begin{aligned} \dot{p}_1^l &= p_2^l, \\ \dot{p}_2^l &= k^l u^l, \end{aligned} \tag{10}$$

where u^l is known law, the trajectories of other agents are being built respect to him. This approach allows to enter two terminate state such as start state (0, 0, 0) and final state (p_k, 0, 0) for each agent system.

Now consider the three types motion of the aggregation to follow on the route: along line, along curve, and with obstacles.

4.1. Motion along line

In this case, the leader moves without acceleration. Then (10) is transformed into one equation

$$\dot{p}_1^l = p_2^l = const. \tag{11}$$

The mission of i-th agent is to save its position in a group, and to prevent exposure on other agents. The control law formed as a control

$$u^i = \begin{cases} -k_{p_1}(p_{1i} - p_{1j}) - k_{p_2}(p_{2i} - p_{2j}), & if\ i,\ \ j\ \ is\ \ memder, \\ 0, & if\ i\ \ is\ \ not\ \ member. \end{cases} \tag{12}$$

For agent leader is set $j = l$. Here $k > 0$ is the positive factor that define velocity of agent-member. In addition, there are a couple of small $\xi_{p1} \neq 0$, $\xi_{p2} \neq 0$ such that deviations $|p_{1i} - p_{1j}| \leq \xi_{p1}$ and $|p_{2i} - p_{2j}| \leq \xi_{p2}$, which occur in (12) and is needed to maintain stable movement.

If the leader is in the center of the group, its coordinates determined by equation (3), namely

$$p^l = \frac{1}{N^*}\sum_{i=1}^{N^*} p_i,\ \ \dot{p}^l = \frac{1}{N^*}\sum_{i=1}^{N^*} \dot{p}_i\ , \tag{13}$$

where $N^* < N$ is the quantity of neighbors or agents in a group. Such type of motion is shown on Figure 4.

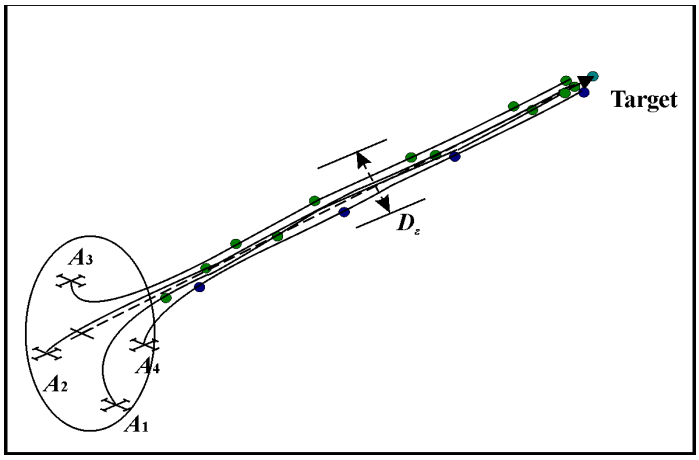

Figure 4. Motion UAVs swarm along line

LEMMA 1. The movement of each agent of group that consist of N agents is described by system of differential equations of second order in form

$$\begin{aligned} \dot{p}_1 &= p_2, \\ \dot{p}_2 &= \overline{u} = -k_{p_1}(p_{1i} - p_{1j}) - k_{p_2}(p_{2i} - p_{2j}). \end{aligned} \tag{14}$$

where $p = p_i - p_j$ is the appropriate coordinates of i-th and j-th agents, $i \neq j$, $i \leq n$, and $j \leq n$. If $j = l$, is a leader of the group member.

Proof. This statement follows from (9), (11).

Corollary 1. Closed loop dynamic system (14) converges to the equilibrium position

$$p_{1i} - p_{1j} \neq 0,\ \ p_{2i} - p_{2j} \neq 0. \tag{15}$$

Corollary 2. Agent-members velocity asymptotically converges to the agent-leader velocity.

Corollary 3. In system (14) coordinates p_i is $p_i \neq p_j$ for any $i \neq j$, $t \geq 0$.

Corollary 4. If $d = \| p_i - p_j \| < \varepsilon$ is maximal size between UAVs in group, the size of formation is $D(p) < D_\varepsilon(p)$.

4.2. Motion along curve

This type of movement is performed with an acceleration, condition (11) is not satisfied, and dynamic system (14) is transformed into

$$\begin{aligned} \dot{p}_1 &= p_2, \\ \dot{p}_2 &= \dot{p}_2^l + \overline{u}. \end{aligned} \tag{16}$$

Coordinates p_1, p_2 in (16) coincide with the same coordinates in equation system (14), but control signal is value $|\overline{u}| < U_{\max}$. This motion type is shown on Figure 5.

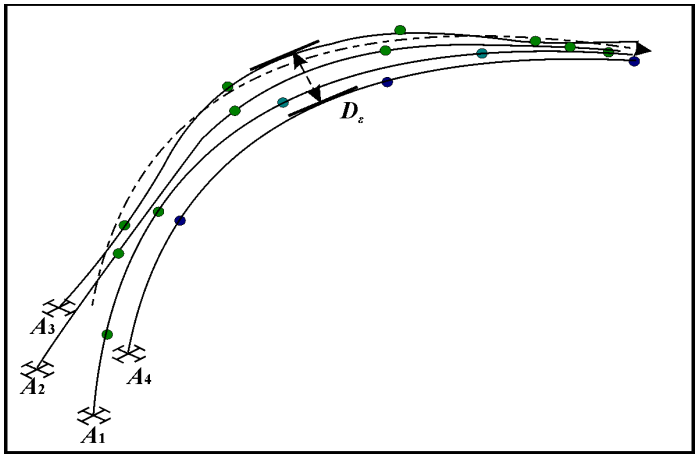

Figure 5. Motion UAVs along curve

LEMMA 2. Let given factors k_y and k_p such as $k_y > 0$, $k_p > 0$ is true inequality $0{,}5k_y / k_p < 0$, system (15) has exponential stability.

Proof. We represent the system of differential equations (16) in the form of a differential equation

$$k_p \ddot{e}_p(t) + k_y \dot{e}_y(t) + k_{\dot{y}} e_{\dot{y}}(t) = 0, \tag{17}$$

where $e_p = p_i - p_j$, $e_y = y_i - y_j$, $e_{\dot{y}} = \dot{y}_i - \dot{y}_l$. If the $k_p \neq 0$, and the (k_p, k_y, $k_{\dot{y}}$) are positive factors, this equation can be represented as

$$s^2(t) + k_y / k_p s(t) + k_{\dot{y}} / k_p = 0. \tag{18}$$

Then condition of exponential stability of (15) is a negative real part of the roots (18) that is satisfied for $k_y/(2k_p) < 0$.

Corollary 1. If $k_y = 0$, we have oscillation movement around leader with constant amplitude and it frequency is equal to $\sqrt{k_{\dot{y}}/k_p}$.

Corollary 2. If $k_y/\sqrt{4k_{\dot{y}}k_p} > 0$, we have asymptotically stability movement.

Corollary3. If $0 < k_y/\sqrt{4k_{\dot{y}}k_p} < 1$, we have oscillation with error that is decreasing.

Corollary4. If $k_y/\sqrt{4k_{\dot{y}}k_p} > 1$, we have aperiodic movement of agent-member.

Corollary 5. If maximal size between UAVs in group is $d = \| p_i - p_j \| \le \varepsilon$, size is $D(p) \le D_\varepsilon(p)$.

4.3. Motion with obstacles

Existing approaches to the consideration of the motion agents with obstacles assume a repulsive force from the obstacle that is located on the route to goal. Action of this forces increases when agent is approaching to obstacle (deceleration of agent), and diminishes with distance. In order to bypass the obstacles, agent should make additional efforts that will lead to the deflection of the original route. It can be made by introducing repulsive force of the additive components of the agent respect to velocity and acceleration of motion

$$u_i = \begin{cases} u_{rep\ p_i} + u_{rep\ p_{1i}} + u_{rep\ p_{2i}}, \\ \quad if\ (d-2r) \le d_0,\ \ p_{1i} > 0,\ \ p_{2i} > 0 \\ u_{rep\ p_i} + u_{rep\ p_{1i}}, \\ \quad if\ (d-2r) \le d_0,\ \ p_{1i} > 0,\ \ p_{2i} \le 0, \\ 0,\ \ if\ (d-2r) > d_0,\ \ or\ p_{2i} \le 0. \end{cases} \tag{19}$$

In equation system (19) uses

$$u_{rep\ p_i} = k_1\left(\frac{1}{d-2r} - \frac{1}{d_0}\right), \tag{20}$$

$$u_{rep\ p_{1i}} = k_2 p_{1iobs}, \tag{21}$$

$$u_{rep\ p_{2i}} = k_3 p_{2iobs}, \tag{22}$$

value r is the maximal geometric size of an agent,

$$p_{1iobs} = p_{1i}^T n_{aobs}, \tag{23}$$

and

$$p_{2iobs} = p_{2iobs}^{\ T} n_{aobs}, \tag{24}$$

where n_{aobs} is a unit vector pointing from i-th agent to obstacle. The value p_{1iobs} shows agent movement, if $p_{1iobs} > 0$ is agent moving to obstacle and $p_{1iobs} \le 0$ moving from obstacle. Motion of N=4 agent in the presence of obstacles is shown on Figure 6.

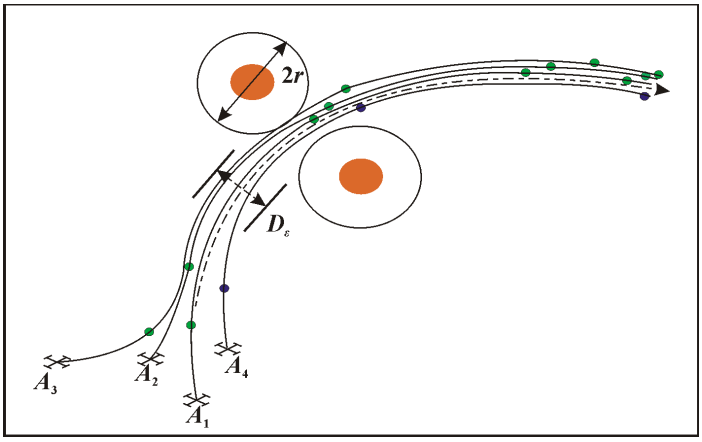

Figure 6. Motion N=4 UAVs in obstacles

The order to overcome the obstacles type of bottlenecks, as shown in Figure 6, is determined by the control signal, that is defined by the equation (19), and UAVs are sorts in order decreasing its velocity, $p_{1N} < p_{1(N-1)} < \ldots < p_{12} < p_{11}$. Sorting can be done otherwise if you choose group leader as a reference.

5. Quadrotor model

As a dynamic model of UAV selected model Quadrotor that management is simple, stable movement, the ability to hang in the air. A complete description of the model is described in [21]. Model of Quadrotor is presented by following equations system

$$\begin{cases} \ddot{\phi} = \dot{\theta}\dot{\psi}\left(\frac{I_y - I_x}{I_x}\right) - \frac{J_r}{I_x}\dot{\theta}w + \frac{l}{I_x}U_2, \\ \ddot{\theta} = \dot{\phi}\dot{\psi}\left(\frac{I_z - I_x}{I_y}\right) - \frac{J_r}{I_y}\dot{\phi}w + \frac{l}{I_y}U_3, \\ \ddot{\psi} = \dot{\phi}\dot{\theta}\left(\frac{I_x - I_y}{I_z}\right) + \frac{1}{I_z}U_4, \\ \ddot{z} = -g + (\cos\phi\cos\theta)kU_1, \\ \ddot{x} = (\cos\phi\cos\theta\cos\psi + \sin\phi\sin\psi)kU_1, \\ \ddot{y} = (\cos\phi\cos\theta\cos\psi + \sin\phi\cos\psi)kU_1 \end{cases} \tag{25}$$

Here (ϕ, θ, ψ) is the roll, pitch and yaw angles, $I_{x,y,z}$ is the inertia UAV, J_r is the inertia rotor, l is the lever in coordinate system with the Quadrotor, k=1/m, m is the mass UAV, w is the rotor speed, and U_1, U_2, U_3, U_4, are calculated as

$$\begin{cases} w = w_2 + w_4 - w_1 - w_3, \\ U_1 = b(w_1^2 + w_2^2 + w_3^2 + w_4^2), \\ U_2 = b(w_4^2 - w_2^2), \\ U_3 = b(w_3^2 - w_1^2), \\ U_4 = d(w_2^2 + w_4^2 - w_1^2 - w_3^2), \end{cases} \tag{26}$$

where b is the thrust factor, and d is the drag factor.

For simulation the model (25) is transformed to a space-state form $\dot{X} = f(X,U)$, where $X \in \Re^{12}$ is the state vector with the coordinates

$$\begin{aligned} &x_1 = \phi,\ x_2 = \dot{x}_1 = \dot{\phi},\ x_3 = \theta,\ x_4 = \dot{x}_3 = \dot{\theta},\\ &x_5 = \psi,\ x_6 = \dot{x}_5 = \dot{\psi},\ x_7 = z,\ x_8 = \dot{x}_8 = \dot{z},\\ &x_9 = x,\ x_{10} = \dot{x}_9 = \dot{x},\ x_{11} = y,\ x_{12} = \dot{x}_{11} = \dot{y}. \end{aligned} \tag{27}$$

Then, we can present equations system as

$$\dot{X} = \begin{cases} x_2, \\ x_4 x_6 a_1 + x_4 a_2 w + b_1 U_2, \\ x_4, \\ x_2 x_6 a_3 + x_2 a_4 w + b_2 U_3, \\ x_6, \\ x_4 x_2 a_5 + b_3 U_4, \\ x_8, \\ -g + (\cos x_1 \cos x_3) k U_1, \\ x_{10}, \\ u_x k U_1, \\ x_{12}, \\ u_y k U_1, \end{cases} \tag{28}$$

where

$$\begin{aligned} &a_1 = \frac{(I_y - I_z)}{I_x},\ a_2 = -\frac{J_r}{I_x},\ a_3 = \frac{(I_z - I_x)}{I_y},\ a_4 = \frac{J_r}{I_y},\\ &a_5 = \frac{(I_x - I_y)}{I_z},\ b_1 = \frac{l}{I_x},\ b_2 = \frac{l}{I_y},\ b_3 = \frac{l}{I_z}, \end{aligned} \tag{29}$$

$$\begin{aligned} u_x &= \cos x_1 \sin x_3 \cos x_5 + \sin x_1 \sin x_5, \\ u_y &= \cos x_1 \sin x_3 \cos x_5 - \sin x_1 \sin x_5. \end{aligned} \tag{30}$$

In contrast to [21], which used to create a sliding mode for control, the control actions (U_1, U_2, U_3, U_4, u_x, u_y) of each agent are smooth functions of time t.

6. Simulation

The motion of group of Quadrotors that moves in the potential field towards to goal on the route on which there are obstacles, is considered.

We assume that this group consists of three agent-members and one agent-leader. The route of agents gives start positions and goal position: $p_{A1}=(100,\ 30,\ 0)^T$, $p_{A2}=(75,\ 20,\ 0)^T$, $p_{A3}=(130,\ 50,\ 0)^T$, $p_{A4l}=(110,\ 70,\ 0)^T$, $p_f=(600,\ 270,\ 0)^T$. The coordinates of the located fixed obstacles on the route are known as $p_{o1} = (270,\ 130)^T$, $p_{o2} = (220,\ 210)^T$, and $D_\varepsilon(p_A) \le 50$. The altitude of obstacles is higher than altitude of Quadrotors that lead to their maneuver in horizontal plane. The altitude for calculations is taken z = 10. The movement of agent-members and agent-leader to target is shown on the Figure 7.

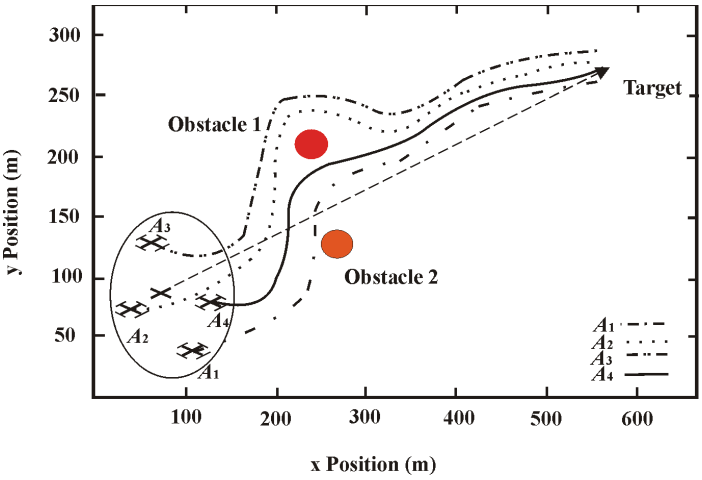

Figure 7. Bypass movement of agent-leader and agent-members to the target

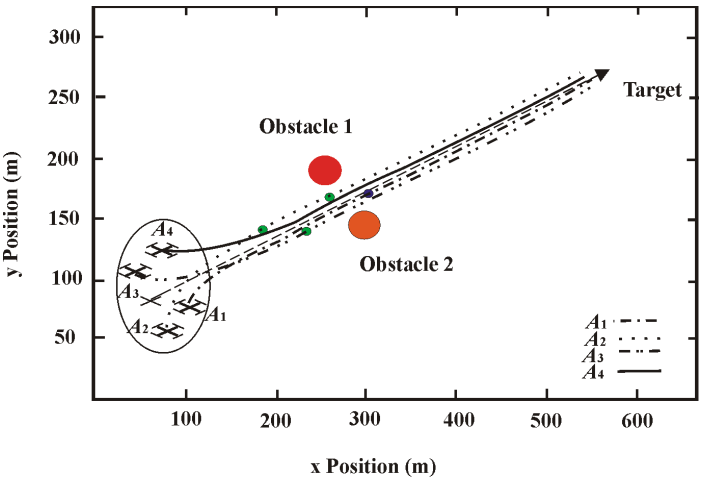

Figure 8. Group of UAVs overcomes side-by-side obstacles by line type motion

Figure 7 shows that group of agents bypasses obstacles and continues its movement to target. Sometimes, when overcoming obstacles group of agents can change its formation size and the formation of agents is remains without changes, if there are no obstacles on the route,.

Figure 8 represents reconfiguration of the group of UAVs in line type motion, if there are located obstacles on the route side-by-side. In this case, the tactic of UAVs is similar to column and UAVs follow in rigidly defined order: $A_4 \to A_3 \to A_2 \to A_1$, where A_1 is the first and A_4 is the last.

7. Conclusions

The paper presents a synthesis of control law of motion of multi-agent system to follow on the route on which possible the obstacles of movement. The feature of the proposed approach is synthesized control law with a smooth function of a time. Two ways of overcoming obstacles, one of them based at the bypassing and the other on reconfiguration are also shown. Control law is formed by two special potential functions, one of which creates an attraction force agents to the center of the structure, the other repels its from neighbors and obstacles. Configuration flight group in terms of obstacles to change, suggesting appropriate changes size and shape.

On the basis of the proposed control law created algorithm by which the simulation was conducted multi-agent system.

Examples of the system behavior modeling show stable movement of the agents. Study of system parameters allow to ensure its stable movement and revealed relevant system parameters. Its behavior includes such stages as gathering into group, tracking on the given trajectory and avoidance of the obstacles. Research shows that successful simulation depends on such parameters as μ and ν of potential function.

In view of the fact that in the conditions of obstacles the movement along the curve is typical, because of which the signal in the control channels increase and it is switch it at a high speed, which is the so-called «sliding mode». The investigation of a multi-agent system in slide mode and effectiveness of proposed potential functions for movement one is the topic of our future research.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

A company's ability to find the most profitable technology is based on a precise forecast of achievement potential. Technology Management (TM) uses forecasting models to analyse future potentials, e.g. the Gartner Hype Cycle, Arthur D. Little's technology lifecycle or McKinsey's S-curve model. All these methods are useful for qualitative analysis in the planning of strategic research and development (R&D) expenses. In a new approach, exponential and logistic growth functions are used to identify and quantify characteristic stages of technology development. Innovations from electrical, mechanical and computer engineering are observed and projected until the year 2025. Datasets from different industry sectors are analysed, as the number of active Facebook users worldwide, the tensile yield point of flat bar steel, the number of transistors per unit area on integrated circuits, the fuel efficiency per dimension of passenger cars, and the energy density of Lithium-Ion cells. Results show the period of performance doubling and the forecast for the end of the technological achievement potential. The methodology can help to answer key entrepreneurial questions such as the search for alternatives to applied technologies, as well as identifying the risk of substitution technology.

1. Introduction

This paper is an extension of work originally presented at the IEEE International Conference on Industrial Engineering and Engineering Management, Indonesia in December 2016 [1]. The positive feedback from the audience helped in writing a more detailed mathematical description of the growth functions. Furthermore, the energy density of Li-Ion cells was analysed and added to the case studies, because of its relevance in future automotive driveline systems. The summary section includes an overview of the technology assessment for this newly added energy storage technology. An extended conclusion shows the influence of the approach introduced on strategical Technology Management. The newly added outlook paragraph discusses the benefits of a fundamental figure-based approach in combination with data mining for strategic decision making in research and development departments. With the help of a reporting system and individually derived performance indicators the future possibilities of making the right decisions will rise. In a big data driven, rapidly growing digital environment, new fields of application in many engineering branches will appear for the integration of the method.

Due to the rapid arrival of substitution technologies, companies are under growing pressure to make fast and sustainable decisions. In the past, even companies with market leader positions such as AOL, Kodak, Nokia and Grundig [2]have disappeared due to their reliance on outdated technology. According to methods such as the Gartner Hype Cycle and the technological lifecycle of Arthur D. Little [3], different stages of maturity describe the acceleration and deceleration of the achievable potential. The beginning and end of technological growth is qualitatively described by the S-curve model [4]. Figure 1 shows a qualitative example of technology substitution due to different growth phases. The objective of this paper is to forecast performance development and maximisation of the achievable potential. Therefore, logistic and exponential growth functions are used to quantify different growth patterns. This paper proposes a mathematical approach for technology forecasting and assessment.

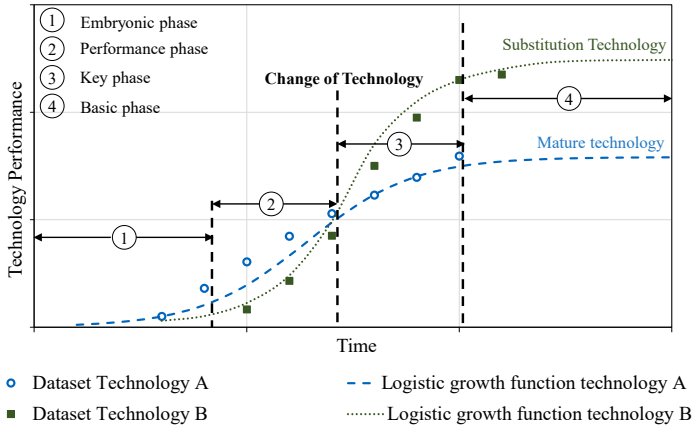

Figure 1: S-curve model, Technology A is substituted by Technology B, the growth phases refer to Technology A [5].

2. Methodology

Data collected from different branches of industry are analysed with the logistic growth function from [6] and [7] to determine the growth phases. If the technology is in its performance phase, the data are fitted with an exponential growth function from [8] to identify the future performance development. The exponential growth is similar to the performance phase of the S-curve model. The overall shape of the S-curve follows the logistic growth function. Figure 2 displays the overlay of the performance phases of a mature technology and a substitution technology that leads to extended exponential performance growth.

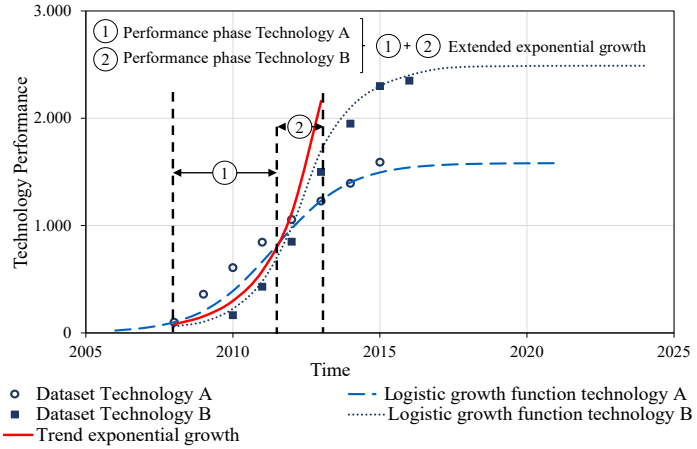

Figure. 2: Extended performance phase by the overlap of two logistic growth functions.

2.1. Mathematical description of logistic growth

Logistic growth is characterised by the growth coefficient r changing over time x, with y representing the performance of the technology and K the maximum value to be approximated, [6], [7]. Equation (1) gives the formula for the growth rate:

$$\frac{dy}{dx} = ry\left(1-\frac{y}{K}\right) \quad (1)$$

A positive slope in the growth rate leads to a continuous rise in technology performance. A negative slope of the growth rate corresponds to a slowdown in performance until the maximum value is approximated, Figure 3.

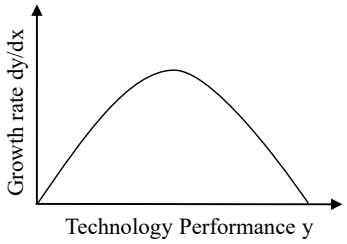

Figure 3: Slope of the technology growth rate

The logistic growth equation (2) follows from integrating (1) with the initial performance value $y = y_0$ at time $x_0 = 0$:

$$y = \frac{K}{1+\left(\frac{K}{y_0}-1\right)e^{-rx}} \quad (2)$$

The relative growth of the performance of a technology divided by the absolute performance y is linear relative to the absolute performance y. The linear equation can be derived from Figure 4.

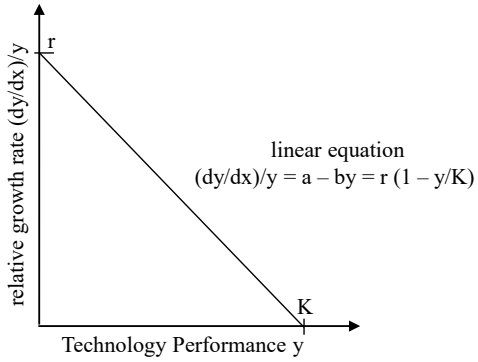

Figure 4: Determination of the growth coefficient r and the max. value K

Relative growth in relation to the absolute technology performance is described by the linear equation (3).

$$\frac{(dy/dx)}{y} = a - by \quad (3)$$

The maximum value K and the growth coefficient r, from (2), can be determined by solving the linear equation (3).

$$a - by = r\left(1-\frac{y}{K}\right) \quad (4)$$

The growth rate r and the maximum value K follow from Equation (4):

$$r = a \quad \text{and} \quad (5)$$

$$K = \frac{a}{b} \quad (6)$$

Given the maximum value K and the growth coefficient r, the logistic growth function from (2) is described completely (see Figure 5.)

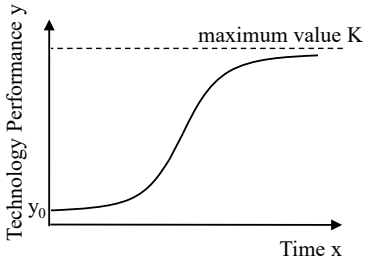

Figure 5: Logistic growth function from Equation (2)

2.2. Mathematical description of exponential growth

As shown in Figure. 2 the sum of the performance phases of multiple logistic growth functions leads to the continuous exponential growth of the technology performance. The effect is valid for many market developments.

Exponential growth is characterised by the growth coefficient r, the starting technology performance y_0 in the embryonic phase and the time x shown in (7) and [8]:

$$y = y_0 e^{rx} \quad . \tag{7}$$

In exponential regression analysis, the existing data y are compared with the values calculated from the exponential curve equation (7). Equation (7) is logarithmised in Equation (8) to apply the method of least squares to the performance phase of a technology, [9].

$$\ln(\hat{y}) = \ln(y_0\, e^{r\,\hat{x}}) = r\,\hat{x} + \ln(y_0). \tag{8}$$

ŷ

$$V = \sum_{i=1}^{k} (y_i - \hat{y}_i)^2 \tag{8}$$

and

$$V\,(r, \ln(y_0)) = \sum_{i=1}^{k} \Big(\ln(y_i) - r\,x_i - \ln(y_0 \tag{9}$$

To determine the constants r and y_0 as two unknowns with two equations, (10) is modified and the partial derivatives are set to zero to obtain the minimum.

Partially differentiating with respect to y_0:

$$\frac{\delta V\big(r, \ln(y_0)\big)}{\delta V\big(\ln(y_0)\big)} = 2 \sum_{i=1}^{k} \big(\ln(y_i) - r\,x_i - \ln(y_0)\big)(-1) = 0 \tag{10}$$

$$\rightarrow \quad \sum_{i=1}^{k} y_i = r \sum_{i=1}^{k} x_i + \ln(y_0) k \tag{11}$$

,

$$\rightarrow \quad \overline{\ln(y_i)} = r\,\overline{x}_i + \ln(y_0) \tag{12}$$

$$\rightarrow \quad \overline{\ln(y_0)} = \overline{\ln(y_i)}\, r\,\overline{x}_i. \tag{13}$$

Partially differentiating with respect to r:

$$\frac{\delta V\big(r, \ln(y_0)\big)}{\delta V\big(\ln(y_0)\big)} = 2 \sum_{i=1}^{k} \big(\ln(y_i) - r\,x_i - \ln(y_0)\big)(-1) = 0 \tag{14}$$

.

$$\rightarrow \sum_{i=1}^{k} (x_i\, y_i) = r \sum_{i=1}^{k} x_i^2 + \ln(y_0) \sum_{i=1}^{k} x_i \tag{15}$$

$$\rightarrow \quad \overline{x_i\, \ln(y_i)} = r\,\overline{x_i^2} + \ln(y_0)\overline{x_i} \tag{16}$$

$$\rightarrow r = \frac{\overline{x_i\, \ln(y_i)} - \overline{\ln(y_i)}\,\overline{x_i}}{\overline{x_i^2} - \overline{x_i}^2} \tag{17}$$

ŷ

(7)

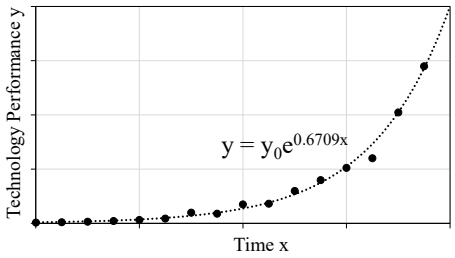

Figure 6: Determination of the growth coefficient r, in the graph r =0.6709, which corresponds to an annual technology growth of 67.09%.

Given the growth coefficient r, the exponential growth function from (7) is described completely. The period during which the performance of technology doubles is calculated with the equations (19) and (20):

$$x = \ln\left(\frac{y}{y_0}\right)\frac{1}{r} \tag{19}$$

Doubling the performance implies $y/y_0 = 2$:

$$\ln(2) = 0.69314718 \approx 0.70 \tag{20}$$

The fact that the natural logarithm of 2 equals 0.7 is the reason behind the 70-Rule, cf. (20), which is used in the automotive industry as a rule of thumb for rapid technology forecast and assessment.

$$x = 0.7\frac{1}{r} = 70\frac{1}{100\ r} \quad (21)$$

In the example of Figure 6, the period of doubling of the technology performance is 70 divided by 67.09, resulting in 1.04 years.

3. Analysed cases

In this section, the mathematical description of the technology performance is compared with actual data from technology undergoing continuous development. Five examples show the dependence of technology performance on growth functions. Each of the examples considered was individually analysed to identify logistic or exponential growth rates. The chosen examples are:

- Number of active Facebook users worldwide
- Tensile yield point of flat bar steel
- Number of transistors per unit area on integrated circuits
- Fuel efficiency per dimension of the VW Golf series
- Energy density of Li- Ion cells

3.1. Number of active Facebook users worldwide

Table I gives the number of active Facebook users from 2008 to 2015 [10]. The data considered for the analysis begins in 2008, when Facebook launched French, German and Spanish versions, leading to a surge in users worldwide [11].

Table 1: Annual Number Of Active Facebook Users Worldwide, [10]

Active Facebook users worldwide	
x	***y***
Quarter / Year	Number in millions
Q4 / 2008	100
Q4 / 2009	360
Q4 / 2010	608
Q4 / 2011	845
Q4 / 2012	1,056
Q4 / 2013	1,228
Q4 / 2014	1,393
Q4 / 2015	1,591

Figure 7 shows the determination of the growth coefficient r = 0.791 and the maximum value K = 1,582 using the linear equation (4).

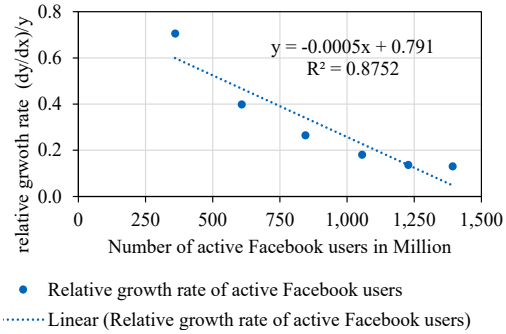

Figure 7: Relative growth rate in relation to the absolute technology performance

Figure 8 displays the S-curve including the coefficients of the logistic growth from equation (2).

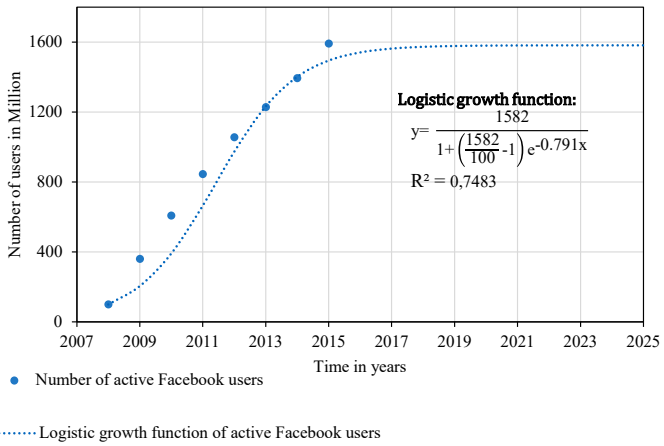

Figure 8: Active Facebook users worldwide, described by logistic growth.

Conclusion: The relative growth rate of active Facebook users worldwide slowed down after the years 2009 and 2010. People without internet access represent the sleeping potential of the technology performance. Despite the slowdown in user growth, no substitute technology has been identified thus far.

3.2. Tensile yield point of flat bar steel

The tensile yield point is a material parameter and designates the tension limit of non-permanent plastic deformation in the material. Table II gives an overview of the technological progression of the achievement potential.

Table 2: Tensile yield point of flat bar steel [12]

Tensile yield point of flat bar steel	
x	***y***
Year	*Tensile yield point in* MPa
1926	355
1955	460
1965	690
1972	890
1980	960
1996	1,100
2013	1,200

Figure 9 shows the linear equation of the relative growth rate in relation to the absolute technology performance. Solving the linear Equation with Equation (4), the values r and K are found to be equal to r = 0.0411, K = 1,500.

Figure 10 displays the logistic growth function adapted from r = 0.0411 to 0.03 due to a minimum set of data pairs relative to the period.

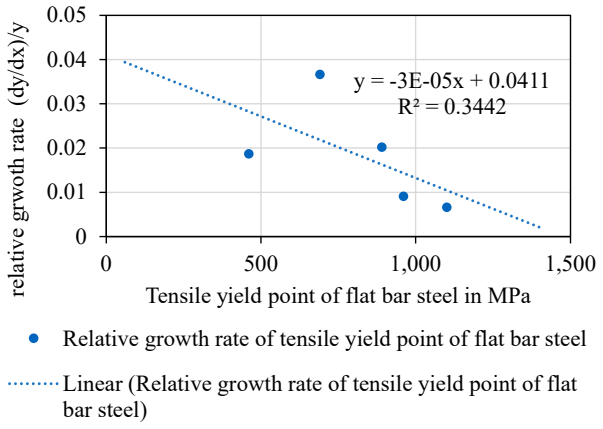

Figure 9: Relative growth rate in relation to the absolute technology performance of flat bar steel

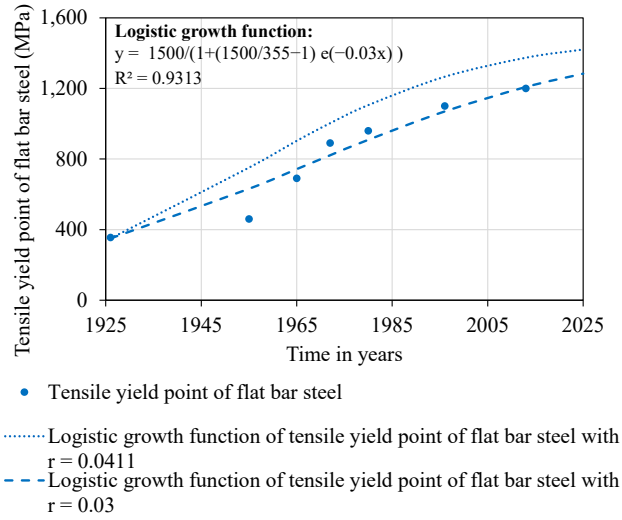

Figure 10: Logistic growth function of the tensile yield point of flat bar steel with adapted growth rate from 0.0411 to 0.03.

Conclusion: The tensile yield point of flat bar steel from [12] has left the performance phase and is now in its key phase.

3.3. Number of transistors per unit area on integrated chips

The number of transistors per unit area on integrated circuits is designated as the integration density, [13]. In 1965 Gordon Moore, Co-founder of Intel, predicted that the integration density will double every 12 to 24 months. This observation is known as Moore's law. In [14] the executive Vice President of Intel William M. Holt, showed that there are leading technology options in the near future beyond complementary metal-oxide-semiconductors (CMOS) that can advance the exponential prediction of Gordon Moore. Table III depicts the integration density development.

Table 3: Overview of Integration density development on integrated chips [13]

Number of transistors per unit area on integrated circuits (integration density)		
Processor	***x***	***y***
	Year	Integration density
Intel 4004	1971	2,300
Intel 8008	1972	3,500
Intel 8080	1974	4,500
Intel 8088	1979	29,000
Intel 80286	1982	134,000
Intel 80386	1985	275,000
Intel 80486	1989	1,180,235
Pentium	1993	3,100,000
AMD K5	1996	4,300,000
Pentium II	1997	7,500,000
Pentium 4	2000	42,000,000
AMD K8	2003	105,900,000
Itanium 2 with 9MB cache	2004	592,000,000
Cell	2006	241,000,000
Core 2 Duo	2006	291,000,000
Six core opteron 2400	2009	904,000,000
8-core Xeon nehalem-ex	2010	2,300,000,000
8-core Itanium Poulson	2012	3,100,000,000
Xbox One main SoC	2013	5,000,000,000
22-core Xeon Broadwell-E5	2016	7,200,000,000

Figure 11 shows that the mathematical determination of the growth coefficient r and the maximum value K with (4) is not possible. The reason is the continuous relative growth rate of the integration density, which has not slowed down over the years.

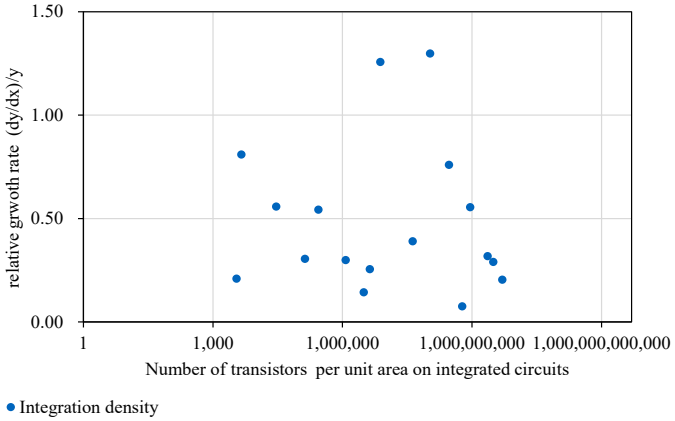

Figure 11: Relative growth rate over a number of transistors per unit area on integrated circuits.

According to [14] the exponential growth of the integration density is based on the substitution of the process and the device technology. This leads to an extension of the performance phase. Figure 12 gives an overview of the innovations leading to the performance increase. The exponential fit uses the method of least squares from [9].

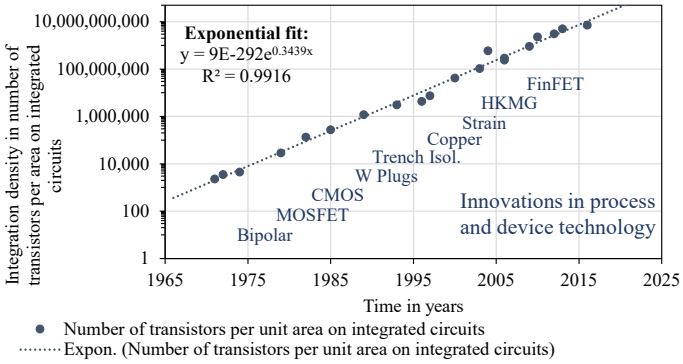

Figure 12: Exponential growth of integration density on logarithmic scale

Conclusion: The trend demonstrated in Figure 12 shows the substitution of process and device technology leading to an extended performance phase. The time for doubling the number of transistors per unit area is around 2.04 years, taking into account an annual growth rate of 34.39 %. Moore's prediction from 1965 is still valid.

3.4. Fuel Efficiency per dimension of VW Golf series

The automotive industry faces new challenges such as carbon dioxide (CO_2) legislation in Europe with an upper limit of 95 g/km for every newly licensed passenger car from the beginning of 2020 [20]. In the United States, the Environmental Protection Agency (EPA) tightened the regulatory programme to 225 gram CO_2 per mile for passenger cars [21] this year. As a contrary trend, vehicle dimensions (length, width, height) are still increasing. Table V shows the fuel efficiency in kilometre per litre and the growing dimensions of the VW Golf series since 1976. That year, the VW Golf had its start of production (SOP) with its first diesel engine.

Table 4: Fuel efficiency Per vehicle dimensionS of VW Golf series I to Vii [22], [23], [24]

Fuel efficiency per vehicle dimension of VW Golf series (diesel engine)							
	x						***y***
Series	Year of SOP	l/100 km	km/l	hp	ccm	*l w h in* m³	*(*km/l) m³
Golf I	1976	5	20.0	50	1,500	8.4	167
Golf II	1983	5	20.0	54	1,577	9.4	188
Golf III	1996	5	20.0	110	1,896	9.7	194
Golf IV	1997	4.9	20.4	110	1,896	10.4	211
Golf V	2007	4.5	22.2	105	1,896	11.0	244
Golf VI	2009	4.1	24.4	105	1,598	11.0	269
Golf VII	2012	3.8	26.3	105	1,598	11.1	292

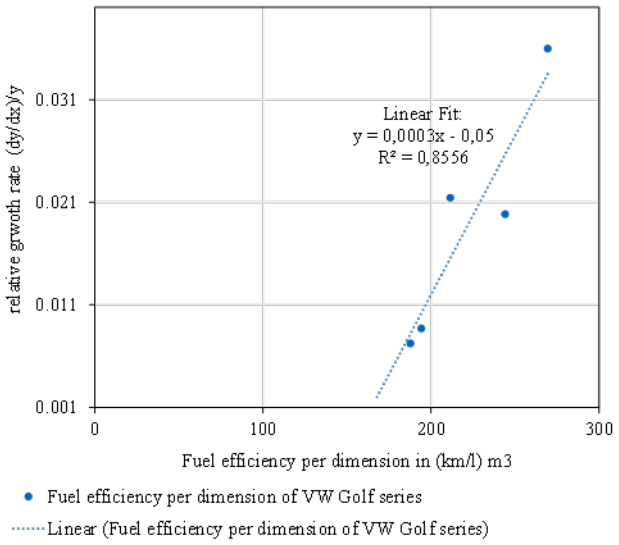

Figure 14 displays the exponential growth of the fuel efficiency per dimension. The coefficient of determination shows a correspondence of $R^2 = 0.9062$.

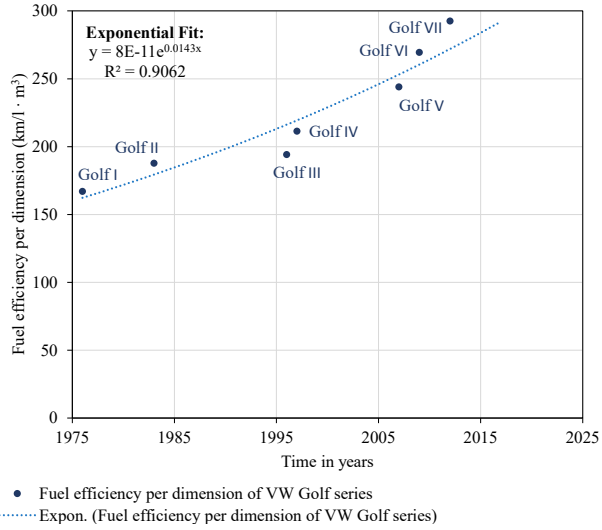

Figure 14: Exponential growth of fuel efficiency per vehicle dimension of VW Golf series.

Conclusion: The fuel efficiency per vehicle dimension of the VW Golf series is exponentially increasing. The fuel efficiency of successive generations of vehicles has improved despite the increasing vehicle dimensions (length, width and height). The substitution of technologies in each vehicle generation has caused this effect, leading to the extension of the performance phase. The exponential annual growth rate determined amounts to 1.43 %. The 70 rule predicts a doubling of performance in 48.95 years.

3.5. Energy density of Li-Ion cells

Over the next ten years, Li-Ion cells will not be only used in stationary and portable applications. According to [20], about 50 % to 70 % will be used in electro-mobility.

Table 5: Energy density of Li-ion cells with 18650 format [21], [22], [23] and [24]

Energy Density of LI-Ion cells	
x	***y***
Year	*Density in* Wh/kg
1992	100
1996	110
1998	130
2000	140
2001	150
2002	160
2004	180
2005	200
2009	210
2010	230
2012	270

Figure 15 displays the relative growth of Li-Ion cells compared to technology performance in Wh/kg. The linear equation from (4) cannot be solved, as the relative growth rate does not slow down, while the growth coefficient r for logistic growth and the maximum value are not identified. The reason is the ongoing exponential growth.

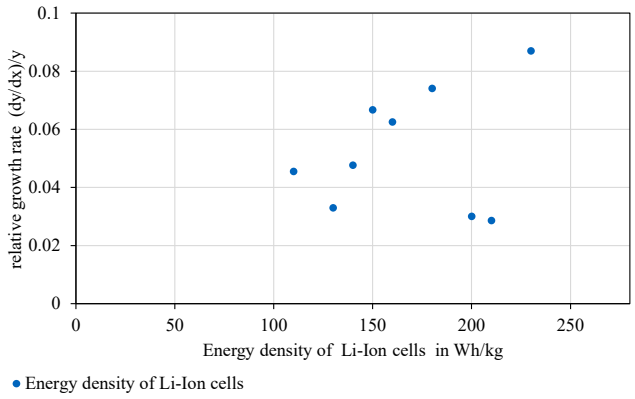

Figure 15: Relative growth rate over energy density of Li-Ion cells

In Fig 16, the exponential fit shows a correspondence of 0.976 for the coefficient of determination R^2. Data points were matched with the names of cells from Sanyo/Panasonic.

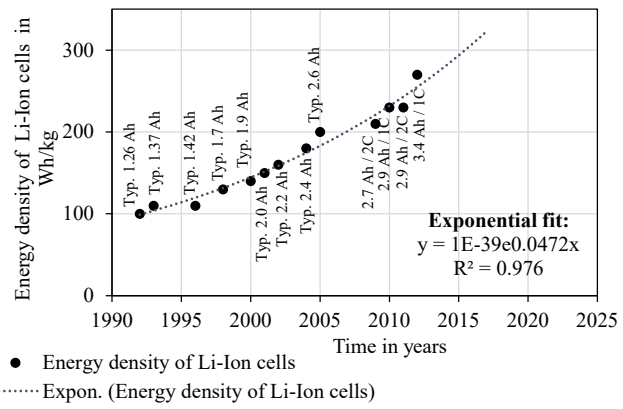

Fig 16: Exponential growth of energy density of Li-Ion cells.

Conclusion: The energy density of Li-Ion cells is still in its performance phase. The substitution of the material composition of anode, cathode or separator leads to the extension of the exponential performance. The ongoing exponential growth has an annual growth rate of 4.72 %. Using the 70 rule, a performance doubling of the energy density in Li-Ion cells can be expected in 14.83 years. The Fraunhofer Institute for System and Innovation Research predicts that post-Li-Ion technology can reach a performance of up to 500 Wh/kg on the level of individual cells [20].

4. Summary and Conclusion

In response to the rising demand of companies to make reliable decisions based on TM and technology road maps, this paper proposed a mathematical approach for technology forecasting and assessment. The benefit for academics and industry is a quantitative method for identifying the level of technology maturity. The mathematical description of achievement potential using the logistic growth function has been introduced and compared with the S-curve model. Table VI gives an overview of the analysed case studies.

Table 6: Overview of results

Overview of results		
Technology	***Phase in the S-curve model***	***Period of performance doubling in years***
Facebook user	Key phase	-
Tensile yield point of flat bar steel	Key phase	-
Number of transistors per unit area on integrated chips	Performance phase	2.04
Fuel efficiency per dimension of VW Golf series	Performance phase	48.95
Energy density of Li-Ion cells	Performance phase	14.83

The 70 rule for deriving the period of performance doubling, is a method for forecasting the technological development in its performance phase. Both rules are applied to a series of example cases. The results clearly show that the key technologies such as the number of transistors per unit area on integrated chips, the fuel efficiency per dimension and the energy density of Li-Ion cells are still growing exponentially.

5. Outlook

Further investigation and discussion is needed to clarify whether integrating other relevant aspects that influence the technology performance forecast is meaningful. Firstly, an analysis must clarify which aspects can be considered as relevant for technological growth besides improvements in process and device technology: For instance, it is generally assumed that interdependencies exist between the improvement of the growth rate and aspects such as the financial environment and its

characteristics such as resources, organisational structure and corporate culture. Secondly, the renewal time, during which the technology performance improves, must be measured precisely. It influences the shape of the S-curve model and can lead to transitions between the technological growth phases. Further possibilities, such as data mining and deriving key indicators for research and development topics, e.g. more precise online map data [25], lead to well-grounded decisions in strategic technology management. Technology road maps based on fundamental figures will be more successful in the long run. One of the next steps is the integration of automated search algorithms to gain a larger database for more accurate predictions of growth rates. An approach based on big data can help to gather more information over a shorter period. The future management of research and development will lead to a new dimension of decision-making tools.

Contributions

Special thanks go to Mr. Claudio Sutter, who helped to collect raw data for further investigation into technological growth during his master's thesis in 2015.

ABSTRACT

Cloud computing is a power platform to deal with big data. Among several software frameworks used for the construction of cloud computing systems, Apache Hadoop, which is an open-source software, becomes a popular one. Hadoop supports for distributed data storage and the process of large data sets on computer clusters based on a MapReduce parallel processing framework. The performance of Hadoop in parallel data processing is depended on the efficiency of a job scheduling algorithm underworking. In this paper, we improve the performance of the well-known fair scheduling algorithm adopted in Hadoop by introducing several mechanisms. The modified scheduling algorithm can dynamically adjust resource allocation to user jobs and the precedence of user jobs to be executed. Our approach can properly adapt to the runtime environment's condition with the objective of achieving job fairness and reducing job turnaround time. Performance evaluations verify the superiority of the proposed scheduler over the original fair scheduler. The average turnaround time of jobs can be largely reduced in our experiments.

1. Introduction

This paper is an extension of work originally presented in PlatCon-17 [1], where we show the general ideas. Significant changes are added in this extended paper to explain more about background knowledge, related work, design philosophy, and performance evaluation. Nowadays, huge volumes of data are generated on the Internet every day due to the popularity of social media and portable devices, and this opens up a new era of big data [2]. How to extract interesting information from these data has become a hot topic in science and commercial fields. Big data analytics needs the support of scalable data storage and powerful data process. Cloud computing [3], which provides distributed storage and parallel data processing on commodity computer clusters, just meets this requirement on data analysis.

Cloud computing, as defined by National Institute of Standards and Technology (NIST) [4], should be composed of five essential characteristics: broad network access, rapid elasticity, measured service, on-demand self-service, and resource pooling. Moreover, cloud computing has four basic deployment models: public cloud, private cloud, community cloud, and hybrid cloud, and has three service models: software as a service (SaaS), platform as a service (PaaS), and infrastructure as a service (IaaS).

Many large on-line services are constructed by the technique of cloud computing. These services are usually developed on business-based cloud platforms such as Amazon's EC2, Google's GAE, and Microsoft's Azure. In academic research, Apache Hadoop is a popular cloud platform to test and verify research ideas. Hadoop is a Java-based and open-source software framework that supports a full set of cloud techniques: distributed file system, parallel data processing, and distributed database system.

To do parallel data processing in Hadoop, users need to write MapReduce programs [5]. These kinds of programs include two major processing codes: map and reduce to reflect a two-phase data processing flow. The map code mainly deals with data filtering and data transforming, and the reduce code mainly deals with data aggregating. Users submit these MapReduce programs into the Hadoop system as jobs. Each job contains several map tasks and reduce tasks. The map task typically reads an input data file in the form of key-value pairs, and then generates an intermediate result file in key-value pairs as well. All values with the same key will be grouped together, and then are processed by the reduce task that usually generates aggregated values.

The WordCount application that outputs the frequency of each distinct word occurred in a document file is usually used to explain the MapReduce framework. The map task will scan the input file and output the occurrence of each word in the format of (founded

*Corresponding Author: Shou-Chih Lo, Email: sclo@gms.ndhu.edu.tw

word, 1). Apparently, we only need to accumulate this value 1 for those outputs having the same founded word to be the word frequency. The reduce task just does this grouping and counting.

A Hadoop system can be built over clusters of computers that are typically named as nodes. All map and reduce tasks will be dispatched to these nodes. For parallel data processing, the input data file to a MapReduce job will be equally partitioned into several data chunks (or blocks) with a typical size of 64 MB. Each of these data chunks will be replicated and distributed into different nodes for fault tolerance. The same number of map tasks to the number of data chunks are cloned, and each copy of the map task handles one data chunk. Because there are redundant data chunks, the map task will select the closest data chunk for access efficiency. The reduce task can be cloned as well, and each copy handles the values corresponding to a certain set of keys. This MapReduce working model is outlined in Figure 1.

The Hadoop system can simultaneously run many map and reduce tasks from different users in a computer cluster environment. These tasks will contend system resources such as CPU, memory, and disk I/O for the completion of their jobs. Moreover, those tasks reading data chunks from far-away nodes will compete for network bandwidth. Therefore, a proper task scheduling algorithm is necessary for optimizing resource utilization and avoiding any resource starvation.

Hadoop provides three built-in scheduling modules: First-In-First-Out (FIFO) scheduler, fair scheduler, and capacity scheduler. These schedulers have their own features and have different influences on performance such as execution time and waiting time in different situations [6-10]. Fair scheduler and capacity scheduler generally perform better than FIFO scheduler. These built-in schedulers have a common drawback, which the scheduling policy is almost fixed and is not flexible to the change of working conditions. In this paper, we focus on the fair scheduler and propose some modifications to improve the scheduling throughput under the goal of resource fairness among users.

Our proposed scheduling algorithm is adaptive, because it can dynamically tune some working parameters such as the job priority and the waiting time for resource allocation. The runtime environment's conditions such as current workload and remaining resources are considered in the determination of job running order and the amount of resources allocated to each job. A modified fair scheduler is then coded into the Hadoop system and is examined in a real testing environment. Evaluation results show that the modified fair scheduler can significantly reduce the average turnaround time of a job by over 20 percent as compared to the original fair scheduler.

The remainder of this paper is organized as follows. Section 2 briefly introduces the basic job scheduling architecture in Hadoop and the related work on scheduling algorithms. Section 3 presents and discusses the proposed five mechanisms of improving the performance of fair scheduler. Performance evaluation is conducted in Section 4. Finally, some concluding remarks are given in Section 5.

2. Background Knowledge and Related Work

Hadoop, which is developed under the Apache projects, is an open-source software for reliable, scalable, and distributed computing. The Hadoop system is composed of two basic units: a distributed file system and a distributed data processing engine. The Hadoop distributed file system (HDFS), following the similar

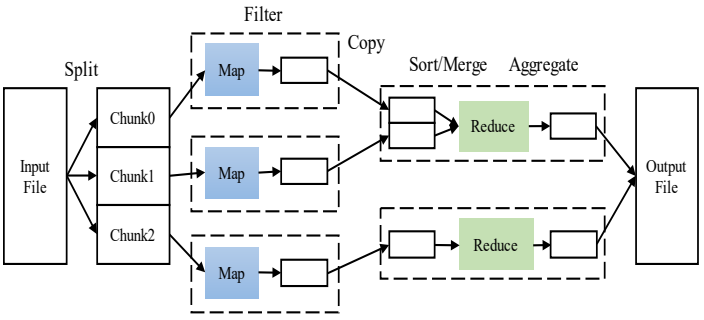

Figure 1. MapReduce working model

concept of Google file system (GFS) [11], can manage distributed data storage across computer clusters built from commodity hardware. A HDFS cluster consists of a single namenode, a master server that manages the namespace and access of files, and multiple datanodes, slave servers that store data chunks and are coordinated by the master server. A file is split into several data chunks which are then stored into datanodes. The namenode will record the mapping of each data chunk to each datanode.

The distributed processing engine in Hadoop is based on the MapReduce framework. A MapReduce program contains a map procedure that performs the data filtering and sorting operations, and a reduce procedure that performs the data summarizing operations. MapReduce programs are submitted by users to Hadoop as jobs. These jobs will be executed over a set of computing nodes where one master node is selected to schedule job executions on the other slave (or worker) nodes. The management functions of system resource and job execution are included in the MapReduce module for Hadoop version 1. These functions, however, are dedicated to anther software module for Hadoop version 2: Yet Another Resource Negotiator (YARN) [12]. No matter the different versions of Hadoop, the job scheduling process is relied on a job scheduler. In this paper, we follow the framework of Hadoop version 1 to illustrate the operation of different job schedulers.

Figure 2 shows the job execution flow in Hadoop. There is a JobTracker at the master node that plays the roles of monitoring/ allocating system resources and scheduling user jobs. The JobTracker gives each submitted job a job ID as an internal identification number and puts the job into a job queue (or pool). A certain sorting policy is applied to these jobs in the queue according to some comparing factors such as job ID, job priority, and job submitted time. When a job is ready to be executed, the associated map and reduce tasks are created. The number of map tasks is determined by the number of data chunks split from an input file. The number of reduce tasks can be configured by the user but is usually one by default.

The JobTracker will manage and monitor all system resources such as CPU, memory, and disk contributed from all slave nodes. These system resources for job running are configured as resource slots in Hadoop. The resource slot used for the running of a map (or reduce) task is called a map (or reduce) slot, respectively. Due to the limited system resource, map and reduce tasks will contend these resource slots. On each slave node, a TaskTracker will manage the actual running of tasks. The TaskTracker will request a task to run from the JobTracker whenever there is a free resource slot. The TaskTracker will also periodically report the execution status and the available resource to the JobTracker by sending a heartbeat message.

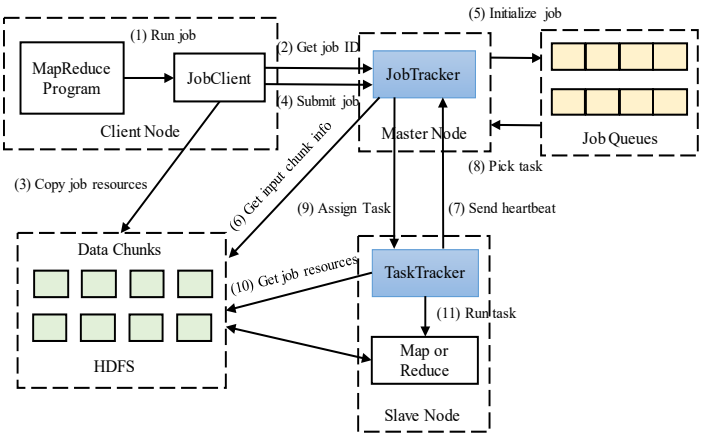

Figure 2. The job execution flow in Hadoop

A map task will read an input data chuck through the HDFS. To save network bandwidth, this data retrieval should happen locally or be done from a close node. This raises the data locality issue when assigning a task to a slave node [13]. There are three levels of data localities (see Figure 3) from good to bad:

- Node-locality: The node where data are stored is the same as the node where data are processed.
- Rack-locality: The node where data are stored is different from the node where data are processed, but these two nodes are located in the same rack.
- Non-locality: The node where data are stored is different from the node where data are processed, and these two nodes are located in different racks.

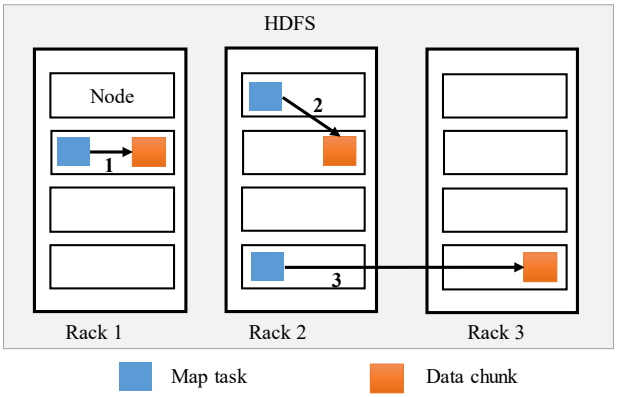

Figure 3. Data locality: (1) Node-locality, (2) Rack-locality, and (3) Non-locality

The Hadoop scheduling problem can be described below: Suppose that each node is configured with some map and reduce slots for the execution of map and reduce tasks, respectively. Given a set of jobs and nodes, we need to determine the order of running jobs and the slot assignment to tasks with the objective of high data locality and high execution throughput. This problem with multi-objective optimization is proven to be NP-hard [14].

In Hadoop, there are three well-known scheduling algorithms implemented as three schedulers: FIFO scheduler, fair scheduler, and capacity scheduler, respectively. The default FIFO scheduler uses one job queue to do slot allocation. Jobs in the queue are sorted in ascending order of their submitted times. To break the tie, the job ID assigned by the JobTracker is considered. All free map and reduce slots in the system can serve the job being scheduled.

In the example of Figure 4, suppose that there are three map slots and three reduce slots in the system, and each job (i.e., Job1~Job3) has three map tasks and three reduce tasks. The sequence to allocate slots to these jobs is Job1, Job2, and then Job3. For simplicity, we assume that each task uses one resource slot with the same occupation time in the figure. At first, all the map tasks of Job1 get map slots for 20 s execution time. Next, these map slots are released and re-allocated to the map tasks of Job2. Meanwhile, all the reduce tasks of Job1 get reduce slots for 20 s execution time. As can be seen, reduce tasks start executing just after the finish of all map tasks of the same job. The drawback of this scheduler is the possible long waiting time for a task to be executed when there are many jobs in the queue. This becomes unfair particularly when a user submits many jobs and the latter users need to wait.

The fair scheduler developed by Facebook equally allocates resources to job users. Each user has its own job queue (or pool), and all resource slots are fairly distributed to these user pools. Figure 5 shows the example slot allocation under the same condition with the previous example. Here three pools (P1, P2, and P3) are introduced with each pool having the resource of one map slot and one reduce slot. Each map task of these three jobs gets one map slot at the same time and runs for 20 s. The same case happens for reduce tasks. As compared to the previous example, each submitted job can start running immediately but the time to finish the job becomes longer. In a real situation, one pool without sufficient resources can borrow free (or idle) slots from another pool to increase resource utilization. To prevent resource unfairness, each pool is configured with the minimum and maximum resource capacity. Fair scheduler also supports preemptive mode by which a low-priority running job can be aborted for releasing resource to a high-priority job.

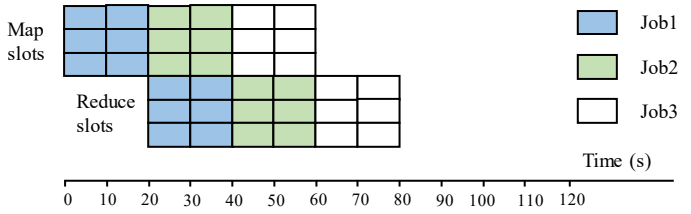

Figure 4. A scheduling example using FIFO scheduler

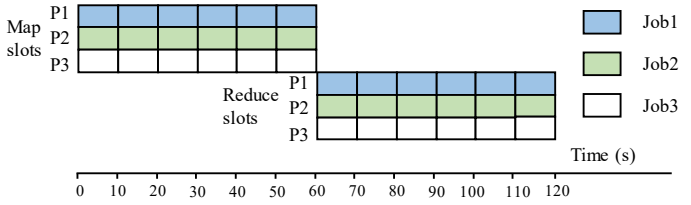

Figure 5. A scheduling example using fair scheduler

The capacity scheduler developed by Yahoo acts similar to fair scheduler, but uses queues instead of pools. Each queue has a defined resource capacity and is assigned to an organization or a group of users. Due to the nature of organization structure, queues can be constructed into a multi-level hierarchy. To increase running efficiency, capacity scheduler can allocate more than one resource slot to a heavy task. Moreover, several tasks can be assigned together to the same TaskTracker in batch mode to reduce the scheduling overhead. Overusing this batch mode, however, would cause load unbalancing among slave nodes. A summary table (see Table 1) is given to compare the characteristics of these three schedulers.

There are several scheduling algorithms proposed to improve the built-in schedulers. The reader is referred to [15-16] for a complete view. To increase data locality, the LATE (Longest Approximate Time to End) scheduler was proposed [17], where a delay timer is set during which a TaskTracker will wait for a suitable task that can fetch data locally. When a TaskTracker requests a task to do from the JobTracker, the JobTracker will scan the job queue to find a task with the node-locality data access level within a short time interval. If it is failed to find such a task, a task with the rack-locality data access level is then searched within a long time interval. If it is still failed, the JobTracker will randomly select one task to this TaskTracker.

The delay concept above is introduced into the naïve fair scheduler [18-19]. The setting of suitable delay time would be challenging in a dynamic changing environment. This delay time is configured as a fixed value in fair scheduler. To increase data locality, one research work implements two job queues for the FIFO scheduler [20]. Jobs having the node-locality potential are put into one queue, and jobs having the rack-locality potential are put into the other queue. Finally, these two queues are merged together and are fed into the FIFO scheduler. The process of data may have certain relationships. For example, some rare data are only processed by certain tasks. In this situation, the system can mark the locations of these rare data and assign irrelevant tasks to other locations for increasing data locality [21].

Table 1. Summary of different schedulers

Scheduler	Characteristics
FIFO Scheduler	• Single job queue • Resource allocation to jobs is considered one by one. • Scheduling overhead is low • There are resource starvation problems
Fair Scheduler	• Multiple job queues • Resource allocation to jobs is considered together. • System resources are fairly allocated to users • Support preemptive mode and resource borrowing
Capacity Scheduler	• Multiple job queues • Resource allocation to jobs is considered together. • System resources are allocated to users according to a certain organization policy • More than one resource slot can be allocated to one task • Support batch mode in job scheduling

The job priority will affect the job order in a job queue. If each user can freely assign the job priority, all users tend to set their jobs to the highest level, and this does not make sense. One auto-setting mechanism is proposed in [22] by considering several factors such as the job size, the average execution time and the scheduled time of a task in a job. A high priority is usually given to a small-size or fast running job. The job size can be simply estimated by the number of tasks involved in a job [23].

In Hadoop, map slots and reduce slots are separated and cannot be interchangeably used. Dynamic borrowing between them can improve slot utilization and system throughput [24]. The map or reduce slot in Hadoop represents a computing unit and the amount of available slots in a node is configured in advance. Dynamically changing the slot number according to the real computing power in speeds of CPU and I/O can also improve system performance [25-26].

The diversity of data, jobs, and computer nodes will also affect the scheduling performance, and this is called the skew problem [27]. Different map tasks from the same job may generate different amounts of data, causing data skew. Different jobs take different execution times depending on algorithms but not job sizes, causing computational skew. Resource slots from different computer nodes have different computing powers, causing machine skew. These skews cause unbalancing workload in a distributed computer cluster. There are many research efforts on designing load balancing scheduling algorithms [28-31]. For example, jobs are classified into CPU-bound and I/O-bound types and are put into different job queues [31].

3. Modified Fair Scheduler

Fair scheduler with the delay mechanism has good performance in general against the other schedulers in Hadoop. However, fair scheduler overemphasizes fair resource allocation to jobs and ignores the differences between jobs. These differences may even change over time when jobs are running. We hope to improve the performance of fair scheduler by considering some runtime conditions and further adjusting resource allocation to jobs. We provide some modifications to the fair scheduler by introducing the following mechanisms: job classification, pool resource allocation, resource-aware job sorting, delay time adjustment, and job priority adjustment. Their brief introductions are given in Table 2.

Table 2. The goal of each proposed mechanism

Mechanism	Goal
Job classification	Separate small-sized jobs from large-sized jobs
Pool resource allocation	Periodically reallocate resource slots to pools according to their remaining actual needs
Resource-aware job sorting	Determine the job or pool order for resource allocation based on more criteria including resource requirement and occupation
Delay time adjustment	Dynamically adjust the delay time for a suitable task with high data locality
Job priority adjustment	Dynamically adjust the job priority based on the change of its data locality level

3.1. Job Classification

In fair scheduler, system resources are equally allocated to user pools. All jobs belonging to the same pool will contend for the limited resource. In real cases, different jobs would have different resource requirements. A large-sized job consumes more resource than a small-sized job. Based on the principle of shortest job first, we separate small-sized jobs from large-sized jobs and allocate resources to them individually.

The job size is measured by the number of map and reduce tasks in a job. In general, the number of map tasks is greater than

that of reduce tasks, because most MapReduce jobs focus on data extraction from large input data sets. For simplicity, we concentrate on the map slot allocation to map tasks, so the job size is defined as the number of map tasks only. A job is recognized as a small-sized one if its job size is no greater than a threshold (minJobSize). This threshold value is not a fixed value but is updated periodically by the JobTracker (per 500 ms in our implementation) to be the currently smallest job size among all jobs in the system.

The basic concept of the proposed job classification is to direct all small-sized jobs into another system pool (called sharedPool) and all large-sized jobs into their originally belonging pools. In other words, there is a system pool shared by all users besides individual user pools. Jobs in the sharedPool are scheduled using FIFO for simplicity.

In an extreme case, if all jobs are small-sized, this job classification becomes useless. To prevent this condition, the ratio of the number of total small-sized jobs (SmallJobs) to the number of total jobs (TotalJobs) in the current system is considered. If this ratio is greater than a threshold, the sharedPool mechanism is disabled and all small-sized jobs remain in their own user pools. This threshold value is set to be the reciprocal of the average number of map slots configured in a salve node. For example, if each slave node has four map slots on average, the threshold value is 0.25. This means that we allow using sharePool when there is at most one small-sized job running on a slave node on average. Figure 6 shows the flow of job classification.

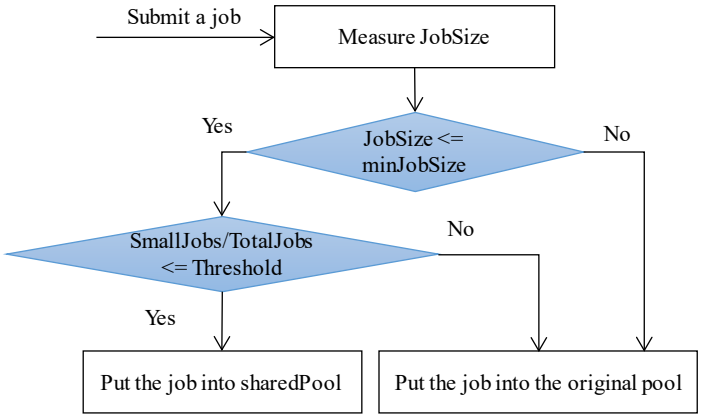

Figure 6. Job classification flow

3.2. Pool Resource Allocation

System resources are proportionally allocated to user pools according to weighted values assigned to user pools in fair scheduler. Without the pre-knowledge of traffic shape, it is hard to set a suitable weighted value to each user pool, and this weighted value is set to be equal most of the time. However, if this weighted value can automatically reflect the current resource requirement, resource allocation can always fit real situations and becomes more efficient. Based on this concept, a dynamic pool resource allocation is proposed.

The resource allocation to pools is periodically adjusted every 500 ms in our implementation. The allocation of map slots and reduce slots to each user pool is performed separately. We first check whether the sharedPool is enabled without any allocated resource. If that is the case, a certain amount of resource slots is allocated to the sharedPool. For the efficient schedule of this small amount of small-sized jobs in the sharePool, the FIFO scheduler is applied here. We allocate a half of resource slots needed by the currently smallest job in the system to the sharedPool. That is, the number of resource slots allocated to the sharedPool is $\lceil minJobSize/2 \rceil$. This decision is for the reason that large-sized jobs should get more resource and hence we allocate limited resource to small-sized jobs. For example, if minJobSize is four in map tasks and two in reduce tasks, this sharedPool gets two map slots and one reduce slots.

The remaining free resource slots (RemainingSlots) are proportionally allocated to the other user pools according to their actual needs. The portion of total resources allocated to a user pool is based on the ratio of the number of pending tasks in a user pool (PoolTasks) to the number of total pending tasks in all user pools (allPoolsTasks). A pending task is a task that is not allocated with any resource slots and is waiting for execution. The ratio above indicates the remaining resource requirements of a user pool against the total remaining resource requirements of all jobs. Remember that only map (or reduce) tasks are considered in the counting of the number of tasks when map (or reduce) slots are allocated. To prevent one user pool with heavy workload from getting too much resource, the actual number of allocated slots cannot exceed the maximum number (maxAllocated) configured in the system. Figure 7 shows the flow of this dynamic pool resource allocation.

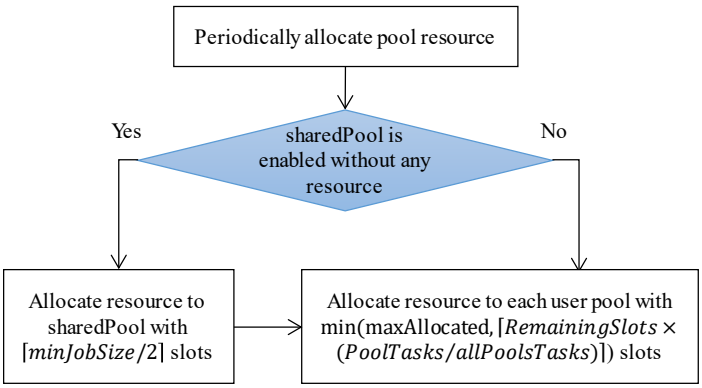

Figure 7. Pool resource allocation flow

3.3. Resource-Aware Job Sorting

The order to allocate resource to jobs is based on the order of jobs. All jobs are in the same system pool for FIFO scheduler, but are in different user pools for fair scheduler. Therefore, another pool sorting is necessary besides the job sorting for fair scheduler. The job or pool order is determined based on a sorting policy applied in the FIFO comparator or the FairShare comparator in Hadoop. These two comparators, which are involved in FIFO scheduler and fair scheduler, respectively, will return the order between two target jobs or two target pools based on some reference factors. Normally, these reference factors include the job priority, job ID, and submitted time. Here, we additionally consider the remaining resource requirements and the current resource occupation of a job or a user pool to do fine-grained sorting. The principle is to allocate resource first to those jobs or pools that have occupied less resource or desire for more resource.

At first, we describe the way to determine the job order in the same pool, which can be used both in FIFO scheduler and fair scheduler. We measure the remaining resource requirements of a

job by the number of pending map or reduce tasks in the job. Remember that only map tasks are counted when we consider the map slot allocation. We define the pending task ratio of a job (JobPendingRatio) in (1) as the number of pending tasks in a job to the number of total pending tasks in a pool. This ratio is high if the corresponding job has more unfinished tasks against other jobs, implying high resource requirements in the future.

JobPendingRatio = (#pending tasks in a job)/(#pending tasks in a pool) (1)

The current resource occupation of job is measured by the number of currently running tasks in the job. We define the occupied resource ratio of a job (JobOccupiedRatio) in (2) as the number of currently running tasks in a job to the number of totally allocated slots to a pool. If a task is assigned with at most one resource slot, the number of allocated slots is equal to the number of running tasks. A job with more occupied resource should have low precedence to contend new resource.

JobOccupiedRatio = (#running tasks in a job)/(#allocated slots to a pool) (2)

Our sorting policy for jobs in the same pool is designed as follows. Five comparing factors are examined in sequence if there is a tie as in Figure 8. The high order is given to the job with a high job priority (more detailed settings are discussed latter). The subsequent order is given to the job with a high JobPendingRatio and then with a low JobOccupiedRatio. To break the tie, the submitted time and the job ID are then examined.

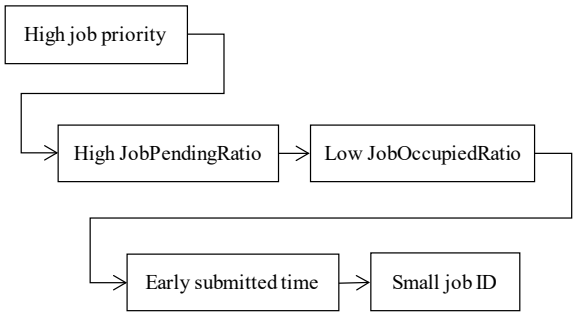

Figure 8. Sequence to examine the job order

In fair scheduler, there are several pools and the order of these pools should be determined before jobs are scheduled. Our sorting policy for pools is also from the perspective on resource requirements. First, the number of all pending tasks for each job in a pool is accumulated as the maximal resource demand of a pool (PoolDemand) in (3). Suppose that each user pool is configured with the minimum number of resource slots (minAllocated) in advance. If PoolDemand is less than minAllocated, minAllocated would be set to be PoolDemand to reflect the actual minimum resource need. This step is for tuning the minAllocated value.

PoolDemand = ∑#pending tasks, for all jobs in a pool (3)

Next, the number of currently running tasks for each job in a pool is accumulated as the current workload of a pool (PoolWorkload) in (4). If PoolWorkload is no greater than minAllocated, this means that the pool has sufficient resource to accommodate new tasks and hence a high pool order is given. That is, the pools are in the order of pools with sufficient resource followed by pools with insufficient resource.

PoolWorkload = ∑#running tasks, for all jobs in a pool (4)

Those pools having sufficient resource are further sorted by comparing the occupied resource ratio (PoolOccupiedRatio) of PoolWorkload to minAllocated in (5). The remaining resource is large if this ratio is low, and hence a high order is given to a pool with small PoolOccupiedRatio.

PoolOccupiedRatio = PoolWorkload / minAllocated (5)

Those pools having insufficient resource are further sorted by comparing the PoolWorkload and the weight of a pool that is given by the user or the system to indicate the pool priority. The ratio of these two values is computed in (6) and is denoted as WeightedPoolWorkload. A high order is given to the pool with small WeightedPoolWorkload. Here we suppose that the pool priority is high if the corresponding pool weight is large. Figure 9 shows the comparing sequence. If any tie happens, a random order is given.

WeightedPoolWorkload = PoolWorkload / (weight of a pool) (6)

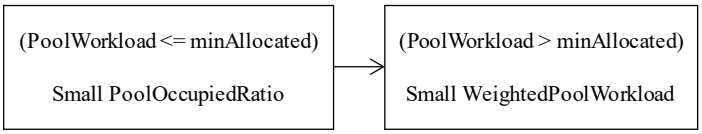

Figure 9. Sequence to examine the pool order

3.4. Delay Time Adjustment

To increase data locality during job scheduling, JobTracker will seek first for those tasks in pools having node-locality or rack-locality levels. The setting of delay time during task scheduling is proven to be helpful on data locality. The TaskTracker will wait for a suitable task satisfying node-locality in a pool until the time out of a short delay timer. If no such task is found, the TaskTracker continues waiting for a suitable task satisfying rack-locality in a pool until the time out of a long delay timer. Otherwise, one task is randomly selected from a pool and is fed to the TaskTracker.

The fixed setting of these delay timers in the current implementation of fair scheduler is not suitable in a dynamically changing environment. A long delay timer will increase the average turnaround time of jobs, and a short delay time will decrease the average data locality level. Here, a dynamic approach is applied by setting the timer according to the recently average waiting time as follows:

NodeLocalityWaitedTime = the average waiting time of tasks satisfying node locality (7)

RackLocalityWaitedTime = the average waiting time of tasks satisfying rack locality (8)

In our implementation, we use two pairs of counters (TimeCount and NumberCount) to maintain each waited timer as the value of TimeCount/NumberCount. If a task is scheduled with node-locality level, the scheduled waiting time is added into TimeCount and NumberCount is increased by one. Another pair of TimeCount and NumberCount is used when a task is scheduled with rack-locality level.

3.5. Job Priority Adjustment

In Hadoop, each job can be given with one of five priority values from high to low: VERY_HIGH, HIGH, NORMAL, LOW, and VERY_LOW. However, the job priority is not fully used and is set to a fixed value (NORMAL) without any specific specification. This priority value is one of the factors that are considered in job sorting. If this priority value can be dynamically adjusted to reflect the data locality level of a task for a job, the job with high data locality will be scheduled with high precedence. This strategy can increase overall data locality level and hence reduce the data access time.

We consider the change of the data locality level according to two recently scheduled tasks of the same job. There are nine possible changes as listed in the first column of Table 3. The job priority remains the same if there is no change on data locality. If the data locality is downgraded with one level (or two levels), the job priority is also downgraded with one level (or two levels). This job after downgrading will be sorted behind other jobs, and hence JobTracker has more opportunities to find other tasks with good data locality levels. Similarly, the job priority is upgraded with one level (or two levels) if the data locality is upgraded with one level (or two levels). If the job priority keeps in VERY_HIGH (or VERY_LOW) due to no change of data locality level, a minor adjustment to HIGH (or LOW) is applied for the balance of fairness. This prevents a job from keeping with very high or very low priority for a long period of time. The former case makes a job having high priority to seize system resource, and the latter case makes a job having the chance to starve for system resource.

Table 3. Change of job priorities

Data locality change	**Original Job Priority**				
	VERY_HIGH	HIGH	NORMAL	LOW	VERY_LOW
Node→Node	VERY_HIGH	HIGH	NORMAL	LOW	VERY_LOW
Node→Rack	HIGH	NORMAL	LOW	VERY_LOW	LOW
Node→None	NORMAL	LOW	VERY_LOW	VERY_LOW	LOW
Rack→Node	HIGH	VERY_HIGH	HIGH	NORMAL	LOW
Rack→Rack	VERY_HIGH	HIGH	NORMAL	LOW	VERY_LOW
Rack→None	HIGH	NORMAL	LOW	VERY_LOW	LOW
None→Node	HIGH	NORMAL	LOW	VERY_LOW	LOW
None→Rack	HIGH	VERY_HIGH	HIGH	NORMAL	LOW
None→None	VERY_HIGH	HIGH	NOMAL	LOW	VERY_LOW

4. Performance Evaluation

An experimental testing environment is established to evaluate the proposed fair-share-based algorithm against the original algorithm. The capacity scheduler is not examined, since it is little bit hard to configure a uniform testing environment to compare these schedulers together. Two physical computer servers are selected from two buildings on our campus. Each server is configured with four virtual machines (VMs) using the software of VMware ESXi. Each VM is installed with the operation system of CentOS 5.5 and Hadoop 1.2.1. These VMs are configured with physical IP addresses and are connected together to be one Hadoop cluster. That is, we have eight nodes in the cluster, and one node acts as both master and slave nodes and the other seven nodes act as slave nodes. Those nodes on the same physical computer are viewed as on the same rack. The hardware specification of the master node is: one dual-core CPU, 8GB memory, and 200 GB disk space. The specification of the slave node is: one dual-core CPU, 4 GB memory, and 200 GB disk space.

The replication factor of HDFS is set to three by default in Hadoop, which implies one data chunk is replicated to three nodes. However, we set the replication factor to one here and make the general node-locality level low. The reason is for the easy observation on the improvement of data locality. All the submitted jobs are based on the WordCount program which outputs the frequency of each distinct word occurred in an input document file. The job size is controlled by the size of input file. In other words, each job can contain a different number of map tasks but contain one single reduce task. The initial job priorities of all jobs are NORMAL. There are three user pools with equal weight in the system. All the submitted jobs will evenly be distributed into these pools. The minAllocated and maxAllocated values for each user pool is three and six in number of map slots, respectively. The default delay time in the original fair scheduler is 3000 ms. The above experimental settings are summarized in Table 4.

Table 4. Experimental settings

Physical server	2
Virtual machine	8
Hadoop system	1.2.1
HDFS replication	1
Default delay time	3000 ms
Job size	6~25 map tasks
User pool	3

Two sets of experiments are performed. All jobs in the first experiment have the same size, but have different sizes in the second experiment. For each experiment, two cost metrics are observed as follows:

- Average turnaround time: The average time taken between the submission of a job for execution and the completion of result output.
- Average node-locality ratio: The ratio of the number of task schedules satisfying node locality to the number of total task schedules.

4.1. Experiment A

In this experiment, each node is configured with four map slots and one reduce slot. There are totally 32 map slots in the system. The job size (in number of map tasks) is set to be 6, 10, and 18. For each case, 5, 10, and 15 jobs are respectively examined. That is, all submitted jobs in each testing round have the same size. For this reason, the following proposed mechanisms does not contribute too much on performance improvement. First, the job classification does not work here. Second, the pool resource allocation makes no significant difference on each user pool. Therefore, we mainly observe the proposed mechanisms on resource-aware job sorting, delay time and job priority adjustments. Experimental results are listed in Table 5 and Table

6. Each gain value shown in the tables, indicating the improvement percentage, is defined as follows:

Gain = (Modified FS – Original FS) / Original FS × 100% (9)

As the total number of tasks is increased, the average turnaround time is increased for both the original fair scheduler and our modified fair scheduler because of heavy workload. The modified fair scheduler can significantly reduce the average turnaround time by 21.4% to 54.5% against the original fair scheduler. This indicates that the modified fair scheduler performs proper job sorting and decreases unnecessary waiting delays. These make the utilization of resource slots high. In general, more reduction gains are achieved if the job size is getting large under the same number of jobs. This shows that the modified fair scheduler makes efficient schedule on many map tasks. The original fair scheduler will suffer from serious resource contentions under heavy workload and the lack of flexible scheduling makes the performance worse.

Table 5. Comparison of average turnaround time for jobs of same size

Job size	Number of jobs	Original FS	Modified FS	Gain (%)
6	5	289.6 s	188.2 s	-35%
	10	1083.2 s	761.3 s	-29.7%
	15	1791.7 s	1175.2 s	-34.4%
10	5	886.9 s	462.2 s	-47.8%
	10	1433.7 s	1103.3 s	-23%
	15	2008.1 s	1577.6 s	-21.4%
18	5	2212.3 s	1003 s	-54.6%
	10	3845 s	1894.1 s	-50.7%
	15	5681.4 s	2988.7 s	-47.3%

Table 6. Comparison of average node-locality ratio for jobs of same size

Job size	Number of jobs	Original FS	Modified FS	Gain (%)
6	5	0.09	0.13	+44.4%
	10	0.22	0.23	+4.5%
	15	0.28	0.28	+0%
10	5	0.29	0.32	+10.3%
	10	0.34	0.32	-5.9%
	15	0.33	0.35	+6.1%
18	5	0.21	0.25	+19%
	10	0.28	0.34	+21.4%
	15	0.3	0.36	+20%

Table 6 shows the performance comparison on data locality. First, the general node-locality ratio is low, because the replication factor is only one. Second, the node-locality ratio is improved in general by using our modified fair scheduler. Among our proposed mechanisms, only the mechanism of job priority adjustment considers the factor of data locality. Therefore, our scheduler can slightly increase the node-locality level but cannot guarantee this is always true as one counterexample in the table. Third, improvement gains become clearer when the job size is getting large. When we take a close look at the experimental result of each round, we found that data-locality levels in the original fair scheduler are variant over different testing rounds. For example, there may have several task schedules with node-locality level in the current testing round but with rack-locality level in the next testing round. However, our modified fair scheduler keeps data-locality level in a more stable state under the same input condition.

4.2. Experiment B

In this experiment, each node is configured with two map slots and one reduce slot. There are totally 16 map slots in the system. The job sizes are mixed with five different scales: 6, 10, 16, 21, and 25. For each job size, one, two, and three jobs are respectively generated such that there are totally 5, 10, and 15 jobs in the system. All the proposed mechanisms will function in this experiment. The experimental results are listed in Table 7 and Table 8. As can be seen, the modified fair scheduler largely decreases the average turnaround time by 57% in average, and slightly increases the average node-locality ratio by 3.87% in average.

As compared to Experiment A where only three proposed mechanisms function well, improvement gains become excellent in this experiment. This means that the proposed job classification works very well and the dynamic pool resource allocation based on real resource requirement makes slot allocation more efficient.

In this experiment, we also examine the FIFO scheduler. The FIFO scheduler runs worse in the first two testing suits of Table 7, but accidently has good performance in the last testing suit. This is because that any fair-based schedulers need to set an upper bound on the number of allocated resource slots to a user pool. The performance is affected when this upper bound is reached. This setting is for allowing more users to share system resources and preventing one user to occupy all resources. The FIFO scheduler however allocates all available resources to the current user and does not consider the future resource needs for other coming users to the system. It is expected that the FIFO scheduler would perform worse when there are many users and many large-size jobs in the system.

The average node-locality ratio is close for these three schedulers as shown in Table 8. This implies that data locality is not a dominant factor on the job turnaround time. Our modified fair scheduler performs more stable and efficient than other schedulers do due to multiple considerations.

Table 7. Comparison of average turnaround time for jobs of different sizes

Job size	Number of jobs	Original FS	Modified FS	FIFO	Gain (%)
6/10/16 /21/25	5	1242 s	364.6 s	513.6 s	-70.6%
	10	2343.1 s	1372.5 s	1532.2 s	-41.4%
	15	5585.3 s	2285.5 s	2131.933 s	-59.1%

Table 8. Comparison of average node-locality ratio for jobs of different sizes

Job size	Number of jobs	Original FS	Modified FS	FIFO	Gain (%)
6/10/16/ 21/25	5	0.25	0.26	0.27	+4%
	10	0.32	0.44	0.36	+3.8%
	15	0.32	0.44	0.36	+3.8%

5. Conclusions

Hadoop provides parallel data processing based on the MapReduce framework. The performance of MapReduce programs is dominated by a job scheduling algorithm. Fair scheduler, which is one of the built-in schedulers in Hadoop, provides good performance in general and is widely used. However, the scheduling policy of this naïve fair scheduler is almost fixed and is not flexible to the change of working conditions. In this paper, we propose five mechanisms: job classification, pool resource allocation, resource-aware job sorting,

delay time adjustment, and job priority adjustment to improve the fair scheduler by monitoring the actual resource usage and the runtime environment's condition. The conducted experiments on a real testing platform show that the modified fair scheduler can largely reduce the average turnaround time of a job and slightly increase data locality against the naïve fair scheduler.

In the future, more types of jobs such as CPU-intensive and I/O-intensive programs will be conducted in the experiment. Also, our current work only emphasizes the slot allocation and data locality for map tasks, more enhancements for reduce tasks can be furthered considered.

Prioritization

ABSTRACT

Many decision problems have more than one objective that need to be dealt with simultaneously. Moreover, because of the qualitative nature of the most of real world problem it is an inevitable activity and very important to interpret and present the uncertain information for making effective decision. The Evidential Reasoning (ER) approach which is one of the latest development within multi criteria decision making (MCDM) seems to be the best fit to synthesize both qualitative and quantitative data under uncertainty. To support this claim, two case studies were tested to illustrate the application of ER for prioritization and ranking of decision alternative to support decision process even with uncertain information. The overall goal of the first case study is to identify and prioritize factors that can be considered maintenance-related waste within the automotive manufacturing industry. The result after applying ER shows "inadequate resources" and "weather /indoor climate," respectively, are the highest and lowest average scores for creating maintenance-related waste. This prioritization methodology can be used as a tool to create awareness for managers seeking to reduce or eliminate maintenance-related waste. The aim of the second case study is to look at the possibility of having a new approach for sustainable design. So through a literature review six design strategies were taken into consideration in order to develop a new approach based on all advantages (sustainable factors) of the six approaches. For ranking and finding out about the most important factors the evidential reasoning (ER) approach is used. Based on ER all the important factors, apart from the one collected from interviews are a part of eco-design. So it means among all strategies eco-design is the most dominant strategy in term of environment. However two of the important factors are not found in any strategy but in interviews. These factors can be used as the building blocks for a new approach. The importance of having a better structured decision process is essential for the success of any organization, so it can be applied widely in most of real world problem dealing with making effective decision.

1. Introduction

It has become more and more difficult to see the world around us in a uni-dimensional way and to use only a single criterion when judging what we see [1]. The decision making process for any organization may be key factor for its success. Decision maker's wishes to evaluate the performance of the alternative with different criteria simultaneously. In many situations these objectives/ criteria may be conflicting. These objectives are associated with the possible consequences (or outcomes) that results from choosing an alternative [2]. The branch of decision analysis which deals with this kind of problem is called multi-criteria decision making (MCDM). Many MCDM methods have been developed, such as multiple attribute utility theory (MAUT) and analytical hierarchy process (AHP) [3, 4]. Most of these methods are suitable for solving small scale MCDM problems without uncertainty. In uncertain situations, the Fuzzy Multi-Criteria Decision Making (FMCDM) approach provides an ideal option; it has been tested by a number of researchers to rank alternatives in different situations [5]. However, the fuzzy approach is used only when uncertainty is predominant. In other words, when a particular parameter is quantifiable with fair degree of accuracy, or there are a missing or incomplete data this approach need not be used. Most real-life decisions use a mixture of qualitative and quantitative attributes with varying degrees of uncertainties, increasing the need for the development of scientific methods and tools that are rational, reliable, repeatable, and transparent. Since, it is essential to properly represent and use uncertain information for making effective decision, it is

* Corresponding Author: Farzaneh Ahmadzadeh, Mälardalens högskola, 631 05 Eskilstuna | Email: Farzaneh.ahmadzadeh@mdh.se

compulsory to use the multi-level evaluation framework for assessing different type of uncertainty inherent in data like missing data, incomplete data which is one of the many research limitation when it comes to qualitative data. Therefore in this paper an evidential reasoning (ER) approach has been introduced to address this problem. Two case studies is examined to emphasize the effectiveness of this approach. The rest of the paper is organized as follows. Section 2 briefly outlines the Evidential Reasoning (ER) approach. Section 3 explains the first case study for prioritization of maintenance related waste. Section 4 provides the second case study when it has been applied for developing a sustainable product design, while Section 5 offers a conclusion.

2. Evidential Reasoning Approach

The Evidential Reasoning (ER) advocates a general, multi-level evaluation process for dealing with MCDM problems. The process can model various types of qualitative and quantitative uncertainties and is developed on the basis of Dempster-Shafer evidence theory [6] and evaluation analysis model and decision theory. In ER, A complex general property which is usually difficult to assess directly is broken down and operationalized by using well-defined, measurable concepts that together constitute the general property. The result of such a breakdown is a multiple attribute framework taking the shape of a tree (hierarchy) structure, with assessable basic attributes at the lowest level. The assessment of these basic attributes can be aggregated to an assessment of the upper level of the tree. The Dempster-Shafer mathematics are designed to aggregate the uncertainties in the basic attributes to a total uncertainty of the total assessment. Steps for the overall assessment of the complex general property are suggested in [6, 7] and summarized in [8] are as following:

2.1. Definition and representation of a multiple attribute decision problem

Define a set of L basic attributes include all the factors influencing the assessment of the upper level attribute as follows:

$E = \{\varepsilon 1, \varepsilon 2, \dots, \varepsilon L\}$

Now estimate the relative weights of the attributes where ω_i is the relative weight for basic attribute ε_i and is normalized so that $\sum \omega_{i=1}$ and $0 \leq \omega_i \leq 1$. Moreover define N distinctive evaluation grades H_n, $n=1,\dots,N$ as a complete set of standards to assess each option on all attributes.

For example:

$H=\{H_1=worst, H_2=poor, .., H_{N-1} = Good, H_N=Excellent\}$

For each attribute ε_i and evaluation grade H_n a degree of belief β_n is assigned. The degree of belief denotes the source's level of confidence when assessing the level of fulfillment of a certain property.

2.2. Basic probability assignments for each basic attribute

Let $m_{n,i}$ be a basic probability mass, representing the degree to which the i^{th} basic attribute ε_i supports a hypothesis that the general attribute is assessed to the n^{th} evaluation grade H_n. Then, $m_{n,i}$ is calculated as follows:

$$m_{n,i} = \omega_i \beta_{n,1} \quad (1)$$

Let $m_{H,i}$ be the remaining probability mass unassigned to each basic attribute $\varepsilon_{i,}$ so $m_{H,i}$ is calculated as follows :

$$m_{H,i} = 1 - \sum_{n=1}^{N} m_{n,i} = 1 - \omega i \sum_{n=1}^{N} \beta_{n,i} \quad (2)$$

Decompose $m_{H,i}$ into $\bar{m}_{H,i}$ and $\tilde{m}_{H,i}$ as follows:

$$\bar{m}_{H,i} = 1-\omega_i \text{ and } \tilde{m}_{H,i} = \omega_i (1 - \sum_{n=1}^{N} \beta_{n,i}) \quad (3)$$

$$m_{H,i} = \bar{m}_{H,i} + \tilde{m}_{H,i} \quad (4)$$

2.3. Combined probability assignments for a general attribute

The assessments of the basic attributes constituting the general property are aggregated to form a single assessment of the general property. The probability masses assigned to the various assessment grades, as well as the probability mass left unassigned, are denoted by $m_{n,I(L)}$, $\bar{m}_{H,I(L)}$, $\tilde{m}_{H,I(L)}$ and $m_{H,I(L)}$. Let $I(1)=1$. This gives us $m_{n,I(1)} = m_{n,1} (n=1,\dots,N)$, $\bar{m}_{H,I(1)} = \bar{m}_{H,1}$, $\tilde{m}_{H,I(1)} = \tilde{m}_{H,1}$ and $m_{H,I(1)} = m_{H,1}$. The combined probability masses can be generated by aggregating all the basic probability assignments using the following recursive ER algorithms:

$\{H_n\}$:

$$m_{n,I(i+1)} = K_{I(i+1)}[m_{n,I(i)} \times m_{n,i+1} + m_{H,I(i)} \times m_{n,i+1} + m_{n,I(i)} \times m_{H,i+1}]$$
$$n = \{1,2,\dots,N\} \quad (5)$$

In equation (5), we continue to let $i=1$. The term $m_{n,1}$, $m_{n,2}$ measures the degree of attributes ε_1 and ε_2 supporting the general attribute y to be assessed to Hn, the term $m_{n,1}$, $m_{H,2}$ measures the degree of only ε_1 supporting y to be assessed to H_n, and the term $m_{H,1}$, $m_{n,2}$ measures the degree of only ε_2 supporting y to be assessed to H_n.

$\{H\}$:

$$m_{H,I(i)} = \bar{m}_{H,I(i)} + \tilde{m}_{H,I(i)} \quad (6)$$

$$\tilde{m}_{H,I(i+1)} = K_{I(i+1)}[\tilde{m}_{H,I(i)} \times \tilde{m}_{H,i+1} + \bar{m}_{H,I(i)} \times \tilde{m}_{H,i+1} + \tilde{m}_{H,I(i)} \times \bar{m}_{H,i+1}] \quad (7)$$

$$\bar{m}_{H,I(i+1)} = K_{I(i+1)}[\bar{m}_{H,I(i)} \times \bar{m}_{H,i+1}] \quad (8)$$

$$K_{I(i+1)} = \left[1 - \sum_{t=1}^{N} \sum_{\substack{j=1 \\ j \neq t}}^{N} m_{t,I(i)} \cdot m_{j,i+1}\right]^{-1} \quad i = \{1,2,\dots,L-1\} \quad (9)$$

In equation (7), the term $\tilde{m}_{H,1}$, $\tilde{m}_{H,2}$ measures the degree to which y cannot be assessed to any individual grades due to the incomplete assessments for both ε_1 and ε_2. The term $\bar{m}_{H,1}$, $\tilde{m}_{H,2}$ measures the degree to which y cannot be assessed due to incomplete assessments for ε_2 only. The term $\tilde{m}_{H,1}$, $\bar{m}_{H,2}$ measures the degree to which y cannot be assessed due to incomplete assessments for ε_1 only. The term $\bar{m}_{H,1}$, $\bar{m}_{H,2}$ in equation (8) measures the degree to which y has not yet been assessed to individual grades due to the relative importance of ε_1 and ε_2 after ε_1 and ε_2 have been aggregated. $K_{I(2)}$ as calculated by equation (9) is used to normalize $m_{n,I(2)}$ and $m_{H,I(2)}$ so that :

$$\sum_{n=1}^{N} m_{n,I(2)} + m_{H,I(2)} = 1 \quad (10)$$

2.4. Calculation of the combined degrees of belief for a general property

Calculating the combined degrees of belief for a higher level property. Let β_n denote the combined degree of belief that the higher level property assessed to the grade H_n, generated by combining the assessments for all the associated basic attributes ε_i. β_n is then calculated by:

$$\{H_n\}: \beta n = \frac{m_{n,I(L)}}{1-\bar{m}_{H,I(L)}} \quad n = \{1,2,\dots,N\} \quad (11)$$

$$\{H\}: \beta n = \frac{\tilde{m}_{H,I(L)}}{1-\bar{m}_{H,I(L)}} \quad (12)$$

Steps 1-4 can now be employed for the other sub-trees, to obtain combined degree of belief for the higher level of the hierarchy model.

2.5. Using linear utility function

In this step, the utilities of the respective assessment grades $H_{1...n}$ are estimated via utility functions ($u(H_n)$). This estimation can be accomplished for instance by means of a range of methods and techniques that can be utilized for this purpose. In this paper however we will not dwell on the subject of utility estimations, rather we assume that the utilities of the respective assessments grade can be appreciated in a linear fashion. Therefore top level score of the hierarchy model can be obtained by $\sum \beta n\, u(H_n)$, n=1…N.

3. First Case Study: Prioritization Of Maintenance-Related Waste

The reduction and elimination of maintenance-related waste is receiving increasing attention because of the negative effect of such waste on production costs. The overall goal of this research is to identify and prioritize factors that can be considered maintenance-related waste within the automotive manufacturing industry [9].

3.1. Identification of Waste

To identify maintenance-related waste in the manufacturing industry, we held six workshops at five manufacturing companies. Brain writing and brainstorming were the main data collection tools. In total 465 maintenance-related wastes were discussed during the workshops. The classification into categories was performed by three researchers and through discussions, 16 final categories were decided upon. It was visible from the workshop analysis that the origin and cause of the maintenance-related waste could be linked to human factors. Therefore, in order for classification and model provision of maintenance-related waste linked to human activities, different literature in the area of human errors in maintenance field have been studied. the most efficient and relevant classification was related to a study about maintainer error by the Naval Safety Center's Human Factors Analysis and Classification System-Maintenance Extension (HFACS-ME) which was adapted for maintenance mishaps in aviation [10]. So, HFACS-ME is accepted as the basic framework and the 16 categories are incorporated into this model based on their similarity. The mentioned model is revised when no suitable category were found.

3.2. Constructing Survey

A survey was developed based on the identified maintenance-related wastes on the lowest level of the hierarchy model. It contains 28 questions; because of having no informative knowledge about different type of the waste it is assumed that all the waste attributes have equal relative weight (importance). Five distinctive evaluation grades are used to assess each question: H= {Very low, Low, Average, High, Very high}. The respondents were asked to assess each waste by assigning their belief degree to these five grades. A belief degree represents the strength to which the grade is believed to be appropriate for describing the opinion on the criterion. For example subjective judgement of an expert for the first question about "how much "inadequate process" are responsible for waste was: (Very high=0%, High= 10%, Average=20%, Low= "no idea", Very low=40%).

3.3. Data Analysis and Discussion

The main purpose in prioritization the human factors responsible for maintenance-related waste was to identify strengths and weaknesses which could form a basis for subsequent detailed assessments and help create action plans to address the weaknesses. This means management teams can focus on different factors to reduce or eliminate waste based on their importance for creating waste. A Windows-based Intelligent Decision System (IDS) is applied to implement the ER approach. IDS is a general-purpose multiple criteria decision analysis tool; it provides graphical interfaces to build a decision. The group belief degrees entered for each evaluation grades and for 28 questions (which were designed based on the lowest level of MWC-HF model) into IDS. As result of IDS for rankings of maintenance-related waste at the lowest level shows, "inadequate resources" and "weather /indoor climate," with average scores of 54% and 22% respectively, are the highest and lowest average scores for creating maintenance-related waste; see Table 1. This prioritization methodology can be used as a tool to create awareness for managers seeking to reduce or eliminate maintenance-related waste.

Table 1. Ranking of the maintenance related waste created by human factors

Maintenance related waste based on human factors	Score (%)	Rank
Inadequate Resources	54	1
Inadequate Supervision	52	2
Mental State	50	3
Poor EEM (Early Equipment Management)	48	4
Inadequate Process	47	5
Inadequate Documentation	46	6
Poor Spare Part Handling	45	7
Adaptability/ Flexibility	43	8
Inadequate Design	42	9
Inappropriate Operation	42	10
Judgment / Decision Making	40	11
Assertiveness	38	12
Communication	37	13
Training Preparation	37	14
Physical State	35	15
Unavailable/ Inappropriate	35	16
Inadequate Customer Demand	31	17
Certification Qualification	30	18
Lack of Employee Engagement	30	19
Inaccessible	29	20
Supervisory Misconduct	29	21
Limitation	28	22
Infringement	27	23
Uncorrected Problem	27	24
Environmental Hazards	26	25
Confining	24	26
Error and Violation	23	27
Weather /Indoor Climate	22	28

4. Second Case Study: Developing Sustainable Product Development Strategy

It has become increasingly important for producing companies to reduce their environmental impact. Companies are focusing more on preventing environmental issues by taking sustainability into the product development process, and not just reducing emissions from manufacturing the product [11].

Product development needs to be done with considering sustainability and without compromising future generation's ability to satisfy their needs. There are several strategies and methods developed to guide companies towards sustainability. The aim of this case study is to look at the possibility of having a new approach for sustainable design. So through a literature review six design strategies were taken into consideration in order to develop a new approach based on all advantages (sustainable factors) of the six approaches. Those six strategies are: eco-design, green design, cradle-to-cradle, and design for environment, zero waste and life cycle approaches. Together with literature review an interviews were conducted with managers from companies working with product development in Sweden to identify as many sustainable factors as possible. For ranking and finding out about the most important factors the evidential reasoning (ER) approach is used. The reason for application of ER is the qualitative nature of the data (factors) which add more uncertainty. Based on the literature several advantages and disadvantages are defined, both in regard of the environment and in a business perspective [12].

4.1. Result of Literature Review and Interview

Results shows, Eco design is a tool with most advantages, and green design has most disadvantages. By looking at the advantages, patterns emerge in the different approaches. By grouping the 38 advantages below similar advantages are merged. The disadvantages that were found are fewer than the advantages, most likely because the research focus on the benefits of the strategies. Several of the advantages can be seen as factors of sustainable design and by defining them there is a possibility of finding which factors are important to a new approach to sustainable design. The factors that were found is presented, in Table 2 with the design strategies related to each factor. To support the literature review and find other factors than the ones conducted from the literature review, three semi structured interviews were conducted with managers from companies working with product development in Sweden. Factors that were drawn from the interviews are: material selection, reduce energy usage, reduce emissions, minimize use of toxic substances, increased competitiveness and economic benefits. Some of these factors correspond directly to factors drawn from the literature, but two factors are added: "material selection" and "reduce emissions".

Table 2 - Factors of sustainable design and the corresponding strategies

Factors	Design strategy
Reduce energy usage	Eco-design
Reduce material usage	Eco-design, Life-cycle approaches
Reduce use of non-renewable resources	Green design
Reduce waste	Design for Environment
Eliminate waste	Cradle-to-cradle, Zero waste
Eliminate emission	Zero waste
Minimize use of toxic substances	Eco-design, Zero waste
Minimize waste	Green design
Recycle materials/component	Cradle-to-cradle, Design for environment, Zero waste, Life-cycle approaches, Eco-design
Reuse material/components	Zero waste, Life-cycle approaches, Eco-design, Cradle-to-cradle
Increase product functionality	Eco-design
Increase product lifespan	Eco-design
Increase use of renewable energy	Green design, Cradle-to-cradle
Increase use of renewable materials	Green design, Life-cycle approaches, Cradle-to-cradle
Increase use of biodegradable materials	Cradle-to-cradle
Closed loop material flow	Cradle-to-cradle
Holistic Approach	Life-cycle approaches, Cradle-to-cradle
Social standards	Green design, Cradle-to-cradle
Economic benefits	Eco-design, Cradle-to-cradle, Zero waste
Increased competitiveness	Eco-design

4.2. *Constructing Survey*

Based on the 20 factors collected from the literature review and additional 2 factors collected from interviews a survey was designed. The survey was sent together with instructions to people working with product development. The respondents were asked to answer the importance of each factors in sustainable product development based on five grades of H= {un-important, Not very important, Quite important, Important, Very important}. They were given the opportunity to answer the questions by assigning their degree of belief, from 0 to 100%, in different grades and for different answers. If they weren't sure of the importance of a factor, they could give the answer "don't know". The surveys were answered by 10 respondents with an average of 8 years of experience in product development.

4.3. Data Analysis and Discussion

The mean value for each grade and factor based on the results from the survey was calculated by adding up the respondents' degree of belief in each grade and entered into the IDS. The factors of sustainability are not arranged by hierarchy, it is assumed that all factors are top-level criteria.

The result of applying ER through IDS shows that all factors are important but the most important factors, with a percentage score of over 65%, which is the mean value of all factors, are: "Minimize use of toxics substances" (82%), "Increased competitiveness" (76%), "Economic benefits" (75%), "Reduce material usage" (74%), "Material selection" (72%), "Reduce emissions" (69%), "Increase product functionality" (69%), see Table 3.

By looking at the factors from Table 2 it is clear that most of the important factors are part of the eco-design strategy. Material selection" and "reducing emission" are factors that were obtained from interviews with companies. In other words all the important

factors, apart from the one collected from interviews are a part of eco-design. So it means among all strategies eco-design is the most dominant strategy in term of environment.

Table 3 – Important design factors and relevant score

Factors	Score (%)	Rank
Minimize use of toxic substances	82	1
Increased competitiveness	76	2
Economic benefits	75	3
Reduce material usage	74	4
Material selection	72	5
Reduce emissions	69	6
Increase product functionality	69	7
Reduce waste	64	8
Increase use of renewable energy	64	9
Social standards	64	10
Increase use of renewable materials	63	11
Holistic view	62	12
Recycling components/materials	61	13
Reduce use of non-renewable resources	60	14
Minimize waste	59	15
Reusing components/materials	58	16
Increase use of biodegradable materials	58	17
Increase product lifespan	57	18
Eliminate emissions	56	19
Reduce energy usage	55	20
Circular material flow	54	21
Eliminate waste	53	22

5. Conclusion

Many of the real life problems need making decision under uncertainty that is, choosing action among a set of actions considering different criteria based on often imperfect observations, with unknown outcomes. The Evidential Reasoning (ER) is one of the latest developments within MCDM literature and appears to be the best fit to handle uncertain information. ER can model multiple attribute decision problems which have both quantitative and qualitative attributes. In this paper ER is introduced and it is applied in two different case studies for prioritization and ranking of different factors. In the first case study it is applied to rank different maintenance related waste linked to human factors. The result showed, among all 28 factors identified in the workshop studies, “Inadequate Resources”, “Inadequate Supervision”, “Mental State of the workers” are the most important factors for creating waste by human in maintenance context at considered automotive manufacturing industry. Second case study look at the possibility of having a new approach for sustainable design. So through a literature review six design strategies were taken into consideration in order to develop a new approach based on all advantages (sustainable factors) of the six approaches. For ranking and finding out about the most important factors the evidential reasoning (ER) approach is used. After applying ER for the second case study the result showed among the sex sustainable design strategies most of the important factors were found in the eco-design strategy, however that strategy also contains factors that are not as important, and two of the important factors are not found in any strategy but in interviews. These factors represent the building blocks for a new approach. As a future research extension modelling of other type of uncertainty, such as interval uncertainties, uncertainties in other parameters of a decision problem such as criterion weights and belief degrees is recommended.

Acknowledgment

The research work is part of the initiative for Excellence in Production Research (XPRES) which is a cooperation between Mälardalen University, the Royal Institute of Technology, and Swerea. XPRES is one of two governmentally funded Swedish strategic initiatives for research excellence within Production Engineering.

ABSTRACT

At present in Mexico, the renewable energy has become more important due to the great dependence of the country for fossil fuels. Within the several applications of renewable energy, there are the geothermal applications for the air conditioning of spaces. This technology employs heat pumps that interexchange heat with the ground. This technology is relatively young in Mexico, leaving a large field for study and application throughout the country. In this way, to calculate the correct sizing of geothermal heat exchangers, it is necessary to calculate the thermal loads of the complex in which this technology of geothermal heat pumps using vertical heat exchangers type U will be installed, to perform the calculation of thermal loads Autodesk Revit® software was used, with which was possible to make a virtual model in detail of the botanical center that is located in Morelia, Michoacán, Mexico and belongs to the Universidad Michoacana de San Nicolás de Hidalgo (UMNSH).

This study shows the results of the analysis of the installations and determination of the thermal loads of the complex due to this type of infrastructure. By obtaining the values of the thermal loads, the dimensioning of the heat exchanger was archived, which will have to be installed to cover the thermal requirement of this system and his installation, in addition to the selection of the heat pump. This complex of 2 levels, where, on the first floor there are cubicles and laboratories and on the second floor, several common areas.

The design was developed in detail in Autodesk Revit 2015. After obtaining the thermal loads, the GLHEPro software was used for dimensioning the Vertical heat exchangers with the number and depth of the exchangers was obtained. the GLD 2014 software was used for dimensioning the Horizontal heat exchangers with the number and depth of the exchangers was obtained.

1. Introduction

Climate change is, according to experts, one of the greatest challenges facing humanity. This means that all public and private actors in global society must work together to reduce greenhouse gas emissions and adapt them territorially and sectoral to the potential effects so that we build a prosperous, sustainable and peaceful future [1].

An alternative to collaborate with the environment and the application of sources of renewable origin:

Mexico presents in most of the territory medium and low enthalpy resources that are not exploited for the generation of electricity, and to which they are not used for direct uses. In Mexico, geothermal energy is solely employed to power generation. Direct use is still in a developing phase and currently it is restricted to supply bathing and swimming facilities. Geothermal heat pumps usage is minimal and underdeveloped without available data.[2] Geothermal energy is an alternative that can be used to produce electricity, store energy for heating and air conditioning devices in various facilities, and provide heat for a variety of commercial and industrial processes. Due to the constant temperature in the subsoil, a geothermal heat pump

*Corresponding Author: M.C. Oskar Javier González Pedraza, Santiago Tapia 403 Morelia, Michoacan México | Email: oniblueoskar@gmail.com

system typically has better performance than conventional systems. Geothermal heat pumps are used around the world to heating and cooling of buildings. Heat pump efficiency relies on the temperature of the fluid that provides the heat, in the side of ground, which is affected by the annual temperature profile and the pits distribution [3]. Low Temperature Geothermal Energy (LTGE) is the energy accumulated in the field generated from the heat exchange with the atmosphere at low temperature, it is an alternative energy source capable of satisfying the energy demand for domestic heating and cooling.

Horizontal Geothermal heat exchangers (HGHEs) with vertical springs have been increasingly used in Geothermal Sytem of Heat Pumps (GSHP). The current studies have been carried out by utilizing field trials and simulations focused in reveal the heat transfer mechanisms of HGHEs to procure an adequate performance of heat exchenge [4]. In [5] it is analized a solution of the interaction between a Photovoltaic generator (PV) and a GSHP to be used in a residential building. The main goal is to review the operative functioning of a self-sufficient system that enable the maximal self-consumption in the building itself: these systems can provoke a major penetration of Renewable energy sources in a complex energetic context.

Vertical geothermal heat exchangers are more common to be installed in areas where there is not enough space to place horizontal type heat exchangers. For the installation of the type of vertical exchanger configuration, drilling is performed in a very small space of land; The advantage of having a vertical type configuration is that it has a lower temperature fluctuation, which gives higher values of the operating coefficient.

Figure 1 shows schematically the operation of a heat pump with geothermal heat exchangers. In Mexico, the construction of an air conditioning system by means of heat pumps by means of geothermal heat exchangers has not been reported. Therefore, the present study studies the technical viability of the installation of this type of systems in national territory.

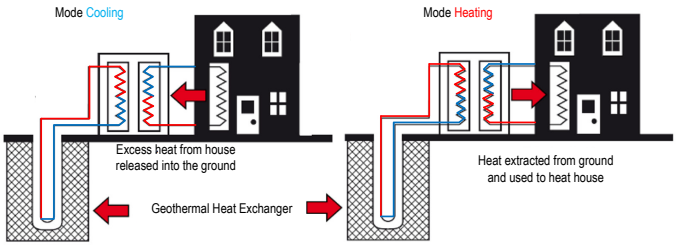

Figure 1. Operating of a conditioning system using a Heat pump with geothermal heat exchangers.

2. Case Study

Revit® software was used to calculate the thermal loads, which is contained within Autodesk® CAD software. This software allows to detail the whole and its spaces, for the calculation of the thermal loads of the complex. The case study refers to a building consisting of 2 levels, in the first level are the laboratories of sinecology, mycology, vascular and non-vascular plants, Palynology and sanitary. On the second level is a cafeteria, herbarium area, a silver reception area, quarantine area, multipurpose room and library. The calculation of thermal loads is essential for the selection of the different heat pumps to be installed in the system, as well as the dimensioning of the air ducts and the geothermal heat exchanger system. In **Figure 2,** show different views of the resort on its facade and plan views of the distribution of spaces.

The construction of the model on the Autodesk Revit® platform is specifically done using the Building Information Model (BIM) technique, and includes architectural design, structural engineering, MEP and construction. BIM is the process of generating and managing building data during its lifecycle, using dynamic real-time, three-dimensional building modeling software to reduce time and resources in design, construction and calculation. This process produces the building information model (also abbreviated BIM), which covers building geometry, spatial relationships, geographic information, as well as the quantities and properties of its components. The software has a basic of international climatic data, which allows, in the software, to locate the exact region of the building, as well as its orientation. When detailing each internal component of the model the software is able to determine the thermal loads through a year and with this determine the loads of summer and winter. The software is based on the methodology ASHRAE 2005[6].

Figure 2. 3D view of the outer facade of the complex.

In this platform, it is possible to calculate the thermal loads for both summer and winter, to locate in detail the location of the complex to increase the accuracy of the calculation of thermal loads due to solar incidences in walls, ceilings and windows, as well as infiltrations due to the Air currents of the area in question, in addition to allowing the dimensioning of the air distribution ducts. Table 1 summarizes the overall calculation of the maximum and peak values shown and flux densities of the entire complex, can be noted that the maximum cooling load is 65.6 kW and maximum load Heating is 1.28 kW. With this we can appreciate that the requirement of these educational facilities will be primarily in cooling mode.

Table 1. Herbarium Summary

Entries	
Types of construction	Educative Center
Area (m²)	756.16
Volumen (m³)	2,080.20
Calculation Results	
Maximum value of total cooling load (W)	**73,906**
Maximum cooling value (month and hour)	May 02:00 p. m.
Maximum value of sensitive cooling load (W)	65,602
Maximum latent cooling load value (W)	8,304
Maximum cooling capacity (W)	73,906
Maximum value of cooling airflow (L / s)	5,821.20
Maximum heating load value (W)	**1,286**
Maximum value of heating air flow (L / s)	5,572.30
Checking Sums	
Density of cooling load (W / m²)	97.74
Density of the cooling flow (L / (s · m²))	7.7
Cooling flow / load (L / (s · kW))	78.77
Cooling area / load (m² / kW)	10.23
Density of heating load (W / m²)	1.7
Density of heating flow (L / (s · m²))	7.37

3. Analysis and Results to the Virtual Model of the Facility

It was conducted a loads analysis to cooling and heating, in order to select the proper zones in the complex to install the Air conditioning System. Once review, the value of load in the two working modes comes from the herbarium, followed by the library and then all the laboratories at the bottom and finally the multipurpose room and the editing room, this can be seen in Figure 3. Figure 4 shows the thermal loads of heating and appreciated that spaces having larger load are the library, the multipurpose room and assembly, and Zone of reception of plants, this is because they are zones with great incidence solar by the windows and of conduction by ceiling and walls, which will be the zones of priority for the system of conditioning.

Figure 3. Distribution of thermal loads of the school of refrigeration loads (W)

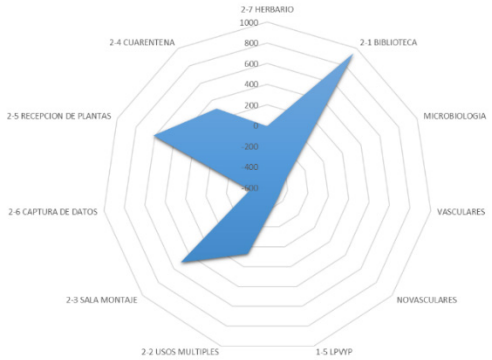

Figure 4. Distribution of heating loads of the school of heating loads (W)

In Figure 5, the monthly average thermal loads shown in cold mode, these loads are due to the transfer of heat generated by the occupants, electrical equipment and laboratory equipment, they are also considered heat gains due to windows and the incidences of the sun, and the transfer of heat through the walls of the enclosure, ceilings and floors. As you can notice the months in which it will require more use of the cold mode of the heat pump will be from the month of May until October of each year.

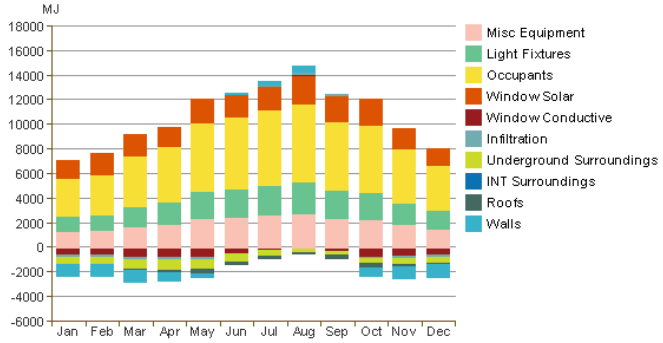

Figure 5. Average monthly heat load in cold mode

In Figure 6, the monthly average thermal loads shown in heat mode, these loads are due to the transfer of heat emitted by the occupants, electrical equipment and laboratory equipment, they are also considered heat gains due to windows and the incidences of the sun, and the transfer of heat through the walls of the enclosure, ceilings and floors. It can be noted in the figure that the months in which the system will be used in heat mode will be the months from November to March of the year.

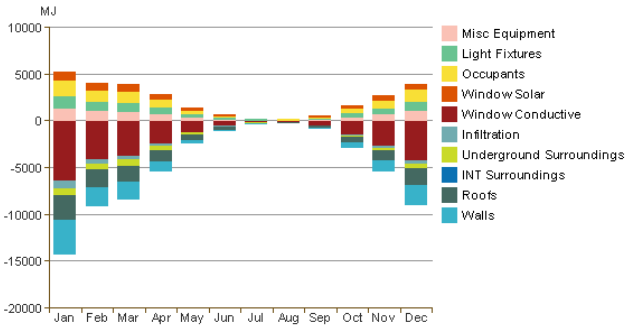

Figure 6. Monthly average heat load in heat mode

In Figure 7, the consumption of electricity over a year shows, you can note that the maximum consumption occurs in the months of December to March, in these months do not have daylight saving and lighting Solar is for few hours so the electricity consumption is higher while the other months have a lower consumption due to the little use of lighting.

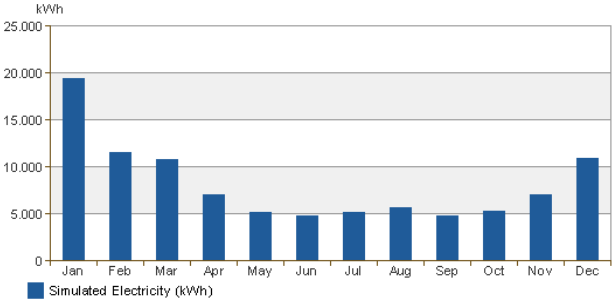

Figure 7. Monthly consumption of electrical energy of the complex

4. Results and Discussion

After obtaining the value of the thermal load under which the whole complex will be operating, the dimensioning of the heat exchangers was started, for which two commercial software's were used. In the first instance, we will perform the dimensioning of the vertical heat exchangers and then the horizontal ones, it is worth mentioning that, between the two systems, the thermal load of the complex will be divided.

In order to calculate the length of the heat exchanger, we will use specialized software tools. In this case, the GLHEPro® numerical tool was used, which specifies the type of heat exchanger to be installed, physical characteristics of the vertical heat exchanger, Specifications of the floor type, in addition to the type of coolant to be used in the heat exchangers which in this case would be water. After all the values required for the simulation of the well are loaded, the thermal loads are introduced to the system which were calculated by the Revit® software.

The U-type heat exchanger, proposed for the storage and recovery of geothermal energy from the well and subject of the present analysis, converting the soil into a thermal sink, the pipes were considered to be high density polyethylene (PAD), the grout is of a mixture of concrete, silica sand and water, the material around the terrain, are those found in the field in which these exchangers are being installed, the type of soil in the area will provide the values of the thermal properties. The average thermal conductivity of the soil obtained by the rheological drilling column is 0.8657 W / (m ° K) and the thermal resistance of the exchanger is 0.3048 ° K / (W / m), the volumetric flow of the system is recommended by IGSHPA [7] of 1.9962 L / s, the thermal conductivity of water 0593 W / (m ° K) and heat capacity of 4173.36 kJ / (° Km $^{3)}$. In Figure 8 the scheme proposed heat exchanger is shown.

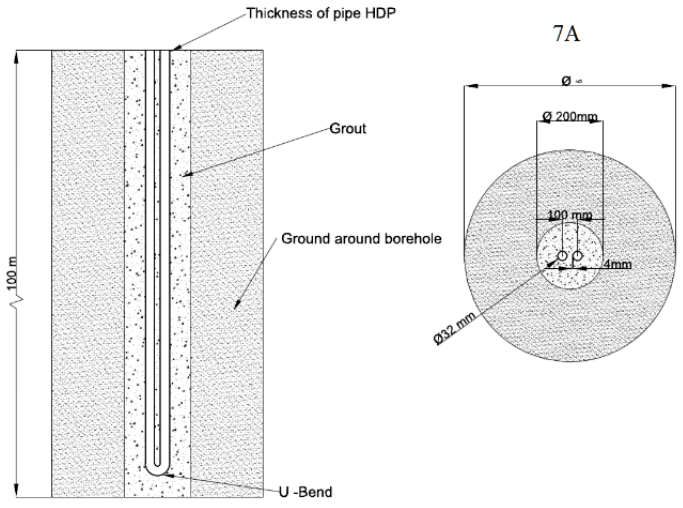

Figure 8. Schematic of the geothermal heat exchanger.

Once the calculation was carried out in the software, the results obtained are from the need of 4 vertical exchangers with a depth of 88.29 m and a total drilling depth of 353.16 m, and a distance between interchangers of 4.57 m. The maximum temperature value will be 25.51 ° C and with a minimum of 6.23 ° C and with temperature peaks ranging from 31.53 ° C and -6.67 ° C. With these temperatures. It can be concluded that it may be necessary to add some antifreeze to the system for its operation and with that the system works properly. The software has a tool to perform the optimize of the appropriate size, using this tool the software tells us that the length of the exchangers will be 81.15 m with a total drilling length of 324.6 m, and a separation distance between exchangers of 4,572 m. The maximum temperature will be 25.93 ° C and with a 6.5 ° C and the temperature peaks at 32.22 ° C and -6.67 ° C. With these temperatures, the need to add some antifreeze to the system is also confirmed for its operation.

Figure 9 shows the proposal for the interconnection of the heat exchangers, the figure shows the dimensioning of pipe exchangers, like the inkjet heads and refrigerant recovering also the dimensioning of the accessories for installation, As well as the mass flow in gal/min in each of the sections of the heat exchanger. For sizing, the horizontal heat exchanger shown in Figure 11 was performed using the software GLD 2014, this tool allows for vertical and horizontal dimensioning exchangers with a large number of configurations. This software uses an iterative method for its solution by feeding parameters divided into specifications of fluid, soil, piping, configuration and auxiliary equipment.

Figure 9. Schematic of the air conditioning system using a geothermal heat pump

Figure 10 shows the behavior of the maximum average temperature of the exchangers during operation over 10 years of operation. It can be observed on the temperature profile curve the effect provoked to the underground due the operation of heat exchangers on this soil. From the graph, it is clear that variations are minimal as well as soil perturbances. The variance of 1°C demonstrate that along 10 years of usage the system will not affect the surroundings or the environment where installed.

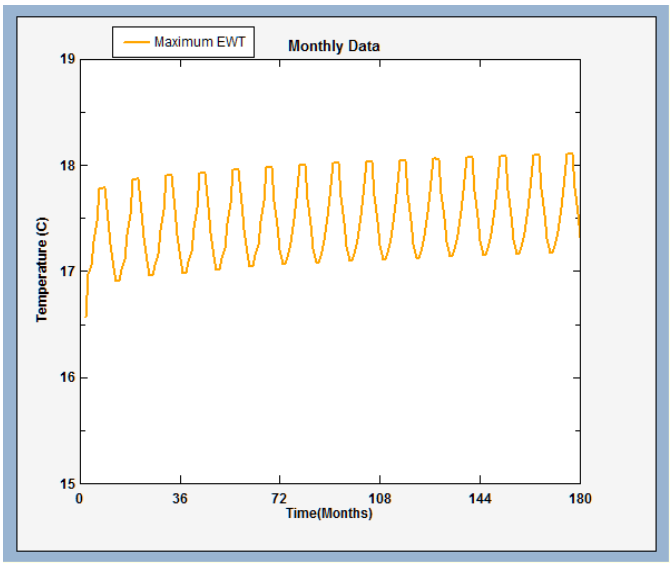

Figure 10. Behavior of the set of heat exchangers with maximum temperature

For the dimensioning of the horizontal heat exchanger shown in Figure 11 was performed with the help of GLD 2014 software, this tool allows the design of vertical and horizontal exchangers with a large number of configurations. This software uses an iterative method for its solution by feeding proper parameters: such as specifications of fluid, soil, piping, configuration and auxiliary equipment.

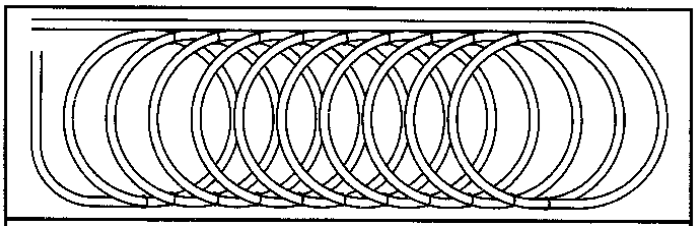

Figure 11. Slinky horizontal geothermal heat exchanger for trenches

The parameters of the pipe comprise the thermal conductivity of the pipe, and its dimensions as outer and inner diameters and the die, plus the type of internal flow of the pipe. In the configuration of the heat exchangers the software has the different types of trenches that can be applied, in this study we used the trench slinky type, this is a pipe coil, this technique requires less space than other techniques, using only 4 lines with a separation of 6.1 m between them to a depth of 1.8 m and a width of 20 cm, the particular measures of the slinky type heat exchanger is a diameter of 91 cm and a separation between them of 52 cm. The next thing is to quantify the heat gains of the system by use of pumps and auxiliary equipment, in this case only a 2.5 HP heat pump is taken into account to be able to move all the fluid through the heat exchangers to the heat pumps.

After entering the parameters required by the software as in the previous calculation, the iteration is performed to be able to quantify the dimensions of the system, in this case the result obtained is 4 trenches with a total length of 101 m, whereby each Trench will have a length of 25.3 m, the total length of the system will be 1347.6 m of pipe

In Table 2**,** the selection of the heat pump for space with increased demand and usage shown. The criterion of the selection of heat pumps is made by means of the air flow of the system for each space and these must also meet the requirements of thermal load in both cold and heat mode [7]. These values are also obtained by the 3D model space subject of analysis which are shown in Table 2. In Mexico it has a large number of companies that provide conventional air conditioning systems, in this case it was decided to make the selection of heat pumps in the catalog of the company Daikin.

Table 2. Selection of heat pump for Herbarium

Space	Maximum cooling load value (W)	Maximum cooling load value (BTU/hr)	Cooling airflow (L/s)	Maximum heating load value (W)	Maximum cooling load value (BTU/hr)	Heating air flow (L/s)	Daikin Unit

5. Conclusion

The purpose of this work was to design the system for air conditioning using heat pumps with U-type vertical heat exchangers through the use of different software for a student laboratory complex located in Morelia, Michoacán, Mexico. With this dimension, it makes clear the feasibility of installing these systems in Mexican territory and the learning of technical and field capacities in a multidisciplinary way. In addition to the development of a methodology for the integration of different software such as Autodesk Revit® and GLHEPro®, in which it was possible to model the building in detail for the calculation of thermal loads and the dimensioning of vertical heat exchangers. The length of the exchangers will be 81.15 m with a total of 4 heat exchangers, and a separation distance between exchangers of 4,572 m In addition to the horizontal heat exchanger system which are formed of 4 trenches with a total length of 101 m, Whereby each trench will have a length of 25.3 m, the total length of the system will be 1347.6 m of pipe, the heat pumps selected for the highest priority spaces for its Daikin models 30, 42 and 48. Which meet the need for mass air flow and thermal load in both heat and cold.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors wish to acknowledge the SENER and CONACYT institutions for their support in CeMIE_Geo projects, particularly the P-30 project.

Space Time diversity

ABSTRACT

The track circuits are very important equipments used in the railway transportation system. Today these are used to send vital information, to the running train, in the same time with the integrity checking of the rail. The actual track circuits have a small problem due to the use of the same transmission medium by the signals containing vital information and the return traction current, the running track rails. But this small problem can produce big disturbances in the train circulation, especially in the rush hours.

To improve the data transmission to the train on-board equipment, the implementation of new track circuits using new communication technology were studied. This technology is used by the mobile and satellite communications and applies the principle of diversity encoding both time and space through the use of multiple transmission points of the track circuit signal for telegram which is sent to the train. Since this implementation does not satisfy the intended purpose, other modern communication principles such as 8PSK signals modulation and encoding using Trellis Coded Modulation were developed. This new track circuit aims to solve the problems which appeared in the current operation of track circuits and theoretically manages to transmit vital information to the train on board equipment without being affected by disturbances in electric traction transport systems.

1. Introduction

In the paper [1] "Track circuit with space-time coding" it has been shown that the present track circuits used in metro lines have some problems, connected with the train transmission telegrams due the electrical perturbation produced by the train return current. To have one conclusion about this problem, at the Bucharest Metro line, measurements were taken and oscillograms picked-up, for more than 100 track circuits. These measurements were conducted to find the real cause of the sudden emergency brakes applied by the running metro trains. The trains lose the command telegram for a while and apply the brakes for safety reasons. The telegram contains the permissive orders to run regarding the permissive speed and distance to go. These emergency brakes lead to disturbances in the train time schedule and jeopardize the passengers' safety. To solve this problem, several solutions have been proposed but none of them have been able to fully meet the proposed goal.

In paper [1] "Track circuit with space-time coding" an embodiment was proposed to be utilized, using the existing signalling equipment, to ensure the transmission of the telegrams to the train using two transmitter points at a fixed position from one another. The two telegrams emitted by tuning unitsTU1-a and TU1-b arrive to the train at a time interval δ one after the other. This interval enables the rapid verification of the telegrams if they contain errors and if they do, the receiver can correct them.

The disadvantage of the embodiment is that on the distance between the two transmitters TU1-a and TU1-b, the train receives only the second telegram, leading to the need of a geographical map at the on board receiver and the verification of the position of the train if it is found between the TU units. But the main disadvantage is the use of additional equipment which has a high cost, namely one TU unit for each track circuit.

The train receives orders that authorize its movement entire in full safety conditions. The orders are embedded in a telegram that is transmitted through the track rails. The telegram addressed to the train can be disrupted and the train cannot recognize the transmitted order. And this fact leads on the train to apply the emergency brake [2].

The telegram is affected while it passes through the communication channel via rails [3]. This channel is not a special channel built for data transmission. Because of this, the telegrams

are affected by the return traction current and electrical noise produced by the electrical motors of the train. In this paper such issues are analyzed and a new solution is proposed to solve the telegram loss by the train, when the telegram is affected by disturbances similar to Dirac impulses.

The QPSK-MIMO track circuit proposed in previous works cannot provide telegram transmission during the window time requested by the receiver. The two telegrams required for MIMO diversity are composed of 8 bits needed to identify the track circuit, 29 bits of information, 1 utility bit, and 33 bits allocated for the verification of the telegram by CRC code totaling 72 bits per telegram [4]

For the transmission of the two telegrams in the window time allocated by the receiver for the reception of a telegram, namely 630 ms [5], one should be reduced the bit time by way of changing the oscillators in the existing receivers, which does not correspond with the scope to improve the current system with minimum changes. The second method of shortening the transmission time of the telegram is to decrease the length of the transmitted telegram. In order to reduce the transmitted telegram, the only option is to drop the CRC code and replace it with another encryption and error protection system. In order to transmit the 38-bit utility telegram it is needed to look for a coding to allow the telegram to be checked and the transmission to be carried out in less than 315 ms even below 300 ms, because 15 ms should be allocated to the time between the two telegrams.

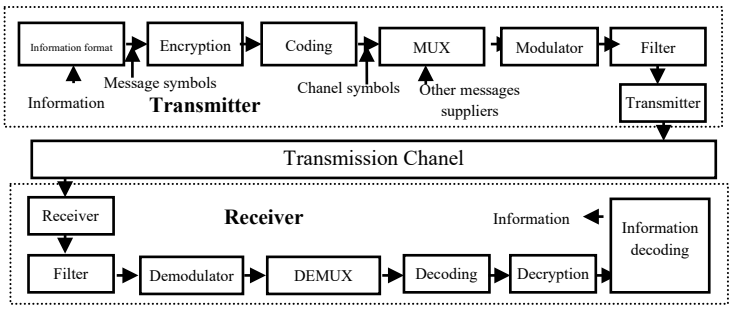

Figure 1. Transmission of information in communication systems

In the previous works have been implemented the transmission technologies used by today's WIFI communications systems so far, in this paper is proposed to try to use Trellis encoding. Trellis encoding is a coding commonly used in current communication systems. The transmission of the telegram in the current system is performed by transmitting the information in 30-bit information blocks which are accompanied by a 33-bit CRC block. If an informational bit is affected at the moment of reception, when performing the polynomial division modulo two, the result is not identical to that of the CRC code, and the telegram is declared disrupted. If a convolution code is used then information bits and control bits are combined into a set structure, practically decoding is bitwise with a continuous bit and if a bit is disturbed then it is not considered to be the entire lost word. In the classical data transmission systems functional blocks appear as in Figure 1. In a communication system two main functional blocks can be distinguished, namely the transmitter and the receiver. The main functionality blocks are: „information formatting block" - it collects the information that is the subject of the transmission and processes it by obtaining the message symbols and then these messages enter into the „encryption block" to ensure data protection.

The message is coded [6] to be transmitted through the communication channel in order to obtain the channel-specific symbols, the „multiplexing block" which allows the access to the transmission channel of several message sources. The received messages are modulated and passed through a „band pass filter" that only allows the passage of useful frequencies to the „broadcasting block". The „broadcast block" amplifies and does the adaptations with the „data transmission channel" towards the reception. At the „reception", the information is extracted by the reverse execution of the operations performed in the „broadcasting block". If a more efficient system is desired, the complexity of the system must be increased, with the advantages and disadvantages of the solution. Increasing the system performance can be done by using Trellis Coded Modulation (TCM). The use of Trellis coding performs coding and modulation of the signal in the same block, which reduces the time required for data processing, but at the same time requires specialized electronic components made by state-of-the-art techniques, allowing complicated operations. Trellis encoded data transmission systems have very good noise protection and are used for high-speed data transmissions. In the case of a limited power communication channel, increasing energy efficiency can be achieved by using error correction codes. Corrector error codes supplement additional bits to the transmitted encoded information sequence. Adding supplementary bits to the useful information results in the need for longer words to be transmitted, and if they need to be received in a given window time, it is necessary for the modulator to work at a higher frequency requiring a wider frequency band. The maximum data transmission speed through an ideal communication channel (stable, homogeneous, invariant in time, without distortion) is limited. This limit, called the capacity of the communication channel C [bit / s], was established by Shannon for an ideal channel with add-on Gaussian white noise, with a mean power of the useful signal and assuming the infinite coding, as to be:

$$C = B \log_2 (1 + P/N) \text{ [bit/s]} \quad (1)$$

Where the capacity of the communication channel is denoted by C and B is the bandwidth available for communication, the average signal power is P and the average noise power is N. In the case of a limited frequency band communication channel, increasing the spectral efficiency can be achieved by using modulators that maintain a large distance between the signals. These modulator processes are based on Shannon's 2nd theorem: a source with the information flow R (bit / s) and a channel with capacity C (bit / s) and if R <C then there is a code with words of length „n" such that the probability of a decoding error P_e to be $P_e \leq 2^{-nE(R)}$ where E (R) is a non-negative function called the exponent errors - the theorem allege that indifferent how much the channel transmission is disturbed, the broadcast can be made with a minimal error probability. The sequence error probability (as well as the probability of symbol error) is limited up by a decreasing function ratio d_{min}^2 / N_0 and is well approximated by this expression when the signal / noise ratio is high. In the above expression d_{min}^2 is the square of the minimum Euclidean distance between two possible signal vector sequences. The Euclidean distance is a straight line between two points "s_1" and "s_2", each point is defined by the Cartesian coordinates (2). The distance between the two symbols is given by the relationship.

$$d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2} \quad (2)$$

For digital transmission, the equivalent of the Euclidean distance is the Hamming distance given by the relation (3), this is

zero if the binary words are the same. These two distances are useful in signals processing.

$$d_H(x,y)=\sum_{i=1}^{n} d_H(x_i,y_i); \quad d_H(x,y)=\begin{cases} 1 \text{ daca } xi \neq yi \\ 0 \text{ daca } xi = yi \end{cases} \qquad (3)$$

For an optimal communication, a long sequence of signals with maximum separation must be transmitted, and the receiver must decide on these long signals rather than individual bits or symbols.

If the designing process of these long signal sequences is properly performed, the error probability of the message „v_e" decreases exponentially with the length n.

$$P_e < k e^{-(R_0-R)n} \qquad (4)$$

Where the transmission rate R is less than the maximum rate R_0 as given by the Shannon capacity of the channel. In conventional transmission, encoding is separate from the signal modulation operation. Coding is done at the digital level, this in generally adds bits to the streams to be transmitted and requires an increased bandwidth. At the receiver the decoding occurs after the signal demodulation. The demodulation can be done by electronic circuits for decision, with voltage thresholds, and is called „hard demodulation" or can be done by sampling the received signal and comparing these samples with memorized patterns of the signal accompanied by Gaussian noise, this is a „soft demodulation". "Soft demodulation" brings a 2 dB gain compared to „hard demodulation". The decoding operation is executed for the entire data stream that feeds the decoder, whether it contains an error or not. Decoding can be done by sampling the received analogue signals and comparing them with memorized patterns, this is a comparative decoding. The theoretical loss of the decoder by electronic decision over the comparative decision is about 2 dB. Modulation of coded signals can be a 2D modulation, which uses the dependence between the initial phase and the phase of the quadratic symbols. It is manageable to have a 4D modulation; where it introduces the dependence of the symbols of two successive time intervals. A Trellis modulation can be used, that introduces the dependence of each successive symbol. Trellis and multidimensional codes are designed to maximize the Euclidean distance between the possible sequences of the transmitted symbols. The distance between the nearest possible symbols transmitted in the signal space determines the performance of the code $Pc \sim e^{-d_{min}^2/2N^2}$ where d_{min} is the minimum distance between the signal sequences and N is the noise power in the channel. Trellis Coded Modulation combines modulation and encoding in the same block, while the bandwidth is not increased. It has the same symbol rate, but redundancy is introduced by using to encode a constellation with more points, than it would be needed without encoding. For Trellis Coded Modulation the number of point doubles but the symbol rate is the same and the spectral power remains the same. Since there are several possible points per symbol, it can be considered that for a given noise signal ratio the probability of error increases. As with the conventional coding, there is a dependency between different symbols. Only certain secure sequences for successive points of the signal constellation are allowed for Trellis encoding. By applying these constraints optimally at the reception, the probability of error decreases, as a measure of the transmission performance while growth the coding gain. This is the difference between the transmission through a channel with the same noise to signal ratio of the same information in a coded system and a non-coded system. The key element of Trellis Coded Modulation, to improve the power efficiency of a coded channel, is to insert a memory circuit. To compensate the redundant bits added at the signal encoding, a constellation with more than 2^n symbols is used. The design of the encoder and the constellation map is collaborated to reduce the complexity of the decoder. Using an 8-layer constellation for signal encoding, theoretically 2 bits per symbol can be transmitted with an error below 13dB. Using a coded modulation it is possible get a 6dB gain at the same symbol rate without increasing bandwidth [7]

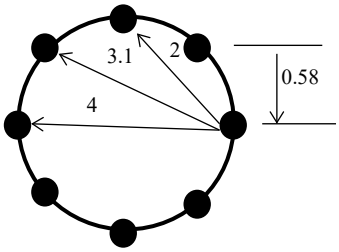

Figure 2. Euclidean distances for 8PSK

Trellis encoding, for a given limited channel bandwidth, at first, will be determined the rate of symbols that can be transmitted. The size of the 2L alphabet, which is required to produce the required bit rate, is determined. The constellation size is doubled and inserted into the encoder, which will generate an extra bit. It is not necessary that all the bits from the encoder input to be passed through the encoder. There are several ways to encode the bits in the symbols. The selected mapping can dramatically improve or dramatically reduce the code performance. Ungerboeck proposed a heuristic technique called mapping symbols, by partitioning symbol sets. The coding philosophy is to position the large constellation of 2^{2L+1} signals in smaller sets. The Euclidean distance between the signal point sequences in the different subsets is substantially increased (can be of the same order for all points in the same subset). Performance can be determined by the distance between symbol sequences in different subsets. Trellis encoding produces a substantial increase in the Euclidean distance between the signal sequence points so that at the receiver, the Viterbi algorithm can be used to detect the signal.

Ungeboeck in 1976 showed that for channels with bandwidth restricted by using convolution signal encoding, the gain of coding by comparison with binary encoding of the same signal can be substantially improved [8]. He proposed the use of modulation and coding together, to increase the Euclidean distance between the signal sequences. This was called Trellis encoding of the channel, because the sequence states in the finite state automaton that encode the signal levels describe a trajectory in the form of trellis for the possible passages. The largest Euclidean distance between the signal sequences, the lowest error rate for the noise signal ratio is $P_e = N_{free} Q(d_{free}/2Z)$ where N_{free} is the mean of the sequence numbers at the distance d_{free} and $Q(x) \sim e^{-x^2/2}$.

The code words consist of level sequences modulated. Trellis encoding uses dense signal sets but restricts what sequences can be used. These produce a minimum distance gain and the code requires a time dependence of the signal sequences that allow the receiver to pass over the noise bursts like the transmitted sequence estimates. Since the shape of the symbol and the transmission rate are unchanged, coding does not require any bandwidth increases.

This theory can be applied in track circuits for telegram transmissions to the train in FSK system, for which two symbols are used. To use a TCM for the order telegram, the FSK modulation signal can be used and, according to Ungerboeck's rules, a dual-signal constellation with 4 frequencies is needed:

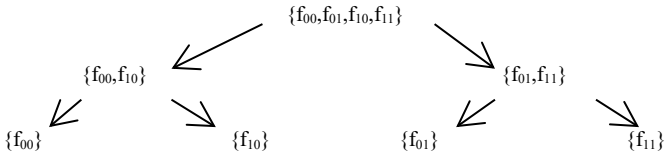
The frequency band is kept by setting the conditions:

$$f_{00}-f_{10}= f_0-f_1$$

$$\text{and} \quad f_{00}-f_{01}=f_{01}-f_{10}=f_{01}-f_{11}$$

This requires a slightly more complicated receiver, but not so much. Indeed, the demodulator is a frequency-to-voltage converter: for example, for the frequency f_0 at the output will have -U (volts) and for the frequency f_1 the output will be + U (volts).

If there are 4 frequencies, the demodulator gives to the output for each frequency a preset voltage value as in the following example: For f_{00} the output will be -3U, for f_{11} is + 3U, for f_{01} is -U and for f_{10} output will be + U. The four-level signal ± U, ± 3U is easy the convert into di-bits (two-bit group). The four-frequency set is divided so that the minimum distance between two characteristic frequencies increase:



The new aspect of coded modulation Trellis is that the encoding and modulation operations are not treated as independent operations, but as a single operation. The signal received, instead of being first demodulated and then decoded, is processed by a receiver that combines demodulation and decoding in a single operation. The detection process involves more soft decisions than hard decisions (the incoming signal is processed before making the decision with which data source symbol it matches). To exemplify the operation, a convolution Trellis coder is used as in Figure 3

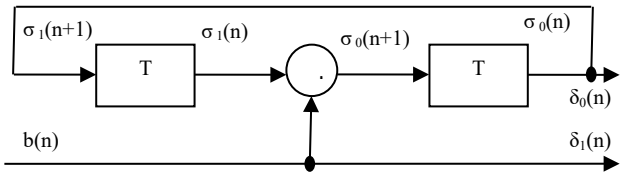


Figure 3. Transmission of information in convolution systems

The input bit b_n goes unmodified at the exit and is renamed $\delta_1(n)$, $\delta_1(n)=bn$

The convolution encoder has 4 states, given by bits $\delta_0(n)$ and $\delta_1(n)$. These states are the outputs of some delay elements (bi-stable, tipping circuits) that use a tact T equal to the duration of one bit. For the coder shown in Figure 3:

$$\sigma_0(n+1) = bn \oplus \sigma_1(n)$$

$$\delta_0(n) = \sigma_0(n)$$

$$\sigma_1(n+1) = \sigma_0(n) \qquad (5)$$

Table 1 Frequencies of signal issued to Trellis encoding

$\delta_1(n)$	$\delta_0(n)$	frequency
0	0	f_{00}
1	0	f_{10}
0	1	f_{01}
1	1	f_{11}

The two output bits δ_0 (n) and δ_1 (n) select the frequency of the transmitted signal as shown in Table 1:

The four-state Trellis graph which represents the operation of the convolution encoder is shown in Figure 4:

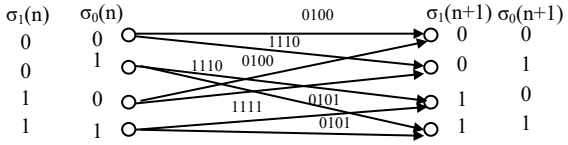

Figure 4. Four-State Trellis Graph

The convolution encoder state table, according to the previous states and the input data described above, is as follows:

Table 2 Trellis convolution coder states

$\sigma_1(n)$	$\sigma_0(n)$	b_n	$\sigma_1(n+1)$	$\sigma_0(n+1)$	$\delta_1(n)$	$\delta_0(n)$	frequency
0	0	0	0	0	0	0	f_{00}
		1	0	1	1	0	f_{10}
0	1	0	1	0	0	1	f_{01}
		1	1	1	1	1	f_{11}
1	0	0	0	1	0	0	f_{00}
		1	0	0	1	0	f_{10}
1	1	0	1	1	0	1	f_{01}
		1	1	0	1	1	f_{11}

If the encoder state is "00" and the input bit is b_n = "1", the encoder switches to the state "01" and the transmitted frequency is f_{01}. One advantage of the FSK modulation is that it does not need to equalize the transmission channel. For demodulation, the receiver uses only the input signal frequency, ignoring the amplitude and phase. For the above Trellis encoded scheme, the Viterbi algorithm can be used at reception. The algorithm was first proposed in 1967 and is an asymptomatic optimal decoding technique for convolution codes. It can be used to determine the encoded signal sequence close to the received signal sequence with the condition that the signal sequences transmitted are finite. The decoder determines the nearest signal sequence coded, directly from the information channel output. The most probable errors made by the decoder's optimal soft decision are related to the Euclidean minimum distance of the transmitted symbols.

2. Trellis Track Circuit - functionality analysis

For the TI21M track circuit an informational telegram, consisting of 29 informational bits, shall be transmitted to the train. They are divided according to the table 3 [9, 10].

From the table 3, it can be seen that the new Trellis Track Circuit must send the following information: [11, 12]

- The target distance - bits 0-7, contains 8 informational bits to transmit the allowed distance whereon the train can travel.

- The target restriction - bits 8-10, contains 3 informational bits to convey the target restriction. This tells to the train if a speed restriction or a change in the type of traffic follows.

- Door left- bit 11, an informational bit to transmit to the train if left-handed doors are allowed.

- Door right - bit 12, an informational bit to transmit to the train if the right door is allowed to be opened.

- Entry into the controlled area- bit 13, an informational bit that informs the train if it enters or exits in the system-controlled area.

- Passing over- bit 17, an informational bit informing the train that an area, where the train can lose the telegram for a short distance, is coming.

- Current speed and target speed- bit 18-24, 7 informational bits informing about the train speed and target speed.

Table 3 Meaning of bits in the telegram transmitted by the TI21M track circuit

bits	information
0-7	Target distance
8-10	Target restriction
11	Left doors
12	Right doors
13	Entrance in an controlled area
14-16	Track circuit markers
17	Over pass
18-24	Target and current speed
25-28	Target Gradient
29	Utility
30-63	CRC Cod

In total there are 22 bits of information to be transmitted to the train. The rest of the information being transmitted, by the current track circuits, is linked to track circuit's markers, which can be assimilated by the track circuit labelling. The CRC code bits can be removed, if another message verification method is used at the reception. The telegram that needs to be transmitted by the track to the train now has 30 informational bits.

If a Trellis encoding scheme is used, like the one shown in Figure 5.30, with a simple systematic feedback response coder and parity check, at two information bits from the encoder input it will have three bits at its output. This type of coding, with a ratio of 2/3, brings at the encoder output a 45-bit encoded trellis with parity check, where "h^i " are the parity coefficients.

For this scheme, Ungerboeck calculated in the article [13] the following characteristics: the number of states is eight for two information symbols per modulation cycle. The parity coefficients are h^2= 04, h^1= 02, h^0=11 and d^2_{free}/Δ_0^2 = 4.586 and coding gain is 3.6dB, all this for 8PSK modulation with

$\Delta i = 2\sin(\pi/8)$, $\sqrt{2}$,, 2 with i = 0,1,2

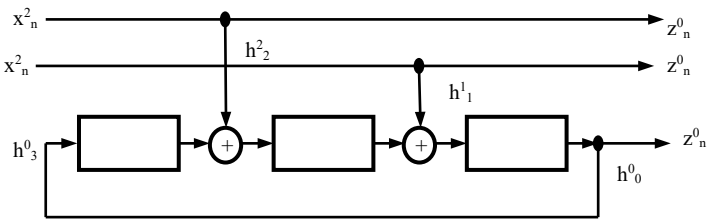

Figure 5. Trellis Systemic with Feedback Coder (3, 2, 3)

For systematic encoding, the input bits appear unchanged at the encoder output; this type of encoder cannot generate a catastrophic code. A catastrophic encoder is a coder for which at least one code word with the finite Hamming distance corresponds to an input with an infinite Hamming distance.

For the track circuit the important thing is that a 2 bits / sec / Hz transfer rate is achieved with a coding gain at the same 3.6 dB noise signal ratio versus a no-coded transmission.

For track circuits, the optimum transmission frequencies are in the audio frequency band due to the limitations imposed by the broadcast channel.

For 200 Hz signal bandwidth and Trellis encoding spectral efficiency 2½ bits / sec / Hz, 252 bits to the reception in the window time of the current system can be sent. This leads the train to be able to receive 4 telegrams in a timely manner with the information required for the system. If the allocated band is increased at 300 Hz, four information telegrams can be sent to the train, each of 64 bits, without reaching the maximum spectral efficiency limit for Trellis encoding. These four telegrams will be transmitted from two different points of the track to the moving train. Using a systematic parity convolution coder, a 45-bit telegram will be obtained; the remaining bits up to 64 bits can be used to send additional information to the train or even to redundantly transmit vital information within the same telegram. The speed and distance information can be transmitted twice in the same telegram.

Practically the new telegram that is sent to the train will contain the following information:

• target distance - bits 0-7 and 33-41, contains 2 * 8 informational bits to transmit the distance where on the train can travel

• target restriction - bits 8-10, contains 3 bits of information to convey the target restriction this tells to the train if there is a reduction in speed or a change in the type of traffic

• Left doors - bit 11, an informational bit to transmit to the train if it is allowed to open the doors on the left side

• Right door - bit 12, an informational bit to send to the train if it is allowed to open the doors on the right side

• Entry into the controlled area - bit 13, an informational bit that informs the train if it enters or exits the system-controlled area

• Pass over - bit 14, an informational bit informing the train that there is an area where the train can lose the telegram over a short distance

• Current speed and target speed - bits 15-21 and 41-47, 2 * 7 informational bits informing about the train speed and target speed.

After applying the Trellis 2/3 modulated encoding with 8PSK and parity checking, the following distribution of information inside the telegram will be obtained:

Target distance-bits 0-12 and 43-55, vital double information
Target Restriction - Bits 13-16
Left - Right Doors - Bits 17-19
Entry into Controlled Area and Over - Bits Crossing 20-22
Current speed and target speed - bits 23-32 and 33-43, vital information doubled
Track circuit label bit 56-64.

Performing the optimal Trellis encoding is done by mapping the symbols to ensure maximization of the free distance between them. This mapping is done by using special software programs to obtain the maximum efficiency of the encoder.

The information telegram set out above contains 37 bits required for the on-board system to meet the safety requirements for automatic train movement. These 37-bit information bits are inserted into a systematic convolution coder with feed-back and parity verification.

The encoder will have at the output 3 bits for every 2 bits at the input. For the transmission of the symbols it is necessary to use an 8-level modulation and for the beginning the use of the 8PSK modulation is to be considered.

The most probable errors made by the decoder's optimal soft decision interfere between the $\{e_n\}$ and the $\{d_n\}$ transmitted and the decoded signals, if they are close in terms of Euclidean square spacing. The free quadratic free distance is called free distance and is given by the relation

$$d^2_{free} = \min \sum_{e_n \neq d_n} |e_n - d_n| \text{ where} \{e_n\}, \{d_n\} \in C. \quad (6)$$

For this, the codes must be designed to have the maximum free Euclidian distance and not for Hamming distance. The redundancy required for coding comes from expanding the signal set without increasing the bandwidth [13]. The mapping should be based on the grouping of signals in symbols with a large distance between the signal subsets. To maximize the free distance the map of the symbol set is used as shown in the example represented in Figure 6.

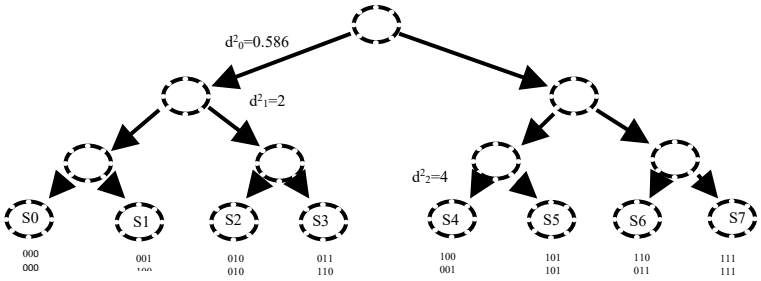

Figure 6. Symbol mapping by partitioning

3. Trellis track circuit – on-board receiver

The on-board receiver must receive the telegrams transmitted in the track from two distinct transmitters located in front of the train. The on-board receiver distinguishes these telegrams by differentiating the Trellis encoded modulated signals. The on-board receiver to process the received telegrams will have the block diagram shown in Figure 7.

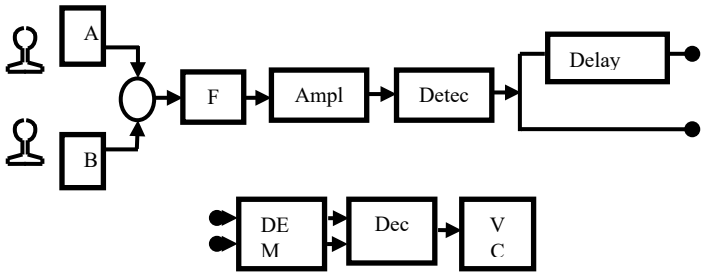

Figure 7. Trellis Track Circuit on-board receiver

The signal captured by the pick-up coils is summed by a differential summing circuit and then passed through the FTB bandwidth filter to keep only the useful signal. The detector block must separate the two telegrams received from the two separate transmitters. The telegrams arrive at a time difference dependent on the distance between the two transmitters and the gap between the telegrams introduced by the interlocking device. The first telegram is entered into a delay line until the second telegram arrives, then the telegrams are inserted into a demodulation and decoding block. The telegrams are inputted into a decision block that extracts the train data from the two telegrams, to transmit them to the train vital computer for execution.

The "Differential Summing Circuit" sums up the useful signals received by the pick-up coils, installed in front of the first axle of the train. The useful signal is passed through a band pass filter which only serves to extract the signals from the useful frequency bands.

The output from the "Band Pass Filter" is amplified and inputted into a delay line, until the second telegram is received. When the second telegram is received, the two telegrams are inserted into the "Demodulation and Decoding Block".

The "Decoding and Demodulation Block" consists of two separate demodulators and decoders for the two telegrams. The signal decoding can be made "hard" by demodulation and then decoding, but this demodulation causes an irreversible loss of information received before decoding. At the receiver a sequence of sampled voltages corresponding to the transmitted bits are created. The received signal is sampled and forms a bit sequence, to decode this sequence which can apply a hard decision process that decodes the samples by assigning them pre-set voltage values. This process can make an erroneous decision especially in the comparison threshold area. In order to avoid these inconveniences of hard decoding, a soft demodulation-decoding is used, which means that the decoder operates directly on the non-quantified "soft" samples of the channel [14]. The patterns are expressed as $v_n = a_n + w_n$, where a_n is the discreet signal transmitted by the modulator and w_n is the representation of the samples of the Gaussian noise addition process. The decoding rule of the decoded optimal sequence is to determine from the set "C" of the encoded signal sequences that can be produced by the coder-modulator system the sequence $\{a_n\}$ with the Euclidian square minimal distance that fulfils the relation:

$$|r_n - a_n|^2 = \text{Min} \sum |r_n - a_n|^2 \text{ with } \{\underline{a}_n\} \in C \quad (7)$$

The Viterbi algorithm is used to perform this decoding-soft demodulation. This algorithm was proposed in 1967 and is an asymptomatic optimal decoding technique for convolution codes. It can be used to determine the sequence $\{a_n\}$ of the encoded signal near the received non-quantized signal sequence $\{r_n\}$ provided that

the sequences of the encoded signal generated $\{a_n\} \in C$. The coder determines the nearest encoded signal sequence, directly from the non-quantized channel output. The most probable errors made by the decoder's soft decision-soft interfere between the $\{a_n\}$ transmitted and $\{b_n\}$ decoded signals, if they are close one to another within the Euclidean quadratic distance, this distance is the free distance and is given by the relationship:

$$d^2_{free}=\min\sum_{e_n\neq b_n}|a_n - b_n| \text{where}\{a_n\},\{b_n\} \in C \quad (8)$$

For this reason, system codes must be designed to have the maximum free Euclidean distance. For Trellis encoding, Viterbi decoder uses two metrics: branch metric and track metric. The branch metric is the measurement of the distance between what was transmitted and what was received and is defined for each path in the signal braiding. For "hard" decoding this branch metric is the Hamming distance between the expected bits and received bits. The track metric is the value associated with the trellis state, the value associated with each node, for the "hard" decision it corresponds to the Hamming distance of the most probable path from the initial state to the current state in the trellis. The most probable path is that with the smallest Hamming distance, measured on all possible paths between two states Hamming's smallest distance minimizes the total number of errors and is the probable path with the smallest bit error ratio [15]. The Viterbi algorithm calculates metric paths for pairs of states using the branch and track metrics calculated for previous states [14]. The key points are as follows: the optimal path of the infinite past signal to all trellis states at time "n" is known. The algorithm extends these interactive paths from state "n" to state at time "n + 1" Choosing the best way, the algorithm applies a "good" tag for each new path or "cancelled" for all other paths that cannot be extended. The good paths tend to unite in the same historical path after a time "n_d" with an effective delay decoding "D" (so the random change of the values of "d" is very likely to be less than "D"). The information associated with a transition is the historical "n_D" path can be selected at the output. The received signals are considered to be disturbed by non-corrected Gaussian noise samples with variable σ^2 in each signal size (in the subway system the noise is not Gaussian and patterns with system-specific disturbances must be used). The probability that at the given time the decoder makes an erroneous decision among the values of the associated signals for parallel transitions or to start making a series of mistaken decisions along the divergent paths for more than one transition from the correct path is called event probability error. At high noise signal ratios this probability is generally approximated by:

$$Pr(e) \approx N_{free}\, Q\left|{}^{d_{free}}/_{2\sigma}\right| \quad (9)$$

Where Q (x) is the Gaussian error integrity (10), and N_{free} is the average of the numbers of neighbouring sequences with the d_{free} distance that go to any state in the transmitted signal sequence and come together after one or more transitions.

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int e^{-y^2/2} dy \quad (10)$$

From the relationship (9) it can be approximated that at high noise signal ratios, the probability of event error associated with the target distance and then d_{free} becomes negligible.

For the embarked system the receiver uses the Viterbi algorithm and it implements two sets of patterns for comparison. The pattern sets for the disturbed signal must be correlated with the communication channel used and the disturbances that occur in it. Depending on the results obtained, the handset can automatically switch between sets of patterns to reduce the probability of error.

Because the 8PSK modulation is used on the receiver, a symbol rotation may occur due to interference or even oscillator instability. If in the Trellis diagram there is a large free square-space between symbols, then a small rotation of the diagram does not affect the received symbol, but if there is a small free square space between the symbols, then a small rotation of the diagram can change the decision boundaries of the symbols to make an erroneous decision. In most of the digital frequency carrier systems, the phase of the loop-specific carrier system has to be tracked. These loops estimate the phase shift of the received signal and decoder decisions, the estimated phase shift controls the phase of the demodulator carrier. For the new system, two symbols are used for each transmitted telegram to synchronise the demodulator with the modulator phase.

The output of the Trellis "Demodulation-Decoding block" is connected to the "Decision block" input. This block receives the two sets of decoded signals, each for a received telegram, compares them and checks the parity bits. Having two telegrams issued by two transmitters at different points of the runway, the train can extract the correct information even if the telegrams have been disturbed during the passage of the communication channel. The "Decision block" maps the bits from the Trellis decoder demodulator output to the telegram pattern and extracts the information about the received orders. The bits received for each telegram contain redundant information on speed and distance (maximum safety information for train running). The "Decision block" has four sets of information that regulate the train speed over a reserved and secured traffic distance. This information is received by the way of two telegrams sent through two transmitters separated from each other by the length of a track circuit.

The verified information is transmitted to the train computer for execution.

4. Trellis track circuit – transmitter

Taking into account the above mentioned functionality, the block diagram of the track circuit transmitter becomes that of Figure 8.

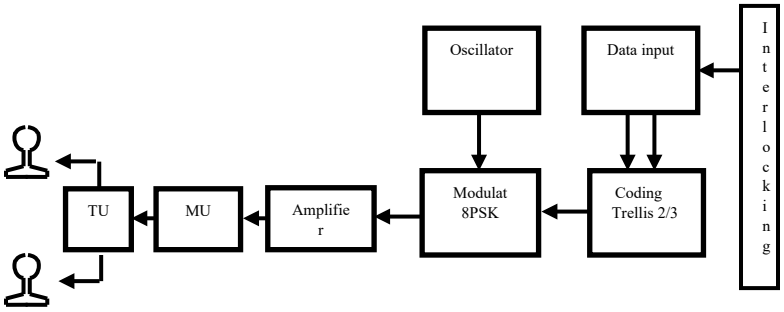

Figure 8. Trellis circuit block diagram scheme

The electronic interlocking system sends the orders to be executed and also the data which will be transmitted to the train, to the track circuit transmitter. The orders received contain instructions on how the track circuit transmitter should work, these modes being "detection mode" and "telegram mode".

The information received from the interlocking is processed in the “Input block”. This block upon receipt of the "detection mode" order extracts from its own memory track circuit label and maps it to obtain the optimal Trellis encoding symbols. This mapping is required to optimize the encoding. The information is cyclically sent by two bits to the “Trellis Encoding block”. This operation is performed by the transmitter until another order is received.

"Telegram mode" is executed upon receipt of the order received from the interlocking. On receipt of this order the transmitter receives the information, which must be included in the telegram to be sent to the train, maps this information to obtain the optimal symbols and sends these symbols to the “Trellis Encoding block”.

The “Input block” will also prepare the synchronization symbols needed to synchronize the receivers; these symbols are included in the train telegram or in the detection message.

The “Trellis Encoding block”, can be that shown in Figure 5, it is a block that encodes the two information bits received from the “Input block”. The “Encoding block” performs Trellis' systemic with feed-back coding and parity verification. The block encodes the received information and sends it by three bits to the “Modulation block”.

The “Modulation block” is designed to modulate a carrier frequency with the three-bit symbol received from the “Encoding block”. The internal diagram of this block is given in Figure 10 and performs the modulation using the symbol diagram shown in Figure 9

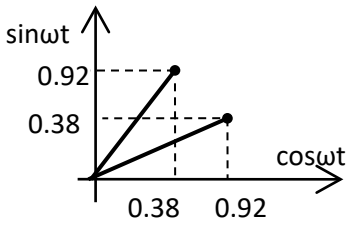

Figure 9. Symbols diagram 8PSK

From the chart shown in Figure 9 it can be noticed that: for QPSK modulation where there are only two coordinates “I” and “Q”, for 8PSK it also need to define two amplitudes ± 0.38 and ± 0.92 to obtain the 8PSK modulation angles in the four quadrants.

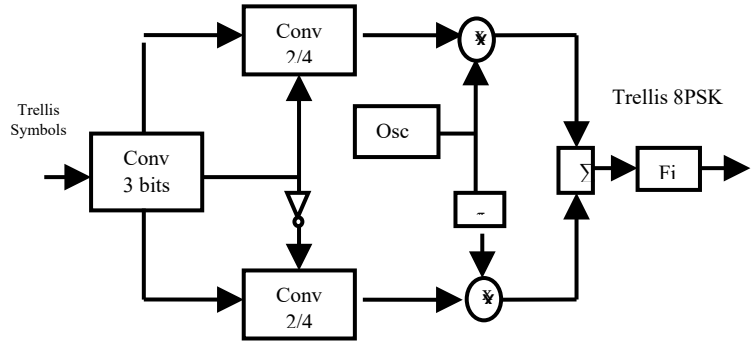

Figure 10. 8PSK Modulator block diagram

In the block diagram shown in Figure 10, the three-bit symbols from the output of the “Trellis Encoding block” are inserted into a serial / parallel converter, which separates the three bits on the three paths that define the symbol in the signal diagram. The bit 1 is used to control channel “I” , bit 2 to control channel “Q”, and bit 3 is used to define the two amplitudes. The amplitudes of the “I” and “Q” signals must be different in order to obtain the spatiality between the 8 phase states needed for 8PSK encoding states. The three bits command the 2-4 amplitude converters located on each channel “I” and “Q”, the bit 3 controls what amplitude is applied to each channel ± 0.38 or ± 0.92.

Outputs from the converters 2-4 are multiplied by the cosine and sine functions having the required carrier frequency, f_1 or f_2 for the line 1 and f_3 or f_4 for the line 2. These two signals are rotated continuously with $3\pi / 8$ before forming the signal pulse to avoid that the signal envelope instantly passes near zero. For an optimal transmission, where must always be a difference between two consecutive symbols of 112.5^0

The two waveforms obtained after multiplication will be summed and applied to the input of a “Band Pass Filter” that only selects the signal useful for transmitting through the communication channel.

The signal rotated at this point is described by the relationship:

$$R_n=S_n\, e^{\frac{j3\pi n}{8}} = e^{\frac{j2\pi C_n}{8}} * e^{\frac{j3\pi n}{8}} = e^{\frac{j\pi(2C_n+3n)}{8}} = a_n + jb_n \quad (11)$$

Where the “S_n “signal is

$$S_n = A_c e^{\frac{j2nC_n}{8}} = A_c \cos\frac{2\pi C_n}{8} + j\, A_c \sin\frac{2\pi C_n}{8} = I + j\, Q;\ \ n = 0 \div 7 \quad (12)$$

At the output of the 8PSK modulator block, it is a Trellis-encoded-modulated signal that, in order to be transmitted through the communication channel, in our case the rail tracks, requires amplification and adaptation to achieve the maximum power transfer to the load. These preparatory operations are performed by the “Amplifier block” and the “Mu” and “Tu” blocks that make the adaptation with the cable or railway tracks.

5. Trellis track circuit – track receiver

The track circuit receiver has the function to make the decision whether the track circuit is free or occupied. In order to do this, the receiver has a schematic block as shown in Figure 11.

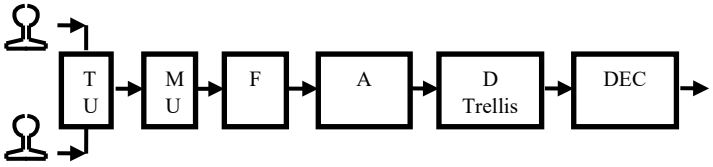

Figure 11. Trellis-8PSK track circuit block diagram

“Tu” and “Mu” units have the role of adapting impedances to get a maximum power transfer. The received signal is passed through a band pass filter that only keeps the useful frequency band

The amplifier “A” takes the signal from the output of the filter “F” and increases its power so it can be applied to the Trellis demodulator-decoder input “D”.

The demodulator - decoder Trellis “D Trellis” applies the Viterbi algorithm to the signal and extracts the received data. The data is extracted by “soft” decisions taken on signal samples that are compared to the noise-signal patterns. The patterns are made

for the type of communication channel specific interference. For the track circuit, the receiver has two types of signal patterns, one with moderate disturbances and another for high disturbances. The receiver estimates the received symbols by applying these patterns and if the estimate does not match, then the receiver will change automatically the pattern sets to obtain optimal decoding and demodulation. The “demodulation-decoding block” also includes a tracking loop for the carrier phase. This block directly controls the frequency of the demodulator. Trellis demodulation and decoding at the track receiver is made identically to the on-board receiver. The symbols on the output of the Trellis demodulator-decoder block are introduced into a “Decision block”.

The “Decision block” is designed to rebuild and check the track circuit label. If the label is correct, the receiver will make the free or occupied track circuit decision. The track circuit receiver also collects other signals transmitted by the neighbouring transmitters, retrieves the track circuit labels and sends the information to the interlocking system. The interlocking system will receive the message with all the labels collected by the track circuit receiver and will have an overview of all the status of the track circuits in that area.

6. Connection of Trellis track circuit equipment

In the track circuit connection scheme, the transmitters and receivers are connected to the rail at the same point via an adapter transformer that has the role of adapting the impedances so as to obtain a maximum power transfer for the 8PSK modulated signal with the carrier frequencies f1 and f2. Frequencies f1 and f2 are chosen to achieve the best transmission performance through the railroad communication channel. This choice of carrier frequencies can be done using the communication channel models described in [16].

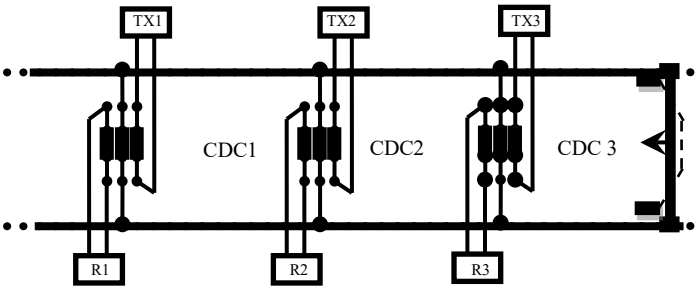

Figure 12. Connection of Trellis track circuit equipment

The carrier frequency is chosen accordingly to the electrical characteristics of the respective section of the line, these characteristics being dependent on humidity, ballast, line, etc.

The operation of the CDC2 track circuit in the two operating modes is as follows:

"Detection" mode - the Tx_2 transmitter conveys a 64-bit telegram made by Trellis 2/3 coding of the 8-bit circuit-specific identification tag and a 30-bit "0" and "1" string modulated at a frequency of 20 Hz. The telegram is received by the R_1, R_2 and R_3 receivers, making the decision that the track portions between them and the transmitter Tx_2 are free, and the receiver R_2 checks the correct operation of the transmitter chain Tx_2.

When the CDC3 track circuit is occupied by the train having the direction of going to the CDC2, the interlocking device decides to switch the Tx_3 transmitter as well as the Tx_2 transmitter in the "telegram" mode.

"Telegram" mode - the Tx_3 transmitter conveys a 64-bit telegram composed by Trellis 2/3 coding of the 8-bit transmitter label Tx_3 and a 30-bit string containing the information required for the ATP system. This telegram is received by the on-board receiver as well as the R_3 receiver that check the transmission chain as well as the receiver R_2 which recognizes the transmitter identification tag Tx_3, making the decision that the CDC2 is free.

"Telegram" mode - the Tx_2 transmitter transmits a 64-bit telegram composed by Trellis 2/3 coding of the 8-bit transmitter label Tx_2 and a 30-bit string containing the information required for the ATP system. This telegram is received by the on-board receiver which has doubled the information received, benefiting from the diversity principle, as well as the receivers R_3 and R_1 which decide that the CDC1 and CDC2 are free and the receiver R_2 is checking the transmitter chain Tx_2.

When the train pass on the CDC2 track circuit, the transmitter Tx_2 and Tx_1 are switched to "telegram" and the Tx_3 transmitter is switched to "detection" mode. The command of the transmitter operations in both modes is performed by the interlocking system according to the train movement authority, and this system also provides the 30-bit string required for the ATP system

It is noted that for the operation of this track circuit there is no need for alternating the carrier frequencies to separate the signals of the neighbouring track circuits. This separation is done digitally by recognizing the labels transmitted. Alternating the carrier frequencies is only to help the receiver to easily separate the telegrams conveyed by two consecutive transmitters.

Identification tags may also be received at greater distances after two or more track circuits and their receivers extract the respective label and send it to the interlocking device, which sees an overview and takes the decision that the distance between the receiver and the transmitter whose label has been received as "free".

Therewith the interlocking system can transmit to the train many telegrams using more than two transmitters, in this case the train has several telegrams that contain the same ATP information with multiple track circuit labels, which leads to a more efficient extraction of the ATP data system even in the case of Dirac disturbances. The limitation is given only by the window time available for telegram reception and the time required to extract the useful information, this being for an ideal line without loss and without attenuation.

In the case of real railway lines, there are losses due to ballast resistance and attenuations due to the constructive impedances of the railway. And in order to transmit the modulated signals on the carrier frequency "f" by the transmitters at a great distance, compensation capacitors can be installed, at each 50m or more. Compensation capacitors have the role of creating resonance points on the carrier frequency used, so it can pass on distances greater than the length of a track circuit. The length of the subway track circuit is about 250 meters, making it ideal for subway trains used.

7. Conclusions for the Trellis track circuit

The new track circuit with TCM aims to solve two of the problems encountered in the operation of the current track circuits, namely the loss of the telegram by the train and the false

occupation of the track circuits in front of the train. These two problems emanate due to the Dirac impulses which arise in the return traction current path.

The new track circuit uses the transmission diversity principle to solve the loss of the telegram by the train.

Due to the limitation imposed by the length of the telegram, it was necessary to use Trellis 2/3 convolution code with a 8PSK signal modulation

The new telegram contains a tag for each transmitter, which it is used to identify free-circuits but also help the train to distinguish between received messages. By using these labels, the second problem encountered in the current track circuits, namely the false occupation of the track circuit in front of the train due to the Dirac disturbances occurring on the traction return side, is solved. The receiver will periodically receive telegrams transmitted from several transmitters and these telegrams are spaced from each other with the time required to travel on the distances from the transmitters to the receiver.

The realization of these circuits requires specialized FPGA circuits that can perform complex functions necessary for the coding-decoding and modulation-demodulation operations of the signals used. Due to these complicated systems the reliability is decreasing but this can be avoided by using good quality components.

Data loss caused by electromagnetic perturbation, especially due to the electrical arch in the return current path, is decreased drastically by using multiple transmitters. On the other hand, the data loss can increase due to 8PSK modulation but this is compensated by using multiple identical telegrams transmitted from different points and a good Trellis code.

The incident response time of the on-board equipment is improved by using the Trellis code and multiple similar telegrams.

The new track circuit uses a new rail connection concept, namely a magnetically coupled return coil with two coils that are tuned to deliver maximum power transfer from the transmitter to the track as well as from the track to the track circuit receiver.

Future works will be done with the scope of improving this new track circuit by finding a suitable Trellis code for metro line conditions and which fits the patterns used by the Viterbi algorithm

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Vehicle analysis is a very useful component in various real world applications. In this paper, we have developed a Vehicle Make and Model Recognition (VMMR) system using Support Vector Machine (SVM). Scale Invariant Feature Transform (SIFT) and Speed-Up Robust Transform (SURF) are used to extract local features from an image. Bag-of-Features (BoF) model is used to create visual dictionaries and convert the local image features into global image feature representation. Multiple dictionaries of different sizes are created for both features; SIFT and SURF and the dataset is coded using these dictionaries to determine the best size for the visual dictionary. NTOU-MMR is a publicly available vehicle dataset which we have used to evaluate the performance of proposed VMMR system. 92% recognition rate is achieved by using the proposed VMMR system.

1. Introduction

This paper is an extension of work originally presented in 2017 IEEE 7th Annual Computing and Communication Workshop and Conference (CCWC) [1]. In original work, we had developed a Vehicle Make and Model Recognition (VMMR) system using Bag of SIFT features and used Support Vector Machine (SVM) for the classification task. In this extended work, we have investigated Speed-Up Robust Features (SURF) along with SIFT features. We have investigated the effect of dictionary size over the recognition rate. We also have analyzed the margin size between for binary SVMs and its relation with the recognition rate.

Machine vision based vehicular analysis is suitable for many scenarios. Machine vision based techniques require installation of cameras to capture the videos and/or images and it also requires computing power to process these captured videos/images. Traffic cameras care widely available at present time; which can be used to capture real-time videos/images. These techniques do not require any installation of devices/sensor in the vehicles; which makes vehicular analysis simple. However, machine vision based applications have their own challenges.

Vehicular analysis applications may include License Plate Recognition, Vehicle Detection, and categorization of vehicles into bus, cars, trucks etc.; the majority of research is done for these mentioned scenarios. The focus of this work is to classify the vehicles according to their Make, Model and Manufacturing year. We are using machine vision-based approach to recognizing a specific instance of a vehicle. We are using Machine learning algorithm to classify input image/video according to the vehicle present. Machine learning algorithm provides the mean to train the system using a training dataset and then predict the outcome for new and unseen images. A lot many challenges are associated with this problem; some of these challenges are:

1. Image acquisition in outdoor environment.
2. Varying and uncontrolled illumination conditions.
3. Varying and uncontrolled weather conditions.
4. Wide variety of available vehicle appearances.
5. Similarities between different vehicle models.

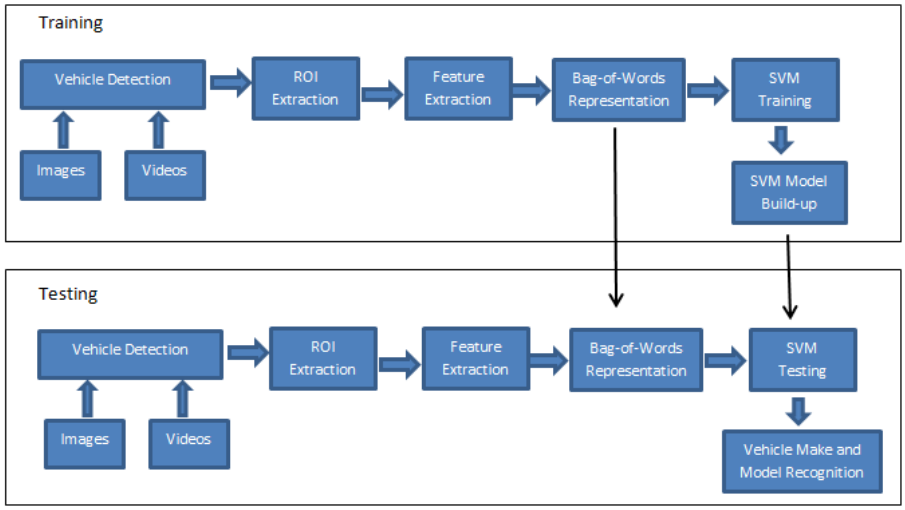

Figure 1: VMMR system Architecture

The architecture of VMMR system developed in this work is given in Figure 1. The system is designed to classify the vehicles using the frontal images. The input to the system can be either images or videos. If the videos are used as input sources, individual frames (images) must be extracted and will be processed separately. First, we must train the VMMR system based on input training dataset. The first step is to detect whether a vehicle exists in the input image. If it does not then we cannot use this non-vehicle image for the training. The vehicular images contain background along with vehicle and some parts of the vehicle (like a windshield) are almost identical for various vehicles' models. Hence, we define Region of Interest (ROI); which can be easily distinguishable for various models. Images features are extracted from this ROI and converted into image feature vector to represent a specific vehicle model. Lastly, machine learning algorithm is trained using these image feature vectors. Scale Invariant Feature Transform (SIFT) [2] and Speed-Up Robust Features (SURF) [3] are used to extract local image features. Bag-of-features (BoF) model is employed here to build the visual dictionaries and to transform the local image features into global image feature vector. We have used Support vector machine (SVM) [4], [5] as classifier in this work; which is supervised learning algorithm.

We have reviewed some related articles in section 2 and presented the dataset used in section 3. Section 4 discusses the VMMR system methodology in detail. Experimental results are provided in section 5 and section 6 conclude this work.

2. Literature Review

VMMR is a challenging task; some of the challenges are presented in Section 1. We will provide an overview of some of the related research work.

In [6], authors proposed VMMR system using the rear-view images. Authors defined the shape and geographical features with respect to taillights and license plate and used these features for vehicle recognition. The proposed system is developed to recognize the vehicles during the night under limited lighting conditions. The initial step is to recognize the location of license plate and authors used license plate location to calculate the features. Genetic Algorithm is also used in this work for feature selection. Genetic algorithm improves the recognition rate by 0.4%. However, the effect of Genetic Algorithm over the computational time is not discussed.

In [7], authors designed a system to identify vehicles' type by using deep convolutional neural network. The proposed system identifies vehicles without vehicle detection. Authors studied VGGNet, GoogLeNet, and CaffeNet (three well known convolutional neural network method). They had suggested including of vehicle/non-vehicle classification as pre-training for three convolutional neural network methods. Data enhancement techniques are used for performance enhancement. The proposed method is tested against cars dataset [8] and 79.5% accuracy is achieved in this work.

In [9], authors used side profile images in their work to recognize the vehicle's Make and Model. Authors have used five different classification techniques in their research to develop VMMR system; Random Forest, Evolutionary Forest, HoG based Random Forest, HoG based Linear SVM and HoG based RBF SVM classifier. A pole-mounted camera is used to capture the images and a dataset is created containing more than 10,000 images. These images contain 86 different make and model and are divided into 9 categories.

In [10], the oriented contour points are extracted from frontal image to recognize the vehicles in their research. Authors have used three voting and distance error to determine the make and model. The dataset tested in this work contains partially occluded images as well and have 830 vehicle images. Authors have reported recognition rate of 90.6%.

In [11], Contourlet transform is applied to extract features and applied localized directional feature selection criterion in their work. They also have used Two-Dimensional Linear Discriminant Analysis to reduce the feature dimensionality. Authors have used support vector machine classifier in their proposed framework.

3. Dataset

[12] is a publicly available dataset which contains vehicular images. We have used this dataset in order to analyze our VMMR system. The dataset contains complete images (vehicle and background) as well as the region of interest images. We have used images in which ROI is already extracted. For a real world scenario, images are captured during different time and different weather conditions. Images are also partially occluded with irrelevant objects like pedestrians. The viewing angle for these images is -20 degrees to 20 degrees. The detailed description of each category and training and testing images available for each category is given in Table 1. The images are divided into classes on the basis of make, model, and shape (manufacturing year). The dataset contains thirty six different types (shapes) of vehicles. The dataset contains 2725 images for training purposes and 3110 images for the testing process. Number of available images for testing and training are given in Test and Train columns respectively in Table 1.

4. Methodology

The architecture of VMMR system is given in figure 1. The dataset provides the images in which Region of Interest is already extracted. Hence we are focusing on following three tasks of the VMMR system.

1. Feature Extraction: we have applied Scale Invariant Feature Transform (SIFT) and Speed-Up Robust Features (SURF) in this work.
2. Bag-of-Features (BoF) model: we have used BoF model to create visual dictionaries and encode the local image features into a global image feature vector.
3. Support Vector Machine (SVM): SVM is a supervised learning algorithm and it is used here as a classifier.

4.1. Feature Extraction

The first step for many machine vision applications is feature extraction. The input image is processed and local prominent interest points are located. A robust descriptor is used to encode these interest points which are invariant to many different kinds of noise.

Scale Invariant Feature Transform (SIFT)

Scale Invariant Feature Transform (SIFT) is introduced by David Lowe [2]. We have computed SIFT interest points in every image (training and testing dataset). Every SIFT descriptor construct a descriptor based on the histogram of gradient direction and magnitude around the interest point. The features, extracted using SIFT algorithm, are invariant to rotation and scaling. These features are also not affected by slight changes in view point, noise, and illumination. The operational flow chart of SIFT feature detection is given is figure 2.

SIFT algorithm detects interest point using scale-space maxima detection. Once the robust and invariant interest points are selected; these are encoded into 128-dimensional feature vector based on their appearance in a 4 x 4 patch. We have used standard SIFT algorithm in our work to detect the local image features.

Speed-Up Robust Features (SURF)

Speed-Up Robust Features (SURF) descriptor works similarly to SIFT descriptor but SURF is quicker as compared to the SIFT [3]. Herbert Bay et al. presented the idea of SURF feature detector at the 2006 European Conference on Computer Vision. SURF is partly inspired by SIFT feature detector algorithm. Hessian Matrix is used to detect the interest points in SURF algorithm. The first step is to apply Hessian Matrix on the integral image. The next step is to locate the Extrema and unstable Extremes points are discarded. Finally, orientations are assigned to construct the SURF descriptor. SURF descriptor is a 64-dimensional feature vector. Figure 3 shows the operational flow chart of SURF feature detection.

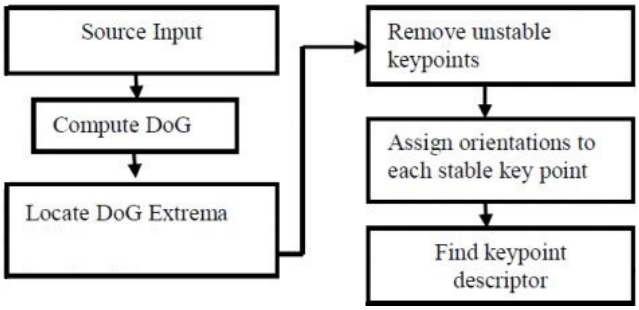

Figure 2: Flow Chart for SIFT feature detection

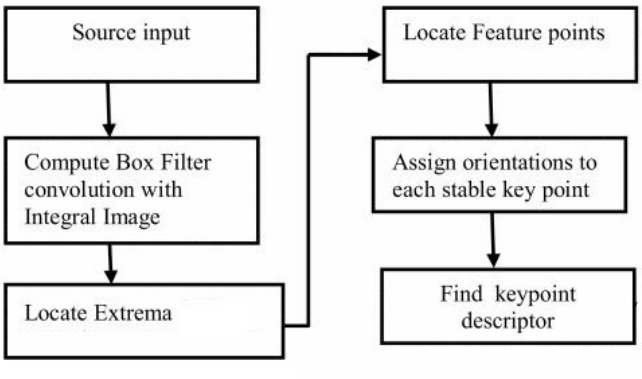

Figure 3: Flow Chart for SURF Feature Detection

4.2. Bag-of-Feature (BoF) Model

Bag-of-features (BoF) model [13] used in this work is based on bag-of-Words (BoW) model. BoW is originally used for document classification; a document is represented using histogram based on the occurrence of words. We must have to create visual dictionaries for an image that can be later used to construct a histogram. Using this histogram of the visual word, an image feature vector is created to represent the image. Whether we are using SIFT or SURF features; both are local image feature and require global feature representation. We will describe the BoF process in terms of SURF descriptor. Same BoF process is applied for SIFT algorithm.

We have used K-means clustering over all SURF features and the centers of each cluster represent a visual word. The collection of these visual words is used to create the dictionary. After creating the dictionary, each SURF feature is mapped into specific visual word and an image is represented by the histogram of the visual words. The dictionary is created by using only training dataset and the same dictionary is used to encode the testing dataset images as shown in figure 1.

Support Vector Machine

Support Vector Machine [4], [5] is binary classifier; multiple binary SVM can be combined to create multi-class SVM. SVM is used for both regression and classification problems. Support vector machine is successfully applied to many real world problems. SVM creates wide decision boundary (as wide as possible) to partition two categories as opposed to other machine learning algorithm; where single line decision boundary is used to separate categories. So SVM is also named as maximum margin classifier. Kernel functions are applied on training dataset to convert linearly non-separable categories into linearly separable classes.

Let assume a training dataset S= $\{(x_1, y_1), (x_2, y_2),\ldots, (x_n, y_n)\}$, where $x_i \in R^n$ and is input feature vector and $y_i \in \{-1, 1\}$ is the category. Let weight and bias of hyper plane is given by w and b. $\varphi(x)$ represents transformed dataset (transformed using kernel function). The hyper plane between the two categories can be defined as:

$$w.\varphi(x) + b = 0 \quad (1)$$

The optimization problem for calculation of w and b is:

Minimize

$$\varphi(w) = \tfrac{1}{2} \|w\|^2 \quad (2)$$

Subject to

$$y_i(w.\varphi(x) + b) \geq 1$$

New variables ζ_i (slack variable) and C (regularization constant) are included in above optimization problem:

Minimize

$$\varphi(w,\zeta) = \tfrac{1}{2} \|w\|^2 + C \sum_{i=1}^{N} \zeta_i \quad (3)$$

Subject to

$$y_i(w.\varphi(x) + b) \geq 1 - \zeta_i, \zeta_i \geq 0$$

Where ζ is used to relax the hard margin constraint and C is used to manage the trade-off between classification error and maximal margin of separation.

One-vs-All [14] and One-vs-One [15] are two popular methods to construct multiclass SVM using multiple binary SVMs to deal with real world scenarios.

5. Experimental Results and Discussion

We have proposed Support Vector Machine based VMMR system and we have used SURF and SIFT features in this work. We have used different sizes and SVM configuration to attain better recognition rate. We have tested our proposed method using publicly available dataset. Figure 4 and Table 2 provides the details about SURF based recognition rate. SIFT based recognition rates are provided in figure 5 and Table 3.

The recognition rate is given on vertical axis and vocabulary size is given on horizontal axis in figure 4. Each graph line is generated for different SVM configuration. The best recognition rate among all the results is 90.90% with using SURF features. As evident from the figure 4 and table 3, better results as compared to others are generated with larger dictionary size and higher value of C. The recognition rate for all the variations is given in tabular format as well. The best recognition rate is achieved at C=8, 10, 12 and the vocabulary size, in this case, is 3000 visual words.

The recognition rate for SIFT image features is given in figure 5. Table 3 shows the recognition rate in a tabular format. The best recognition rate achieved in this case is 92.13%. As compared to SURF, the good recognition rate is achieved at 600 and 1800 vocabulary size; which is less as compared to SURF results. The recognition rate of 92.13% is achieved by using a vocabulary size of 600 visual words.

With these results, we can conclude that the SIFT can achieve better recognition rate as compared to SURF based recognition. However, considering other factors during selection process between SIFT and SURG may change the result.

6. Conclusion

VMMR is an important component of the intelligent transportation system and smart cities. We have presented support vector machine based VMMR system in this work. This VMMR system takes images as input and extracts the SIFT and SURF features; which are later used during the classification process. Bag-of-features (BoF) model is another component of VMMR system; which provides image feature vector. The proposed VMMR system is evaluated with the publicly available dataset and 92.13% recognition rate is achieved.

AC electric railway
Cyclic permutation of phases connection

ABSTRACT

This paper presents the modeling and simulation of the voltage unbalance in the power supply system of an AC electrified railway. The operating voltage at the traction substation is obtained by MATLAB/SIMULINK program and the voltage unbalance is evaluated by considering the voltage unbalance factor (VUF). Suvarnabhumi Airport Rail Link (ARL), in Bangkok, Thailand, is chosen to be a case study. The ARL is supplied by two single-phase traction transformers connected as a cyclic permutation of phases. According to the extension plan of the ARL, four service scenarios with different headways, auxiliary loads and total weights of the trains were simulated to study how the different scenarios influence the VUF at the three-phase side. It can be summarized that at the same headway, the VUF was increased when the train weight and auxiliary power load were increased. In case of different headways, the longer the headway, the more voltage unbalance. The extension plan of the ARL in the near future can be achieved with the voltage unbalance level under the maximum allowable value.

1. Introduction

This paper is an extension of work originally presented in IEEE/SICE International Symposium on System Integration (2016) [1]. However, the additional experimental pieces proposed in this paper is that the voltage unbalance at an AC traction substation is effected by the three factors of the train operation, including train headway, number of train and additional auxiliary power. This consideration is evaluated for the extension plan of the ARL in the near future. The results would be verified and discussed as follows:

There are presently various forms of ground transportation that help the passengers, particularly the international tourists, to make a decision. The mass rapid transit system is one of the most favorite ground transportation systems and currently vital to developing countries, especially regarding the fundamental economy and society. In Thailand, the tourism industry grows quickly. Therefore, the number of the international tourists at the Suvarnabhumi airport also increased. The cheapest cost and shortest time to travel from the Suvarnabhumi airport to Bangkok city center and other mass rapid transit lines is traveling by the Suvarnabhumi airport rail link (ARL).

The power feeding system of the ARL is the 25 kVrms overhead catenary system receiving electric power from the three-phase AC transmission system. The traction substation transformers are connected as a cyclic permutation of phases, i.e. an alternate phase connection such as A-B, B-C, and C-A. In practical, the voltage unbalance and voltage drop are frequently occurred at the point of common coupling depending on the train operations. In additions, the State Railway of Thailand has planned to extend the service from Suvarnabhumi airport to Don Muang airport in the near future. Therefore, the energy consumption by trains at the traction substation will definitely increase. Obviously, the voltage unbalance at the three-phase side of the traction substation is likely to increase too. To assess the feasibility of the extension plan, four expected train operational scenarios have been simulated by using MATLAB/SIMULINK to evaluate the voltage unbalance and to study the effects of the headways, train weight, and auxiliary power on the voltage unbalance.

This paper presents the study of the voltage unbalance at the traction substation of the ARL in four different scenarios. The contents are divided into six sections. Section 1 is an introduction. Section 2 describes a train movement, power consumption, and voltage unbalance factor (VUF) calculation. Section 3 describes the ARL power supply system and parameters calculation. Section 4 presents the modelling in MATAB/SIMULINK and simulation

procedure. Simulation results and discussion are described in section 5. Lastly, a conclusion is in section 6.

2. Train Movement and Voltage Unbalance Calculation

A train motion is calculated by the Newton's second law of motion taking account of gradients, speed limitation, modes of operation, etc. In order to obtain the required power, speed, and position of the train, it is indispensable to simulate a train movement. In this section, the basic modules within the train simulation are briefly reviewed [1]. In addition, the definition of the voltage unbalance factor is proposed.

2.1. Train movement calculation

A train motion is resisted by several resistive forces, e.g. train resistance, track gradient force, etc. The free body diagram of all forces acted upon the train on an inclined plane is shown in Figure 1. By applying Newton's second law, the train movement equation is expressed in (1):

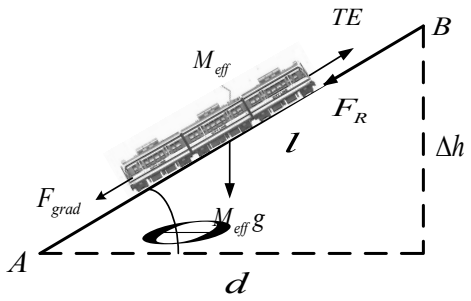

Figure 1. Free body diagram of a train on an inclined plane [1].

$$F = TE - F_{grad} - F_R = M_{eff}\alpha \tag{1}$$

where TE denotes the tractive effort (N), F_{grad} denotes the gradient force (N), F_R denotes the train resistive force (N), M_{eff} denotes the effective mass (kg) and α denotes the train acceleration (m/s^2)

- Tractive effort (TE): the force generated by a locomotive to pull a train [2].
- Gradient force (F_{grad}): the weight of a train opposes the train movement when a train is on a positive slope and helps accelerate when it is on a negative slope. The gradient force is usually expressed in the form of Δh/l, where Δh is the vertical distance, l is the slope length or horizontal distance from point A to B, see Figure 1. With a small arbitrary angle θ the gradient force can be approximated by using (2), where g is the acceleration rate due to gravity of the earth.

$$F_{grad} = M_{eff}\, g \sin\theta = \frac{M_{eff}\, g \Delta h}{l} \tag{2}$$

- Train resistive force (F_R): the motion of the train is opposed by a number of resistive forces. The overall resistance can be formulated as follows [3]:

$$F_R = A + Bv + Cv^2 \tag{3}$$

where v is the vehicle speed (km/h) and the coefficients A (kN), B (kNh/km) and C (kNh^2/km^2) are all constants called the Davis coefficients [4].

- Effective mass (M_{eff}): it is the sum of tare mass (mass of train without loads or passengers) and rotational inertia of the rotating components on the train which is expressed as follows [3]:

$$M_{eff} = M_t\left(1+\lambda_w\right) + M_l \tag{4}$$

where M_t is the tare mass, λ_w is the rotary allowance and M_l is the freight or passenger load.

The modes of train motion considered in this study include accelerating, constant speed, coasting, and braking modes. The speed-distance curve describing each mode of motion is illustrated in Figure 2.

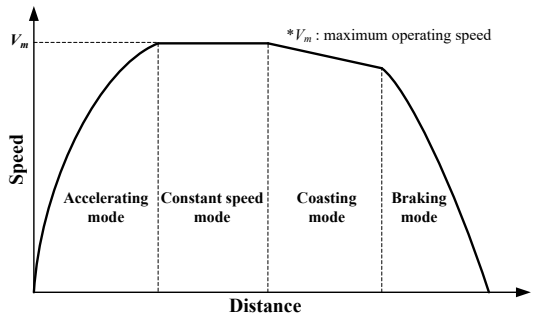

Figure 2. Train operating modes [1].

2.2. Train Power Consumption

The power required by a train P is given by the following expression [5]:

$$P = \frac{TE \times v}{\eta} + P_{aux} \tag{5}$$

where η denotes the efficiency of conversion of the electrical power to the mechanical power, TE denotes the tractive effort, v denotes the instantaneous speed and P_{aux} denotes auxiliary power.

2.3. Voltage Unbalance Factor

The voltages of a three-phase power supply are ideally equal in magnitudes and phase angles of 120º apart from each other. The three-phase system with those conditions are called a balanced three-phase system and its phasor diagram is shown in Figure 3-A. If the three-phase voltage unbalance occurs, both magnitudes and phases are altered, see Figure 3-B. It can be seen that the neutral point (n) will move to the position of n_2. The effects of voltage unbalance, for example, are: the reduction of three-phase induction motor operating lifetime, performance or even failure, etc.

According to IEEE 1159 – 2009, unbalance in a three-phase system is defined as the ratio of the magnitude of the negative sequence component to the magnitude of the positive sequence component, expressed as a percentage. This definition can be applied for either voltage or current. Typically, the voltage

unbalance of a three-phase service is less than 2%, especially when a single-phase load is presented. Mathematically, the voltage imbalance is represented as follows [7]:

$$\%VUF = \frac{|V_{neg}|}{|V_{pos}|} \times 100\% \quad (6)$$

where $\%VUF$ is the percentage of the voltage unbalance factor, V_{pos} is the positive sequence component and V_{neg} is the negative sequence component.

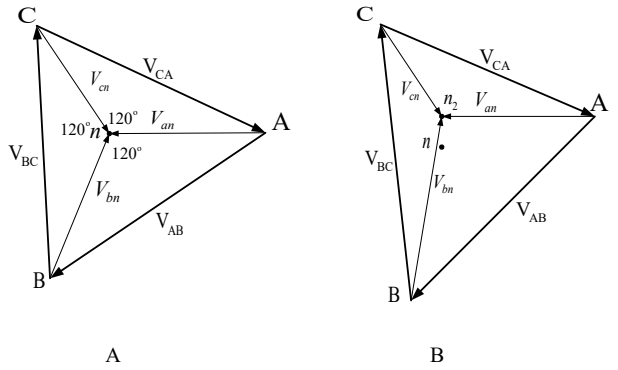

Figure 3. A) Phasor diagram of a three-phase voltage balance and B) Phasor diagram of a three-phase voltage unbalance (modified from [6]).

3. ARL System Description and Parameters Calculation

To obtain the voltage solutions of the three-phase power supply and the voltage unbalance factor at the point of common coupling of the ARL traction substation .The parameters calculation and structure of an AC traction power supply, a transformer connection, and an overhead contact system are briefly proposed as follows:

3.1. Cyclic permutation of phases connection

The connection by cyclic connection of phases as shown in Figure 4 can be considered for the advantages in disposition and easier operation of substations, whereas the three-phase short-circuit power in the primary network is remarkably high if compared with single-phase load power. In this arrangement, the single transformer is fed with two phases and the primary three-phase network can be balanced by systematically distributing the phase connection based on the traction loads [8].

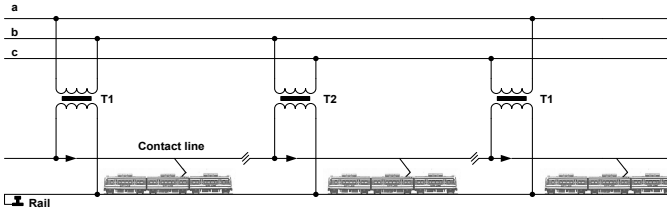

Figure 4. AC traction substation with cyclic permutation of phase

3.2. Structure of the ARL Traction Power Supply

The entire line of the ARL is supplied by a traction power substation (TPS) with 2×20 MVA transformers, located at 8.078 km near Ramkham Haeng station. A minimum short circuit capacity of the utility grid is 2.7 GVA. Transformer's characteristics data are: Ur = 69/27.5 kV, Sr = 20 MVA, Oil Natural Air Natural, Ukr.= 12 %. The single-line diagram of the substation is illustrated in Figure 5.

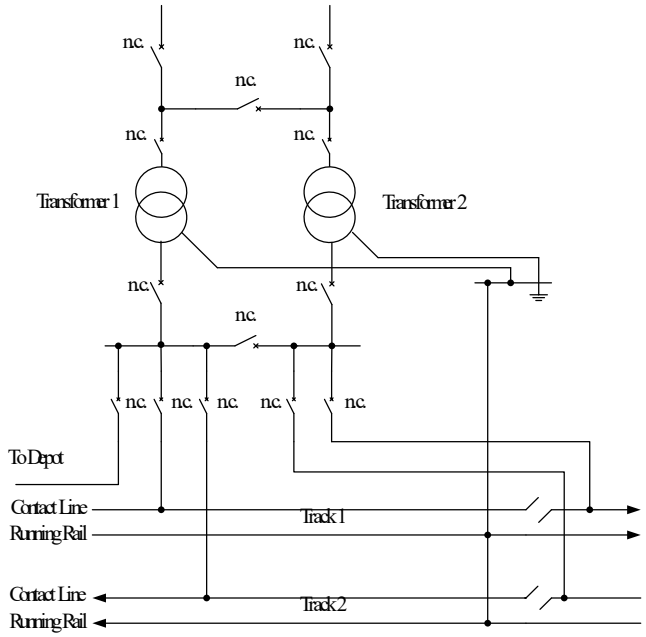

Figure 5. The substation infeed with two transformers [1].

3.3. Overhead Contact System

The overhead contact system in Figure 6 consists of catenary (C), rails (R), and earth (E) described as follows: the catenary (C) is formed by a contact wire and one or two messenger wires. They share the current and are always at the same potential. To reduce the system complexity, their impedances are combined all together to form a single conductor. There are two rails (R) in the same track, which are treated as a single cylindrical conductor. There is a wire called "earth wire" that is used for safety reasons and it normally carries no current. It is assumed that the leakage current from the rails flows underneath the track with a depth of D_E through a virtual conductor called the return earth by (7) and an earth resistivity can be calculated by (8):

$$D_E = 655\sqrt{\frac{\rho_E}{f}} \quad (7)$$

$$\rho_E = 547 f^{-0.434} \quad (8)$$

where f is an operating frequency (Hz) and ρ_E is the earth resistivity ($\Omega \cdot m$).

A reactance caused by electrical induction play an important role in a transmission system for an AC railway power supply. The value of conductor's reactance in the system is dependent on the conductor arrangement and the distance between conductors, see Figure 6. Impedance per unit length of the catenary and running rail is expressed in (9) and (10).[9]:

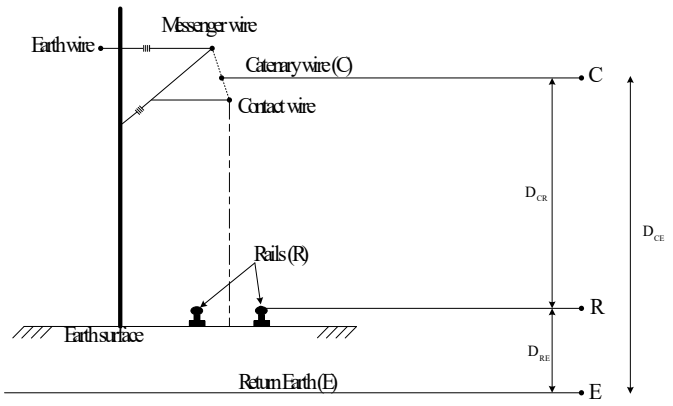

Figure 6. Overhead contact system configuration [9].

$$Z_C = R'_C + j2\pi f \mu_0 \left(\frac{1}{8\pi} + \frac{1}{2\pi} \ln \frac{D_{CE}}{GMR_C} \right) \quad (9)$$

$$Z_R = R'_R + j2\pi f \mu_0 \left(\frac{\mu_R}{8\pi} + \frac{1}{\pi} \ln \frac{D^2_{RE}}{RG \times GMR_R} \right) \quad (10)$$

where

Z_C is catenary's impedance per unit length (Ω/km)

Z_R is rail's impedance per unit length (Ω/km)

R'_C is catenary's resistance per unit length

R'_R is rail's resistance per unit length

μ_0 is magnetic permeability of air

μ_R is magnetic permeability of rails

GMR_C is catenary's geometric mean radius

GMR_R is rail's geometric mean radius

RG is a distance between rails in the same track

D_{CE} is a distance between catenary and earth

D_{RE} is a distance between rail and earth

4. Modelling and Simulation Procedure

The model of the traction transformer, catenary, rails and train of the ARL are modelled by using the built-in blocks in MATLAB/SIMULINK. The configuration of the ARL power supply system is briefly mentioned. Lastly, the evaluation of the VUF at the traction substation of the ARL with different scenarios of the train operations is discussed as follows:

4.1. The model of the transformer in the traction substation

The two traction transformers in the ARL traction substation are alternately connected to different pairs of phases. To estimate the operational voltage and voltage unbalance at the traction substation, the transformer model is formed by using the multi-winding transformer built-in block in MATLAB/SIMULINK program described as follows:

This connection has the same configuration as the single-phase connection except it connects to different pairs of phases. For example, the first transformer is connected to phase AB and the second transformer is connected to phase BC as shown in Figure 7.

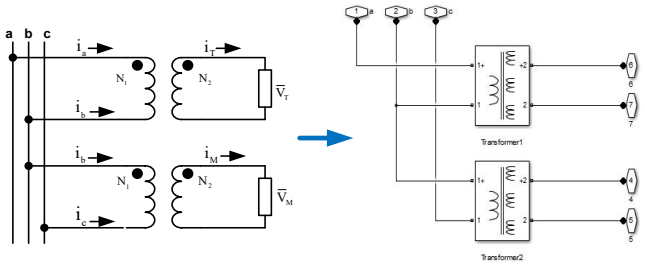

Figure 7. Cyclic permutation of phase connection in MATLAB/SIMULINK.

4.2. ARL traction power supply modelling in MATLAB/ SIMULINK

The AC traction power supply modelling is developed in the block models in MATLAB/SIMULINK. The model consists of 4 main parts: (i) AC traction substation, (ii) transformers, (iii) overhead catenary system, and (iv) electric trains as shown in Figure 8. The 69 kV three-phase AC transmission system is represented by the three-phase source built-in block. The transformers will step down the voltage from 69 kV to 27.5 kV using the multi-winding built-in block connected as a cyclic permutation of phases. The overhead catenary and running rails have the impedances obtained from the textbook [9] and BS EN 50149:2012 standard. The series RLC branch built-in block is used to model this transmission and return circuit system. Lastly, the electric trains are modelled as a series RLC load.

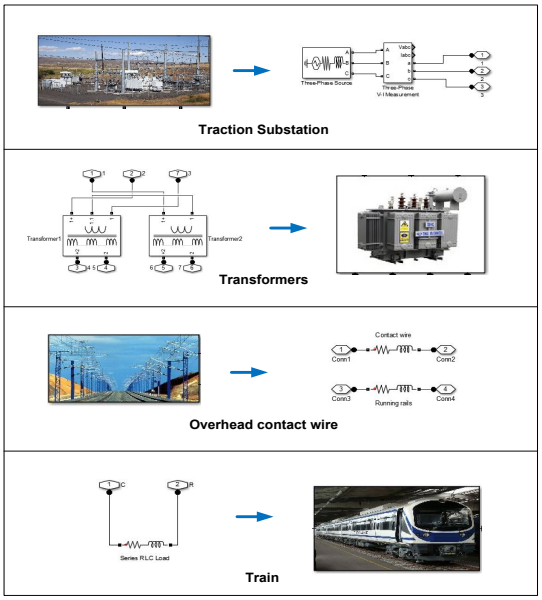

Figure 8. The power feeding components' models in MATLAB/SIMULINK.

The ARL system was modelled for the simulation tests in this paper. The ARL was the first electric mass transit railway operated with overhead catenary system or overhead contact system to commence operations in Thailand. The ARL is composed of 8 passenger stations and one traction substation as shown in Figure 9. Parameters' setting for this simulation can be found in Appendix.

Figure 9. Suvarnabhumi Airport Rail Link map [1].

The AC traction substation of the ARL draws the electrical energy with the voltage level of 69 kV from the metropolitan electricity authority (MEA). The traction substation transformers with an alternate phase connection transform the grid voltage into the train's nominal voltage of 27.5 kV. The total service distance is 28.298 km and the traction substation's position is at 8.078 km. In the simulation, the trains depart from both tracks at the same time with the same headway throughout the service, e.g. the first and fifth trains start the operation at the same time, also the second and the sixth trains and so on as shown in Figure 10.

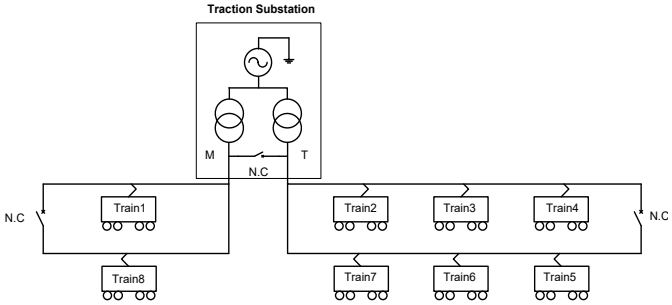

Figure 10. The schematic diagram of the ARL traction power supply system [1].

4.3. Simulator structure

The simulator has 2 major parts: main program (script M-file) and the power network solver (SIMULINK). The main program performs the multi-train movement, performance calculation, and the network capture, i.e. sorting trains on service, setting the distances between the components in the system and the train data. Then, the trains' positions and powers together with the distances recently mentioned are transferred into the SIMULINK block model to solve the voltage solution (primary and secondary voltages of the substation) and VUF. Finally, those values are returned to the main program to be stored and display the graphical illustration. The operating diagram is shown in Figure 11.

5. Simulation Results and Discussion

The results showed the VUFs at the point of common coupling of the ARL traction substation with four different scenarios as shown in Figure 12. The operational conditions, i.e. headways and the train configurations, are given in Table 1. Each train has the maximum speed of 70 km/h and the speed profile is shown in Figure 13.

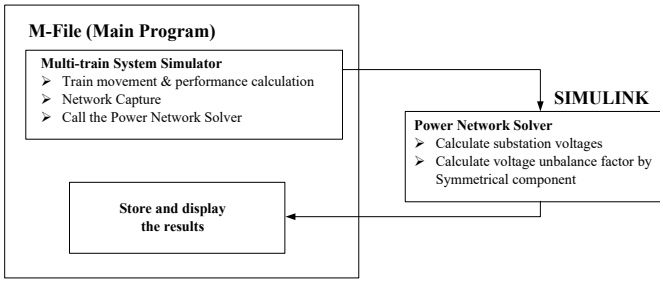

Figure 11. Diagram of the simulation program.

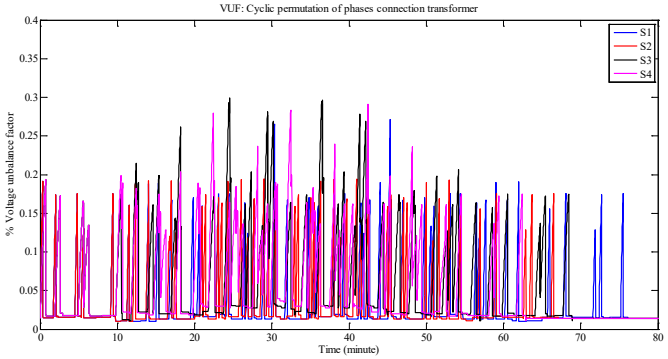

Figure 12. Percentage of VUFs in each scenario

Table 1: Operational conditions of Suvarnabhumi Airport Rail Link.

Scenario	Headway	Train configuration	Total weight	Auxiliary power
S1	15 min	3 car train	183.67 t	200 kVA
S2	12 min	3 car train	183.67 t	200 kVA
S3	12 min	4+3 car train	422.64 t	450 kVA
S4	10 min	4+3 car train	422.64 t	450 kVA

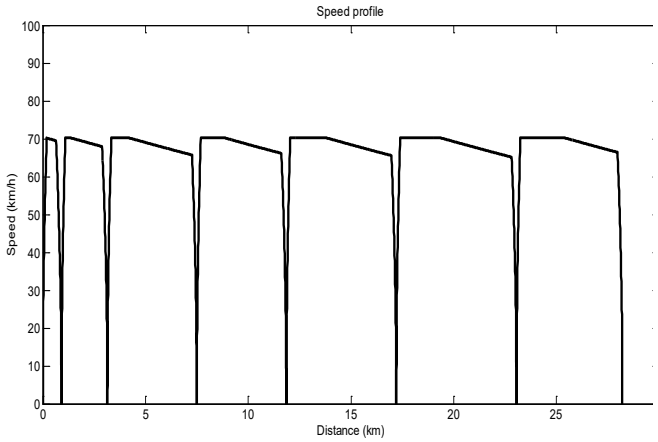

Figure 13. Speed profile.

Considering scenario S1 and S2 in Figure 12, the VUF obtained from S2 was found to be lower than that from S1 because the total weight and auxiliary power of S1 and S2 are equal to each other but the headway of S1 is longer than that of S2. It can be noted that when the headway is shorter, the number of trains appear

in the system, so the total loads on the left and the right of the substation were more likely to have the same values leading to less voltage unbalance. To study the effect of different total weight and auxiliary power of the train on the voltage unbalance, scenario S2 and S3 were compared. As the total weight and auxiliary power load of S3 were greater than those of S2, more power would be consumed in S3, and there was more possibility of different amount of consumed power between the left and right side of the traction substation. Thus, the voltage unbalance of S3 was more than that of S2. In addition, the comparison between S3 and S4 gave the same result as the S1-S2 comparative result. However, due to more weight and auxiliary power load in S3 and S4 compared to S1 and S2, the voltage unbalance in S3 and S4 was more than that of S1 and S2, respectively and the voltage unbalance of S3 was more than that of S4 because the headway of S3 was longer. In the viewpoint of the maximum %VUF for each scenario as shown in Table 2, it helped confirm the above explanation since the results seen from Figure 12 were consistent with the results from Table 2.

From the results, it could be concluded that the longer the headway, the more voltage unbalance. That meant the voltage unbalance was more reduced when the trains were released more frequently. The total weight and auxiliary power also affected the voltage unbalance. According to IEEE 1159 –2009 standard, the %VUF must not exceed 2%. Therefore, the service extension of the ARL can be carried out without any violation of voltage unbalance based on this simulation results.

Table 2: The Maximum %VUF

Scenario	%VUF Max	Comparison with IEEE 1159 -2009 standard (2%)
S1	0.2717	Less than 2% (passed)
S2	0.1946	Less than 2% (passed)
S3	0.2993	Less than 2% (passed)
S4	0.2906	Less than 2% (passed)

6. Conclusion

This paper presents the study of voltage unbalance caused by the AC railway power supply system using MATLAB/Simulink . The VUF was the key factor in this consideration. The test system was the ARL linking Suvarnabhumi airport to the Bangkok city center .The traction transformer connection type was the cyclic permutation of phases .The VUF was estimated in four scenarios of the train operations. The results showed that at the same headway, the VUF was increased when the train weight and auxiliary power load were increased due to the increase in energy drawn by the trains .For different headways, the longer the headway, the more voltage unbalance. However, the increased VUF was still within the limit of 2% imposed by IEEE 1159 – 2009 in every scenario .Accordingly, the extension plan of the ARL by increasing routes, service distance, and the number of trains in the future will slightly affect the voltage unbalance. However the VUF is limited within the acceptable value.

Acknowledgment

We would like to express our sincere gratitude to Suranaree University of Technology for financially supporting this research.

Appendix

Overhead catenary system for ARL:

- Contact wire: Cu 107mm² (20% abrasion)
- Messenger wire: Bz 70mm²
- Return Conductor: E-Al 120mm²
- Rails: UIC 60, 15%

Traction power substation for ARL:

- 2x20 MVA transformers (cyclic connection)
- 69/27.5 kV, 12% impedance, ONAN
- Short-circuit power of the substation is 2.7 GVA

Train resistance parameters:

3-car train	4+3-car train
Tare weight: 131 tons	Tare weight: 299 tons
Rotary portion of tare weight: 6%	Rotary portion of tare weight: 6%
Maximum payload: 44.9 tons	Maximum payload: 105.7 tons
Maximum design speed: 160 km/h	Maximum design speed: 160 km/h
Maximum acceleration: 1 m/s2	Maximum acceleration: 1 m/s2
Maximum deceleration: 0.88 m/s2	Maximum deceleration: 0.88 m/s2
Gear/Motor/converter efficiency: 82%	Gear/Motor/converter efficiency: 82%
Maximum auxiliary power: 200 kVA	Maximum auxiliary power: 450 kVA
Maximum tractive effort: 200 kN	Maximum tractive effort: 400 kN
Train resistance formula: A = 2.1222 B = 0.00618 C = 0.3197	Train resistance formula: A = 4.8438 B = 0.01412 C = 0.53287

ABSTRACT

There is a growing interest in using radio frequency in imaging for problem solving in situational awareness, surveillance, search and rescue operations, and screening for security. This has been fetched from recent development in addition to innovative technologies in microwave radar imaging applications. Despite the fact that no new phenomenology is exposed in this field, the prospects to eventually realize systems that operate under adverse weather conditions, interferences and obscuration has prompted newer prospects. However, the existing systems for RF imaging are not easy to afford and are not easily available and there is a need to make affordable imaging available to support people's lives. The effort provided an economic, compact and easy solution for human body detection applications using Radio Frequency (RF) by designing and developing a microwave transceiver that can give data in a suitable form for further signal processing and data acquisition. In this project, different types of RF imaging techniques and the most feasible techniques that may be employed for under debris search and rescue operations were studied. Link budget analysis and software simulations were conducted. Individual components along with the transmitting and receiving chains were tested on VNA. Gain and radiation pattern of antennas was determined in anechoic chamber. During this project the performance of transceiver, regarding its detection ability, range resolution, signal to noise ratio (SNR) etc., were also investigated. At the end a prototype FMCW transceiver is given that is able to detect human body under debris or behind a walls whether living or dead, which is effective at transmitting as well as receiving the reflections and giving data in an audio format for further signal processing.

1. Introduction

This paper is an extension of work originally presented in 19th IEEE International Multi Topic Conference (INMIC 2016) [1]. The initial scope of the project was to build antennas and conduct software simulations to define the parameters on which a transceiver could be built like type of transceiver design that could be employed, operating frequency, transmit power and bandwidth etc. Furthermore, the work was extended to develop and test an economical and simple transceiver system to demonstrate the concept and feasibility of the prototype. Not all of the initial proposals could come to reality but a transceiver reflectometer was developed to demonstrate the feasibility of proposal. An Analog to Digital Converter (ADC) and a Data Acquisition Device (DAQ) used for conducting experiments and collecting data. There was no dedicated electronic hardware used for data collection and generating image, which reduced the complexity of the technical requirements, but imposed certain constraints on the capability of the system. This project was to provide foundation research and work for more complex system to be built in the future. Figure-1 has been presented for thorough understanding of the project and an idea of what is being conceived through the project. The project outcome may be transformed for commercial use.

The data given by radar contains the bearing and also range to the Transceiver and the body which is buried under debris. Hence, it is employed in a number of areas in which the requirement for this kind of locating is vital. Pakistan is located at the north far western region of the Indian subcontinent which also overlaps with the Indian as well as the Eurasian tectonic plates. The Sindh and also some of the regions in Punjab province rest on the north

*Corresponding Author: Syed Daniyal Ali Shah, House No 135, Street 3, Block C, DHA Phase 8, Lahore Cantt, Pakistan. +92-321-3141555, 9daniyal@gmail.com

western nook of the Indian tectonic plate, whereas, Baluchistan province as well as the vast majority of the Khyber Pakhtunkhwa exists within the Eurasian tectonic plate which primarily makes up the Iranian plateau. The Northern Regions as well as Azad Kashmir rests mostly in Central Asia besides the edge of the Indian tectonic plate, therefore, are vulnerable to ferocious earthquakes exactly where both the tectonic plates collide. Due to the lack of advanced equipment a lot of lives are lost during these natural disasters. If rescue response teams are able to equip themselves with devices that are able to detect life under debris, the amount of lives that can be saved by this device are unimaginable. The objective is to make a microwave transceiver that is able to detect living beings under debris and is man pack handheld.

The capability to discover moving objects inside a structure or behind the wall [2] is also one of the noteworthy applications of the RF transceiver. The transceiver delivers users with situational knowledge for an operational benefit. The through the wall detection capabilities are priceless for both equally the Armed forces and Law Enforcement agencies associated with tactical operations in Urban Terrain. Military Operations in Urban Terrain (MOUT) necessitates successful attainment of military aims. These capabilities significantly improve the pre-planning and also execution of military operations.

An imaging transceiver model comprises a wireless transmitter that produces radio waves in specific direction. Whenever, these waves come in contact with a physical entity they are generally echoed and also dispersed in lots of different directions. The objective is to make some of these radio waves echo back form a living body the place where channel do not favor optical visibility. A Figure 1 of such a transceiver system is shown below which is being conceived for the project.

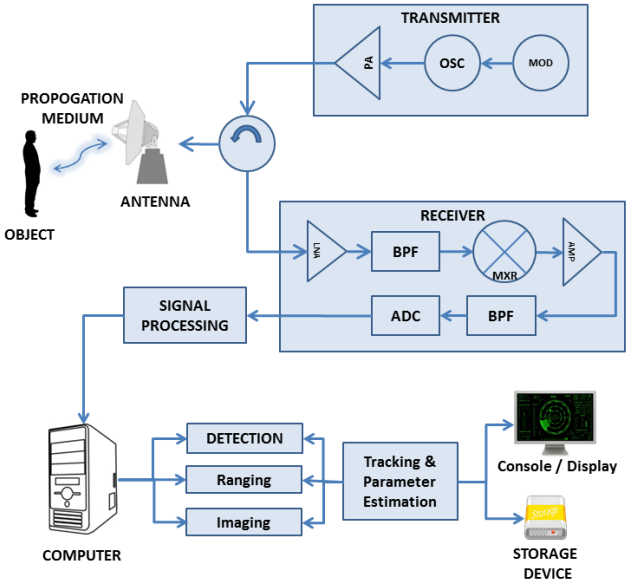

Figure 1 - Overview of Generic Transceiver System.

A link budget calculation of all of the gains and losses of the components and parts of transceiver will be presented and also analyzed. Additionally, the losses inculcated as a result of propagation through the channel would certainly be taken into consideration. Albersheim's equation [3] is used to figure out the needed Signal to Noise Ratio (SNR) for the particular detection and also false alarm probabilities as well as the maximum detectable range for monostatic radar [4] is going to be determined and investigated for the desired range of operation. Comparing between different types of radar techniques, specifically Pulse Doppler (PD) as well as Continuous Wave (CW) [5], the most appropriate technique is going to be implemented for transceiver design. The true to life differences between them may very well rely more upon the compromises than the hypothetical attainable. Antenna selection as well as design is among the most crucial areas of a wireless system for dependable Radio Frequency (RF) communication. One grave constraint using this elucidation is that the Electromagnetic (EM) waves are emitted in an Omni direction pattern, so the quantum energy in the bearing being studied is a very trivial portion of that radiated energy from the antenna. To obtain an acceptable amount of received power, the transmitting antenna should be directional.

1.1. Project overview

To identify the issues in the creating of RF system the properties of such system were investigated along with the environment. Receiver as well as transmitter architectures were studied and also their viability in existing Integrated Circuit (IC) solutions for instance superheterodyne (superhet) technology [6], direct detection and power meters. The operating frequency selected for the project is in industrial, scientific, and medical radio band (ISM band) exactly 2.4 GHz range [7], and follows maximum transmitting output power limit of 30 dBm or simply 1 watt in accordance with the government regulations [8]. In addition to mere component accessibility numerous other issues were also well thought-out while developing and planning this system. Field testing of the prototype was carried out and outcomes are reported. It was summarized by looking at upcoming future directions in RF microwave transceiver concepts and improvements that can be made to the existing system.

2. Design Objectives

There is certain required criterion that need to be met in order to work in conditions the device is intended to operate and function. There are also certain government regulations that need to be met so that the equipment in utility is within the legal boundaries.

2.1. Low cost

The transceiver needs to be low cost, it needs to be easily affordable for governmental and non-governmental organizations, for a poor country with low economic conditions and meagre resources.

2.2. Compact size

The transceiver needs to be compact in size so that it can be easily moved and operated in affected areas like a region struck with earthquake.

2.3. Easy to operate

The transceiver needs to be user-friendly and easy to learn, as complex equipment requires specialized training which is not easy to resource and afford.

2.4. Low maintenance

Transceiver should be low on maintenance as higher maintenance costs needs higher affordability.

2.5. Low operation cost

Transceiver need to have lower operating costs as it matters to buyers why they are operating in large quantities.

3. Regulations requirements

The PTA (Pakistan Telecommunication Authority) guidelines for unrestricted wireless apparatus functioning in the ISM frequency bands [9] is restricted. The ISM RF frequency bands were initially reserved for electromagnetic frequency that is generated by industrial, scientific as well as medical (ISM) apparatus. In order to abide by these rules, the equipment bandwidth will remain within the ISM Band of operation particularly 2.4735 to 2.4835 GHz which also gives us the bandwidth availability of 10 MHz only. Max wireless radiated power to be fed to the antennas should be less than 30 dBm or 1 watt. The obligation for remaining within all these radiated power restrictions falls on the manufacturer. Even if the equipment is professionally built by specialists, or in case if it is self-designed. In order to remain within these regulations, the maximum wireless transmitter output power to be fed to the antennas should not exceed 30 dBm and Effective Isotropic Radiated Power (EIRP) should not exceed 30 dBm. Keeping this in mind it was decided to keep the maximum transmit power at 29 dBm or 794 mW.

4. Zero IF Design

A Direct Conversion Receiver also referred to as Zero Intermediate Frequency (IF) Receiver, synchrodyne or even homodyne is a RF receiver model that down converts the arriving RF signal making use of synchronous demodulation detection which is driven with the help of oscillator, the frequency of which is equal to or close to the transmitted frequency of the expected signal [10]. Whereas, in the case of regular superheterodyne receiver in which this really is achieved after transformation to an IF (Intermediate Frequency).

The simplicity of carrying out merely a single conversion of frequency decreases the elementary RF circuit complication, however, other concerns relating to dynamic range do ensue. In its unaltered form it turned out unsuitable to obtain Amplitude Modulation (AM) as well as Frequency Modulation (FM) radio signals without employing a Phase Locked Loop (PLL). Even though these kinds of engineering problems realized this approach rather unrealistic when the technique was in its initial development stages in 1930's. Present technological innovations and software defined radio have particularly re-established its use in various areas such as certain consumer based equipment [11].

4.1. Zero IF Design

Even though the superhet method happens to be effective receiver architecture, it really is nowadays finding competition from Direct Conversion Receiver (DCR) technique also known as the Zero IF receiver (Figure 1) [6]. Here, the Local Oscillator (LO) frequency is placed very near to RF transmitted frequency of the acquired signal. The mixed output is directly at baseband, and also there is absolutely no IF stage required.

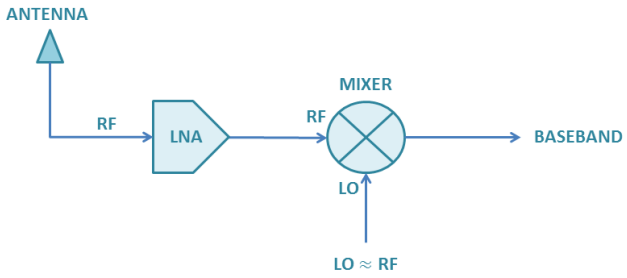

Figure 2 – Block Diagram of Zero If Design.

The RF signal is fed into the mixer in Direct Conversion Receiver the same way as in superheterodyne receiver [6]. In contrast to the superhet, the frequency of LO does not have an offset from RF frequency. The outcome is a demodulated baseband output signal just like the one obtained from a superheterodyne technique employing synchronous detection following an IF stage [10]. To put it differently, the down conversion is performed in just one frequency transformation. This prevents the complication of superhet like image rejection problems, IF stages and a couple of frequency conversions.

Despite the fact that this technique decreases the basic circuit complication in principle, it places serious requirements on almost all stages, as well as noise, stability, dynamic range, tuning range, and distortion. For certain very carefully chosen as well as developed purposes, ICs could make Zero IF receivers competitive or even better than the superhet with its IF stages.

4.2. Technical Problems

To come at par with the efficiency of the superheterodyne down conversion, several of the features typically sorted out by the IF phase needs to be achieved at baseband. Since there are no IF amplifiers with high gain, therefore, by making use of Automatic Gain Control (AGC) the power level at baseband output contrasts over a very wide dynamic range. This really is major engineering challenge which restricted the feasibility of the model. An additional concern is the incapability of the model to employ envelope detection of amplitude modulated signals. Hence, reception of AM or FM signals directly requires locking of the phase of the local oscillator to the transmitted frequency, an even more challenging job as compared with the more widely used envelope detector at the output port of an IF implementation stage in superheterodyne model. Nevertheless, this may be prevented when it comes to a Direct Conversion model making use of quadrature detection and after that Digital Signal Processor (DSP) is employed [12]. Making use of software defined radio approach, the two quadrature outputs could be processed so that any kind of demodulation can be carried out as well as filtering on baseband signals from frequencies around the LO frequency [12]. The significant increase of digital equipment, together with improvements in the analogue components associated with the frequency transformation to demodulated signal, has consequently created this more straightforward topology effective in several applications.

4.3. Advantages

The beat frequency signals which are unwanted by products from the frequency mixing stage do not require any additional signal processing because they are rejected by using a Low Pass

Filter (LPF) at the output. The demodulator model carries the added benefit of higher selectivity, which is for this reason a precision demodulator. The model concepts could be expanded to allow splitting up of adjoining channel transmitted signals in which sidebands might overlay the desired transmitted signal. The model furthermore enhances the detection ability of pulse modulation transmitted signals.

5. Modulation Requirement

Continuous Wave Frequency Modulated (CWFM) also called Frequency Modulated Continuous Wave Radar (FMCW) radar [13] is a small distance calculating radar efficient at figuring out range. This enhanced dependability by delivering range measurement together with velocity measurement, that is certainly important if multiple sources of reflection are arriving at the radar antenna. Additionally, it is put to use as wave radar, proximity sensors and early warning radar. Doppler effect is not necessarily required for identification when frequency modulation is employed.

In such a transceiver the Transmitted (Tx) signal of a well-defined steady continuous wave frequency changes back and forth in regularity over a set time frame by a controlling modulated signal. The distinction of frequency between the receiver and the transmitted signals raises with delay, together with range. This smudges away the Doppler frequency. Reflections from an object are after that mixed with the Tx signal to generate a beat frequency which will lead us to the range of the object after demodulation.

There are lots of feasible modulation forms [14] that can be employed for various measurements & requirement needs but saw tooth or triangular modulation scheme is of the interest. The saw tooth wave modulation pattern is employed in comparatively large distance measurement applications along with a minimal effect of Doppler shift in frequency for instance, a maritime radar for navigation [15]. Saw tooth modulation is the single most widely employed in FMCW radars when distance measurement is favorite for targets that do not have moving elements. Range data and the Doppler speed are mixed by means of this approach. Modulation could be switched off on alternative scans to recognize speed making use of carrier frequency shifts of unmodulated wave. This enables distance and also speed to be found with a single reflectometer set. Triangular waveform modulation is often used to accomplish the identical objectives. In a triangular shaped frequency changing, a range calculation is usually carried out on both the increasing and also on the dropping edge simultaneously, the precise Doppler shift in frequency could be figured out from two measurements. The shift between the two different frequencies is two times the Doppler frequency [15]. Due to the fact the two differential frequencies are not at the same time available this comparison demands digital signal processing, with saving the measured results and processing them later. This modulation enables simple splitting up of the difference frequency Δf of the Doppler shift frequency f_D.

Distance is restricted to one fourth of the wavelength of the transmitted modulation. Measurable distance for 100 Hz FM will be 500,000 meters. That restriction is dependent upon the kind of modulation as well as demodulation. The succeeding normally is applicable [15].

$$IR = f_r - f_t = \frac{c}{(4 \times \lambda)} \quad (1)$$

Where:

$IR = Instrumentrd\ Range$
$c = speed\ of\ light$
$\lambda = Modulated\ Frequency$

The radar will certainly record inaccurate ranges for echoes from ranges beyond the distance resolution, for example from the moon. Range determination for FMCW are merely dependable around 60% of the instrumented distance, or even for about 100 Hz FM is 300 km. In order to maintain versatility of the transceiver system the majority of the modulation patterns such as sinusoidal, triangular and Frequency Shift Keying (FSK) are integrated in the transceiver design but triangular modulation scheme for the intended purpose was used.

6. Dynamic Range

The transceiver needs to be effective at dealing with RF signal reflections from surface of debris and also shorter range objects as well as sense minute RF signals in close proximity to the noise floor form the human skin. The ratio of the highest receivable RF signal to a bare minimum of detectable reception is known as the dynamic range which is calculated for the system as below [4]:

$$Dynamic\ Range = 20 \log \left(\frac{Vrms_{max}}{Vrms_{min}}\right) \quad (2)$$

$$Dynamic\ Range = 20 \log \left(\frac{0.071\ v}{0.018\ v}\right) \quad (3)$$

$$Dynamic\ Range = 11.9\ dB \quad (4)$$

It is actually 11.9 dB for a particular transmit bandwidth. The highest energy of receiver RF signal in terms of maximum Root Mean Square (RMS) voltage at receiver should not saturate the transceiver front end as well as considering a 14 dB Low Noise Amplifier (LNA) is also given to the acquired signal, it is also the highest sampling rate of the ADC. Furthermore, for a FMCW transceiver, the greatest RF signal in the acquired bandwidth is determined by a compression point of 1 dB the down converter mixer in which the gain turns from linear behavior this shoulders virtually no saturation once the mixed signal is achieved. A bare minimum of detectable RF signal power in terms of minimum RMS voltage at receiver needs to be above the received background noise level as well as have a minimum detectable SNR. In the majority of reflectometer in which detection of target is the primary application, SNR of 8 dB is mostly required [16]. In the majority of applications in Ground Penetration Radar (GPR), a minimum voltage also needs to have a nominal amount of signal to clutter ratio (SCR) so that the received signal is capable of determining and also identifying the target profile.

The FMCW transceiver's dynamic range will certainly have an effect on the greatest distance at which an object could be identified. Usually, radars will have a greater equipment dynamic range as compared to sampling dynamic range. The ADCs dynamic range in dB is as comprehensive as $20\ log\ (2^N)$, where N is the amount of bits or even roughly N times 6 dB [17]. Consequently, a 16-Bit ADC will have a 96 dB of calculated dynamic range. However, additional elements impact the authentic attainable dynamic range [18]. There are techniques for

instance like stacking which might be employed to enhance the SNR and also AGC to get over the issue of dynamic range variances [16].

7. Project Architecture

7.1. Methodology

An FMCW radar comprises fundamentally of a transmitting chain and a receiving chain collectively known as transceiver along with a data acquisition device. The transceiver is a small in size, portable and a light weight module which typically consists of the antennas integrated as standalone transmitter as well as receiver antennas. An RF wave typically in microwave region is produced by a Voltage Controlled Oscillator (VCO) which can be a modulated waveform which directly feeds the transmitting antenna, or even its strength may also be amplified by employing a power amplifier. A typical form of transmitting chain is shown below.

Figure 3 - Block Diagram Transmit Chain.

If a single antenna is being used, then a ferrite circulator then to differentiate the receiving and transmitting signals is essentially required, since simultaneously transmitting as well as receiving signals are detected by the FMCW radar. When the Tx and Rx antennas are close to one another there is a direct positive feedback between the two antennas which is like crosstalk in terms of communication. In order to mitigate this typically, the antennas employed are polarized, the polarization direction is rotated by 180° against one another. In order to further decreases crosstalk a shielding plate is also used between the antennas. Considering that the measurement is conducted as a frequency variance between the transmitting and receiving signal, the RF signal that is generated by this direct coupling could be suppressed or filtered because the frequency output is very less as compared to the coupling frequency.

Depending on the application of CW radars solely the Doppler frequency has to be processed, when transmitting a constant frequency or alternatively in the event that very low modulation frequency is applied as compared to the transmitting frequency. This consists of frequencies just approximately 16.5 KHz by applying an FMCW transceiver working in K–Band (24 GHz) and the estimated speeds for recording are around 360 Km/h. Similarly, for the case in which detection of the object is the sole purpose of the transceiver the system does not require very high received signal bandwidth. For that reason, as microprocessor there may be a regular stereo audio processor, that is manufactured in large quantities as well as being used for instance in audio cards for home laptops or computers. Even just in the rectangular shape modulation (FSK) this kind of a processor can be employed conditionally.

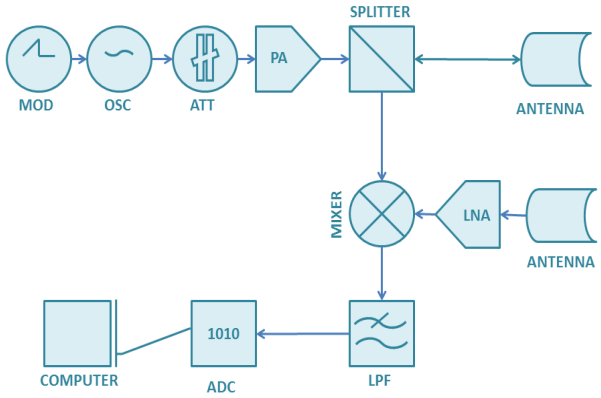

Figure 4 - Block Diagram Generic Transceiver Design Without Circulator.

One of the difficulties of this system design is that the baseband signal also varies over the bandwidth if the transmitted signal. This issue is resolved in signal processing of the received signal in which the reference signal is parsed in to data, wave by wave, with respect to a reference signal which is a square waveform.

7.2. Link budget calculations

Keeping in view all the design criteria, constraints, component losses and previous analysis of the losses and absorption of building materials following designs are visualized. A separate transmitter and receiver design is given below in which approximately 90% signal is lost due to reflection, absorption or attenuation. Signal propagation or path loss models [19] were not calculated although a rough estimation of the propagation losses by carrying out literature review on attenuation in propagation was considered. The transmitted signal bandwidth is kept at 300 MHz which is the maximum bandwidth of the system this allows to achieve a decent range resolution.

Since VCO source that could produce such a high power signal was not available so an amplifier was used to increase the power

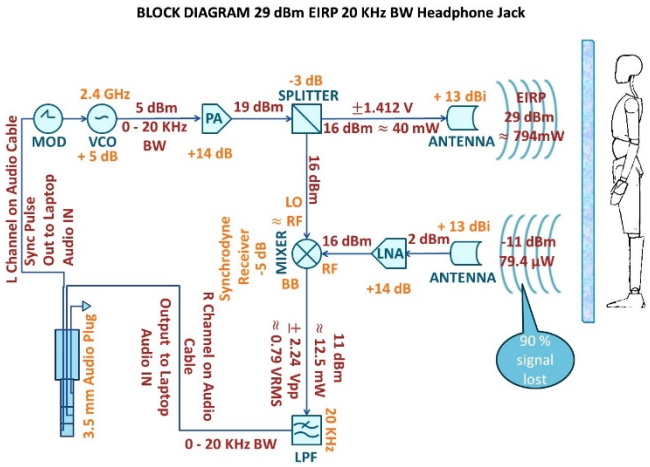
as desired. This lead to an increase in components employing an attenuator in addition to an amplifier lead us to the desired power of 16 dBm. Although this produced the desired results but also increased the noise floor unnecessarily.

An innovative way was devised to decrease the noise floor as well as to reduce the quantity of components required. This ultimately lead to the decreased cost of transceiver which was also one of the main goal to deliver a low cost solution. After transceiver design research and looking deep into radar operational fundamentals [20] a design which is simplistic yet effective for the detection application was conceived.

If the transmit bandwidth of 300 MHz is maintained which is within the frequency range of Data Acquisition Devices (DAQ's) and if the modulation frequency to the VCO is known in real time, then it can be directly down converted from 2.4GHz using stolen carrier from the transmitter. But it is coupled with a problem that the received signal varies over the frequency range of 300 MHz. This seems like there is high rate frequency hopping in the receiver system, which can be tackled in signal processing, when received data is parsed taking reference from the synchronization pulse from the modulator. This design is given below assuming similar characteristics of propagation loosing 90% of the received signal.

Now a data acquisition device had to be acquired it was found out that data acquisition devices that are available nowadays are quite big to be portable enough to use in the application so it required to figure out how to acquire signal using some handheld portable device. It was later suggested that if the transmitted bandwidth is kept at or below 20KHz which is within the frequency range of most audio processors and at such low frequencies (20 KHz) can be directly down converted from 2.4GHz using stolen carrier from the transmitter. The output can then be directly fed to a sound card of a computer or audio processor but the bandwidth of the system is greatly reduced which resulted in decreased range resolution, this technique could be useful in detection but this was not supportive in range measurement or object profiling.

If the transmitted bandwidth is kept in audio range (20 KHz) which can be processed by audio processors and at this frequency range the direct down conversion from 2.4GHz using stolen carrier from the transmitter varies over the frequency range of 20 KHz this indicates there is frequency hopping in the system. This issue was dealt by taking a signal from the modulator which is in Synchronization with the input frequency of VCO this way the data can be parsed wave by wave and hop the frequency at the same rate. The synchronization frequency is given to the left channel of audio jack and the received signal is given to the right channel of the audio jack. The acquired results can be directly fed in an audio jack input of any computer instead of using a DAQ or any other ADC. This greatly reduces the cost of the transceiver as now days a lot of high speed precision DAQ's are quite expensive. The design is given below.



This is the final design of the Microwave transceiver prototype that was implemented.

7.3. Modulator

In order to provide input to VCO's V-Tune XR-2206 IC was utilized. The XR-2206 is a function generator incorporated monolithic circuit effective at generating good quality sine, rectangular, triangle, ramp, and also impulse wave-forms of great stability as well as precision. The generated wave-forms could be both frequency as well as amplitude modulated by an external voltage source. Frequency could be chosen by an external input over a frequency range of 1 Hz to in excess of 1 MHz. The circuit is a good choice for telecommunications, instrumentation applications, and also function generator uses demanding sinusoidal signal FM, AM, or even FSK production requirement. The oscillator's frequency could be swept linearly over a 1:2000 frequency band with an external voltage control, while maintaining minimal signal distortion level.

The circuit designed has a voltage supply of 9-12 V_{DC}. The waveforms that can be generated are Square, Sine & Triangle. The impedance is 600 Ohm + 10% and the frequency range of operation is 1Hz - 2MHz.

The characteristics of the waveforms are given below at the input voltage of 9 volts Direct Current (DC) that can be employed to achieve results.

- Sine Waveform

Amplitude:	0 – 8 V
Distortion:	> 1% (at 1 kHz)
Flatness:	± 0.05 dB (1 Hz – 100 kHz)

- Square Waveform

Amplitude:	0 – 8 V
Rise Time:	> 50 ns at 1 kHz
Fall Time:	> 30 ns at 1 kHz
Symmetry:	> 5% at 1 kHz

- Triangular Waveform

Amplitude:	0 – 8 V
Linearity:	> 1% up to 100 kHz

The square wave is in frequency synchronization with triangle and sine wave forms so it can be used as sync pulse for Data processing [3]. Frequency chirp was carried out in order to cover the bandwidth using triangular wave so demodulated waveform is also scattered over the bandwidth as stolen carrier from the transmitter is being taken.

7.4. Audio Amplifier / Low Pass Filter

A LPF permits signals with a frequency less than a particular cut-off frequency as well as attenuates the frequencies more than the cut-off frequency. The degree of attenuation for every single frequency is dependent upon the LPF model. A Sallen Key Low Pass filter was used to get rid of electronic noise in a circuit, however, it may also be employed to avoid aliasing by restraining the frequencies of signals to be dealt with. The filter response could be transformed by replacing an individual resistor or even capacitor value.

In the case, LPF is utilized to decrease signal noise. Noise is a group of undesirable, random electronic signals that can be found in RF electronic circuits. Almost all RF devices are prone to the unwanted effects of noise, especially the ones that operate at comparatively lower energy signals. One more use for filtering is to avoid aliasing at the time of signal processing. Additionally, an LPF was employed to make sure that only lower frequency signals are allowed to pass through and high frequency noise is going to be discarded.

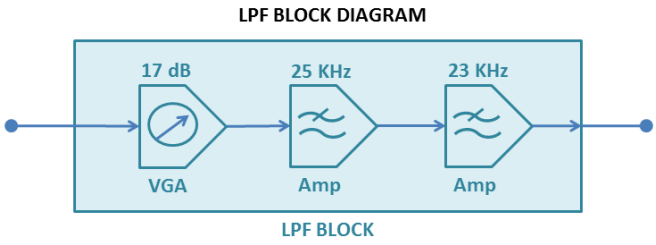


Figure 6 - LPF Block Diagram Representation.

The type of filter employed was Sallen Key Active filter topology simply because it provides a straightforward to execute filtering topology. The cut-off frequency can be adjusted by altering an individual resistor or a capacitor value. The filter constructed in Lab was tested on an oscilloscope at multiple frequencies and a bode plot was produced for the analysis of the constructed LPF. One such reading is shown. The yellow waveform is the input frequency signal and the blue waveform is the output signal that has been passed through the Sallen Key Low Pass Filter.

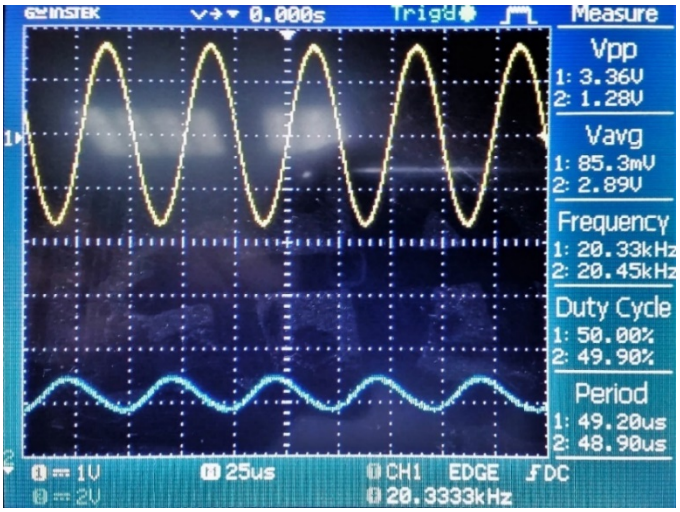

Figure 7 - Sallen Key LPF Result at 20 KHz.

The filter is functioning as desired. A -3dB gain factor was desired at 20 kHz and the filter produced slightly higher attenuation than -3dB. Calculations have been given below:

$$V_{in} = 3.36\,V \tag{5}$$

$$V_{out(IDEAL)} = \frac{V_{in}}{\sqrt{2}} = \frac{3.36\,mV}{\sqrt{2}} = 2.37\ V \tag{7}$$

$$V_{out(actual)} < V_{out(IDEAL)} \tag{8}$$

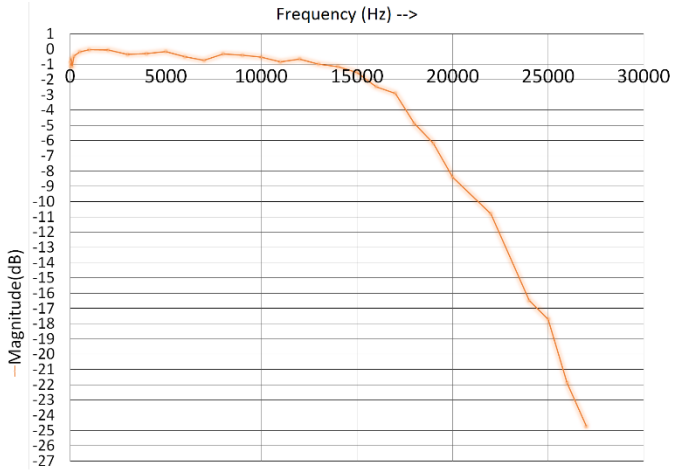

Figure 8 - Bode Plot 20 KHz LPF.

Since the filter is producing better than -3dB attenuation at 20 kHz, the Filter is working better than expected. This is likely due to parts tolerances that varied between 1 % to 5 %. Due to the ease of design and implementation, a Sallen Key filter is the perfect candidate for electronic filtering. It is ideal for eliminating electrical noise and since Operational Amplifiers (OP AMPs)

draw a negligible amount of current, the filter will not load the circuit to which it is attached.

7.5. Understanding Microphone Input Sensitivity

As the analogue to digital microphone input includes different units, comparing a single type to another can be difficult to understand; however, they share a very common unit of measurement in the audio frequency signal domain, input power level in dBV [21]. One may have an analogue voltage input or a PDM modulated input, however, their maximum acoustic input power as well as SNR can be instantly analyzed. The difference between the 94 dB Sound Pressure Level (SPL) reference and the noise floor of microphone input of 65dB, altering the input relative to the 94 dB SPL, would result in changing dBV output at the microphone jack input.

7.6. Choosing Sensitivity and Setting Gain

A balance between the microphone's input port noise floor, distortion, clipping point as well as level of sensitivity decides whether or not a microphone input is an effective match for a specific practical application. A microphone input with significantly higher level of responsiveness may require significantly less pre-amplification gain before the ADC, however, it might have much less headroom before clipping, compared to a microphone with reduced level of responsiveness.

In signal processing applications, similar to the this, in which a microphone with increased level of responsiveness is much more likely to achieve the higher audio input, distortion, as well as result in clipping. Alternatively, a higher level of sensitivity might be suitable in the application forms, in which the audio signal is attenuated as the length from the source to the microphone input port raises.

Nominal line level for consumer equipment is $-10\,dBV$, which is equal to $10^{-10V/20} = 316\,mV_{(RMS)}$. For simple sinusoidal input waves $\sqrt{2}\,.316\,mV_{(RMS)} = 447\,mV_{(peak)}$ or in other words $2\sqrt{2}\,.316mV_{(RMS)} = 894\,mV_{(peak\ to\ peak)}$ theoretical maximum input of microphone jack [22].

However, audio equipment will often include as much as $20\,dB$ of headroom above this value before clipping, so a full scale signal could be $10\,dBV$, or $3.16\,V_{(RMS)}$ or $8.94\,V_{(peak\ to\ peak)}$ [22]. Of course, every manufacturer wants to be louder than everyone else in competition, so devices tend to have higher inputs and outputs than they should be producing, consequently inputs have less headroom than they should have.

The aim would be to remain within the $894\,mV_{(peak\ to\ peak)}$ limit in all circumstances so that problems during signal processing are not experienced.

7.7. Pyramidal horn antenna

Following are the dimensions and pictorial representation of fabricated antenna:

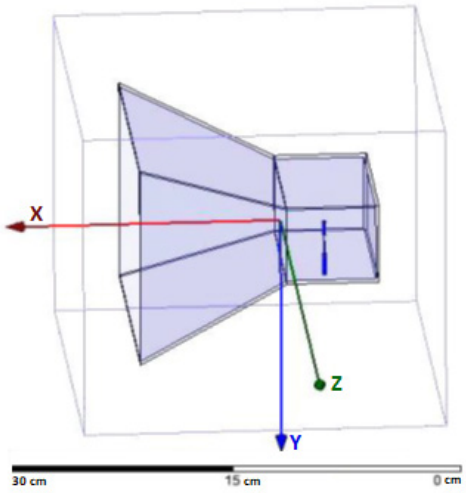

Figure 9 - HFSS Model Visualization Of Ism Band Antenna.

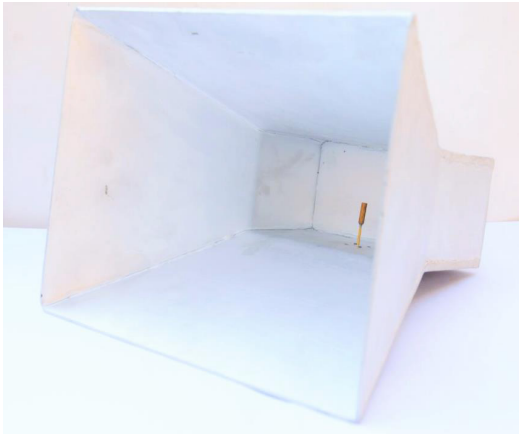

Figure 10 - Fabricated Model of ISM Band Antenna.

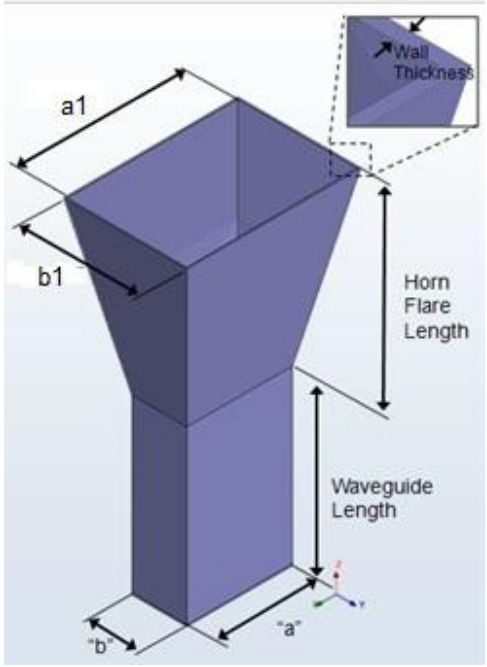

Figure 11 – Dimensions for Horn Antenna .

Table 1 - Dimensions of Horn Antenna

Units	Cm
Material	Aluminum
Connector type	SMA
Waveguide	WR-430
Waveguide “a“ dimension	10.92
Waveguide “b“ dimension	5.46
Waveguide length	10.37
Horn size in “a1“ dimension	18.66
Horn size in “b1“ dimension	14.51
Horn flare length	31.1
Wall thickness	0.203
Gain	Approx. 13dB
Lambda	12.244

7.8. Results of Antenna

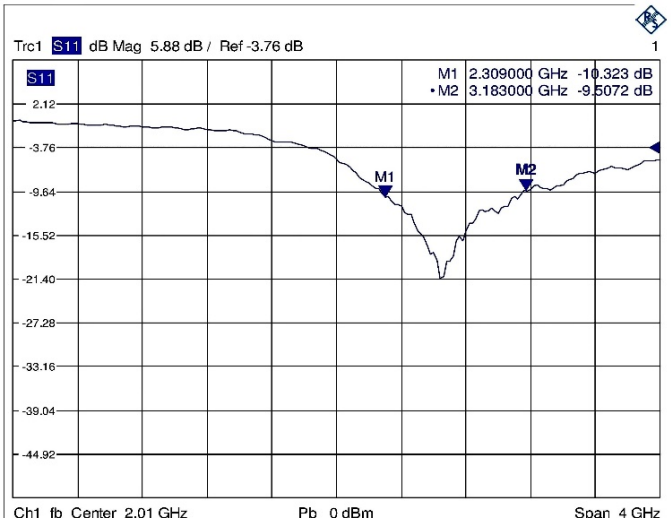

Figure 12 - Return Loss of Fabricated Tx Antenna.

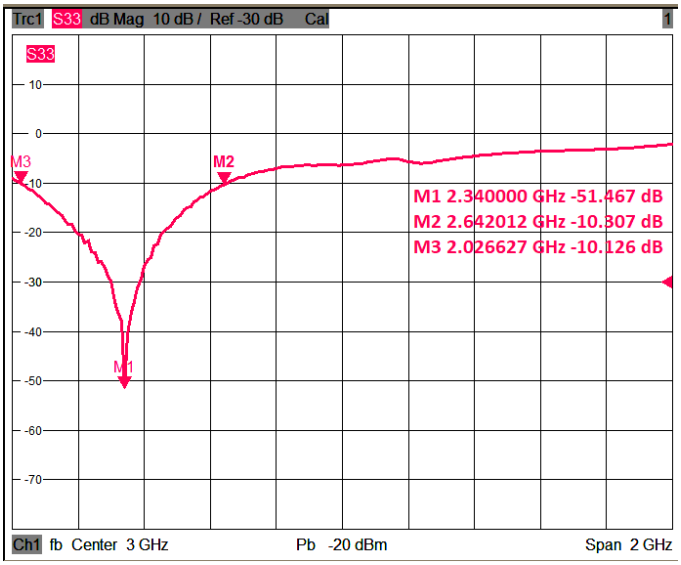

Figure 13 - Return Loss of Fabricated Rx Antenna.

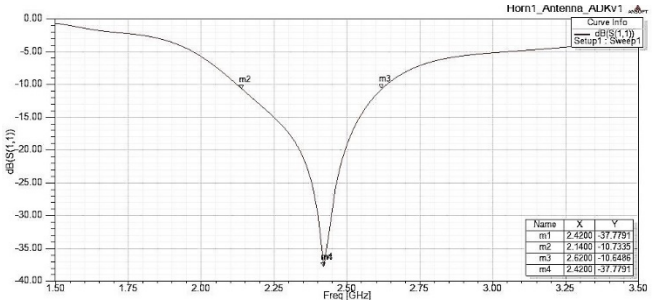

Figure 14 - Return Loss Of HFSS Simulated Antenna.

The return loss that is calculated by High Frequency Structure Simulator (HFSS) software simulation is -37.7791 dB and the return loss measured by the network analyzer is at a minimum of -21.40 dB. The -10 dB bandwidth of the Tx antenna is calculated from simulation as 480 MHz (2.62 GHz - 2.14 GHz) and the one measured from network analyzer is 883 MHz (3.183 GHz - 2.3 GHz) it can be seen that the centre frequency is shifted a little to 2.55 GHz but it still remains within the desired bandwidth of operation. The -10 dB bandwidth of the Rx antenna measured from network analyzer is 622 MHz (2.642 GHz - 2.02 GHz) it can be seen that the centre frequency is shifted a little to 2.34 GHz but it still remains within the desired bandwidth of operation.

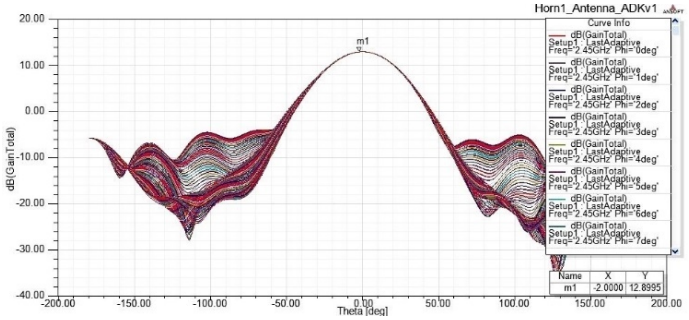

Figure 15 - Gain of HFSS Simulated Antenna.

Antennas Radiation pattern was also tested in Antenna Test Range (ATR) at Space and Upper Atmosphere Research Commission (SUPARCO) Laboratories. The plots of the results obtained are shown below.

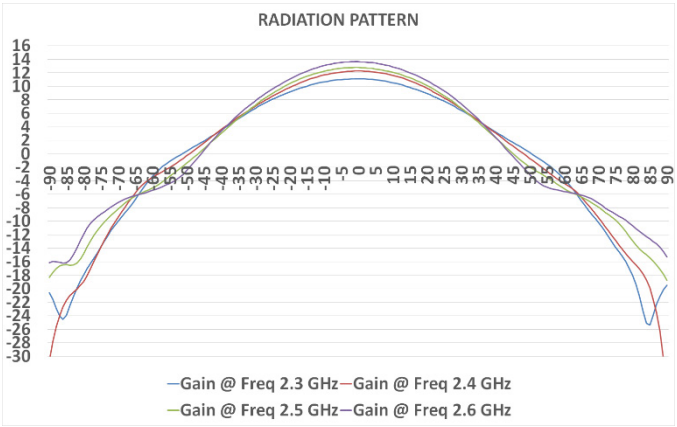

Figure 16 - Gain Measurement at ATR (Tx).

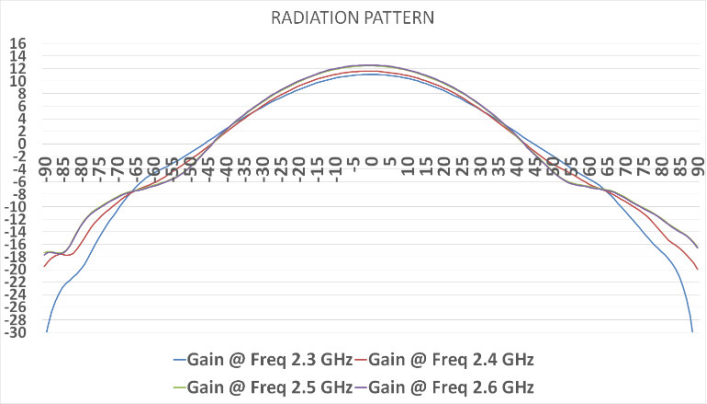

Figure 17 - Gain Measurement at ATR (Rx).

The actual gain measurement at 2.4 GHz of Tx antenna comes out to be 12.2744 dB, whereas, in simulated antenna results it can be seen that it comes out to be 12.8995 dB this is an acceptable loss that may be experienced in practical measurements. Similarly, for Rx antenna it comes out to be 11.5885 dB. Complete detailed results are mentioned in appendix.

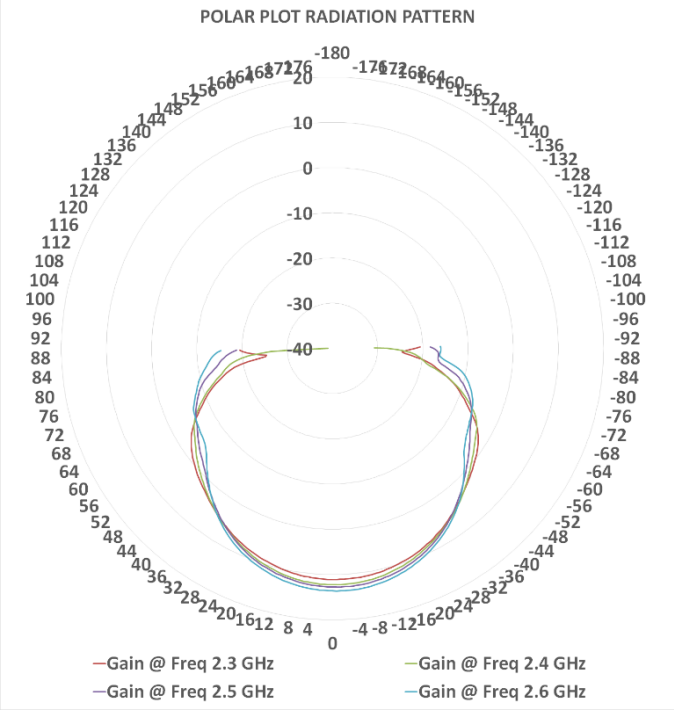

Figure 18 - Polar Radiation Pattern Plot (Tx) in ATR.

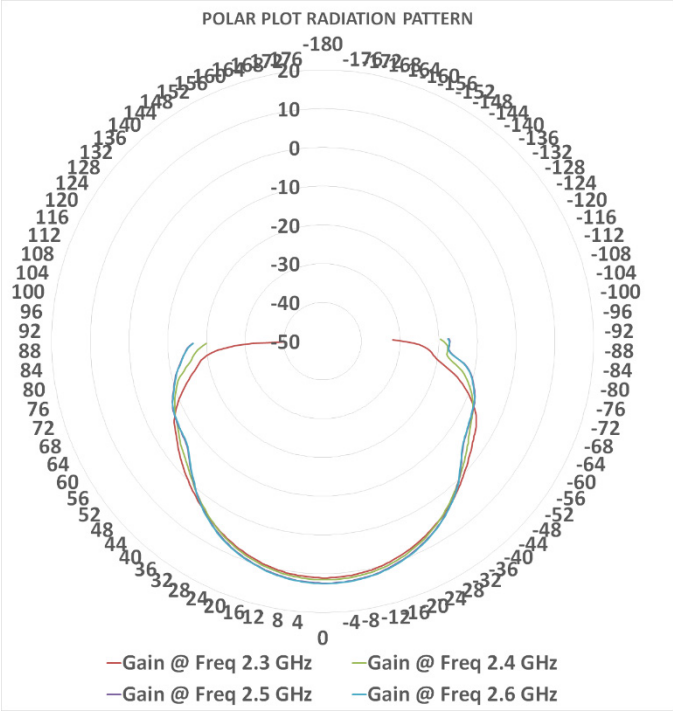

Figure 19 - Polar Radiation Pattern Plot (Rx) at ATR.

7.9. Power supply

In order to power the transceiver, a straightforward yet effective way by making use of widely available voltage regulator IC's to power the system was employed. 12 V DC from electric batteries was employed and required voltage was regulated by the components employing 78xx linear voltage regulator IC's. The 78xx or for certain producers L78xx, LM78xx, MC78xx and so forth are a series of linear static voltage regulators which are self-contained and have a built-in circuit. These are widely used in electric circuits demanding a regulated and managed power source because of their simplicity and inexpensive IC's. They generate a voltage which is positive relative to ground.

Light Emitting Diode (LED) lights were also used for indication of functioning of each separate IC input voltage and used comparatively higher values for capacitance for better ripple free and fixed voltages. The complete circuit diagram of power supply is given on next page. This circuit was implemented in the design. A Printed Circuit Board (PCB) was fabricated which was used to supply power to components.

Schematics of transceiver power supply are given below:

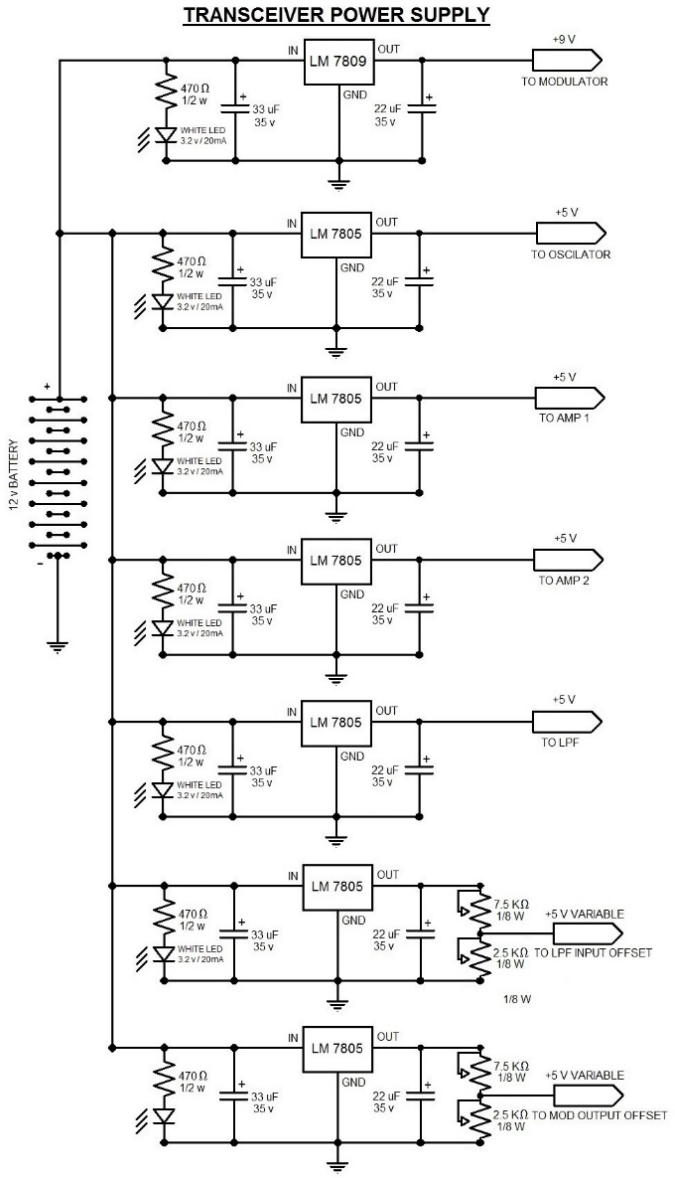

Figure 20 - Transceiver Power Supply Schematic.

8. Design implementation

8.1. Transmitter development stage

Each and every component of transmitter was connected and results were tested with spectrum analyzer.

First of all, VCO was given a constant voltage in order to generate a fixed frequency of 2.4 GHz then amplifier was connected in series and the results were visualized on spectrum analyzer. Similarly, the splitter was added to the chain and a 50 Ω termination was applied to the other port of splitter in order to avoid reflection from it. Then a total gain of 14.65 dBm was achieved and when the cable loss was included which was calculated prior to the testing (approximately 1.5 dB calculated before testing) then the total power comes out to be 16.15 dBm. This is very close to the calculated value of 16 dBm during link budget analysis at 2.4 GHz.

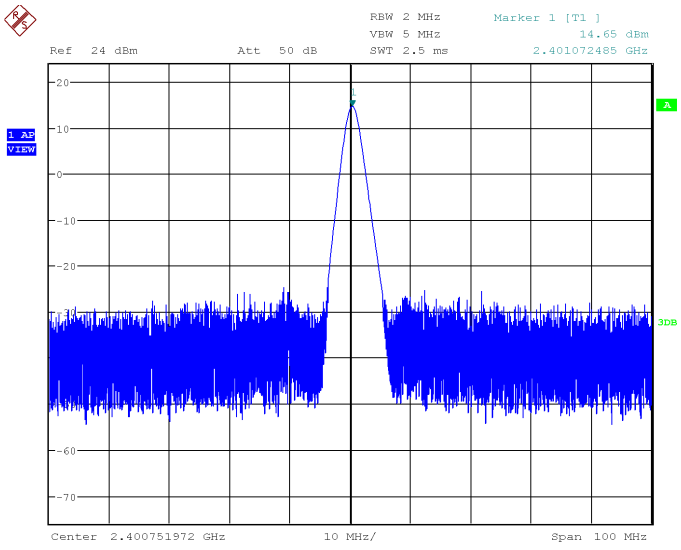

Figure 21 - VCO + PA + Splitter Output Response.

The block diagram of transmitter chain is given below this will be the total power feed into the antennas at 2.4 GHz.

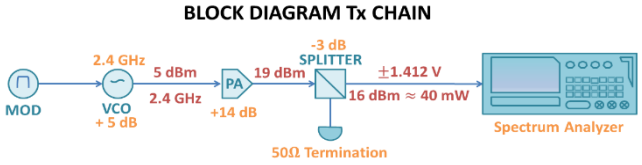

Figure 22 - Block Diagram VCO + PA + Splitter Testing.

8.2. EIRP measurement at anechoic chamber test

The gain of the antenna is measured by using the two antennas with known gain one as a transmitter and other as a receiver. Subsequently replaced the Tx antenna with the fabricated antenna and again measured the gain then with some calculations, the gain of the fabricated antenna can be found. The transmitted power fed into the antennas is measured previously although their values are given in table. The EIRP is calculated at different frequencies in order to cover the entire bandwidth.

Table 2 - EIRP Calculations Table

SR NO.	FREQ (F_C)	TX GAIN (G_T)	TX POWER (P_T)	EIRP (P_T+ G_T)
1	2.3 GHz	11.11 dBi	16.75 dBm	27.86 dBm
2	2.4 GHz	12.27 dBi	16.66 dBm	28.98 dBm
3	2.5 GHz	12.79 dBi	16.68 dBm	29.47 dBm
4	2.6 GHz	13.64 dBi	16.68 dBm	30.32 dBm

All the values are given excluding the cable losses that were calculated prior to the testing for gain measurement which was calculated to be 1.2 dB and for transmitting power fed into the antennas the cable loss was measured to be approximately 1.5 dB.

The calculated EIRP of the transmitter was 29 dBm but it can be seen that the EIRP of the transceiver increases with the increase

in frequency. There is almost 3 dB increase in EIRP when frequency is increased from 2.3 GHz to 2.6 GHz. This is mainly due to the increase in transmitter antenna gain increase, as the frequency increases the beam width of the transmitting antenna increases, which leads to the increase in overall transmitted power.

8.3. Receiver development stage

For any equipment comprising a receiver and a transmitter the loopback test [23] is a smart method to test the receiver. The essential loopback assessment for the integrated Microwave transceiver is conducted. The baseband signal visualization is conducted by oscilloscope which helps as an output analyzer while the microwave front end is in test with the help of a test attenuator. By means of this method in Transceiver (TRX) development, the microwave examination equipment can largely be evaded eventually leading to the reduced cost of test. The existing limitations and trade-offs are also discussed in the next chapter in terms of test observability controllability, and feasibility vs performance also the influence of production tolerances and the detectability threshold test was also conducted. This loopback test is conducted to provide a comprehensive picture of the transceiver functionality also in order to test Tx and Rx front ends before deploying antennas and actually start transmitting and receiving. The actual received signal of applied communication transceiver under test is also included. The receiver was tested using loop back technique where an attenuator is applied at the transmitter feed and is given to the received signal feed. The block diagram of the system under test is given below.

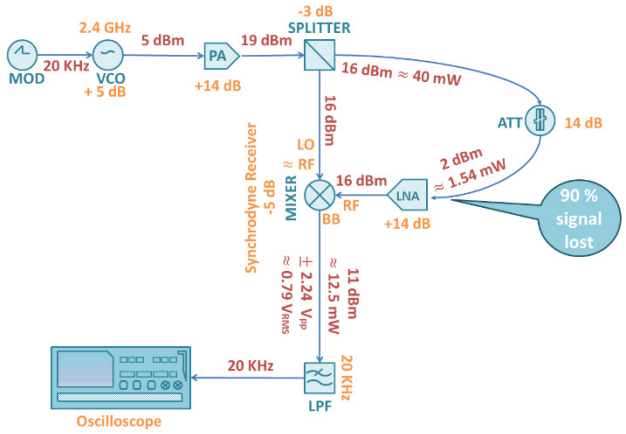

Figure 23 - Block Diagram Receiver Test (Loop Back Test).

Since the RF built-in circuits function at gigahertz frequencies and as they are growing to be more and more sophisticated, in apparatus assessment the typical testing aimed toward comprehensive requirements of the engaged RF components seems unrealistic and also expensive when it comes to the instrumentation as well as evaluation time. Direct RF measurement results on components demand additional contact elements that are likely to degrade the microchip overall performance and efficiency while using the needle probes obstruct the measurement results. The received signal result shown below tells that the receiver is functioning as desired and the frequency in use (20 KHz) would be the maximum frequency that is going to be used for the system.

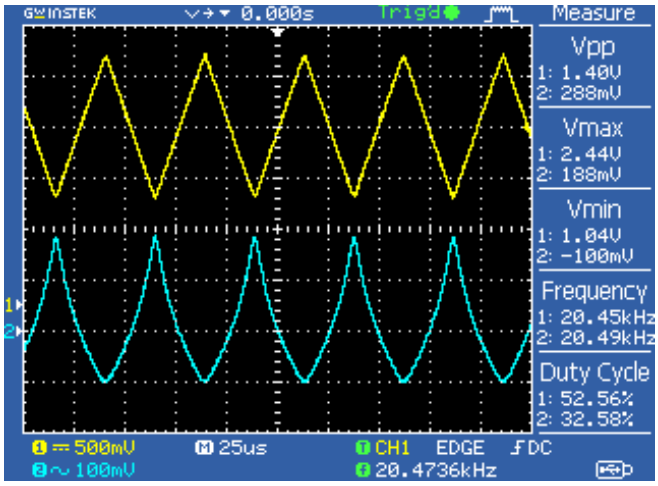

Figure 24 - Receiver Loop Back Result (20 KHz).

Using this approach as carried out in the front end test the detectability thresholds for different errors could be determined as well as various loop back results can be analyzed for the transceivers detectability. As the limitation and tolerances of the RF circuitry are likely to drive the RF components away from specifications the Design for Correction (DFC) is practically essential and also it needs to be merged with link budget analysis for an in depth approach. Through DFC the effect of variation due to tolerances on assessment is mostly alleviated, however, the demand for repeated tests is not reduced.

In spite of the problem of not having the schematics of the microwave components, a simple yet effective way was used to calculate the phase difference that will be produced at the mixer. It can be seen that there is a phase shift of approximately 180° in the transmitted and the received signals.

8.4. Data acquisition stage

A signal processing code block diagram has been given below.

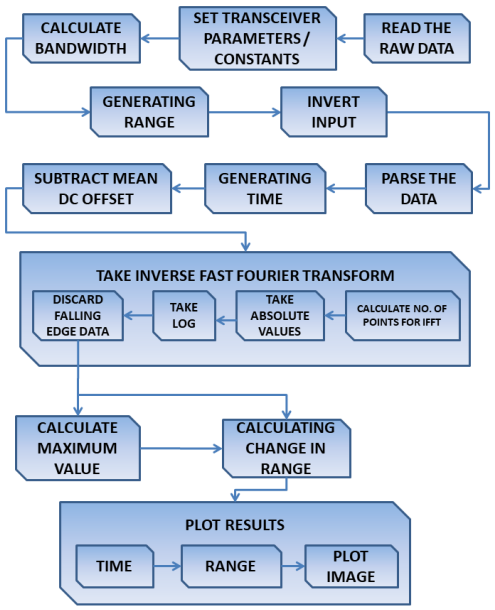

Figure 25 - Block Diagram of DSP MatLab Code.

8.5. System integration

The modules which make the core of the microwave Tx and Rx chain were assembled. The picture below shows the assembly.

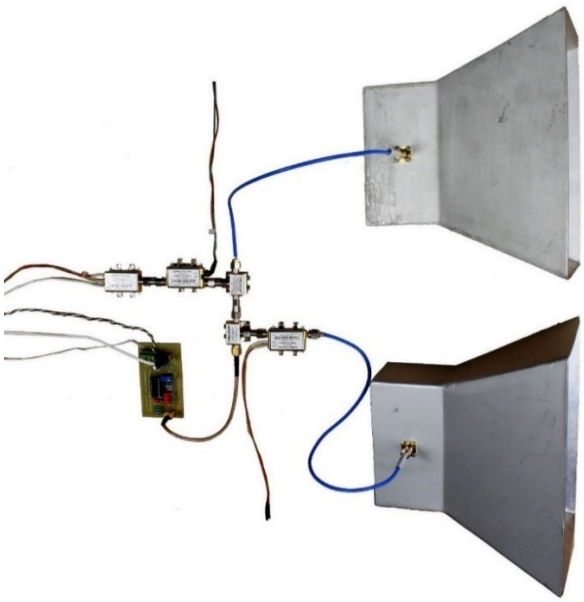

Figure 26 - Complete TRX Assembly with Antennas.

9. Evaluation

9.1. Oscilloscope Rest Results

First of all, the test results are conducted without any material in front of the body. By placing a body directly in front of the transceiver. The results are taken on oscilloscope and also a recording is made which was processed by the MatLab code in order to get a better picture. The test with a 9-inch (22.86 cm) thick wall in between the body and transceiver. The body was placed at a distance of 5 ft. from the wall. The test results in time domain are given below as visualized on oscilloscope.

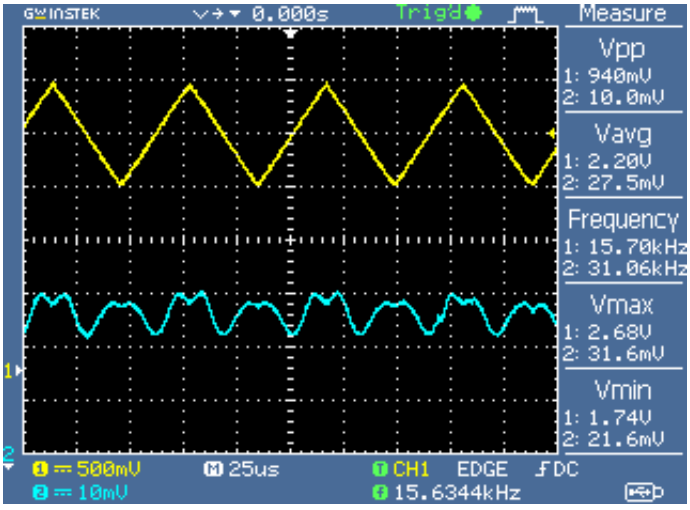

Figure 27 - Far Field (Wall) Test without Body.

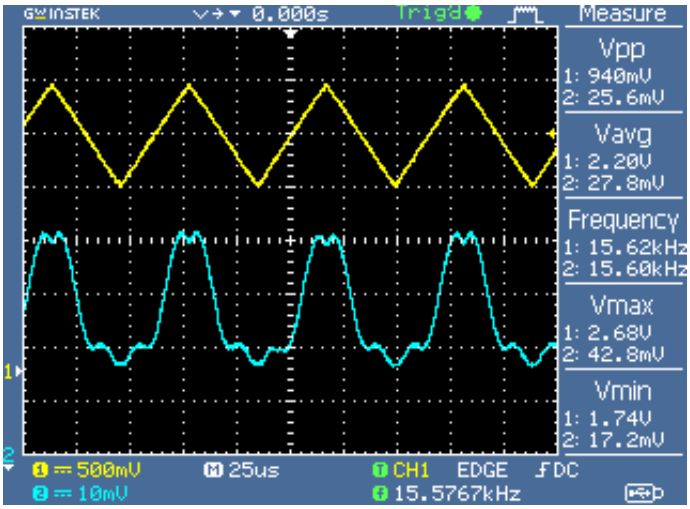

Figure 28 - Far Field (Wall) Test with Body 1 Foot (30.48 Cm) from the Wall.

9.2. Computer Audio Card Results

Audacity software was used to record the test results. First of all, the transceiver results are acquired by placing the transceiver with the wall and body was only placed once behind the wall these results are captured at multiple frequencies.

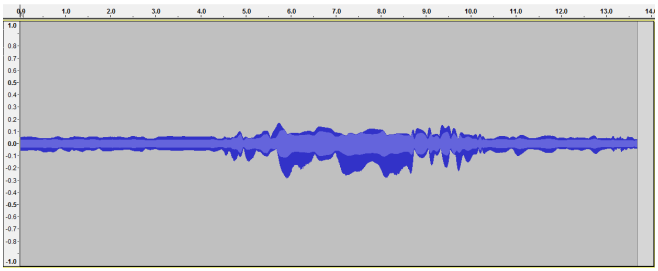

Figure 29 - Audio Pictogram at 5 KHz (Body was Placed Once).

Now the transceiver results are acquired by placing the transceiver with the wall and body was only placed multiple times behind the wall these results are captured at multiple frequencies. The multiple detection was conducted by setting threshold at the noise floor. The resulted pictograms are given below.

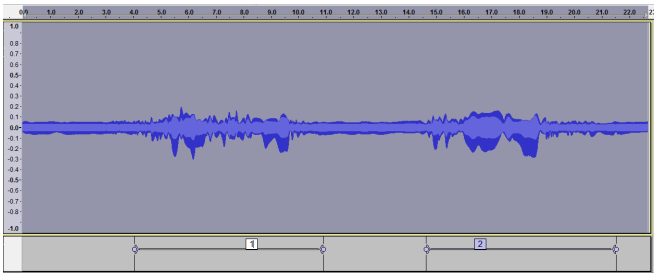

Figure 30 - Audio Pictogram at 5 KHz (Body was Placed 2 Times).

9.3. MATLAB 2D Images Results

Recordings from different frequencies is processed using MATLAB and RTI plot is developed.

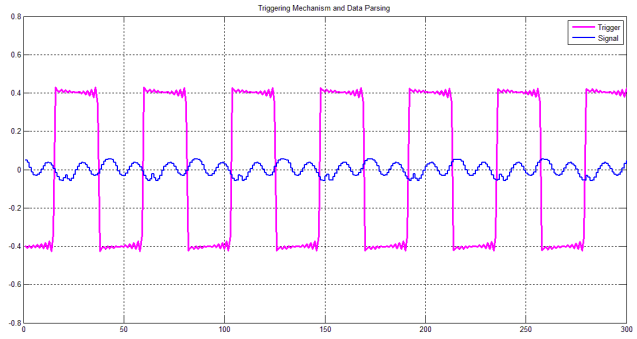

Figure 31 - MatLab Data Parsing 1 KHz.

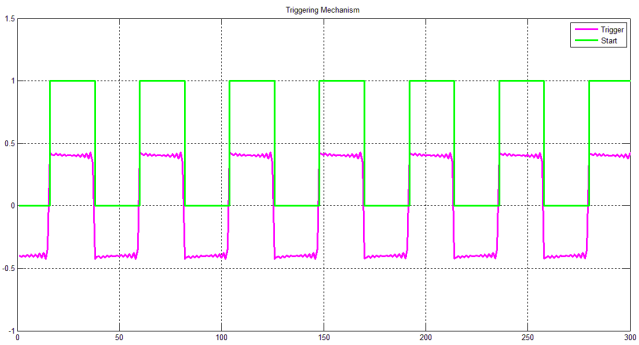

Figure 32 - MatLab Triggering Mechanism 1 KHz.

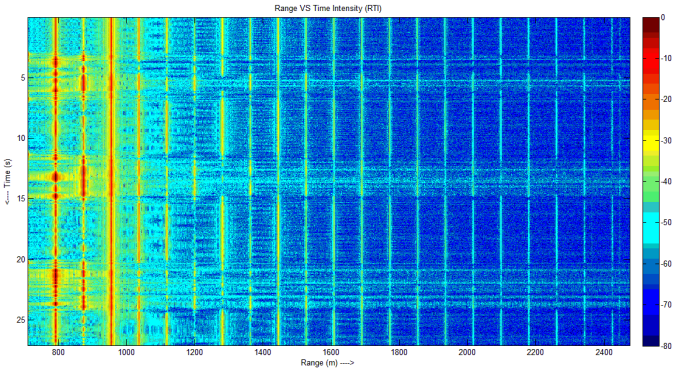

Figure 33 - MatLab Range vs Time Intensity 1 KHz (Body was Placed 3 Times).

The transceiver results are acquired by placing the transceiver with the wall and body was only placed 3 times behind the wall with specific time intervals these results are captured at 11 KHz. The multiple detections can be observed in RTI plot given above.

10. Conclusion

A completely built-in 2.4 GHz FMCW transceiver is basically designed and produced in this particular report. Employing XR 2206 IC for the purpose of function generator IC as an FMCW engine and using module based components with SMA connectors can significantly decrease the complication of the circuit as well as hardware designs. Which helped accomplish the project goals and targets realized that were set within initial project proposal. FMCW within the system was analyzed as well as simulated, using various modulation techniques. Microwave front end came to the realization in MMIC technology is exhibited as well. With baseband processors as well as high-gain antennas incorporated, this project offers an entire transceiver realization instance, which demonstrates encouraging probability of future under debris search and rescue or through wall imaging applications. After designing the transceiver and horn antennas, several experiments were conducted on human skin and other materials (concrete, wood, glass and sand), to understand and distinguish between if a living or nonliving body is present behind the material or otherwise. From the experiments that were conducted, it was observed that the body was easily detectable and materials are easily distinguishable when the body was close to the material but when the body moved away from the material it was difficult to detect the body beyond a distance of 7 ft (2.1 m).

Developing of this kind of a transceiver experiences a lot of challenging problems. Nevertheless, the energy requirements of this kind of a transceiver which is effective at detecting body of a human under rubble is dependent on operating environments. To be able to model a time domain relying microwave transceiver, antenna gain, wireless transmitter, energy consumption, highest possible input power and the highest possible voltage levels as well as form of modulation is must. Frequency generator, system dynamic range together with noise figure of Rx are the variables that depend on the attenuation along with the operating environments. Consequently, Link Budget Analysis own fundamental share when planning these kinds of transceivers. Within this report, a Simulation of Link Budget Analysis, that is in MatLab environment, is presented to be able to evaluate the functional bandwidth of the System. Moreover, these simulation outcomes are reconfirmed by actual measurements.

One of the most interesting observation was a presence of beat pulse in the form of amplitude variance of the received signal when living being is placed in front to the transceiver. Which was not received during presence of nonliving body. Similarly, there was a repeated pattern in received frequency components when living being is placed in front of the transceiver. This could be due to heart beat or breathing of a person if so then this could also be employed to detect living and nonliving beings under debris. More research is needed to look into this observation.

This range of the system is greatly increased by using high power amplifiers and employing horn antennas. During the tests performed, the antenna was directly interfaced with the transceiver that enabled us to transmit 794 mW of power or 29 dBm EIRP. That much power would greatly increase the penetrating and distinguishing ability of the antenna. Further experimentation, research and analysis will determine exactly how much power is to be used in real life scenarios.

This project provided foundation for further research and work on more complex system to be built in the future by upcoming students. This will also help students gain understanding and interest in subjects such as electromagnetic theory, antenna & radio wave propagation and radar systems.

Conflict of Interest

I certify that there are no affiliations with or involvement in any organization or entity with any financial interest, or non-financial interest in the subject matter or materials discussed in this manuscript.

Acknowledgment

First of all, I would like to thank Almighty Allah and then my parent's, relatives & friends who kept supporting me in all the phases of my study, both economically and morally.

Here, I would explicitly like to acknowledge my teachers and professors, for their guidance and encouragement to work hard, being my mentors. I have found them enormously supportive, caring and reassuring throughout my course of studies at CIIT. Their analytical, systematic and investigative comments on my work yielded positive results by stimulating my mind and inspired me to think of novel ideas, approaches as well as procedures in the field of electrical telecommunications.

I must here acknowledge support given to me by Space & Upper Atmosphere Research Commission (SUPARCO) Pakistan in test and trials of project work at SUPARCO LABS. Without their kindness proofing of equipment would not have been possible. Staff at Satellite Research and Development Centre SUPARCO had been extremely forthcoming in providing the training and test equipment for proofing.

Once again all praises are for Allah Almighty who provides us with all the resources and knowledge, making sure that we are able to make their adequate use for the benefit of humanity.

Toroidal Core Tests

ABSTRACT

Rotary cutting of electrical steel laminations is a novel, promising alternative in the processing of electrical steel strip with enormous economical and technical potentials. This paper is an extension of work originally presented on the 6th International Electric Drives Production Conference (E|DPC) in Nuremberg, Germany 2016. The scope of this paper includes a theoretical description of the rotary cutting process, an explanation of the machine and tooling setup, the basics of the Toroidal Core Tests and a discussion of the theoretical and experimental results. The methodology applied is basing on the Toroidal Core Test per DIN 60404-6, which is elementary described in section 3. Toroidal core tests allow a characterization in regards of technical, process and functional aspects, what is also mainly extended in this work. Finally, a classification of the rotary cutting process into existing processing technologies of electrical steel strip is feasible with respect to its limits and possibilities.

1. Introduction

Due to increasing demand of high-performance electric drives for the automotive market, German manufacturers are under pressure towards global competitors. The lamination stack forms the skeleton of the electric drive and guides the magnetic field in application. [1, 2]

In mass production of laminations, stamping is the technology with the highest application rate. Furthermore, the stacking process can be fully integrated into the stamping tool with e.g. the interlocking technology. However, complex machine tools are very expensive and thus, small volumes and frequent product changes are not profitable. Instead laser cutting can also be used for small lot sizes as no expensive tools are necessary. Despite high flexibility, laser cutting is not competitive due to long cycle times and high energy costs. Moreover, the unloading and stacking of laminations is currently only possible manually. [1, 2]

In the production of very thin laminations (smaller than 0.30 mm) for electric drive systems to reduce eddy current losses at high frequencies, the conventional stamping process reaches its limits due to several reasons: The cutting gap widths between punch and die tools is very small (2%-5% of the sheet thickness). Thus, the production of the complex cutting tools is no longer profitable. To absorb the high stamping forces, the kinematics structure of the stamping machine and machine´s foundation are very massive. Consequently, high investment costs occur. Moreover, the stamping machine cuts sheets at intervals. Thereby large masses must be accelerated and decelerated, what leads to high energy costs and noise pollutions. Due to these reasons, the enormous demand to thin sheets cannot be handled with the conventional stamping process. [2]

This is the reason why a new approach is required. Rotary cutting of thin electrical steel laminations is very promising. Rotary cutting is a continuous cutting process which is currently used in paper industry or for metal profiles. There are several advantages due to its compact structure and special cutting kinematics: [2]

- The distribution of the cutting force over the entire cutting profile is more uniform and the maximum force is lower.
- The continuous cutting process without accelerations and decelerations in strip feed and tools increases the productivity and the quality of the cutting edges.
- The cutting gap can be set to zero as the stamp does not immerse into the die.
- The tool structure is simpler and the tooling costs are lower.
- Fast tool introduction for new tools, as the development and the production is less complex.

*Corresponding Author: Markus Hubert, Fuerther Straße 246b, 90429 Nuernberg, Germany | Email: markus.hubert@faps.fau.de

- The machine structure is more compact thus the energy costs are lower.

The rotary cutting process is characterized by a counter movement of two parallel driven shafts. These tool rollers consist of a punch and a die cylinder. Due to the movement of the cylinders, the electric steel sheet is carried frictionally through the shaft´s gap. Hence the laminations are cut out by the mesh of the rollers. The tool rollers may not lift off during the cutting process, thus a radial preload is necessary.

In contrast to conventional stamping, the kinematic motion of the rotary cutting process is described by a cycloid movement. Basically, each point on a rotating circle describes a cycloid curve on a straight line or a circle wheel. Thus, the punch also describes cycloid curves on the steel strip. [4, 5]

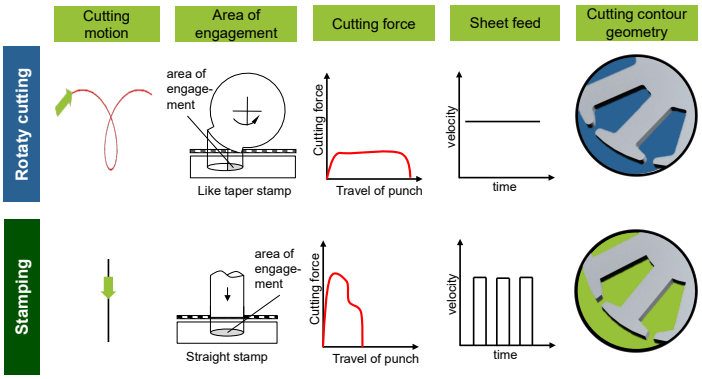

Figure 1 Comparison of Rotary Cutting with Stamping [3]

According to Figure 1 and [3], the conventional stamping process differs significantly from rotary cutting process through the following points:

- The cutting movement at stamping is linear with a permanent acceleration, deceleration and change of direction. In contrast, the rotary cutting cylinder moves continuous and describes a cycloid motion.
- During the rotary cutting process, the area of engagement is very small. At conventional stamping, the entire outline is cut at once.
- The maximum cutting force at stamping is very high and the travel of punch is very low.
- The speed of the sheet feed is constant during the rotary cutting process. Instead, the sheet feed speed is cyclical and clocked at stamping.
- Regarding the cutting contour geometry, laminations show sharp edged corners instead of a curved outline.

2. Comprehensive Analysis of the Rotary Cutting Method using Toroidal Core Tests

For a methodical examination of the cutting process, a suitable geometry is necessary. This is secured by toroidal core tests. With this simple geometry, the process behavior can be investigated during the separation process. Especially, cutting parameters, process stability and wear behavior can be evaluated. Thereby, it is possible to focus the tests on the cutting process without additional influences by complex contour elements, such as small radii. Secondly, it is possible to determine important characteristic values like power losses or magnetic and electric properties. In addition, an assessment of the sheet geometry is possible. Thus, process influences on the geometry can be investigated. To enable this, the toroidal core tests are comprehensively analyzed according to DIN IEC 60404-6. [4]

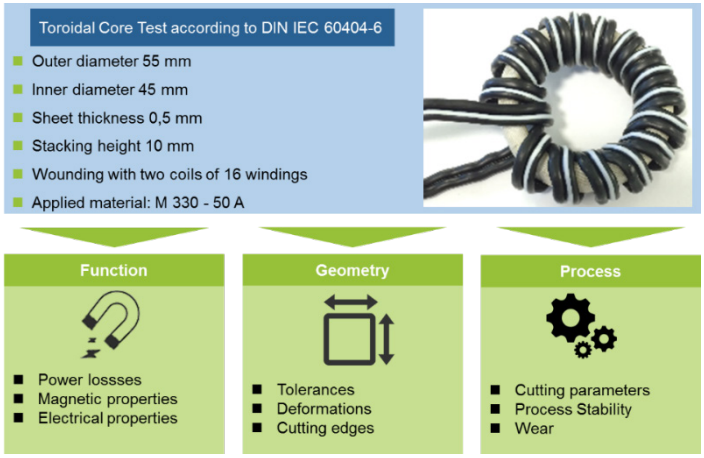

Figure 2 Toroidal core test per DIN 60404-6

The toroidal test specimens' inner diameter D_i is 45 mm and outer diameter D_o is 55 mm. The lamination stack length l_{stack} is 10 mm consisting of 20 single toroidal laminations with sheet thickness s = 0,5 mm. The single laminations are stacked without additional insulation layers between the laminations and wrapped with tape to a toroidal core. Finally, for investigation of electrical and magnetic properties, the toroidal core is wound with two coils of 16 windings each. [4]

Table 1 provides an overview of the manufacturers specific mechanical and magnetic properties for the applied material M 330 - 50 A. [4]

Table 1 Material Card for M 330 – 50 A

Material designation	EN 10027-1	M330-50A
Producer	Langhagel	
Nominal thickness	[mm]	0,50
Density	[kg/dm³]	7,65
Max. hysteresis and eddy-current losses	1,0 T / 50 Hz [W/kg]	1,35
	1,5 T / 50 Hz [W/kg]	3,30
Anisotropy of the losses	[%]	±14
Min. magnetic polarisation	2500 A/m [T]	1,49
	5000 A/m [T]	1,60

3. Machine Setup and Process Description for Rotary Cutting of Toroidal laminations

3.1. Machine and Tooling Setup

The prototype rotary cutting machine for toroidal laminations consists of four main components: Cutting unit, electric drive,

control and decoiler. The drive unit is an *SIEMENS* asynchronous servomotor of type *"SIMOTICS M-1PH8"*. With a higher-level control, important motor parameters such as number of revolutions or torque can be set, controlled and monitored. [4]

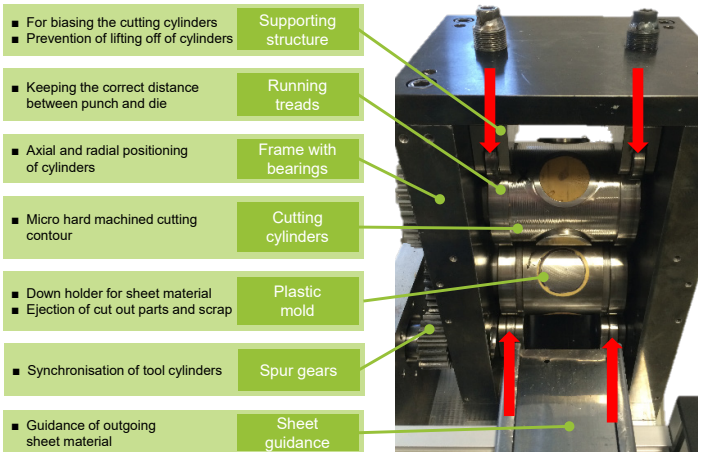

Figure 3 Prototype Rotary Cutting Device for Toroidal Core Samples [4]

The cutting unit itself essentially consists of five components: Tool set, gear box, pressure rollers, bearing unit and housing. The housing consists of four plates which are detachably connected by screws and pins. Thus, the cutting cylinders can be changed or subsequently adjusted. Two pressure rollers, which press against the running treads, relate to the housing to transfer the preload force on the cutting cylinders. Therefore, the cutting cylinder immerses in the material without lifting. [4]

The bearing unit is in the side walls of the housing. One side consists of two double-row angular contact ball bearings to absorb radial as well as axial forces. On the other side two cylindrical roller bearings are mounted as floating bearings. [4]

Moreover, at the drive side of the tool set, the spur gear is located. To ensure a synchronous and opposite rotation two gears of the same size are mounted on the shaft ends of the cylinders. To ensure the required dimensional accuracy and perfect cutting edges, one gear is being secured by a clamping sleeve in order to align both tool cylinders in radial direction. The pinion transmits the torque from the drive shaft to the spur gears. [4]

The cutting cylinders are core components of the rotary cutting machine for electrical steel. The tool set is arranged on top of each other. For rotary cutting processes in general, three tooling concepts are possible: wedge-action cutting, resilient cutting and stamp-die-cutting. However, for rotary cutting of electrical steel, only stamp-die-cutting is viable. [2, 4]

With this tooling concept, one cylinder acts as stamp and the other cylinder as die. For simple stamped holes with low accuracy requirements, the stamp may immerse into the die. For electrical steel processing with complex contour geometries and complete outlines, the stamp does not immerse into the die. Instead, the cutting unit must be designed in a way, that the stamp is located on the outer diameter of the die, the so called "zero to zero cutting" [5]. As a result, the lamination is cut by the stamp without immersion. Thus, a small die clearance is sufficient. To obtain reproducible cutting results, all process parameters have to harmonize with each other. [4]

In the conducted experiment, the geometry of the stamp is given by the toroidal geometry. The die has the corresponding negative form. In pre-trials the die clearance of 0.03 mm was determined as optimum for different sheet thicknesses. Thus, the outer diameter of the die D_{oD} is manufactured 0.06 mm larger and the inner diameter D_{iD} is manufactured 0.06 mm smaller compared to the stamp. The circumference of each cylinder is equipped with four cavities in total. The cutting circle diameter d_c of the stamp cylinder as well as of the die cylinder is 108 mm. [4]

All cavities of the stamp and the die cylinders´ are filled with an elastic polyurethane casting compound with hardness of 90 Shore A. During the cutting process, the plastic performs as sheet downholder stamp-side and counterholder die-side. Moreover, the plastic ejects the lamination from the cutting area. This is necessary as otherwise the sheet remains stuck in the cavities after cutting. [5]

Since the sheet does not automatically exit the stamp completely after cutting, an external tensile force must act in sheet feed direction. Consequently, the sheet leaves the machining zone completely without jamming up. [4]

3.2. Description of the Rotary Cutting Process

The rotary cutting process is divided into 4 phases (according Figure 4). Following, the rotary cutting phases are described for stamp-die-cutting with closed cutting outline. [4, 6]

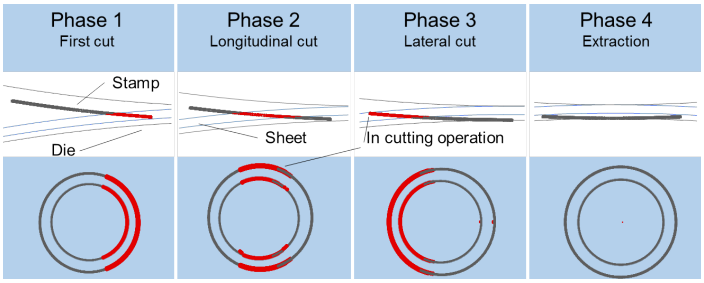

Figure 4 Four phases of rotary cutting referring to [6]

When the front edge of the stamp touches the sheet surface, the 1st phase of the cutting process starts. By further rotation, the cutting force is constantly increasing by forming the first crack until the entire sheet thickness is severed. [4, 6]

The cylinders continue to rotate, whereby the lateral cutting edges of the stamp cuts in the 2nd phase. The force level remains almost constant. [4, 6]

During phase 3, the back cutting edge impinges on the sheet metal and completes the cut. When the sheet is completely divided, the force level decreases abruptly. [4, 6]

After the rotary cutting process, the cutting sheet is pressed out of the die in the 4th phase. [4, 6]

For the description of the rotary cutting process, many different parameters are given. A decisively parameter is the angle of impact α, which defines starting- and endpoint of the line of action [7]. The angle of impact α depends on the circle diameter d, the vertical center distance a and the sheet thickness s and is derived from law of cosines. For good cutting results, the angle α should be very small. Thus, the length of line in action l_s and length of the contour in action l_c are getting small. [4]

According to [3], the angle of impact for equal diameters is defined by (1).

$$\alpha = \cos^{-1}\left(1 - \frac{s}{d} + \frac{s^2}{d^2}\right) \quad (1)$$

With a sheet thickness s of 0.5 mm and a cutting circle diameter d of 108 mm, the angle of impact α is located at 5.5°. [4]

In contrast to the angle of impact α, the force progression during cutting is difficult to determine. By means of a calculating software, the length of contour in action l_c for each contour can be calculated. This parameter behaves similarly to the force progression and can be used as a reference value. For the toroidal core test, the following diagram results (according Figure 5): [4, 8]

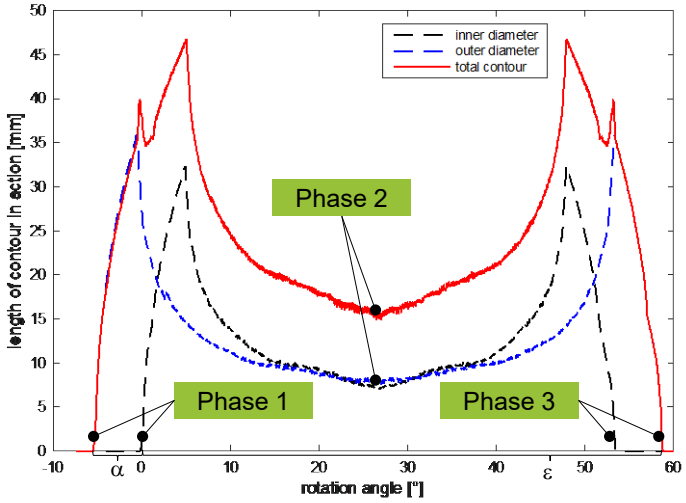

Figure 5 Length of contour in action per angle [8]

The total contour (red line) is explained as the summed curve of inner and outer diameter (black and blue line). [4]

A further parameter is the immersion depth of the stamp into the sheet Δy. This value is varying during the cutting process and depends on the circle diameter d, the sheet thickness s, the angle of impact α and the entry angle β. According to [3], the immersion depth Δy is: [4]

$$\Delta y = \left(\frac{d}{2} + s\right) \cdot \cos\beta + \frac{d}{2} \cdot \cos\alpha - d \quad (2)$$

with:

$$\beta = \cos^{-1}\left(\frac{d^2 + d \cdot s + s^2}{d^2 + 2 \cdot d \cdot s}\right) \approx \alpha \quad (3)$$

During the cutting process several velocities arise at the rotary cutting machine. The most important parameter is the circumferential speed v_c, which results from the circumference $d \cdot \pi$ and the number of revolutions n.[4]

$$v_c = d \cdot \pi \cdot n \quad (4)$$

By means of (4), the resulting speed in x- and y-direction can be calculated. All equations for the different speed components can be found in [3]. [4]

Since the speed of the lower sheet surface is faster than the upper one, there is a sheet speed difference Δv_{sheet} [4]. Table 2 gives an overview of applied process parameters.

Table 2 Applied Parameters of the test bench

Cutting circle diameter	d	[mm]	108
Diameter of lamination	d_c	[mm]	55
Sheet thickness	s	[mm]	0.5
Angular range	ε	[°]	58.4
Max. length of line of action	$l_{s,max}$	[mm]	5.18
Number of cavities	N_{Cav}	-	4
Number of revolutions	n	[min^{-1}]	10
Preload torque	M_P	[Nm]	60
Output per minute	X	-	20
Sheet speed difference	Δv_{sheet}	%	≈1
Transmission ratio motor/ cutting unit	I	-	1:2
Cutting speed in X-direction	v_x	[m/min]	3.4
Max. cutting speed in Y-direction	v_y	[m/min]	0.65

3.3. Simulation model

Within the research project, a simulation model is created in ANSYS Workbench 15.0 and explicit finite element calculations are done by the LS-DYNA solver. Thereby, the tool cylinders are defined as not deformable rigid bodies and the electrical steel sheet as a flexible solid body. The simulation model is assumed as quasi static. [8]

The material model of the electrical steel is defined by Johnson and Cook. This approach is very popular in metal cutting process simulations [9]. The three elementary material behaviors included in the model are material hardening, strain rate effects and thermal softening [10]. However, in this FEM model strain rate effects and thermal softening are neglected. [8]

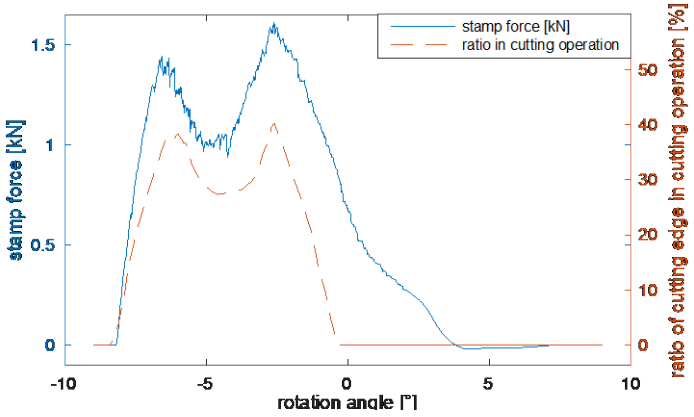

Figure 6 Simulated force-rotation path [8]

The CAD model of the geometry only includes important components. In addition, the cylinders are limited to 7° large shell elements. These simplifications reduce the required calculation time significantly. [8]

Figure 6 shows a comparison of the stamp force engaged cutting length over the rotation angel for a simplified geometry of a round stamp with a diameter of 5.00 mm and a steel strip thickness of 0.50 mm. At a rotation angle of -2.5°, the maximum stamp force of about 1.6 kN is reached. At this point, the entire cutting edge is in contact with the sheet. The pulling out of the sheet causes a negative stamp force. [8]

4. Results and Discussion of the Rotary Cutting Experiments

To analyze the influence of the cutting process, several electric sheet strips are cut with the test bench. The preload torque for all tests is 60 Nm and the sheet thickness is 0.5 mm. First, the process behavior is evaluated. Second, the geometry and the functionality of the laminations are analyzed. Micro sections of the different phases are made to investigate the cutting edges of the toroidal laminations. The contour of the geometry is analyzed with a multi-sensor coordinate measuring machine *VideoCheck IP 400 HA* from *Werth*. And third, the electrical and magnetic behavior of the toroidal core is evaluated on an electrical steel tester *MPG 200* from *Brockhaus Measurements*. [4]

4.1. Characteristics of process behavior

The toroidal core samples are cut completely from the steel strip. However, the samples adhere at the inner contour due to slight wedging. Thus, the separation occurs manually. The toroidal samples are slightly deformed and bent in sheet feed direction, as high forces occur. Thus, the laminations must be arranged after cutting. A further reduction of the bending arises with an adjustment of the machine settings. Larger cylinders or an additional recoiler with a further tensile force decrease the deformations. Since the design of the test bench is very simple, the cutting speed is very low. However, a higher cutting speed improves the results significantly. The cutting results at a sheet thickness of 0.5 mm and 60 Nm preload torque is shown in Figure 7. [4]

Figure 7 Rotary cut toroidal laminations

A high process stability is mandatory for a high cutting quality at the rotary cutting process. To fulfil perfect process settings, several important parameters must be optimized. A precise alignment of the tool set is essential to provide a perfect cutting clearance and avoid squeezing the sheet. Another important factor of the rotary cutting process is the setup of the correct preload torque. The cutting cylinders may not take-off, when the stamp immerses the sheet. However, deformation gets stronger with increasing preload torque. [4]

To implement the downholder and ejector function, the cavities of stamp and die are filled with plastics. During the cutting process, the plastic performs as a downholder and establishes a counterforce to avoid deformation. After cutting it also applies the force to eject the lamination from the die. In absence of the plastics component, the sheet strongly deforms and is pulled into the die by tensile stresses after the cutting process. Consequently, strong deformation occurs at the cutting edges and in the lamination. [4]

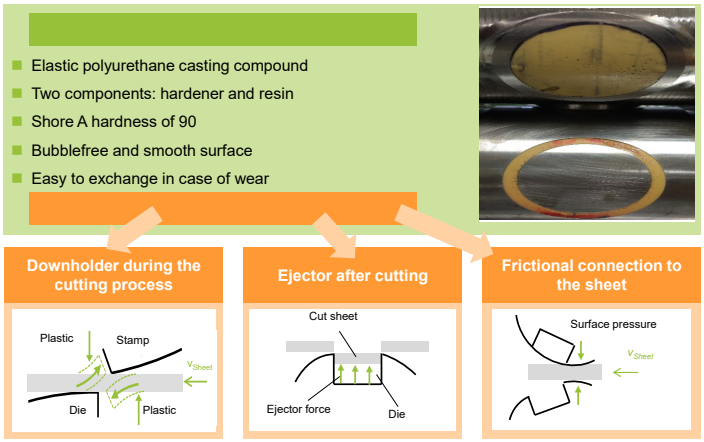

Figure 8 Characteristics of the plastics matrix

In contrast to the rotary cutting process, the process stability of the conventional stamping is very high. This is due to long experiences in this traditional process. The cutting speed and the application rate is thereby very high. In addition, the flat tooling structure and further downholder generate flat blanks without any deformations. However, the high cutting forces of up to 2,500 kN are very inefficient. To reach the required accuracy, massive and rigid stamps are necessary, which cause high investment costs. The High production costs of tools and large conversion effort are the main challenges of stamping with a wide variety. [1]

4.2. Toroidal lamination geometric properties

For the geometry measurement of the toroidal laminations, the Werth VideoCheck IP is used. In Figure 9 the results of the toroidal core sample are shown with a tolerance of ± 0.05 mm. The areas marked in red represent an exceedance of the tolerance limit. Consequently, the green areas are inside the tolerance. A total of approximately 25% of the measurement points are within the tolerances of ± 0.05 mm. [4]

	Lower tolerance	Upper tolerance
Outer diameter of stamp	55.02 mm	55.13 mm
Outer diameter of die	55.04 mm	55.06 mm
Inner diameter of stamp	44.87 mm	44.99 mm
Inner diameter of die	44.94 mm	44.96 mm

Figure 9 Matching of actual and target toroidal contour

In the tolerance field of ± 0.05 mm, the measured contour of the inner diameter exceeds the lower tolerance limit and the measured contour of the outer diameter exceeds the upper tolerance limit. Further investigations on the outer diameter show, that all measured values for the outer diameter are between 55.02 mm and 55.13 mm. Therefore, the average outer diameter is 55.07 mm. At the inner diameter, the measured values are between 44.87 mm and 44.99 mm. The average inner diameter is 44.93 mm. [4]

When considering the results of measurement, two factors are particularly of relevance. First, a general deviation of the dimensions of inner and outer diameter. The outer diameter is at most of the measuring points larger and the inner diameter smaller than the target contour. This is due to the tolerances of the tools. The cutting clearance of 0.03 mm is applied die sided and tolerated from 55.04 mm to 55.06 mm on the outer diameter and from 44.96 mm to 44.94 mm on the inner diameter. As a consequence, for future design of tools, the die is to be tolerated with the nominal dimension and the stamp must be adapted for the cutting clearance. The second deviation is at the inner diameter. It deviates most from the nominal dimension right of the inlet. The corresponding range on the outer diameter is close to the target dimension. This context implies a slight general deformation of the sheet. This can be explained by bumpy placement of the toroidal laminations on the measuring table and as a result the inner and outer diameter appear smaller in evaluation. [4]

An advantage of stamping is the very high accuracy of the manufactured parts. Stamped laminations do not have any deviations or failures and reach tolerance classes up to IT6/7. The separated laminations also can be stacked or packaged in the stamping machine. However, stamping of very thin sheets (lower than 0.30 mm) is process-related very difficult. Furthermore, the production of thin sheets with a high accuracy is cost-intensive and the processing speed must be reduced. This is due to the exact positioning of the thin and limp sheets in the stamping tools. [1]

For investigation of the cutting edge and burr, micro sections of the rotary cut laminations are made. The shown sectors in Figure 10 are the different phases of the rotary cutting process. The top of each micro section shows the stamp side and the bottom the die side of the lamination. [4]

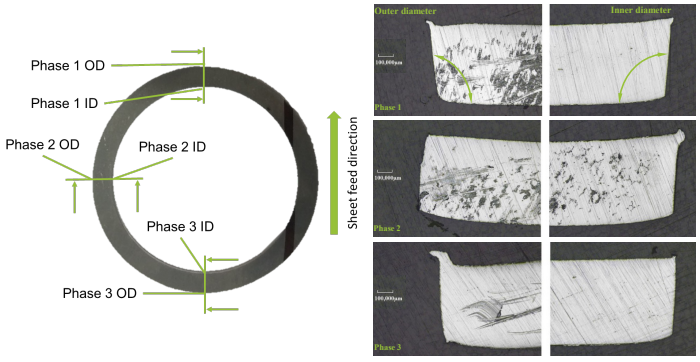

Figure 10 Microsections of rotary cut toroidal lamninations

The cutting edges of phase 1 show a typical cutting surface of shear cutting with the following areas. Top sided, there is a fractured face with burr. In the middle of the cutting edge, a smooth cutting zone is visible. Lastly, dented edges are at the bottom. Resulting from the inaccurate orientation of the cylinders, the largest burr formation is at the outer diameter of phase 3. In contrast, the inner diameter of phase 3 is nearly burr-free. Consequently, the cutting clearances of inner and outer diameter are different. The test results show that the cutting clearance of the outer diameter is too small. Moreover, it is possible that the stamp pushes against the sheet. As the cutting clearance is perfect at the inner diameter, no burr appears. The angels of all cutting edges are between 94.0° and 98.0°. These deviations arise from tilting between stamp and die. Due to the rotary movement, the angle changes constantly during cutting process. [4]

4.3. Toroidal lamination magnetic and electric properties

The electric and magnetic properties of the rotary cut toroidal cores are determined with an *Brockhaus Measurements* electrical steel tester. The Toroidal cores specimens consist of 20 single laminations, wrapped in tape and wound with two coils of 16 windings. [4]

To determine the hysteresis loop and the hysteresis- and eddy-current losses, measurements are carried out at polarizations of up to 1.50 T and frequencies between 50 Hz and 200 Hz. [4]

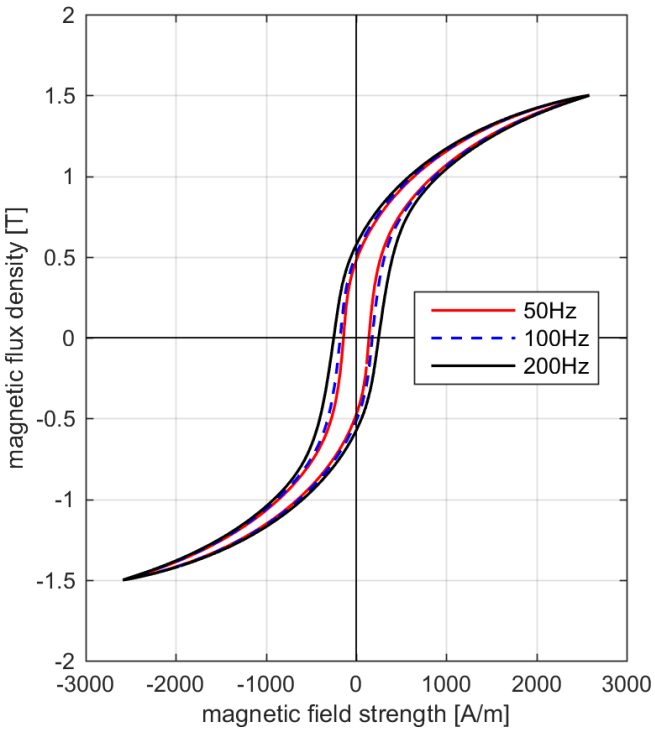

Figure 11 Hysteresis loops for rotrary cut electrical steel at 50, 100 and 200 Hz

At a frequency of 50 Hz and a field strength of 2,500 A/m, the toroidal core shows a polarization of 1.48 T. However, the hysteresis curve is very flat and does not have the desired Z-shape. Thus, the remanence is not very high after magnetizing the toroidal core. In a magnetization of 200 Hz, the remanence of the toroidal core is 0.57 T. With optimal magnetic properties, this would be as close as possible to the applied polarization of 1.5 T. [4]

According to Table 1, the total losses of the starting material at a polarization of 1.50 T and a frequency of 50 Hz are 3.30 W/kg. Although hysteresis and eddy-current losses, which are influenced by unevenness, burr formation and air gaps between the individual sheets, are significantly higher in case of the rotary cut toroidal cores, the result is typical for electric steel laminations. Due to deformation during the cutting process, cold forming occurs in the metal sheets, what is negatively effecting electrical and magnetic properties. Figure 12 shows the hysteresis and eddy-current losses of the toroidal core at different frequencies. [4]

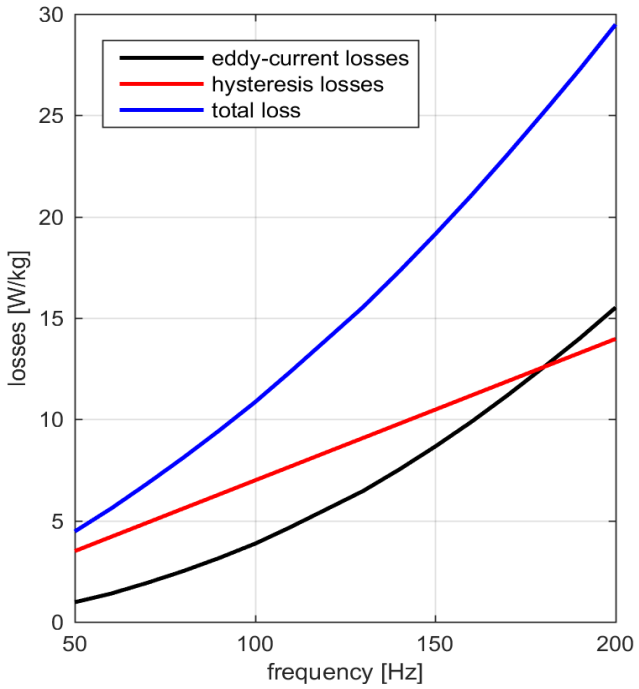

Figure 12 Hysteresis and eddy current losses of the toroidal core

The total of hysteresis and eddy current losses in the toroidal core at 50 Hz is 4.46 W/kg. This value is factor 1.35 greater than the starting value. After conventional stamping, the increasing of total losses is similar to this value. In order to achieve improvements in electrical and magnetic properties, deformation during rotary cutting has to be reduced by further development of the process. [4]

5. Conclusion

With the help of the rotary cut toroidal core samples, it has been shown that the process is generally suitable for the processing of electrical steel strip. However, the results also indicate that a great deal of development work still needs to be done. In particular, a detailed adjustment of the process parameters is necessary to achieve a stable level of high quality. To further intensify process understanding, a long-term experiment with a real application is recommended. Process stability, reproducibility and tool life can then be demonstrated.

6. Summary

This publication constitutes the state of research of rotary cutting of electrical steel strip using a toroidal core sample. Based on this analysis, a distinct statement on the technically feasible parameters is achieved and it allows a comparison with applied industrial processes.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

For the design of Information and Communications Technology (ICT) related products, basic level of technical expertise and simple development tools were enough in the early 1980s. As time goes by, new generation products designed by engineers are always expected to be smaller, lighter and faster, due to the increasing global competition and the application of hardware and software in every area of our lives. In order to be able to respond to these needs, engineers have always had to produce new technologies and solutions. In this sense, hardware related technologies have been growing much faster such as System on Chips (SoC), displays, batteries and other materials used in the ICT products. Designers have been diversifying software development processes and tools remarkably for new applications and constantly developing new communication standards. In this article, all the main design phases are presented starting from the system design to the product validation and test. As can be seen from the relevant sections, in order to design an ICT product, very deep technical expertise, expensive development and verification infrastructures are needed in the relevant fields.

1. Introduction

Before the 1980s, in the design process of Information and Communication Technology (ICT) products, it was sufficient to have technical expertise at the basic level such as entry-level material knowledge, basic skills in using measurement equipment, and the ability to use simple compilers in related fields. In those years, functionality was the main concern for the product design. Furthermore, the development processes and infrastructures were much simpler than today. In the modern era, due to the advents in technology, the emergence of new composite materials, the introduction of effective production methods and the rise and on-going diversification of consumer expectations, product design process is getting more complex. In order to meet new product development requirements, a multidisciplinary approach is required to synthesize respective knowledge from various disciplines, such as anthropology, sociology, physics, chemistry, environment, etc.. In the rise of today's consumer culture, functional satisfaction is no longer a mere reason of purchasing goods and services, while social factors substantially affect consumer decisions. Especially for mobile and wearable ICT products, the owned products are tools through which consumers express their identities. Thus, besides the proper functionality of the product, different factors, such as emotional response of the customers should be taken into account in the product design. Therefore, today's development processes are becoming too complex and multifaceted.

Until mid 1970s, the design and manufacturing processes of ICT products were mostly based on nonautomated or semi-automated processes, where technical hand-skill of the operator usually plays a crucial role. PCB (Printed Circuit Board) design and production were made by hand work, with Letraset and paper [1]. The use of the computer in the design process of ICT products was a revolution. Computer-aided design not only accelerated the design and manufacturing processes, but also resulted in a significant reduction in the related human errors. Moreover, the decrease in the duration of the design allows the production of more complex ICT products. The automation of the manufacturing of ICT products greatly increased the manufacturing volume and reduced the cost of the products that could provide the functionality never achieved before.

The first commercial microprocessor was Intel 4004 (4-bit), which was intended for use for use in a calculator in 1971 [2]. Today, multi-core processors with high processing power are required in the design of broadband wired or wireless products or high-capacity IP (Internet Protocol) switching devices. These processors include dedicated coprocessors, special data transfer paths and data processing units, along with a large number of ARM (Advanced RISC-Reduced Instruction Set Computing-Machine) and DSP (Digital Signal Processor) processor cores running at gigahertz speeds [3]. In order to meet wide range of the required features, it is necessary to develop high performance software spread across tens of thousands of source files and, composed of millions of lines, which is designed to exploit the potential of the available hardware resources [4]. On the other hand, the hardware provides multi-core CPUs capable of performing hundreds of billions of operations per second and very high-speed and high-capacity data transmission interfaces. In addition, for the design of an ICT product, technical expertise and dedicated infrastructure is required related to mechanical design, thermal analysis, electromagnetic compatibility, product integrity and reliability, product testing and verification. As a result, the complex technological structure of ICT products entails the use of various advanced engineering skills in the design process.

In this article, various technical expertise, infrastructure and processes necessary to design an ICT product will be described. These technical expertises are related to system design, hardware design, mechanical design and software design, verification and production.

After a brief and formal definition of system design given in Section 2, issues in today's hardware design is discussed in details in Section 3. In this section, PCB design, signal and power integrity, recent developments in IC (Integrated Circuit) technologies, developments in manufacturing technologies, System on Chip (SoC) technologies, recent developments in RF (Radio Frequency) design and EMC/EMI, and concerns related to energy efficiency are considered. In this section, the requirements of a specific hardware design in today's technology are considered as an example.

Section 4 is concerned with mechanical design and discusses design considerations in the choice of materials to meet the requirements of the used process.

Section 5 discusses issues in software design. In this section, the development steps and troubles from the past to the present are given, followed by the related development processes, which are formed because of these progresses. In this section, trends emerged in the field of software development, especially in virtualization technologies, open source code development and effective use of frameworks are considered in order to create cost effective short-term software development. In addition, virtualization and IoT (Internet of Things) software emerged in this field are discussed. In Section 6, software validation tests and test methodologies are considered. In Section 7, the state-of-the-art ICT production processes are described and discussed. Finally, in Section 8, a practical implementation for a cutting edge ICT product design is described.

2. Design for Requirements: System Design

System engineering manages the product development process by taking into consideration the technical requirements, time and cost elements of the product design, production, delivery and maintenance activities [5]. System engineers may suggest either a new product on a new product or adding a new feature to an existing product, based on the feasibility study. Prior to a detailed system design, the general system-level design needs to be prepared by the system engineers. After performing a detailed study of product description, the functional behaviour and the basic system architecture are developed. This is the most critical step in the design of complex products. The ability to meet the additional requirements for the designed system depends on the flexibility and extensibility of the system design. For a system engineer, expertise and skills in all areas described in this paper are required in order to achieve the necessary engineering activities.

3. Design for Software Platform: Hardware Design

Hardware design consists of establishing system and/or subsystem hardware and mechanical infrastructure in order to achieve defined system, software and platform requirements. These requirements are concerned with the platform, mechanical dimensions, power consumption and environmental conditions, such as high/low temperature, humidity, shock, vibration, radiation, air pressure, Electromagnetic Compatibility (EMC) and Electromagnetic Interference (EMI).

In this Section, first PCB design with signal and power integrity issues will be introduced. After that, the evolution of hardware IC design and developments in manufacturing techniques will be explained. Later, SoC IC concept; application specific and high capacity ICs with multiple functions and interfaces will be pointed out. On the last part, 3D(3 Dimension) IC design technique for smaller and less power consuming ICs, developments in RF design, EMI/EMC and energy efficiency subjects will be covered.

3.1. PCBs (Printed Circuit Boards)

The first PCBs were used as early as 1900's. In those years, various materials like Bakelite and Masonite, plain old thin wooden pieces were used as PCB materials [6]. These PCB materials were drilled into the holes and the brass wires were riveting on the material. Over the following years, circuit sizes were reduced with the use of double-sided and multilayer PCBs and hot air soldering methods.

In the 1980s, surface mount components became the preferred option rather than through-hole components. In the 1990s and 2000s, the complexity of modern circuit boards increased and "micro-via" technology emerged in PCB manufacturing. In those years, the use of 5-6 mils of trace and space on PCBs was getting more widespread. On the other hand, Flex and Rigid-Flex PCBs have become an economical option and widely used. Today, ELIC (Every Layer Interconnect) technology allows for dynamic connection between any two layers within the circuit layout.

Nowadays the number of layers in a typical high-density PCB has increased up to 40. There are more than 350 kinds of dielectric materials in aerospace, communications, high-speed digital design, power, and wearable device areas. The operating frequency for epoxy / glass (FR4) material has been increased to 40GHz. In recent years, flex and rigid-flex cards have gained popularity. Since rigid-flex cards require fewer connections, they are more reliable and their long-term maintenance cost is reduced.

Printed Circuit Design was made manually before the introduction of Computer Aided Design (CAD) tools. Placement

of the components is done on transparent paper with ICs plotted as templates. Using this paper, a film that corresponds to the circuit layout is prepared and by the use of dry transfer technique, PCB is produced. PCB design is finalized by adding copper lines formed using Letraset papers.

Today there are several advanced CAD tools for the hardware design development. These tools enable multi-layer PCB design with high-speed signals and allows the diagnosis of layout problems related to built-in signal integrity, power integrity, cross talk, reflection add-on's before PCB production. Using 3D modelling features of these tools, mechanical mismatches can be detected on 3D PCB layout view. With the help of these tools, multi-layer, densely populated PCB design including high-speed data paths with low latency providing hundred billions per second processing power can be accomplished [7].

Figure 1 shows the layout of the baseband card of a 4G base station. On this card, there are both high-speed data paths (>50 Gbps) and high-speed transmission lines for inter-card communication (>10 Gbps). The design of the PCB enables the reference clock signals (312.5 MHz, 156.25 MHz and 122.88 MHz) to have very low jitter (4 ps RMS) and very small 50 ps rise/fall time.

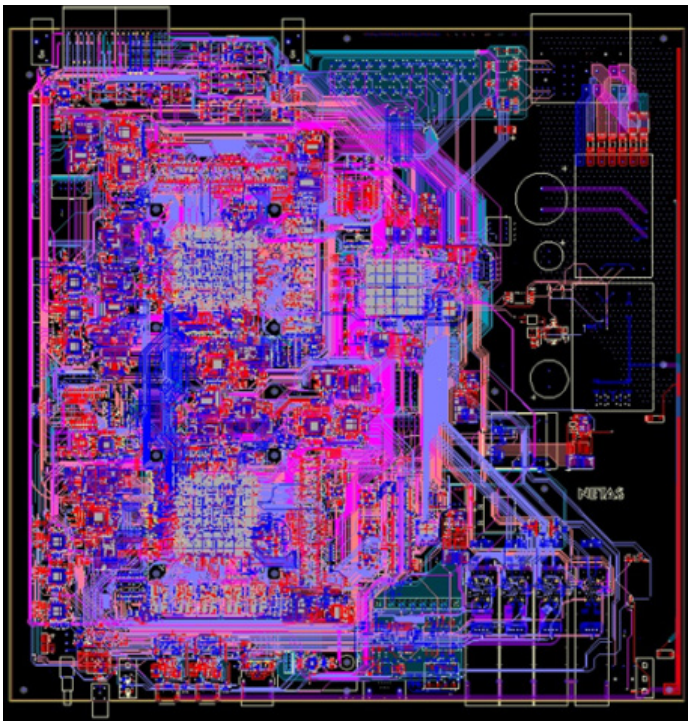

Figure 1 PCB layout for a 4G baseband card.

3.2. Solving Transmission Issues for High Speed Digital Design: Signal & Power Integrity

Signal Integrity deals primarily with the signal transmission performance within an electronic product. This issue is due to the electromagnetic behaviour of the system and the tools to study the related effects remain more or less the same since the beginning of electronic transmission. First transatlantic telegraph cable was exposed to serious signal integrity problems, and this led to invention of the mathematical tools for signal integrity analysis, such as telegraph equations, which we still use today [8].

Typical ideal and real waveforms of a signal are shown in Figure 2.

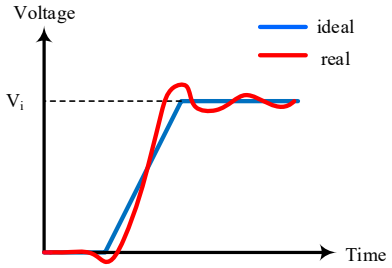

Figure 2 Ideal and real waveforms at the receiving gate.

On PCBs, when propagation delay of a signal approaches signal transition times (rise/fall time) and the system speeds exceed a few tens of megahertz, signal integrity analysis becomes a necessity. Today signal speeds reach several GHz.

Since 1990's, the requirements for signal integrity analysis are getting more and more important. Initially, PCB trace speeds have become an important issue in the PCB design. Designers approached this problem by considering analog characteristics of digital data paths. The main objective of signal integrity study is to ensure reliable transmission of digital signals between transmitter and receiver. While initially the main focus in signal integrity study was the connection between transmitter and receiver, in modern designs, signal integrity models are used in the design of transmitters, receivers and every part in between.

By the years of 2000s, power supply for digital circuits has become a big problem and a need for Power Integrity (PI) analysis has emerged. Signal integrity (SI) analysis shows signal's behaviour through PCB traces, conductors and passive elements. However, PI analysis examines power distribution lines by evaluating power plane impedance and decoupling capacitors. While PI is related to the system reliability analysis, its main goal is to ensure that drivers and receiver have enough current to send and receive 1's and 0's [9].

In the early phases of electronic circuit industry, available ICs came with one power and one ground pin. A bypass or decoupling capacitor between the power rail and the ground pin was more than enough to filter out the noise. Today, a complex Ball Grid Array (BGA) features hundreds of power and ground pins and more than 10 different voltages under 1V. These complex ICs typically draw currents of tens of amperes. In order to supply clean and noiseless power at these levels, a large capacitor network is required. The effective design of this capacitive network requires the accurate analysis of the propagation of energy in a power distribution network, which includes capacitors, vias and power/ground planes. For instance, , since 1990s the operating voltages drops from 5V to sub 1V's, where operating currents rises from 1A to several 10A's. These show that power consumption rises from 5W to several 10W's and impedance target drops from 500mΩ to1mΩ.

Today, EMC and Signal Integrity (SI) are the most important issues in electronic product design, which should be considered through all the design process. The main reason is the high data bandwidth demand of new generation high performance products and servers, which operate over hundreds of Gbps. EMC and SI Technologies on PCB and IC packages are one of the bottlenecks at these bandwidth requirements.

In Figure 3, the variation of signal rates used in serial links in the last 40 years is shown.

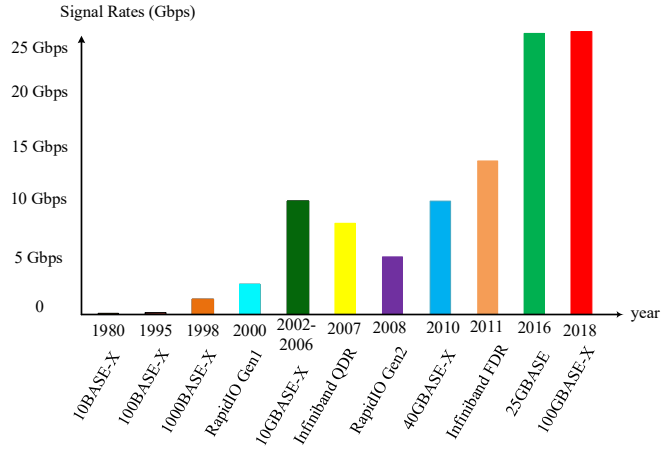

Figure 3 Signal rates of serial links in the last 40 years.

As seen in this figure, signal rates that were around 10 Mbps for 10 Base-X Ethernet in 1980, have reached 25 Gbps today. An interesting feature in this graph is the decrease in signal rates, which appear in years 2007 and 2008 [10]. In these years, implementation difficulties of 10 Gbps per line on long backplanes due to signal integrity issues led way to interconnect standards consist of multiple port high-speed serial lines such as RapidIO or Infiniband QDR. In 2007, Infiniband QDR drops line rate to 8 Gbps, however supports operation on four parallel lines to achieve 32 Gbps data throughput. In 2008, Serial Rapid IO standard defines the maximum line rate as 5 Gbps and supports 2, 8 and 16 parallel lines, which in turn supports total throughput of 10, 40 and 80 Gbps respectively.

One possible approach to increase data rates is to increase the Non-Return-to-Zero (NRZ) data rate with very high-speed serial links. Another possible way is to encode the data using PAM4 (Pulse Amplitude Modulation). Using PAM4 modulation, it is theoretically possible to reach a collective data transfer rate of 800 Gbps.

Nowadays, for PAM-4 coding, 13 GHz clock frequency is used and 400 Gbps Ethernet speed is reached with 8 lines, each featuring 53 Gbps speed [11].

As mentioned above, the ultimate goal is still smaller, lighter and faster products. In order to achieve these goals, additional issues such as the implementation of appropriate inter-system connection interfaces should be taken into account. In order to meet the design requirements, robust, miniature and high-speed connectivity solutions should be considered.

3.3. Progresses on Integrated Circuit and Manufacturing Technologies

The fastest change in the semiconductor technology era emerges in the field of processor and memory oriented semiconductor manufacturing. The key drive factors in this evolution are higher speed (executed commands per second, data transfer rate) and higher capacity (memory, number and different types of interfaces). Transistor size in IC's reaches from several micrometers to tens of nanometers. The prediction of Gordon Moore, one of Intel's co-founders, about transistor number in a dense integrated circuit will double every two year in 1965, proved to be right in the following 50 years as can be seen in below Figure 4 [12].

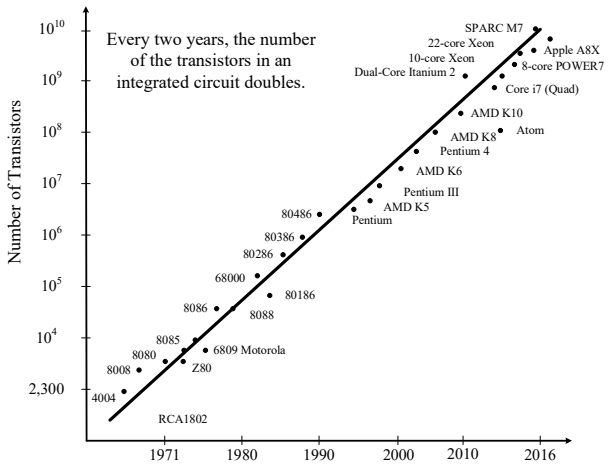

Figure 4 Number of transistors for CPUs and Moore law.

Due to the high integration capability, programmable semiconductors for different features in the same package can be developed for digital circuits, interfaces, power electronics, RF (Radio Frequency) and analog circuits as well as processors. Every new integrated circuit has more rule set and documentation for usage. Design, manufacturing and test processes become more and more complex and need different methods and tools than the previous ICs.

In recent years, performance and success metrics in integrated circuit design and manufacturing has changed dramatically. Up today, the main success metric for personal computer ICs is clock speed. Therefore, the manufacturing technology has developed according to these criteria. Nowadays, form-factor, cost and power consumption are the critical driving factors, especially in mobile market; that in turn has increased the importance of on-chip integration of functional hardware (e.g. power management, computing, audio/video, graphics and radio). In order to integrate these hardware on-chip, specifically designed for purpose design and simulation techniques are used. Today, there are around 20 fabs that can manufacture analog and basic digital ICs with 130nm ~ 28 nm process where there are only 5 fabs which can use 14/10nm process to manufacture market dominator SoCs [13].

The need in the present decade drives technology markets to use more and more integration such as mobile communication, data centers, automotive and IoT platforms. This demand has increased the importance of lower nanometer process and more complex manufacturing technologies. 7 nm processes is expected to be realized within the next two years, where studies and early trials continue for 5 nm [14]. As a result, more analog and digital functional block will be integrated within a single chip. Analog functional blocks will be manufactured with 14 nm process and very low power analog/RF circuits targeting IoT platforms can be designed. FinFET (Fin Field-Effect Transistor) technology may be one of the viable methods to achieve this goal.

The distinctive feature of the FinFET is that the conducting channel is wrapped by a slender semiconductor "fin" that forms the body of the device and the fin thickness determines the effective channel length of the device. FinFET technology will be the basic infrastructure for the complex semiconductors produced within next decade. Because of its features like the ability to be fabricated with its channel along different orientations in a single

die due to its nonplanar structure, the reduction of "Short Channel Effect according to its fin thickness and fin length, ability to control its threshold voltage with multiple voltage sources and reduction of off-state current. For example, a mobile chipset produced with 14 nm FinFET technology in August 2016 is performing % 30 faster, increased core speed by % 20 and consumes % 35 less power compared to its predecessor [15].

3D IC comes forward as an alternative to improve manufacturing technology and managing processes under 14 nm. 3D ICs are manufactured by placing silicon layers vertically on top of each other and connecting layers with TSVs (Through-silicon vias). Using this technology, a cost and performance effective development can be accomplished. $16 billion investment is forecast to build a foundry for a more advanced technology level of 7 nm process node [16]. 3D IC design is discussed in detail in the section 3.6 for size reduction and low power consumption purposes.

3.4. Processors: CPU, GPU, NPU, APU, PPU and TPU

CPU (Central Processing Unit) is the central processing unit of computers. After the invention of transistor, Intel 4004 CPU with 2300 transistors was produced in 1971 using a 10 µm technology operating at 740 kHz. Today, processors can be manufactured with 14 nm technology and contain 10 billion transistors. These processors are capable of running at 4.2 GHz speeds and support many types of instruction sets. General-purpose processors perform general purpose operations and are used in many areas, especially in personal computers and [17].

In GPU (Graphical Processing Unit) processors, it is important to have parallel command processing capabilities, as well as sequential processing capabilities that conventional CPUs have. This feature is also used for accelerating computation in areas such as 3D rendering in computer games, advanced scientific research, oil and gas exploration and self-controlled driving technology [18].

In terms of architecture, general-purpose processors can be made up of several CPU cores and can do several jobs simultaneously. Similarly, GPU processors have hundreds of cores to process parallel jobs efficiently. Today, Multi-GPU processors with many GPU processors are produced [19].

A NPU (Network Processing Unit) is a dedicated processor specially designed to perform network related functions. While these units are often intended to be used in embedded systems, they are also employed in the personal computers. For example, Mellanox's Indigo NPS-400 unit has an internal processor unit, which provide all services including traffic management at 400 Gbps capacity. This processor has development support in C programming language [20].

Large processor vendors such as Intel and AMD (Advanced Micro Devices) have developed APU (Accelerated Processing Unit) technology by combining the superior features of CPUs and GPUs. APU processors are used in areas where power consumption and performance are important. For example, a large GPU manufacturer Nvidia has collaborated with the ARM Company, to produce the APU named Tegra, and has entered the mobile and smartphone markets [21].

A PPU (Physics Processing Unit) is an interface, which has been developed for processing physics rules in graphics processing. These processors compute special operations such as the effect of gravity and the effects of collision of objects in accordance with the laws of physics. It was originally developed by Ageia in 2006. However, after merging with Nvidia, it is developed continuously as a middleware running on GPUs under the name PhysX [22].

A TPU (Tensor Processing Unit) is developed by Google for TensorFlow open source library. It is application-specific ASIC technology specially developed for machine learning. These units are widely used in the data centers of Google. An important asset of these units is reduced computational accuracy compared to GPUs. However, since fewer transistors are used in these units, they offer better performance than their counter parts in terms of unit power consumption [23].

3.5. Design for High Capacity: SoC (System on Chips)

In the ICT products developed today, processors, which include several different functional blocks, are used for high capacity and special function needs that cannot be met with generic processors on the market. In these processors, there are several CPU cores, general-purpose DSP cores and application-specific co-processors, which provide low latency required in applications such as error coding/decoding and Fast Fourier Transform (FFT) algorithms. These processors provides performance, easy development cycle, flexibility and product cost advantages. Today, programmable SoC, FPGA based SoC and RF specific SoCs are used for different applications.

Today, SoC manufacturers are purchasing the IP Core license from ARM to integrate it into the chip design. In this way, fabless companies can develop designed, tested and production ready processor cores. The new chips designed by these companies are produced in semiconductor fabrication plants (fabs) to meet high performance and low-cost requirements [24].

Figure 5 shows functional block diagram of a general SoC used in the design of ICT products.

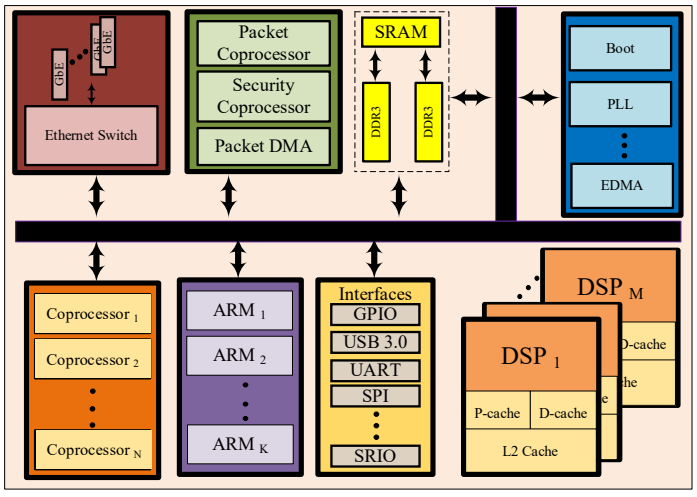

Figure 5 Functional block diagram of a SoC.

3.5.1. PSoC (Programmable System on Chip)

A cost effective solution to general purpose SoC ICs are programmable SoCs, which includes only specific functional blocks and interfaces required in the designed system. Using this architecture, unused functions and interfaces are not integrated into the specifically designed ICs and this provides the main advantages of ASIC (Application Specific Integrated Circuit), such as performance, form-factor and product cost. The

availability of the optimized use design of these functional blocks reduces design time and eliminates nonrecurring engineering cost of programmable SoCs. The flexibility of this architecture enables adding or removal of functional blocks in a very short time. Currently, these PSoCs can provide low capacity microcontroller, memory and interfaces and therefore they are being used for products and solutions targeting IOT platforms [25]. Cypress announced that an IOT solution using PSoC 6 series will be provided soon.

3.5.2. FPGA Based SoC (System on Chip)

To provide an alternative to general purpose processors used in product design, FPGA firms developed "soft" processors that can be put into standard FPGA components as object or source code. "Microblaze" and "Picoblaze" processors are good examples for this approach. The next step is placing "hard" "Power PC" processor core into "Virtex" FPGA. The latest FPGA family ZYNQ includes 2 ARM cores as standard product. ZYNQ Ultra scale+ SoCs are produced with 6 ARM core and 1 GPU (Graphic Processing Unit) core [26].

Central Processing Units (CPU) work sequential by design, increasing their performance can only be accomplished by increasing operating frequency or number of CPU cores. FPGA based processors have the advantage of parallel processing architecture, low latency and gigabit high-speed interfaces.

3.5.3. RF SoC (System on Chip)

In the future of the communication, transport, energy and automotive sectors as well as vertical IOT market, integrated circuits produced with low nanometer technologies are expected to be dominant. AMS (Analog-Mixed Signal) technologies and nm based analog block manufacturing processes used during production of these ICs are the main differentiating factor. Because of increased device model complexity of FinFET, complex layout effects impacting design specs, increased parasitic complexity, low-voltage driving intensive noise analysis issues during transition into nanometer production process reveals long and lots of simulation work and huge net lists. Lacking of fast, nm-accurate mixed signal verification limits design and manufacturing success, which leads to 50% first silicon failures. Research continues to integrate analog, digital and RF technologies to provide ultra-low power requirement of IOT applications. Main focus is developing new mixed-signal circuit architecture. In addition, the need and usage of RF MEMS (Micro Electro Mechanical Systems) in satellite communications, radar systems, and adjustable antennas increases.

3.6. IC Design for Size Reduction & Low Power: 3D Integrated Circuits

As mentioned in section 3.3, 3D integrated circuit emerged out as an alternative to improve manufacturing technology. Ever since the combination of analog and digital integration becomes a necessity; 3D ICs, which enables manufacturing of functional blocks with different technologies and rule-sets separately and integrate them in the last stage of the production, offer significant improvements over two-dimensional circuits. Average connections inside 3D ICs are much shorter and interfaces inside the IC can be work faster consuming less power. An application processor designed as 3D IC is reported to have 43% less space, 13% less power and 14% less connection length in average compared to conventional designs [27].

Figure 6 shows 3D IC structure including many different circuits with 3D interconnect.

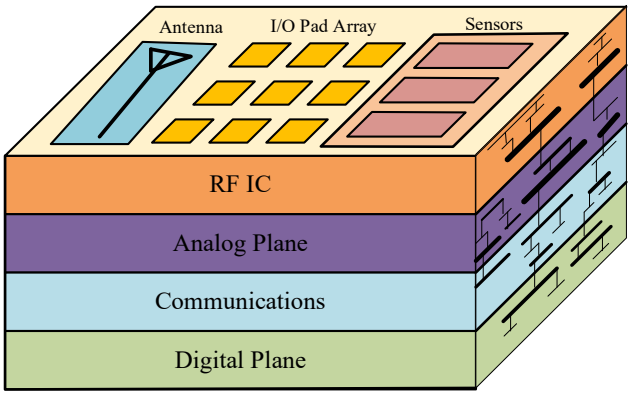

Figure 6 Different circuits on the same die, tied together with different 3D interconnect.

3.7. Batteries

When choosing a battery for a product, there are many criteria to take into account, such as capacity/volume, charging duration, voltage match, polarization/rate capability, weight, and cycle life/shelf life, operating temperature range, safety, toxicity and cost. For instance at the beginning of 1900's nickel cadmium batteries helped pave the way for modern technology, but because of cadmium's toxicity, alkaline batteries spread in the market after 1950's. Alkaline batteries were safer and cheaper but their energy density was not enough to supply high performance devices.

While electronic devices are getting more and more complex, more energy density and form factor are required. Nickel-metal-hydride and lithium-ion, emerged in the early 1990s, provides high energy density. For example, the energy density of lithium-ion is typically twice that of the standard nickel-cadmium. Today, lithium-ion is the fastest growing and most promising battery chemistry [28].

The high cell voltage (3.6V) capacity of li-ion's allow battery pack designs with only one cell and most of today's mobile phones run on a single cell. A nickel-based pack would require three 1.2 V cells connected in series. This allowed smart phones to have relatively larger display size and longer lifetime [29]. Lithium-ion batteries suit well to low temperature and warmer environments compared to NiMH cells. Li-ion can operate to a temperature of as low as –40°C that increases the data security at harsh environments.

There are specific cathode types for each application for instance laptops and smartphones use lithium cobalt dioxide (LiCoO2) and electrical vehicles use lithium nickel cobalt aluminium oxide (LiNiCoAlO2). Nearly half of the global cobalt supply is being used by in lithium-ion battery industry. Therefore in order to overcome from the lack of cobalt and achieve better battery performance researchers work on different alternative technologies such as calcium ion batteries, Na-Ion batteries, metal-air based rechargeable batteries and sulphur based rechargeable batteries.

3.8. Sensors

3.8.1. Magnetic Sensors

Essentially there are two types of magnetic sensor: which measures total magnetic field and magnetic field vector components [30]. There are various ways to sense magnetic fields and there are also many factors such as size, sensitivity, linearity, range, frequency bandwidth, dimensions, cost and power, which affects what sensor is best suited for an application.

Magnetic sensors contributed lots of field in ICT and industry. For instance, computers now have storage disks with very big capacity, higher safety standards have been achieved because of the high reliability of without contact switching in aircrafts [30].

Magnetic sensor application may be listed in four categories as given below.

- Low-Sensitivity Application: Hall Effect sensors are most commonly used ones to detect fields greater than the Earth's field.
- Medium-Sensitivity Applications: Anisotropic Magneto Resistance sensors have become standard off-the-shelf devices for use in medium-accuracy applications, such as compasses for mobile devices [31].
- High-Sensitivity Applications: Flux-gate sensors are widely used in military industry to detect ferromagnetic objects such as a mine, ship, tank, or aircraft [31].
- Medical/Biological Applications: The SQUID sensors are mainly used in bio magnetic applications, which helped to measure extremely weak magnetic fields generated by the brain [32].

3.8.2. Accelerometers

An accelerometer measures linear or angular acceleration. There are many types of accelerometers developed and reported in the literature. The vast majority is based on piezo-electric crystals, but they are too big to use in small products. Therefore, engineers developed smaller accelerometers using MEMS (Micro Electromechanical Systems) technology [33].

With their robust sensing with little power consumption, MEMS accelerometers have an important commercial potential [33]. Accelerometers are also used in medical equipment such as prosthetic arms. Another important application field is inertial navigation.

Inertial navigation is a navigation technique, which incorporates accelerometers and gyroscopes to track the position and orientation of an object relative to a known starting point, orientation and velocity [34]. For example, PIGA (Pendulous Integrating Gyroscopic Accelerometer) type of accelerometer is used in inertial navigation systems. PIGA sensors are used in guidance system of missile systems today, such as German Rocket V2 [35].

3.9. Displays

Until the beginning of this century CRT displays, which have low picture quality had been widely used in computers and televisions [36]. In the last 20 years, various display technologies have been developed by researchers. Generally brightness, contrast ratio, resolution, size, number of colours, viewing angle, power consumption, response time and life time are key points when selecting the right display for your application. LCD, LED and OLED displays have been most commonly used in consumer products and with the development of rugged touch displays defence industry has started to use them in many applications. Sun light & night vision readable, glove friendly touch screens are the most popular ones in defence industry. Additionally, helmet mounted wearable displays provides augmented data and reality for the next generation soldiers.

Progress in LCD technology has enabled the development of thin, high definition, large display screens. The development of curved screens has been provided with OLED technology. On the other hand, with the development of LAFi (Luminous Array Film) technology curved super-large screens are possible [37].

There are also other display technology such as DLPs, PDPs, FEDs, and electronic paper (electronic ink) competing for market share [38].

In recent years, considerable attention has been paid to 4K, or 8K TV displays, that makes the viewer feel immersed in the image scene [39]. 3D holography image, bendable flexible display with plasma technologies are also hot topics in this field.

3.10. RF Design for 5G

5G (5th Generation) communication technology and IoT are the main driving applications shaping future RF technologies. 5G technology is being developed as a solution for high data speed, low-latency and low power consumption requirements of Ultra HD, 360 degree video transfer, VR (Virtual Reality), smart home, smart city, autonomous vehicles, M2M (Machine-to-machine) communication applications. All these applications require high bandwidth to answer high data throughput needs. Existing bandwidths of frequency bands used for cellular communication cannot support requirements of 5G, research is being done to use 10 GHz, 28 GHz, 32 GHz, 43 GHz, 46-50 GHz, 56-76 GHz and 81-86 GHz bands [40]. Radio signal on these candidate frequencies is deeply affected by atmospheric fading, rain, buildings, human beings, flora and reflection. To overcome these difficulties in RF design, signal processing studies focus on adaptive beamforming. With adaptive beam forming, high data speeds according to the receiver locations can be achieved [41]. Complex circuit structures are used to solve the problems of adaptive beam forming and massive MIMO (Multiple-Input Multiple-Output) technologies. RF Insertion Loss should be lowered to reduce circuit complexity, dimensions and power consumption, which are usually very costly in microwave frequencies. Zero-IF architecture is used for this purpose. The resulting local oscillator leakage issue in Zero-IF architecture is solved with signal processing techniques in digital domain [42].

From semiconductor technology perspective, GaAs (Gallium Arsenide) is the dominating technology of microwave industry for years. SiGe (Silicon-Germanium) technology has major benefits over GaAs in high-speed applications. SiGe BiCMOS (Bipolar Complementary Metal-Oxide Semiconductor) technology also fulfils high-level integration requirements of beamforming systems [43].

Mechanical design is also an important part of RF IC design. Substrate and antenna should be taken into account in order to minimize the losses in integrated circuit design. Less than 50 GHz, antenna and several passive components can be designed as part of the substrate. Studies on SIW (Substrate Integrated Waveguide) continue to be used in this type IC designs. Antenna elements above 50 GHz are small enough to fit into integrated circuit [44].

3.11. Design for EMC/EMI

EMC and EMI technologies become a critical design criteria due to technological developments [45,46]. When necessary precautions against EMC and EMI are not taken during design process, design time and hardware design, mechanical design and test cost can be much higher. To verify if EMC requirements of the designed system are met, very expensive test infrastructure (anechoic chamber, signal generators with several signal types and output power, spectrum analysers, antenna, etc.) should be established. If required by regulations, these tests should be carried by certificated labs.

Today, the voltages in the circuits are low and the currents are high. For this reason, noise and interference problems in digital circuits are mostly due to magnetic field and inductance. For this reason, engineers should take precautions for the magnetic field instead of the electric field for the products they develop [47].

3.12. Energy Efficiency

Total electric consumption of the world has reached 20567 TWh (Tera Watt hour) in 2015 [48]. ICT sector share is %4.6 of total power consumption [49]. Although the figure is relatively low, studies to reduce electric consumption continue due to environmental concerns and cost. Sector participates in initiatives such as EARTH (Energy Aware Radio and network TecHnologies). In addition, operators with the collaboration of universities and research institutes conduct studies about future network infrastructures to reduce CO2 emission.

Figure 7 shows global energy network infrastructure and energy consumption of user terminals [50].

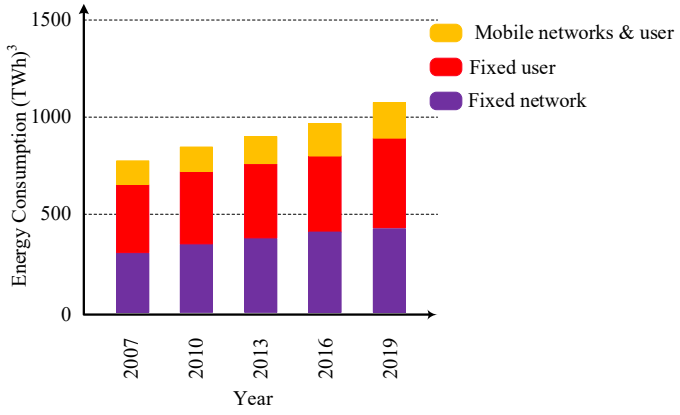

Figure 7 Global energy consumption for network infrastructure and user equipment during operational phase.

The first studies in mobile communication aimed to reduce energy consumption, targeted reducing current draw from battery in order to extend battery life. Advanced RF design techniques like linear and efficient PA (Power Amplifier) design with envelope tracking, adaptive transmit power control, radio aware software management, and development in semiconductor production, extend the battery life of smart phones from 310 minutes to 430 minutes in 5 years [51].

Increasing data requirements of smart phones, laptops and smart TV devices raises energy consumption of mobile communication systems. According to ITU (International Telecommunications Union), energy consumed in the network is %10 of the energy consumed by ICT eco-system and this value is sufficient to illuminate the entire world in 1985 [52].

In mobile communication sector, %80 of the energy is consumed in base stations [53]. Most of this energy is spent for cooling equipment, transmission losses, power amplifiers, transmitter/receiver devices, baseband processing and AC/DC and DC/DC converters.

Base stations do not operate at maximum capacity most of the day. Reducing power consumed at this low traffic intervals, reduces CO2 emission and operator costs dramatically. For this purpose, antenna muting, small cell usage and power-save mode implementation on radios are widely used.

Passive cooling design, their ability to provide service at network edge and low RF power of Small Cell devices helps to reduce operational costs. Small Cell usage improves battery life and coverage area for the users as it helps operators by optimizing energy consumption and easy-to-deploy characteristics in crowded areas.

Figure 8 shows power consumption in cellular networks [54].

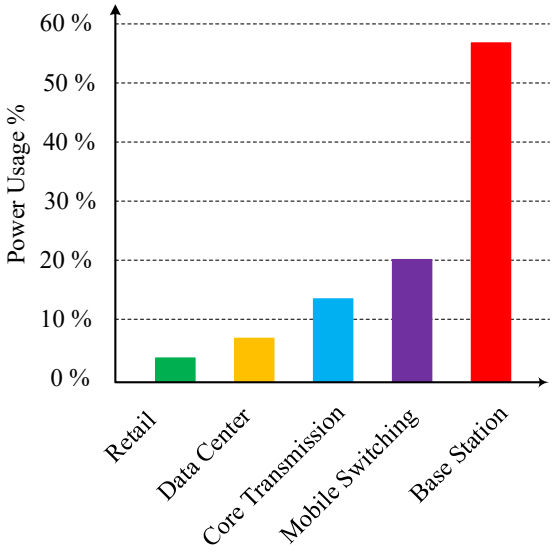

Figure 8 Power consumption in cellular networks.

Macro base stations are becoming more efficient over time. Thanks to improvements in active RF component design, it was possible to use RRH (Remote Radio Head) units. RRH units contribute to energy efficiency because they are designed with passive cooling and are close to the antenna, reducing RF transmission losses. For example, because of the 3 dB reduction in transmission losses to the antenna using RRH, the output power of the power amplifier is reduced by half.

As the use of massive MIMO and adaptive beam forming technologies in base stations, the power used per transmitted bit is reduced. In these technologies, passive cooling is possible because of the use of many small amplifiers in the base station and because the amplifiers are spread over a large area. On the other hand, the beam gains generated by a large number of antennas are significantly increased. This means that less power is consumed from each power amplifier. In addition, as the capacity of the base stations increases, the total amount of energy consumed by the network decreases.

Use of small cell base stations, massive MIMO and adaptive beam forming technologies and use of RRH devices equipped with technologies such as envelope tracking and Doherty design GaN amplifier will enable lower power consumption.

3.13. An Example: LTE-Advanced Baseband Hardware Design

For today's advanced technology product design, the LTE-Advanced (Long Term Evolution) Baseband unit is an example. This unit has various peripheral cards such as baseband cards, backplane, redundant control card, fan card and power card. There are various high speed signals (Ethernet, Serial Rapid I/O, SGMII Ethernet) in the backplane of the unit with the highest 10 Gbps.

An exemplary Baseband Card is shown in Figure 9. This card contains 550 types of components, 62 of which are integrated circuit. The total number of components in the card is 4212. These electronic components are arranged on a 16-layer PCB with a width and length of 32 cm.

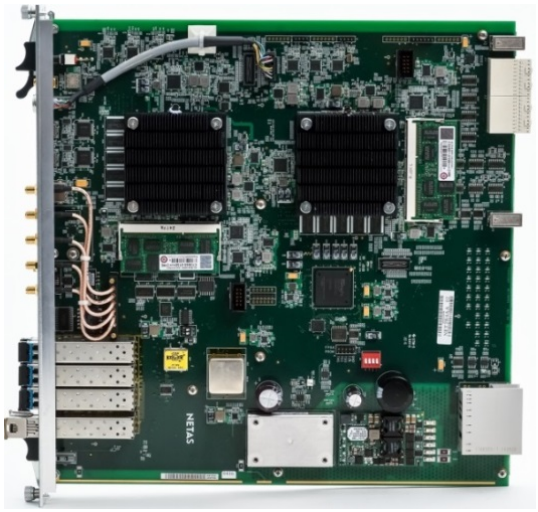

Figure 9 Baseband Card for 4G base station.

There are 10 different supply voltages between 5V and 0.75V, which supply the baseband card. The total current drawn from a 1V supply on one card can reach 40A.

There are various interfaces (CPRI-Common Public Radio Interface, Ethernet, reference clock) up to 4.9 Gbps on the baseband card. There are also various interfaces (hyperlink, serial rapid I/O, SGMII Ethernet) up to 6.25 Gbps among the master and slave processors of the card.

The SoC used in the baseband card has 8 DSP cores (1.2 GHz), 4 ARM cores (1.4 GHz) and 30 application specific coprocessors. Only the hardware documentation required for the hardware design constitutes a 5700 page document set.

There are 1517 pins of the SoC integrated circuit on the baseband card. In order to be able to perform the layout process, advanced production techniques such as blind and buried via, micro via, and bypass via are used.

Layout constraints for fast differential paths such as 10 GHz must be applied very rigidly, taking into consideration both the distances between the differential paths (at most 0.14 mm) and the distances between the source and the target of the signal (at most 0.24 mm). This situation is illustrated in the Figure 10 below.

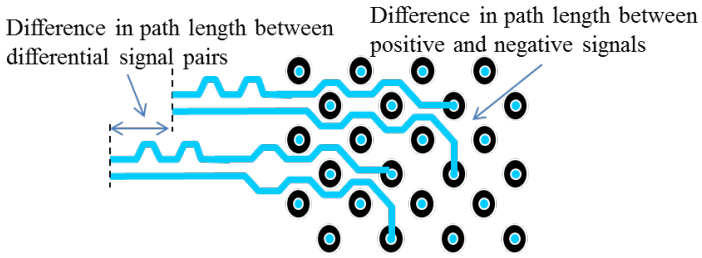

Figure 10 Path length definitions for differential signals.

Layout constraints for fast differential paths of the Baseband Card are illustrated in the Table below. Considering that 1 ps (pico second) is one in a trillionths of a second, and the thickness of the hair is 40 micrometers, it can be seen how difficult the following layout constraints can be achieved.

EMC/EMI precautions for high-speed interfaces must also be held in order for this card to function properly and the relevant processes must be implemented from the beginning of the hardware and mechanical design.

Table Layout constraints for fast differential paths.

Interface	Difference in path length between positive and negative signals	Difference in path length between differential signal pairs
1 Gbps Ethernet	< 5 ps – 700 µm	< 10 ps – 1.400 µm
4.915 Gbps CPRI	< 5 ps – 700 µm	< 10 ps – 1.400 µm
5 Gbps Serial Data	< 1 ps – 140 µm	< 15 ps – 2.100 µm
50 Gbps Hyperlink	< 1 ps – 140 µm	< 15 ps – 2.100 µm

4. Design for User Services: Software Design

Today, software has entered into all areas of life without exception. The diversity of emerging technologies and demands makes the software even more complex. The software now communicates more with peripherals and external systems. The development of network structures requires that software be more aware of each other. Manual data transfers over the past years are now done in real time. All of this has increased the compatibility issues of software.

It is said that the progress on hardware follows Moore's rule. But it is not possible to say that the software fits into this progress. In the early years when the software was growing and becoming more complicated, the designers faced more difficulties than the hardware because the processes were not fully matured [55]. For this reason, most software projects have been delayed for years. As a result, costly and unreliable, hard-to-maintain software is designed for these projects. During this period, software design has entered a crisis period. Hardware costs have fallen while software costs have increased.

Today, new techniques, design methods and tools are developed to control the natural complexity of large software systems. However, software design and test costs still constitute a large part of the design cost of ICT products today.

4.1. Software Development Processes

Companies working in software development are choosing different software development methods ranging from traditional approaches to agile approaches, depending on the needs of the projects they develop. The results of research on methodology selection in software projects show that traditional methods, including the Waterfall model, are still popular, although agile methodologies like Agile Unified Process and Scrum are more common than they were 10 years ago [55]. These surveys have shown that software development organizations also use a hybrid approach based on a large number of methodologies on projects.

Today, widely used software design methods are listed below. One or more of these methods may be preferred depending on the complexity of the software to be developed, the number of software engineers to work with, whether the customer requests are specific, the priority of the documentation, the design time, and whether the system requirements are evident clearly [55].

- Ad hoc
- Waterfall
- Evolutionary Process Models
    - Incremental
    - Spiral
    - Rational Integration Process
- Agile Methods
    - Feature-Driven Development
    - XP (Extreme Programming)

4.2. Current Trends for Software Development

Today, the complexity of software and the number of developers working on software projects are increasing. In addition, competition in this area is increasing. As the reliability requirements of the software increase, the duration of the project is also shortened. There are various developments in the field of software development, mainly open source code and framework usage, in order to enter the market quickly and cost effectively. This section describes the trends in software development today.

4.2.1. Open Source Software Development

Open source software is a software model that enables the source code to be reviewed, modified and distributed to third parties for free or for a fee. Today, almost all open source software is available for free. The fee for such codes is usually for additional services such as documentation and guides, technical support, maintenance, etc. provided with the source code of the software [56].

In the 1970s, open source software began to become widespread with the release of an open version of the Unix source code, an operating system with a large user base. This new type of software, which has a license that anyone can edit the source code as they like, has received great interest and has since become widespread.

Open source and traditional software are different in terms of total cost of ownership, flexibility, software quality, security, firm dependency and open standards. In some software products, such as Operating System, Web Browser, Web Server, Web Content Management, Mobile Operating Systems and Applications, the products developed as open source have become bigger market share than their alternatives. Today, the use of open source code has become increasingly widespread due to cost, and faster entry to market advantages.

4.2.2. Universal & Reusable Software Environments: Frameworks

The Framework contains many software libraries and allows developers to add their own libraries to them. It also guides how the software should be developed. In this way, the designers work with previously tested and reliable software. In addition, the designers can be guided on how to develop the software project to prevent the development mistakes.

Frameworks include libraries as well as design patterns, compilers and test tools. In this way, a development environment is also provided to designers to develop the software project. For example, big chip manufacturers in the embedded design world are no longer just producing chips. These companies also offer software development environments that include customized libraries, compilers suitable for the development environment, and even operating systems for the chips [57].

Chip manufacturers distribute their own product development environments free of charge, in order to promote the use of development environments and to dominate the market. Software project developers choose the framework they need to meet their requirements, leaving the details to the "framework".

Today, widely used libraries and frameworks are given below.

a) OpenCV (Open Source Computer Vision Library)

It is a cross-platform library originally developed by Intel for computer vision. Windows and Linux platforms are supported. Since this library includes advanced image processing algorithms, it is possible to develop image processing applications quickly using this library [58].

b) OpenCL (Open Computing Language)

It is a kind of framework designed to develop programs in heterogeneous systems including CPU, DSP, FPGA, GPU and similar hardware accelerators. OpenCL offers APIs (Application Programming Interfaces) to program and control these processing units. This framework also provides a standard interface for data and task based parallel programming [59].

c) .NET Framework

It is a software development framework originally developed by Microsoft for Windows installed machines. Using this framework is advantageous for designers who want to develop software on Windows. The use of this framework has now become standard for windows machines. Today, this framework is also attractive to iOS and Linux developers by providing cross-platform support. This platform continues to evolve with the principles: any designer, any application and any platform [60].

d) Coca Touch

It is a framework, which is developed by Apple to develop applications on iOS (IPhone, IPad), watcOS (AppleWatch) and tvOS (AppleTV) operating systems. Applications developed with this framework can only work on the MAC operating system. These applications are developed with the Objective C ++ language. This "framework" also provides hardware drivers and software support, and applications developed using this framework can be downloaded from the AppStore [61].

e) ActiveX

This framework is developed by Microsoft and is used to manage downloading of content over the internet. This framework is designed for downloading and updating the software modules over the internet. The first version was released in 1996. Today it is still supported on Windows 10 and by Internet Explorer 11 [62].

4.2.3. Virtualization

For virtualization, IT (Information Technology) and Telecom sectors have been conducting researches and realizations for many years. Virtualization can be defined as software-based representation of physical resources. The work in this area is focused on servers, data storage devices and communication networks. The goal is to allocate existing physical resources efficiently to services that use these resources, increase service continuity, and reduce installation and operating costs. Because of these advantages, cloud computing applications can be preferred in terms of installation and operating costs, especially with pay-as-you-go model for small and medium-sized businesses. Recently, new concepts such as "fog computing" have emerged in this area [63,64]. In this concept, resources that are used flexibly via the cloud are transported to devices at the edge of the network, for example, to WiFi hot-spot devices, sensors or IoT devices. In this model, approaches such as caching is used to optimize the use of bandwidth, reduce latency and network traffic. In this way, the service quality of the users in the access networks is being improved.

Network function virtualization is a special application of the concept of virtualization to communication networks. In this concept, network functions realized with special hardware are realized with software modules on standard server hardware. This is actually the application of virtualization techniques used in data processing centers to communication networks. Nowadays, this concept can be used in web servers and data processing centers. However, there are some problems to be solved to apply this concept to real-time network devices. The most important of these troubles are high performance requirements and data processing delay variations.

In addition, live migration of network functions between hardware platforms is underway from the point of view of performance of transport time and service interruption time.

The use of this architecture is becoming more widespread as NFV (Network Function Virtualization) technologies reduce investment and operating costs, especially power consumption costs.

4.2.4. Software Development for IoT (Internet of Things)

Despite the intensive software work for today's Internet of IoT platforms, a general software engineering approach to systematically developing IoT systems and applications does not exist [65]. So far, researches have been conducted on communication and interoperability issues in this field. Lately, researchers have been working to provide resources and user services with distributed services defined by the software. For example, within the vision of WoT (Web of Things), standard Web technologies are used to provide the development of coordinated IoT services [65]. There are several approaches to interface and programming support for the development of IoT systems and applications. However, work for a common model, methodology and discipline-based approach is still ongoing. There are also work on development environments and development tools in this field.

An article published on this field [66] proposed an IoT middleware that enables IoT systems and the functions of these systems to work together so that the related IoT systems work together. As the technologies used in the IoT become more mature and experience related to the subject grows, it is envisaged that more research on software engineering for IoT systems will be done in the coming years [65].

5. Methods for Product Validation & Test

The product validation is performed to verify if the system works correctly, that is if the product meets the specified requirements and standards, and to evaluate differences between the expected and observed results. The testing process begin by determining the requirements in product design and is performed in accordance with the following objectives:

- To ensure product quality
- To reduce re-development costs
- To increase customer satisfaction

The preparations of the test case and the proper setup are vital in order to follow test procedures, appropriately. System analysis and evaluation of the requirements are performed during this preparation step. Cooperation of different teams is vital to evaluate requirements in terms of testability. Any additional activities and required resources to meet the test objectives need to be planned. Possible risks are determined and backup solutions are planned. Test conditions and scenarios, as well as test exit criteria should be defined. A test plan including well-defined steps to follow should be prepared. After the preparation step, the application is taken.

In general, an important class of tests is referred to as box approach [67]. This approach concerns with whether the code or algorithm is tested by taking into account the internal components or only the inputs and outputs. While black-box and white-box approaches have been widely used, gray box approach has received considerable interest in recent years. The black box approach regards the function as a closed structure and is not interested in its design. It is only considered that the right outputs are produced for given inputs. The white box approach checks whether the internal variables and algorithm are appropriate as well as the function works correctly. The gray box approach is related to the design of the test. The gray box tests are applied like the same black box, but the internal data and algorithm structure of the function are considered when the test is designed.

Another point of view, software tests can be classified as follows [68].

- Unit Test
- Integration Test
- Functional Test
- Compliance Test
- Regression Test
- Performance Test

After the errors found in the verification tests are corrected, the test termination criteria are checked. The test is terminated if all criteria are found to be acceptable. After the test is finished, customer acceptance tests are started for the product. The same process is repeated for the faults, additions or changes requested by the customers. After this phase, the customer tests are repeated if necessary, and the test process is terminated.

Competition is increasing due to developments in the ICT sector. On the other hand, the quality of the product is getting more and more important. The importance given to the testing process has also increased for products to be presented to the user with fewer errors. Today, TMMI (Test Maturity Model Integration) model is defined to improve only the test processes, as CMMI (Capability Maturity Model Integration) model that measures software design processes [69].

In the traditional product design process, the first sample production is done at the end of the design and it is tested whether the requirements are met or not. If desired performance cannot be achieved, design change is made by returning to the design process and new sample production is made. The process is completed following this cycle. Constant sample production to test each design leads to both time loss and cost increase. In today's conditions, the number of initial samples is reduced by computer-aided design. In this way, both the time loss and the cost are reduced. This method is accepted as the modern product design process of today.

6. Mechanical Design & Material Engineering

In the mechanical design of the product, various criteria such as material selection, production methods and mold type and its mechanics should be evaluated in computer environment.

In the 1960s, metals were often used as engineering material. In the following years, demand for steel and cast iron was declined, and today generally, two main materials are used in the production of mechanical systems. These are metal and plastic materials. While metal materials are generally used in machining methods, plastic materials are used in injection molding technology [70,71].

Machining is the shaping process by removing material called sawdust from the inside of materials such as metal, plastic and wood. Along with this, unconventional manufacturing methods such as water jet and laser have started to be used.

Plastic molding is a manufacturing method, which involves pouring and shaping a melted plastic raw material into a mold with the help of temperature and cooling and removing it from the mold. Today, plastic materials can be shaped in a very short time.

One of the latest and greatest developments in manufacturing is the three-dimensional printer technology [72]. Although this method is currently used in rapid prototyping, production with this method in the future will not be surprising. Surface roughness cannot be achieved with the existing technology. For this reason, additional processing is required. Moreover, with this technology, very durable products cannot be produced due to the materials they can process.

In recent years, the production of high performance ceramics, polymers and composite industries has developed rapidly. Today, there are more than a hundred kinds of materials, and choosing materials from such a wide spectrum has become a separate engineering subject. Today, in material engineering and researches, various imaging techniques, thermal analysis methods and X-rays are widely used.

7. Manufacturing

Electronic components used in today's ICT devices are divided into two groups as SMD (Surface Mount Device) and through-hole. The through-hole components frequently used in previous years have been left almost entirely to SMD by the developing technology. The through-hole electronic components must be inserted and soldered in holes in electronic cards. The SMD elements are attached to the card surface and fired.

Surface mounting components can be manufactured much smaller than legged through-hole components [73]. Using small and lightweight components, it is possible to design cards that produce less heat and consume less power. The SMD components can be arranged on both surfaces of the card. Moreover, these components are more resistant to mechanical vibration and shock effects. The weakness of the surface mounting technology compared to the through-hole is the difficulty of manual intervention and repair.

BGA packages offer more pin connections than other SMT (Surface-Mount Technology) package types. For this reason, the BGA package is widely used for components with a high number of pins such as microprocessor and SoC. However, soldering to PCB is much more difficult than other types of packages and requires special stations.

In case of faulty installation, the relevant circuit element is dismounted by local heating method using special devices. At the next stage, the soldering balls are fixed and replaced by local heating under computer control. The BGA rework station is shown below. In this case, a baseband card is reworked for the SoC component.

In BGA packages, the pins are very close to each other and when they are soldered to the PCB, no pins can be seen. A short

circuit may occur between nearby pins, resulting in errors during production, or soldering.

BGA surface mount assembly is difficult to test, once it has been assembled. In this case, X-ray devices can be used to control the deformation and fracture of solder balls.

An X-Ray view of the SoC used in a Baseband card is given in Figure 11. In this view, the pins and the connections between them can be clearly seen. At the end of the review, it is confirmed that the pin connections are correct.

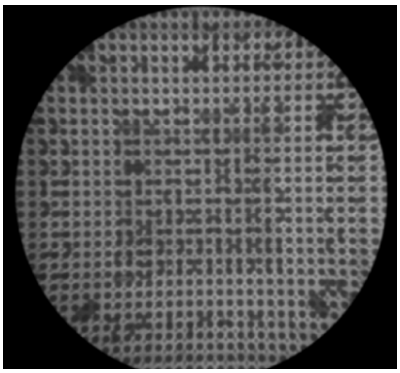

Figure 11 An X-Ray view of the SoC.

7.1. Environment Friendly Approaches for Manufacturing

As the electronic goods sector grows with industrialization and usage habits, the negative effects of electronic waste are increasing rapidly. In order to reduce these effects, environmentally sensitive design has become a mandatory legal requirement. In 2003, the European Union published two important directives for electronic producers. These are Restriction of Hazardous Substances (RoHS) and Waste Electrical and Electronic Equipment (WEEE) directives. These directives are concentrated in two main points. The first is to limit the use of toxic and harmful substances in newly manufactured electronic products and secondly to take into account recycling criteria in product design. In this context, the concept of environmentally friendly design, called eco-design, has emerged. In addition to the traditional design processes, eco-design includes processes from raw material acquisition, product recycling and disposal. For this reason, designers are expected to design by evaluating the recycling and dismount ability criteria of the products [74].

Under the RoHS directive, the use of lead, cadmium, mercury, chromium and brominated components is prohibited. The use of these components in electronic and electrical equipment is causing toxic particles to interfere with the environment. For example, the use of hydrocarbon fluoride to clean the PCB assembly is prohibited because it causes wear on the ozone layer.

8. A Practical Implementation: LTE-Advanced Baseband Unit

In this section, in order to illustrate some of the key features in a cutting edge ICT product design, a LTE-A Baseband Unit (BBU) is considered and the technical competencies, infrastructure and design processes required to develop this product are highlighted.

The first stage for the design of the BBU unit is system-level design, where functional features are derived from the expected characteristics, customer requirements, competitive product analysis and product roadmaps. This step consists of general block design and technical features such as interface characteristics, power supply and cooling. At this stage, it is decided to support some operator specific features in addition to 3GPP Release 10 & Release 11 standards.

The hardware design features of the BBU unit are given in detail in section 3.13. In order to design a high-tech product at this level, advanced technical expertise is required on the high density interconnect PCB production techniques using blind and buried via, micro via, and bypass via. The BBU hardware includes 82 CPU cores and is designed to provide the processing power required by the features specified in the system design phase. This corresponds to a capacity above 1 trillion operations per second. There are 18 CPRI (Common Public Radio Interface) interfaces for radio connections and 2 gigabit Ethernet interfaces for EPC (Evolved Packet Core) connections on this unit. Each radio interface is comply with the CPRI standard.

BBU unit software was developed on a System-on-Chip (SoC) specially developed for Macro Base Station products. Electronics Engineering, Telecommunications Engineering and Mathematical Engineering disciplines have been used together to develop highly optimized and real-time digital signal processing algorithms. BBU software which contains thousands of source files and millions of lines of source code, can be developed with roughly 100 software engineers and many years of design and coding work.

Testing infrastructure which requires tens of millions of dollars in investment cost is required for functional testing of the BBU unit. Using these infrastructures, thousands of functional test scenarios are implemented in the laboratory and in the field. Verification tests of a BBU unit can only be performed using high-tech and complex test equipment, examples of which are given above. For example, in order to use the multi user terminal simulator, it is necessary to examine over 1,000 pages of document and take the training for weeks. Some of the device types included in the test infrastructure required for functional testing of the BBU unit are Multi-user terminal simulators, Channel simulators, EPC (Evolved Packet Core) simulators, Air interface analysers, CPRI (Common Public Radio Interface) test devices, Remote radio units and antennas, Vector signal analyser and generator and Mobile packet analysers.

Finally, ICT products must comply with the relevant hardware, software, product integrity, reliability, environmental and EMC standards. To design LTE-Advanced BBU, tens of thousands of page standard, data sheet and papers have been studied and implemented.

9. Conclusion

Prior to the industrial revolution, goods and equipment to meet daily needs can be produced with simple techniques in small workshops. Later, large factories allowing mass production started to be established and needs for special expertise in various areas of manufacturing techniques have arisen. This trend continued increasingly in mechanical world until 1970s. From the mid-twentieth, first the emergence of transistor and later the invention of the integrated circuit caused a similar development in the electronic world. While in the beginning, mechanical expertise was still predominant in product design, the technical expertise on hardware and software design has become the most crucial parts, in the next two decades.

With the market launch of the first commercial microprocessor, electronic devices started to enter into many areas of our lives. This led to product diversity and consequently to the need for expertise in different areas. Until the 1980s, simple tools for ICT product design and testing were sufficient, but in the next 20 years, more sophisticated design tools and test equipment were required. Nevertheless, the tools and equipment needed to develop an ICT product remained affordable for a start-up company.

After the 1990s, the use of mobile devices in all areas of our lives led to the acceleration of development of technology in the ICT world. Especially, development of display and battery technologies has caused tremendous increase in the use of mobile devices. At the beginning of the new millennium, with the widespread use of internet and video-based services, more bandwidth was needed, which forced new solutions to be developed in cable and wireless communication technologies. However, the emergence of complex modulation techniques to address these demands caused additional hardware requirements, such as faster processors, faster memories, and faster peripheral components.

All of these effects have initiated the key design concepts: smaller, lighter and faster products. Therefore, the dimensions of the components have to be reduced despite the increasing performance and durability requirements. Today lightweight sensors which can be fitted even to swallow birds can be produced, and they can collect and store data for as long as a year. The first commercial microprocessor incorporated 2,300 transistors. Now, new generation processors have around 1.3 billion transistors. Nowadays, the processors produced in the size of one fourth of the 1 cm2 area for wearable devices, deliver 200 times more performance than the processors used in the first PCs. However, with the use of these new technologies in product design, the design process are becoming increasingly complex, engineering skills are becoming increasingly diverse, and the infrastructures needed are becoming increasingly expensive.

In this paper, all the design stages of ICT products are explained. Due to rapid development of hardware technologies, hardware design is getting more and more intriguing. As can be seen in the relevant sections, in order to design an ICT product, very deep technical expertise, expensive development and verification infrastructures are needed in the respective fields.

ABSTRACT

This work is dedicated to present a new pipeline-parallel architecture of Discrete Wavelet Packet Transform (DWPT) for all wavelet family implemented in FPGA technology. The main target of our architecture is to provide an effective performance trade-off, where it significantly increases the throughput with a restricted amount of hardware. In this article, we propose two kinds of configurable architecture: first architecture with a very strict amount of hardware base of pipeline and sharing resource, and the second architecture provide an ultra-high speed by propose P-parallel DWPT and a parallel direct FIR filter under the strategy of pipeline-parallel and sharing resource. The pipeline and the clever sharing of the hardware resources are smartly connect based on low-pass and high-pass filters in the Mallat-tree algorithm. These architectures are fully configurable in synthesis according to parallel degree, the tree depth (number of tree levels), the order of the filters and the filter quantization coefficient. Consequently, the simulation results accelerated to an approximate value of P(Frequency). Furthermore, the tree depth and filters order has little impact (only due to place and route variations) on throughput. This architecture was synthesized using Altera Quartus prime lite edition targeting an Altera Cyclone IV - (FPGA) and it was developed in VHDL at RTL level modeling.*

1. Introduction

From the work of Coifman and Wickerhuaser in 1992, the wavelet packet transform has a lot of attention from both academic and industry establishments. Where in the literature, we found a lot of research dedicated of wavelet packet transform and there implemented in different domains: communication, image, video, data compression, wireless sensor network and other. But in the last years, we saw a rise in the amount of data that needs to trait and transmit. That requires a new throughput level and need a new platform or program logic device (PLD), which can provide a high speed, with low cost and low power consummation.

The powerful of Discrete Wavelet Packet Transform (DWPT) is due to the ability of represent both transient and stationary behaviors of data signal by a few of transform coefficients. The most implemented solution of wavelet transform is based on the FIR (Finite Impulse Response filter) filter banks concept [1]. To benefit as maximum possible of this characteristic, many works have addressed the implementation of DWPT in hardware device like processor or FPGA.

In this context, the first work try to implement the DWPT on processor was recorded in 1999 by [2]. However, DWPT (based of FIR filter banks) complexity makes it hard to fulfill high throughput and low area (Material resource) consumption. To provide these constraints, we find many works dedicated of the implementation of DWPT on FPGA like [3-16].

The architecture of Daubechies wavelet on scale 6 (DB6) based on algebraic integers is proposed in [3], the authors have developed architectures for one and two dimensions of DB6 with minimization of the number of used adders.

An integrated systolic architecture for computation of the 1-D of DWPT/IDWPT are presented in [4] where the architecture can limited the number of page requirements. In [5], DWPT/IDWPT are implemented using Embedded Instruction Codes (EIC) where the authors used two multipliers and four adders for the symmetric filters. [6] presented a word-serial pipeline architecture and parallel filter processing for DWPT/IDWPT. The same authors are followed their work in [7] where they are used high-pass and low-pass filters to speed up transformation. Then, the same authors are also developed the implementation of the wavelet packet transform on FPGA with three types of multipliers in [8]. In 2006, [9] presented a word-serial pipeline architecture with a new parallel FIR filter processor to perform the DWPT/IDWPT transform. And between the years 2013-2014, [10] presented a flexible architecture of DWP/IDWPT based directly on the registers and on an efficient multiplexing structure.

Another architecture of DWPT implement the tree search algorithm is presented in [11], then their implementation on FPGA is discussed in [12]. The same authors in [13] have developed parallelized architectures in two modes: serial-word and parallel- word of the direct and inverse DWPT transform.

The authors in [14] was proposed an architecture for implementing fast and configurable DWPT based on FIFO inputs, dual-port memory, multipliers and adders. [15] also presented a hardware design of DWPT based of frame-partitioned architecture. And in our previous work [16], we propose a fast and reconfigurable architecture but non parallel of DWPT.

This paper proposes a novel P-parallel (Parallel degree P) architecture of DWPT transform and also reconfigurable, based on the Mallat tree scheme [17], with a parallel direct FIR bank filter structure. It is very suitable for the implementation in global parallel DWPT architecture. The architecture aims to offer a suitable compromise between computational performance (throughput rate) and resource consumption (area cost). The core of our architecture is flexible and can provide an elegant sharing of computational resources (multipliers and adders) between the approximation and details related filter banks. The architecture is fully configurable in synthesis according to parallel degree, the tree depth (number of tree levels), the order of the filters and the filter coefficient quantization.

This paper describes in section II a brief theory of the wavelet and wavelet packet transform concepts. In section III, we propose our DWPT architecture compared with the results obtained from HDL coder. Our proposed P-parallel DWPT architecture in section IV. That summarizes the results obtained for this architecture on a FPGA implementation and compared with other previous work in literature. Finally in section V, we will set forth the conclusion part.

2. Review of wavelet packet transform

In the wavelet transform theory, a signal x(t) is decompose by projecting it into a family of functions $\Psi_{s,\tau}(t)$, all derived obtained from the same original single function called "Mother wavelet" by translation and dilation or contraction:

$$\Psi_{s,\tau}(t) = \frac{1}{\sqrt{s}}\Psi\left(\frac{t-\tau}{s}\right) \quad (1)$$

where $s \in R^*, \tau \in R$. For large s, the basis function becomes a stretched version of the prototype wavelet, that is a low frequency function, while for small s, the basis function becomes a contracted wavelet, that is a high frequency function.

Therefore, the discrete wavelets transform (DWT) are discretely scalable and translatable. This was achieved by modifying the wavelet representation in (1) to create Daubechies (1992) [18]:

$$\Psi_{j,k}(t) = \frac{1}{\sqrt{s_0^j}}\Psi\left(\frac{t-ks_0^j\tau_0}{s_0^j}\right) \quad (2)$$

So the Discrete Wavelet Transform (DWT) of signal $x(t)$ present in (3):

$$X(j,k) = 2^{-j/2}\int_{-\infty}^{+\infty} x(t)\Psi \quad (2^{-j}t-k)\,dt \quad (3)$$

DWT can be implemented by the convolution operation between signal x and mask $Mother\ wavelet$ " Ψ ". But also, DWT can be implemented by non-uniform filter banks. Where the input signal separates into low frequency component signal and high frequency component signal. The first is called smooth coefficient while the second part is called wavelet coefficients. The smooth coefficient is separated into two parts repeatedly. In the classical way, we indicate the two parts via low-pass digital filter H and a high pass-filter G. By using the scaling function and there corresponding mother wavelets, we obtain both digital filter H and G. We suppose H and G like a FIR filters non-recursive with L length, the transfer functions of H and G can be expressed as:

$$H(Z) = h_0 + h_1z^{-1} + h_2z^{-2} + \cdots + h_{L-1}z^{-(L-1)} \quad (4)$$

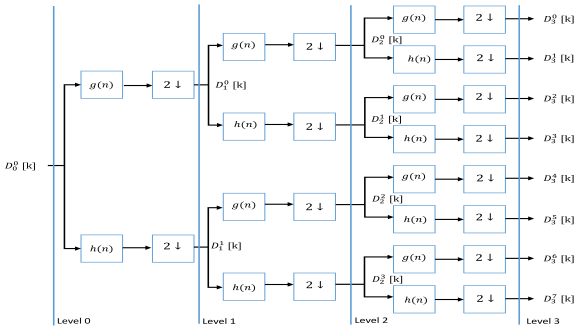
$$G(Z) = g_0 + g_1z^{-1} + g_2z^{-2} + \cdots + g_{L-1}z^{-(L-1)} \quad (5)$$

Mallat's tree algorithm or pyramid algorithm [19] can be used to find the multiresolution decomposition of DWT, the two scale relations (4) and (5) leads to scaling functions and wavelet functions similar to that in scalar wavelets. But the equations are two scale matrix equations and can be given as:

$$\phi(t) = \sum_n h(n)\phi(2t-n) \quad (7)$$

$$\Psi(t) = \sum_n g(n)\Psi(2t-n) \quad (8)$$

Where $\phi(t) = [\phi_1(t)\phi_2(t)\ldots\phi_r(t)]^T$ and $\Psi(t) = [\Psi_1(t)\Psi_2(t)\ldots\Psi_r(t)]^T$ forms the set of scaling functions and corresponding wavelets. The suffix r denotes the number of wavelets and is dubbed as multiplicity.



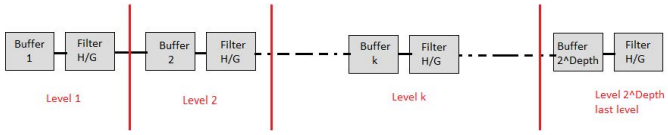
3. Our proposed architecture N°1: smart sharing and pipeline architecture

In the recent work, the most important challenge for developer is design a new DWPT architecture can ensure high speed data processing with low consummation resource. That leads to minimize the needed energy and size hardware (critical constraint in many application domain like WSN, Body area Network, and others).

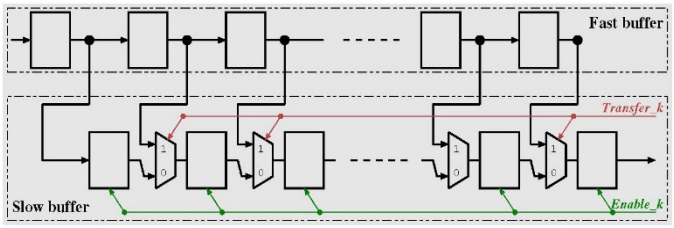
3.1. Fast and reconfigurable architecture unparalleled

To answer of their challenge, we are developed in the first time in [16], our first fast and configurable DWPT architecture based of Mallat tree approach (Figure 1) and transposed digital FIR filters in the filter banks.

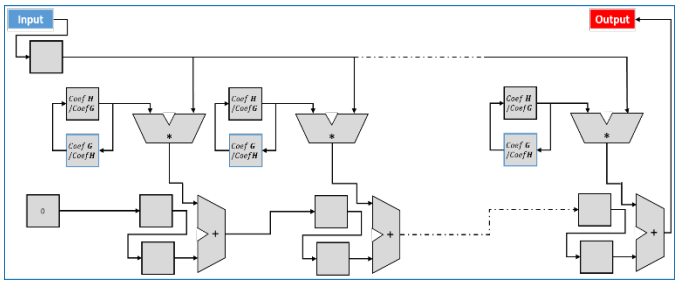
In Figure 2, we present the proposed unparalleled-pipeline architecture. That take advantage of this present in original Mallat tree where instead using a 2^k classic FIR filter in stage k (the amount of data to be processed by any filter of stage k is $2^{-k}\times$ the amount to be processed the filter or stage 1.), only one modified filter is implemented. The power of modified proposed filter can process all data in the same stage k and serve the functionality of low-pass filter and high pass in the same time.



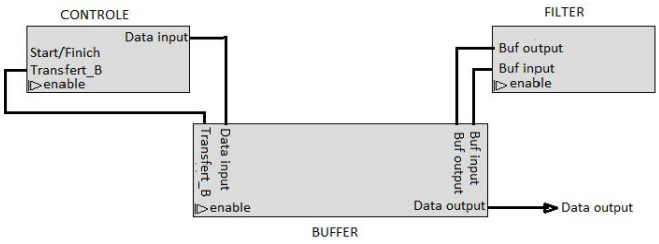
In each level, the simple architecture is based of two blocks: block "Buffer" and block d'un modified FIR filter "Filter H/G". The structure of the block buffer is shown in Figure 3. As her name buffer block, it is built up on two shift register: fast shift register represented by "Fast buffer" and slow shift register represented by "Slow buffer". An important characteristic of these blocs are the dynamic size i.e. the size of the block buffer depends on the stage k (where k parameter in the figure 2 and 3 is related to the number of the stage in which the buffer is implemented, example for k=1, we implement the first block buffer). The working mechanism of block buffer is the key word in our architecture where each buffer is built up as we mention bellow on two shift register of 2^{k-1} positions: a fast shit buffer that takes its data from the previous stage, and a slow buffer that feeds its own stage filter. The "fast buffer" achieve one shift on each clock while the slow buffer shift rate is one shift on each two clock cycles. As we show in figure3, the $enable_k$ signal controls the rate of slow buffer registers. And the $transfer_k$ signal is driven on each 2^k cycles, all the data in the fast buffer in parallel to the slow buffer.



In Figure 4, $block\ H/G$ are the modified blocks filters, they play the function of high pass filter and low pass filter and they are related to $H(Z)$ and $G(Z)$, in equation (4) and (5), respectively.



A control unit (figure 5) was also proposed in our work, to manager the BUFFER block and H/G FITLER block, we used a central CONTROLLE block provides the $enable_k$ and $transfer_k$ signals to the related K stage.



3.2. Results and synthesis

This proposed architecture was writing in VHDL-RTL modeling and we make a big effort to write a generic VHDL code (i.e. independent of target FPGA hardware). The synthesize of our architecture has been done by using Altera Quartus prime lite edition and it is targeted onto Altera FPGA belonging to Cyclone IV family. As we mentioned in [16], the architecture is fully configurable at synthesis in respect to the tree depth (number of tree levels), the order of the filters and the filter coefficient quantization.

Table 1. Implementation results of unparalleled DWPT

Design parameters	Clock frequency	Resource usage
(2, 2, 5)	207.68	(158, 74)
(3, 2, 5)	194.93	(252, 130)
(4, 2, 5)	200.28	(397, 233)
(2, 4, 5)	205.25	(296, 114)
(3, 4, 5)	181.23	(446, 180)
(4, 4, 5)	187.69	(647, 293)
(2, 16, 5)	178.99	(1103, 354)
(3, 16, 5)	179.73	(1598, 480)
(4, 16, 5)	170.36	(2138, 653)
(2, 2, 16)	104.14	(857, 228)
(3, 2,16)	101.31	(1332, 405)
(4, 2,16)	104.94	(1940, 717)
(2, 4,16)	102.54	(1676, 356)
(3, 4,16)	102.54	(1676, 356)
(4, 4,16)	92.06	(3473, 909)
(2, 16,16)	106.73	(1609, 1108)
(3, 16,16)	109.66	(2250, 1493)
(4, 16,16)	111.96	(3032, 2013)

Table 1, we obtained the result of needed area (consumption) and clock frequency for different values of the configuration parameters. In the table, design parameters are presented as a 3-tuple, depth (depth of Mallat tree), order (filter order), and quantization (number of bits of coefficient quantization). Clock frequency is given in MHz. And the resource usage is given as a 2-tuple, (l_e, l_r) where l_e stands for logic elements and l_r for logic registers.

3.3. Results obtained by HDL Workflow Advisor tools

In the last years, many tool are developed to facilate the designer work and to optomize the generate VHDL code of circuit. One of the important tools is HDL Workflow Advisor, this tool is developed by Mathwork society and it built in MATLAB/SIMULINk software. The aim in this section is to evaluate our unparalleled architecture by compare the results in table 1 with that obtained from optimizer HDL tool.

We developed a Simulink model of the some functional architecture of DWPT and then we are generated the optimized HDL code by using the HDL Workflow Advisor. The obtained VHDL code has been synthesized using the same software (Altera Quartus prime lite edition) and also target the same FPGA. The implementation results are present in table 2.

The synthesis in respect the parameter presented below in part B. but we add as result a furthest colon present the needed DSP block.

Table 2. Implementation results of DWPT from Simulink / Quartus.

Design parameters	Clock frequency	Resource usage	DSP block
(2, 2, 5)	286.29	(18,25)	0
(3, 2, 5)	207.25	(29,38)	0
(4, 2, 5)	127.29	(54,70)	0
(2, 4, 5)	134.66	(29,41)	0
(3, 4, 5)	96.72	(48,62)	0
(4, 4, 5)	64.24	(88,110)	0
(2, 16, 5)	31.2	(155,262)	12
(3, 16, 5)	21.66	(425,606)	28
(4, 16, 5)	14.03	(818,1380)	62
(2, 2, 16)	216.5	(44,69)	0
(3, 2,16)	165.4	(74,104)	0
(4, 2,16)	102.01	(131,180)	0
(2, 4,16)	103.77	(142,129)	0
(3, 4,16)	76.58	(258,210)	0
(4, 4,16)	50.36	(606,439)	0
(2, 16,16)	26.37	(839,823)	12
(3, 16,16)	20.65	(1985,1915)	28
(4, 16,16)	12.63	(4449,4361)	62

Base of implantation results presented in table I and II. It can easily make a comparison between our proposed architecture and other one from HDL tool. The synthesis of our architecture is done without any needed of DSP block when the optimized architecture (code) from Matalb/Simulink need from 12 to 62 DSP blocks depended of design parameters. When we increase the order of quantization from 5 to 16 that decrease approximately 50% the clock frequency but that decrease the Clock frequency to 95.5% with the optimized DWPT architecture by coded HDL tool from Matalb/ Simulink.

4. Our proposed architecture N°2: Parallel-Pipeline architecture with sharing resources

In this section, we propose a high throughput parallel architecture for DWPT, base of Mallat tree approach and using the direct P-parallel digital FIR filters in the filter banks. Figure 1 present a three-level decomposition tree for single parallel degree that provides eight frequency bands with P parallel degree. The filter bank consists of wavelet functions as the low pass filter $h(n)$ and its dual high-pass filter $g(n)$.

Considering the diagram in figure 6, the needed resource with classic Mallat tree is multiply by P. For example with degree of parallelism P=10 and depth=3, we need $P * (2^{depth+1} - 1) = 140$, we need 140 low/high pass filters where is a huge number. Furthermore, it can be observed that the data rate on any filter of given stage of the Mallat tree is just half the rate of any filter of the adjacent stage in input side, and twice the rate of any filter of the adjacent stage on the output side (factor 2 under-sampling from stage to stage). Indeed, instead of implementing $P * 2^k/2$ low pass filters and $P * 2^k/2$ low pass filters on bank filter stage$k$, only one and just modified one filter is implemented. As we show

in figure 7. It is important to mention that modified single filter (Block Filter H/G) will have to process all the data that would have been otherwise processed by the original $P * 2^k$ filters of stage$k$.

The structure for the modified filter is shown in figure 8. It follows the basic scheme. The main difference with the original filters is related to the handling of the filter coefficients and a smart shift to serve P sampling in each clock cycle. Respect the z^{-p} buffer order, it is the most sensitive and it is the core of the serial FIR filter to parallel operation. The diagram of P-input of n-tap transposed FIR filter as shown in Figure 4. Similar to coding theory, the Serial direct FIR filter is like a single-input single-output ($SISO$) system and parallel direct FIR filter is like a multiple-input multiple-output ($MIMO$) system. Each clock cycle, there are P parallel inputs signals, hence P outputs signals.

In our proposed, we don't have a limited of degree of parallel but it is necessary to choose degree of parallelism equal 2^x where $x \in \mathbb{N}^+$. The choice of $P = 2^x$is pivotal to organized data between different level.

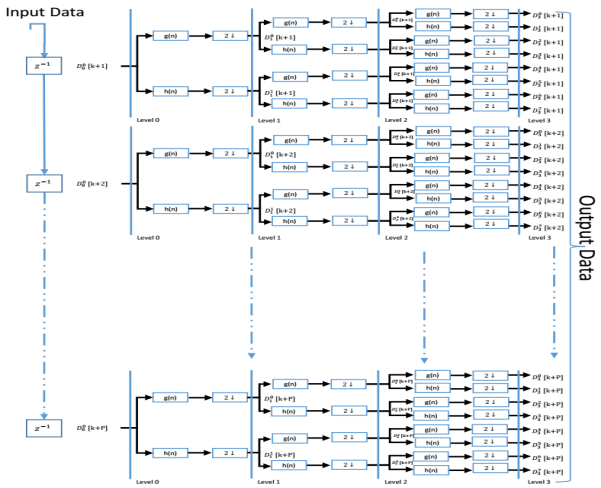


Figure 6 – P-parallel, Three-level DWPT decomposition tree

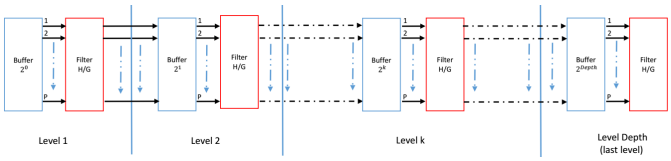

Figure 7. Block view of the proposed parallel DWPT architecture datapath

In Figure 8, $\frac{H}{G}$ $block$is the high pass filter and low pass filter and they are related to $H(Z)$ and $G(Z)$, in equation (4) and (5), respectively. Instead of using two filter with the same architecture, we use an alternatively process. Hence, the alternatively process (on consecutive cycles) force each filter to take a sample for the $H(Z)$ and the for$G(Z)$ and so on. This requires the filter to be feed by correctly scheduled data. This role is devoted to the buffers situated between the filters. The structure of a single buffer is shown in figure 9. The k parameter in the figure is related to the number of the stage in which the buffer is implemented. Then in each level k, the buffer is built up on two shift register of 2^{k-1} positions: a fast shit buffer that takes its data from the previous stage, and a slow buffer that feeds its own stage filter. And in global, the size buffer depends on parallel degree P and level k in which it is implemented. From its name fast buffer, it is fast than "slow buffer". The "fast buffer" achieve P-shift on each clock while the slow buffer shift rate is P-shift on each two clock cycles. To manage this latency, we use enable signal called "$enable_k$" xhich was driven the slower shift rate. For fast buffer, we used a counter signal equal 2^k control the $transfer_k$ signal which every 2^k cycles; all the data in the fast buffer is transferred in parallel to the slow buffer. This transfer operation its done P times on each stage.

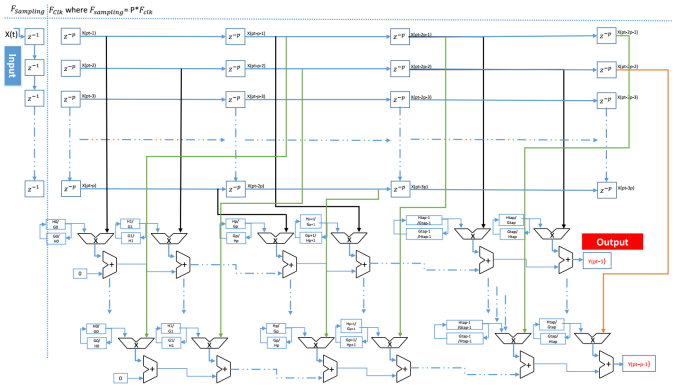

Figure 8. Architecture of a single modified FIR filter

Actually, we used those two signals "$enable_k$" *and* "$transfer_k$" allowing P-times on each stage to combine the down-sampling ($2\downarrow$) and to synchronize (sample selection/ordering) output data on stage (k-1) with input data on stage (k), because we respect the same samples in the original Mallat tree. In this new scheme, the output of all the related stage filters are stored together in the fast buffer (and hence in the slow buffer too) in an interleaved ordered disposition. Only half of the samples can be transferred from the fast to the slow buffer on each 2^k cycles as the buffers size is only half the number of samples being feed to the fast buffer during the same period of time. Furthermore, each sample flowing out from the fast buffer must be presented twice to the next stage in order to be processed by both the $H(z)$ and $G(z)$ sets of coefficients. This is granted by the low rate of the slow buffer. A control unit is used also like that used in figure 5 to manage different stage, and the interleaved on every stage called "$Control_block$". "$Control_block$" used to provides the "$enable_k$" and "$transfer_k$" signals to the related K stage.

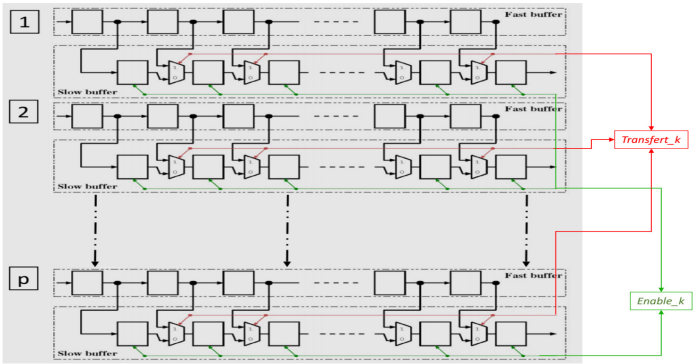

Figure 9. Structure of the buffers in stage k

4.1. Results and performances

The prove of the potential of our architecture isn't stop in the parallel features but also this architecture is fully configurable, so at synthesis the implementation structure diagram have implemented under four parameter: parallel degree (rate of parallelism), tree depth (number of tree levels), the order of the filters and the filter coefficient quantization. We presented the real hardware implementation of our architecture onto Altera 5CGXFC9E6F35C7 FPGA belonging to Cyclone V family with a speed grade of –7 and we have synthesized it by using Altera Quartus prime lite edition. The compilation results of clock frequency and area consumption for different values of the configuration parameters, i. e. Tree depth, Filter order, Coefficient quantization (in number of bits) will presented in table 1 and table 2 of two different parallel degree. In those table, design parameters are presented as a 3-tuple $(depth, order, quantization)$. *Clock frequency* is given in MHz is directly related to input sampling rate (half the clock frequency). Resource usage is given as a 2-tuple (l_e, l_r) where l_e stands for logic elements and l_r for logic registers.

Although the highest rate of our architecture isn't required any memory or DSP block. All results of implementation 4, 8 and 16 parallel DWPT is presented in Table 3, 4 and 5 respectively.

Table 3. Implementation results of 4-parallel DWPT

Design parameters	Clock frequency	Resource usage

Table 6. Comparison of proposed architectures with existing DWPT architectures

4.2. Comparison: our architecture VS other work

In section III, we pare presented the potential of our first architecture of DWPT with the optimized HDL tools. In fact, that gave us strength to go far to propose a novel very fast, configurable, and P-parallel-pipeline a generic architecture of DWPT transform for all discrete wavelet family. To improve, the performance of these architectures, we must compare the obtained results with other recent works.

In table 6, we compared our proposed architectures with several DWPT transform designs achieved in literature. Well, a quantitative and comprehensive comparative of the most published of DWPT architectures are provides. This table present clearly the high frequency of our architecture with the other one and the full flexibility in all design parameters. Additionally, our architecture was implemented without used memory and present unlimited quantization or depth order, and they are suitable for all wavelet family (where the wavelet family are simplify by the filters orders).

5. Conclusion

We proposed a novel Discrete Wavelet Packet Transform (DWPT) architecture based on Mallat tree concept, by using a FIR filter banc. We have implemented unparalleled and P-parallel, very fast, and reconfigurable DWPT in VHDL-RTL model. We proposed also a P-Parallel architecture of modified direct FIR filter.

The final results indicate that it can efficiently increase the equivalent rate with reduced hardware resource consumption. And implement high-speed filtering, which cannot be achieved by the traditional Mallat tree or serial transformation. The architectures are fully configurable at synthesis in respect to P-parallel degree, depth (number of tree stages), filter order and filter coefficient quantization (generic parameters in the VHDL-RTL model). Filter coefficients are loaded dynamically during operation (after synthesis), providing high operational flexibility. The parallel model and also parallel direct FIR filter can be widely applied to various occasions where high-speed digital transformations are required. An FPGA Cyclone V the clock frequency is operational at 125MHz, after synthetized compiling we obtained 718.13MHz clock frequency of 2 level DWPT transform (order filter 2 and order of quantization 5) and intermediate level of parallelizing i.e. 16.

Conflict of Interest

The authors declare no conflict of interest.

Transformer Condition

ABSTRACT

A3S(Arwin-Adang-Aciek-Sembiring) is a method of information fusion at a single observation and OMA3S(Observation Multi-time A3S) is a method of information fusion for time-series data. This paper proposes OMA3S-based Cognitive Artificial-Intelligence method for interpreting Transformer Condition, which is calculated based on maintenance data from Indonesia National Electric Company (PLN). First, the proposed method is tested using the previously published data, and then followed by implementation on maintenance data. Maintenance data are fused to obtain part condition, and part conditions are fused to obtain transformer condition. Result shows proposed method is valid for DGA fault identification with the average accuracy of 91.1%. The proposed method not only can interpret the major fault, it can also identify the minor fault occurring along with the major fault, allowing early warning feature. Result also shows part conditions can be interpreted using information fusion on maintenance data, and the transformer condition can be interpreted using information fusion on part conditions. The future works on this research is to gather more data, to elaborate more factors to be fused, and to design a cognitive processor that can be used to implement this concept of intelligent instrumentation.

1. Introduction

In the earlier paper [1], transformer condition is used to estimate its end of life using instant data. In this paper, transformer condition is calculated using maintenance data from Indonesia Electric Company (PLN) and is interpreted using Cognitive-Artificial method. Each factor influencing the same component is assumed to have the same weight in the condition calculation. The condition is then interpreted to provide early warning system for the potential failure and to estimate the transformer end of life.

There are no single conventional method of transformer diagnosis can be used to define transformer condition accurately. Usually there are several methods combined to perform such a task. These methods are very expert-dependant and are not formulated. Therefore, an automated method for transformer condition monitoring is proposed. Using Cognitive-Artificial-Intelligence (CAI) method, the transformer condition interpretation can be accurately performed, and the expert-dependency can be reduced as well.

2. Transformer Condition Component

Transformer condition can be calculated using some factors. These factors are shown in Figure 1 [2].

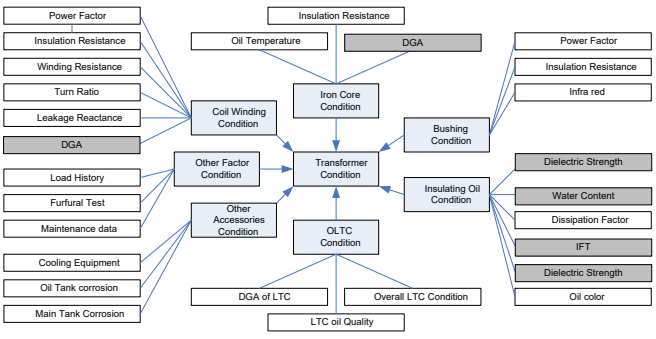

Figure 1 Transformer Condition Factors [2]

Email: adangsahmad@yahoo.com.

Data are collected from PLN and fused to obtain part conditions, part conditions are then fused to obtain transformer condition. Figure 2 explains how transformers degrade over time.

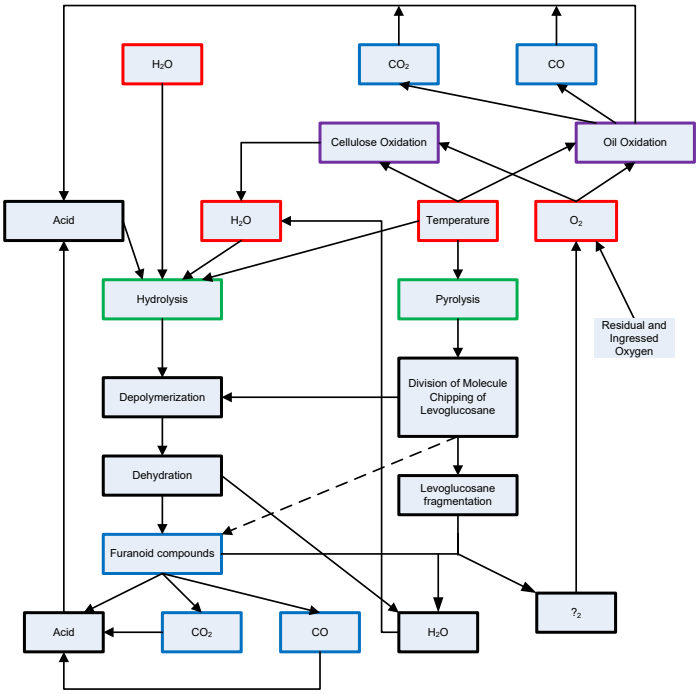

Figure 2 Transformer Degradation Diagram [3]

There are two main processes of the transformer degradation process, hydrolysis and pyrolysis. Hydrolysis is related to water, while pyrolysis is related to fire. The main cause of hydrolysis is water, acids and temperature causes hydrolysis as well. Pyrolysis is caused by temperature [3].

Hydrolysis causes depolymerization of transformer insulating system, and later produces furanoid compounds, which produces carbon dioxide and carbon monoxide, which is the main cause of acids [3]. Acid will then cause hydrolysis.

Pyrolysis causes levoglucosane fragmentation, which produces diatomic oxygen. Oxygen is the cause of oxidation in cellulose and oil, which leads to hydrolysis [3]. These two degradation processes and the compounds they produce makes the transformer degradation processes accelerate over time. The impact of diatomic oxygen will be discussed in Load Tap Changer.

3. The Mathematical Model of Arwin-Adang-Aciek-Sembiring (A3S) [4]

How knowledge grows in the system can be described using Figure 2 [4, 5]. There are two main parts of Knowledge-Growing System. The upper part of Figure 3 contains Information Fusion, while the lower part of the diagram contains knowledge fusion.

The system receives multi-source information from sensors and performs information fusion. When the information exceeds certain level of desirable Degree of Certainty, the information will be considered as knowledge.

The knowledge will be fused with the existing knowledge in the knowledge part of the system to obtain new knowledge and is stored. When the new knowledge exceeds certain level of DoC, it will become the ultimate knowledge.

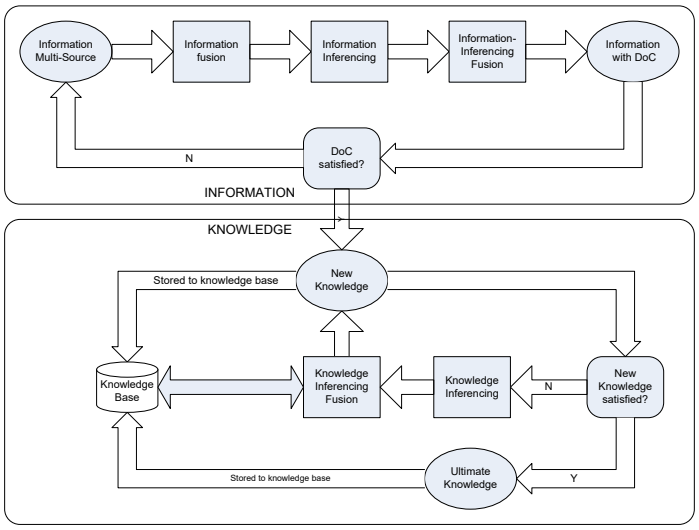

Figure 3 Knowledge-Growing System [5]

A3S (Arwin-Adang-Aciek-Sembiring) algorithm [5] is information fusion algorithm based on Bayesian Inference Method. When a problem occurs, the system collects information and fuses them to produce new knowledge. A3S starts with (1).

$$P\left(B_j \middle| A_i\right) = \sum_{i=1}^{n} \left(\frac{P\left(A_i \middle| B_j\right) P\left(B_j\right)}{\sum_{k=1}^{m} P\left(A_i \middle| B_k\right) P\left(B_k\right)} \right) \tag{1}$$

Where $P\left(B_j \middle| A_i\right)$ is the probability of B_j is true given the presence of the fusion or combination of all events A_i [4]. Maximum A Posteriori (MAP) is determined by (2)

$$P\left(B_j \underset{\max}{\boxplus} A_i\right)_{estimate} = \max_j \left(\frac{P\left(B_j \middle| A_i\right)}{n} \right) \tag{2}$$

It is then simplified to become (3)

$$P\left(\psi_1^j\right) = \frac{\sum_{i=1}^{\delta} P\left(\upsilon_i^j\right)}{\delta} \tag{3}$$

Where $P\left(\psi_i^j\right)$ will be the New Knowledge Probability Distribution (NKPD) at a certain observation time γ_1 [4]. The new knowledge will be obtained by applying (4).

$$P\left(\psi_1^j\right)_{estimate} = \max\left(\left[P\left(\psi_1^j\right)\right]\right) \tag{4}$$

The system will keep collecting information (NKPD) on each observation, $P(\psi_1^j)$, …, $P(\psi_\gamma^j)$, …, $P(\psi_\Gamma^j)$ [4]. The inferencing can be determined using (5).

$$P(\phi_\gamma^j)=\begin{cases}1, & P(\psi_\gamma^j)>\dfrac{P(\psi_\gamma^j)}{\lambda}\\ 0, & P(\psi_\gamma^j)\le\dfrac{P(\psi_\gamma^j)}{\lambda}\end{cases} \quad (5)$$

Where $P(\phi_\gamma^j)$ is inferencing of each information to the knowledge distribution.

Information-inferencing fusion will be calculated using OMA3S method, a dynamic version of A3S resulting NKPD over Time (NKPDT) [4].

$$P(\theta_j)=\frac{\sum_{\chi=1}^{\Gamma}P(\phi_\gamma^j)}{\Gamma} \quad (6)$$

$$P(\theta)_{estimate}=\max\left[P(\theta_j)\right] \quad (7)$$

4. Transformer condition calculation

System's block diagram is shown in Figure 4.

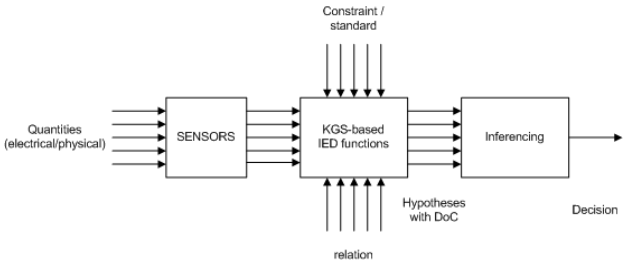

Figure 4 System's block diagram

Data is collected using sensors and is compared to standards and relation. The system fills the observation table using (1). After each observation, there will be new knowledge shown by New Knowledge Probability Distribution (NKPD). Each NKPD is fused with the previous NKPD to produce NKPD over time (NKPDT). Decisions are made based on NKPDT.

There are two kinds of faults in transformers. They are electrical faults and thermal faults [9]. Electrical faults are Partial Discharge, Low-Energy Discharge, and High Energy Discharge, while thermal faults are Thermal-Low and Thermal-High [9]. The proposed method is tested using previously published DGA dataset, which is classified based on the identified fault [9]. Table 1 shows Partial Discharge dataset, Table 2 shows Low-Energy Discharge, Table 3 shows High-Energy Discharge, Table 4 shows Thermal-Low, and Table 5 shows High-Energy Discharge.

In order to analyze the DGA, there are several ratios required, they are [5]:

$$R_1 = [CH_4]/[H_2] \quad (6)$$

$$R_2 = [C_2H_2]/[C_2H_4] \quad (7)$$

$$R_5 = [C_2H_4]/[C_2H_6] \quad (8)$$

These ratios are put into groups based on Table 6.

Table 6 Gas Ratio grouping [9].

	R2	R1	R5
< 0.1	0	1	0
0.1 - 1.0	1	0	0
1.0 - 3.0	1	2	1
> 3	2	2	2

Estimated faults can be determined using the rules shown in Table 7 [9].

Table 7 Gas Ratio grouping [9].

No.	Characteristic Fault	R2	R1	R5
0	No fault	0	0	0
1	Partial Discharge	0 or 1	1	0
2	Low-Energy Discharge	1 or 2	0	1 or 2
3	High-Energy Discharge	1	0	2
4	Thermal-Low	0	0 or 2	0 or 1
5	Thermal-High	0	2	2

Datasets are made into Ratios and are put into groups as shown in Table 8 to Table 12.

2.35	0.03	3.90	2	0	2

Ratio Groups are arranged into observation table as shown in Table 13 to Table 17 where:

- H_PD: Hypothesis Partial Discharge.
- H_LE: Hypothesis Low-Energy Discharge.
- H_HE: Hypothesis High-Energy Discharge.
- H_TL: Hypothesis Thermal-Low.
- H_TH: Hypothesis Thermal-High.

Table 13 Observation: Partial Discharge.

Nth Obs.	sensors	Range Group	hypotheses

0.00	0.36	0.19	0.08	0.36
0.00	0.36	0.19	0.08	0.36

Table 19 shows hypothesis H_LE has the highest value of Degree of Certainty (DoC) on nine out of nine samples with most of them showing other hypothesis with significant DoC.

Table 20 NKPD: High-Energy Discharge.

H_PD	H_LE	H_HE	H_TL	H_TH
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19
0.11	0.31	0.31	0.08	0.19

Table 20 shows hypothesis H_HE has the highest value of Degree of Certainty (DoC) on nine out of nine samples with all of them showing significant H_LE and other hypothesis with less significant DoC.

Table 21 NKPD: Thermal-Low.

H_PD	H_LE	H_HE	H_TL	H_TH
0.11	0.11	0.00	0.61	0.17
0.00	0.11	0.11	0.67	0.11
0.11	0.11	0.00	0.78	0.00
0.11	0.11	0.11	0.67	0.00
0.00	0.11	0.11	0.67	0.11
0.00	0.00	0.00	1.00	0.00
0.11	0.11	0.00	0.78	0.00
0.00	0.19	0.19	0.42	0.19
0.22	0.31	0.19	0.19	0.08

Table 21 shows hypothesis H_TL has the highest value of Degree of Certainty (DoC) on eight out of nine samples with some of them showing other hypotheses with less significant DoC.

Table 22 NKPD: Thermal-High.

H_PD	H_LE	H_HE	H_TL	H_TH
0.08	0.08	0.00	0.42	0.42
0.00	0.11	0.11	0.33	0.44
0.00	0.11	0.11	0.33	0.44
0.00	0.11	0.11	0.33	0.44
0.08	0.08	0.00	0.42	0.42
0.11	0.22	0.22	0.17	0.28
0.00	0.11	0.11	0.33	0.44
0.11	0.33	0.33	0.11	0.11
0.00	0.11	0.11	0.33	0.44

Table 22 shows hypothesis H_TH has the highest value of Degree of Certainty (DoC) on eight out of nine samples with all of them showing other hypotheses with significant DoC.

The overall accuracy of A3S algorithm is 91.1% as shown in Table 23.

Table 23 NKPD: Thermal-High.

Fault Identification	Accuracy (%)
Partial Discharge	77.8
Low-Energy Discharge	100
High-Energy Discharge	100
Thermal Low	88.9
Thermal-High	88.9
Average	**91.1**

The algorithm is then used to calculate transformer condition and make interpretation of the calculated condition based on DGA data. The condition of a transformer depends on several factors. In this research, the condition is calculated is based on DGA data. Table 24 shows Dissolved Gas Analysis (DGA) data collected from PLN and Table 25 shows other quantities included in transformer condition factors.

Table 24 DGA data

	gas concentration (ppm)

1692	68
1882	75
2034	66
2203	77
2315	84
2316	84

The total condition can be drawn in form of Figure 5.

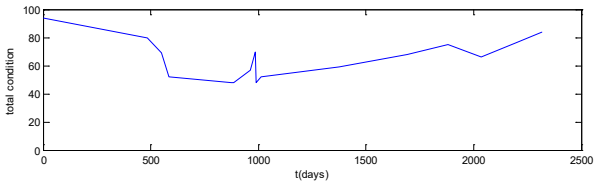

Figure 5 Condition curve

At first, transformer condition has high value, as time passes, it decreases due to the degradation process. The degradation process produces gases, acid, water, which accelerate the degradation process.

There is a sudden increase in condition and then followed by a sudden decrease, this is probably caused by the maintenance process and the setting process after maintenance. After maintenance, the condition began to increase with small gradient.

The gradient of condition is shown in Figure 6.

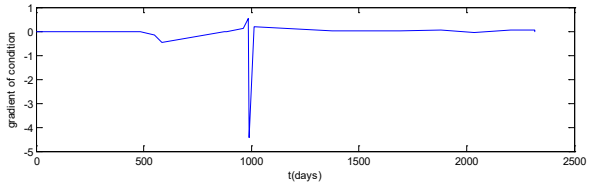

Figure 6 Gradient of condition

The gradient of condition depends on condition. In general, it is relatively stable. There is a sudden decrease at day 990 and then followed by sudden increase.

The observation table is shown in Table 29.

Table 29 Observation table

t (days)	cond	gradient	SC	SG	NKPD	
					HW	HL
0	94	0.0000	1	0	1	1
486	80	-0.0305	1	0	1	1
551	69	-0.1709	1	1	0	1
586	52	-0.4762	1	1	1	0
873	48	-0.0129	0	0	1	1
884	48	0.0000	0	0	1	1
961	57	0.1203	1	1	1	0
985	70	0.5401	1	1	0	1
990	48	-4.4444	0	1	1	0
1011	52	0.1764	1	1	1	0
1374	59	0.0204	1	0	1	1
1692	68	0.0277	1	0	1	1
1882	76	0.0390	1	0	1	1
2034	66	-0.0624	1	1	1	1
2203	77	0.0657	1	1	1	1
2315	85	0.0661	1	1	1	1
2316	85	0.0000	1	0	1	1

Where:

- Cond: condition of the transformer
- Gradient: condition change over time
- SC: cond, after compared to standard
- SG: gradient, after compared to standard

NKPD is knowledge of the system at each time of observation. To obtain knowledge growth, NKPD is fused with the previous NKPD, in this case, NKPD from the beginning of observation. This process produced NKPD over time (NKPDT)

Knowledge growth is represented by NKPDT can be calculated using (6) and is shown in Table 30. Knowledge growth can also be represented using Figure 7.

Table 30 NKPDT

t (days)	NKPD	
	HW	HL
0	0.5000	0.5000
486	0.5000	0.5000
551	0.3333	0.6667

2316	0.2941	0.7059

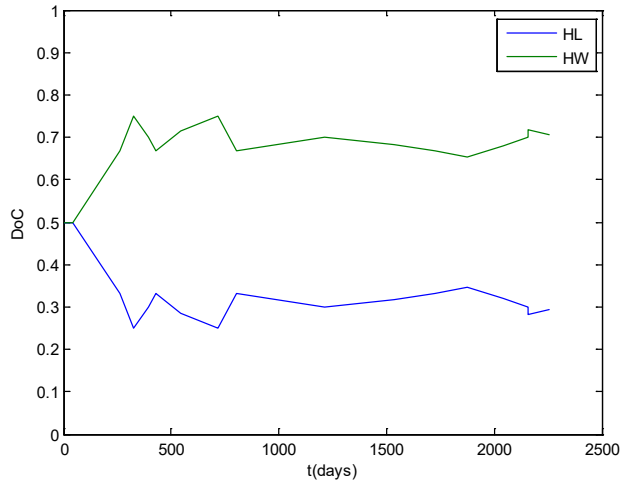

Figure 7 Hypotheses/Knowledge growth

Where HL shows Hypothesis-Life and HW shows Hypothesis-Warning. Both hypotheses show the same value at the first observation. As time passes, HW increases, while HL decreases. It indicates that the transformer condition is in the limit and there are some changes in the gradient. The positive gradient shows maintenance, while negative condition shows degradation.

Spikes in Figure 7 shows there is an occurrence of a phenomenon indicating a hypothesis. In this case, there is a change in gradient of condition, making it in a warning condition. As gradient is dependent to condition, the hypothesis HW is dependent to HL as well.

5. Concluding Remarks

A3S has successfully interpreted DGA data to identified fault based on the classified dataset. It has successfully identified not only the main fault, which has the most significant DoC. It has successfully identified the fault(s) occurred along with the main fault, which has less significant of DoC. This feature acts as the early warning system.

OMA3S has successfully interpreted transformer condition by fusing the parameter Condition (SC) and Gradient (SG) to produce Hypothesis-Life (HL) and Hypothesis-Warning (HW). HL and HW both are fused with the previous values to obtain knowledge growth.

In the next research, more parameters will be included and elaborated to increase accuracy. The number of hypothesis will be added as well to reduce the direct impact of the change of one hypothesis to the other when using only two hypotheses.

This algorithm will be implemented in form of a processor called cognitive processor. Using a special purposes processor will have advantages, such as energy efficiency and minimize disturbance caused by electromagnetic transmission.

Conflict of Interest

Hereby, The authors would like to declares that this article “Cognitive Artificial Intelligence Method for Interpreting Transformer Condition Based on Maintenance Data“ is an original work of our research group and has no conflict of interests.

Acknowledgment

The first author would like to appreciate Yokeu Wibisana for the maintenance data and Harry Gumilang of PLN for the discussion and information provided.

A B S T R A C T

A functional near-infrared spectroscopy (fNIRS) can be employed to investigate brain activation by measuring the absorption of near-infrared light through the intact skull. The general linear model (GLM) as a standard model for fMRI analysis has been applied to functional near-infrared spectroscopic (fNIRS) imaging analysis as well. The GLM has drawback of failure in fNIRS signals, when they have drift globally. Wavelet based detrending technique is very popular to correct the baseline drift (BD) in fNIRS. However, this method globally distorted the total multi-channel signals even if just one channel's signal was locally drifted. This paper suggests the selective detrending method using BD detection index to indicate BD as an objective index. The experiments show the performance of the proposed method as graphic results and objective evaluation index with current detrending algorithms.

1. Introduction

A functional near-infrared spectroscopy (fNIRS) can detect regional cerebral blood flow (rCBF) variations through the absorption changes of the near-infrared light at wavelengths between 650–950 nm [1, 2]. fNIRS has important advantages of low cost, portability, and the ability to extend research to young children and within more ecological environments [3]. fNIRS shows similar results to blood-oxygenation-level-dependent (BOLD) outputs of fMRI for same cortical regions and fNIRS also has quite similar cortical activation with fMRI from same BOLD signal [4]. fNIRS analysis has been to adapt well-established methods optimized for fMRI such as statistical parameter mapping (SPM) based on the general linear model (GLM) [5]. However, there is noises, the GLM often fails to find cortical activations. During NIRS measurements, the noises are accrued various reasons, such as subject movement, blood pressure variation, and instrumental instability. When subjects move, the fNIRS optodes may shift relative to the head and alter the coupling between the optodes and scalp, and this results in an artifact that abruptly changes, potentially inducing spikes with amplitude much larger than the true signal [6]. These issues can generate system noise, baseline drift (BD), and baseline jumping in fNIRS signals. Especially, the BD is a very important component which can generate errors of brain activation detection. In order to eliminate the BD high-pass filtering is usually used. However, the frequency response of the hemodynamic response can also be affected during high-pass filtering [8]. To overcome this problem, there were many studies that apply a wavelet-based detrending algorithm. They have good performance of detrending and adjusting baseline. However, they have a problem that cannot distinguish between an increase of fNIRS signal by blood flow and BD at single task stimuli.

This paper suggests a new selective detrending method using BD detection index. The proposed method included the BD detection method using an objective index which use an increase-to-decrease ratio of the fNIRS signal trend. According to the BD detection index, the baseline drifted channels are detected and detrended.

2. Theory and Method

2.1. General Linear Model for fNIRS

In general, most analysis of functional hemodynamic changes in neuroimaging such as fNIRS and fMRI is based on an assumption of the linear addition of hemodynamic changes. The GLM has been used as a standard analyzing method for fNIRS signal analysis, and statistical parametric mapping (SPM) [9] is widely used programs based on the GLM. The GLM describes an

*Corresponding Author: Jinung An, Convergence Research Center for Wellness, Daegu Gyeongbuk Institute of Science and Technology, 42988, Korea
Email: robot@dgist.ac.kr

expression of the noisy oxy-hemoglobin signal in terms of a linear combination of L explanatory variables and each error terms:

$$y_{HbO}(r,t) = x_1(t)\beta_1 + \cdots + x_L(t)\beta_L + \varepsilon_{HbO}(r,t), \quad (1)$$

where β_i denotes an unknown strength of response, and $x_i(t)$ is an explanatory variable from a model of hemodynamic responses [10]. Let y and ε denote the vector of the time series of the hemodynamic signal and noise at the location r:

$$\mathbf{y} = [y_{HbO}(r,t_1) y_{HbO}(r,t_2) \cdots y_{HbO}(r,t_N)]^T, \quad (2)$$

$$\boldsymbol{\varepsilon} = [\varepsilon_{HbO}(r,t_1) \varepsilon_{HbO}(r,t_2) \cdots \varepsilon_{HbO}(r,t_N)]^T. \quad (3)$$

The corresponding GLM model is represented by a matrix form as follows:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\varepsilon}, \quad (4)$$

where $\mathbf{y}$ is an N-dimensional column vector, $\boldsymbol{\varepsilon}$ is error vector, and $\boldsymbol{\beta}$ is L-dimensional column vector that represented from unknown strengths of the response.

2.2. Modifed GLM with Baseline Drift

When there exist BD of a signal, the GLM often fails in the fNIRS measurements [11]. In a novel detrending algorithm for fNIRS, the BD is included as part of the GLM:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\varepsilon} + \theta, \quad (5)$$

where θ is additional global BD. According to the modified Beer-Lambert law (MBLL), the change of the noisy measured optical density (OD) data is described by the following matrix formulation for fNIRS:

$$\begin{bmatrix} \Delta OD(r,t;\lambda_1) \\ \Delta OD(r,t;\lambda 2) \end{bmatrix} = d(r)l(r) \begin{bmatrix} a_1(\lambda_1) & a_2(\lambda_1) \\ a_1(\lambda_2) & a_2(\lambda_2) \end{bmatrix} \begin{bmatrix} \Delta c_{HbO}(r,t) \\ \Delta c_{HbR}(r,t) \end{bmatrix} + \begin{bmatrix} w(r,t;\lambda_1) \\ w(r,t;\lambda 2) \end{bmatrix} + \begin{bmatrix} \widetilde{\theta}(r,t;\lambda_1) \\ \widetilde{\theta}(r,t;\lambda 2) \end{bmatrix}, \quad (6)$$

Where $d(r)$ is differential path length factor (DPF) and $l(r)$ is distance between the sources to detector at position r. $a_i(\lambda_i)$ is the extinction coefficient of the i'th chromophore at wavelength (λ). $\widetilde{\theta}(r,t;\lambda_i)$ denotes the global trend for wavelength (λ_i) at the location r. Let $\mathbf{y}_{HbO}$, $\boldsymbol{\varepsilon}_{HbO}$, and $\boldsymbol{\theta}_{HbO}$ denote vectors of the oxy-hemodynamic response signal, noise signal, and global trend signal. The modified GLM is represented for fNIRS as follows:

$$\mathbf{y}_{HbO} = \mathbf{X}_{HbO}\boldsymbol{\beta}_{HbO} + \boldsymbol{\varepsilon}_{HbO} + \boldsymbol{\theta}_{HbO}. \quad (7)$$

2.3. Proposed Selective Detrending Method

The measured oxy-hemodynamic noisy signal (ŷ) can be represented by time-channel form as follows:

$$\hat{\mathbf{y}}(t,c) = \begin{bmatrix} y(t_1,c_1) & y(t_2,c_1) & \cdots & y(t_L,c_1) \\ y(t_1,c_2) & y(t_2,c_2) & \cdots & y(t_L,c_2) \\ \vdots & \vdots & \ddots & \vdots \\ y(t_1,c_N) & y(t_2,c_N) & \cdots & y(t_L,c_N) \end{bmatrix}, \quad (8)$$

where L is length of acquisition time, c is acquisition channel, and N is number of channel from NIRS signal acquisition system.

On the other hands, wavelet transform is widely used in various signal processing because it is very efficient and powerful for frequency analysis of a signal. In this paper, the measured oxy-hemodynamic noisy signal (ŷ) is decomposed using modified wavelet transform based on Daubechies6 wavelet basis. The modified wavelet transform consist of 11 level tree and 12 sub-bands of the wavelet coefficient. The decomposed oxy-hemodynamic noisy signal (wjŷ(t,c)) is the wavelet coefficient of the j'th level at time (t) and channel (c), and it can be expressed in 3-demensional matrix as follows:

$$w^j\hat{\mathbf{y}}(t,c) = \begin{bmatrix} w^1\hat{\mathbf{y}}(t,c) \\ w^2\hat{\mathbf{y}}(t,c) \\ \vdots \\ w^{11}\hat{\mathbf{y}}(t,c) \end{bmatrix}. \quad (9)$$

The wavelet coefficient of the 6th level (w6ŷ) is well represented on the signal trend of hemodynamic response, and the 11th level (w11ŷ) is represented on the signal slope of the global baseline. The BD generates a difference between length of increase sections and decrease sections. Using the difference of the wavelet coefficients, we calculate a new index for the BD detection. Let γ+ is increase and γ- decrease length of the wavelet coefficient of the 6th level (w6ŷ):

$$\gamma^+ = \int diff[w^6\hat{\mathbf{y}}]^+, \quad \gamma^- = \int diff[w^6\hat{\mathbf{y}}]^-, \quad (10)$$

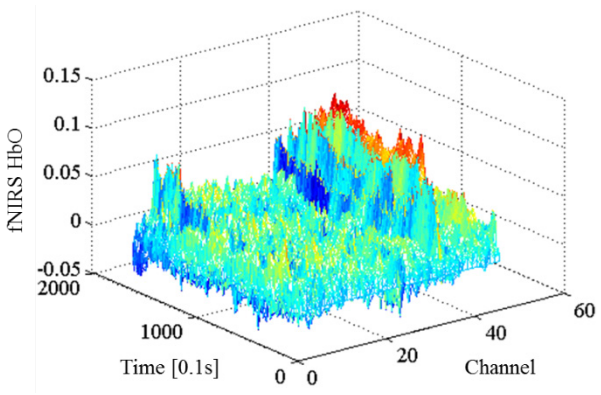
where diff[w6ŷ]+ is a positive differential value of w6ŷ, and [w6ŷ]- is negative differential value of w6ŷ. The BD index (BI) defined as follows:

$$BI(c) = \frac{\gamma^+}{\gamma^-} \cdot \sum_{i=1}^{L} [w^{11}(i,c) - w^{11}(i-1,c)], \quad (11)$$

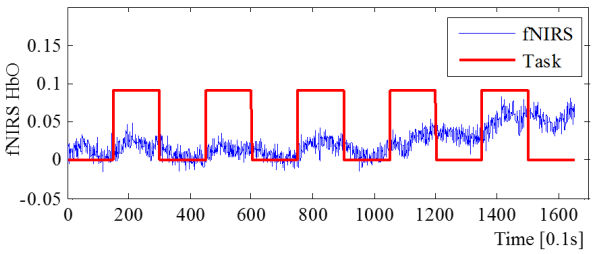
here, BI(c) objectively indicates a degree of the BD for each measured channels. And then, the detrending process is selectively performed depending on a BD threshold, and it is determined by abrupt increase changing point on sorted channel. If an index (BI) of some channels have high values, the detrending process of the fNIRS signals of the channels are selectively performed using wavelet-MDL (minimum description length) [10].

3. Experimental Result

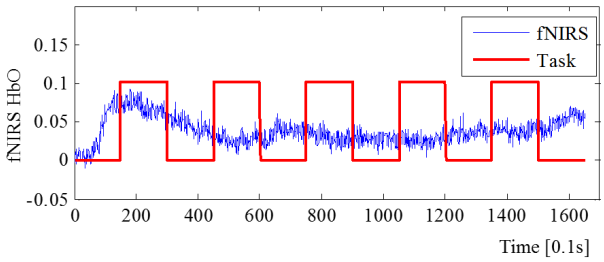
The fNIRS data were obtained by fNIRS brain imaging system (FOIRE-3000, Shimadzu, Japan) at 10 Hz sampling frequency. All of data were approved by the Institutional Review Board (IRB) at Daegu Gyeongbuk Institute of Science & Technology (DGIST). To perform experiment of the proposed BD index, a subject who is right-handed without known neurological, physical illness participated. Fig. 1 shows the task-dependant test data 1 which is obtained from general motions of upper-limb rehabilitation in a block design (5 repetitions with 15s task and 15s rest). BD can be found in channel 6, 33, and 43 in Fig. 1 (a). Oxy-hemoglobin (HbO) signals for the selected channels are shown in Fig. 1 (b)-(d).



(a)



(b)



(c)

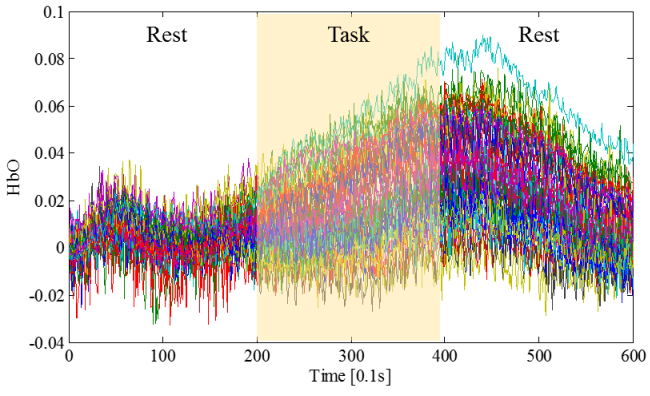
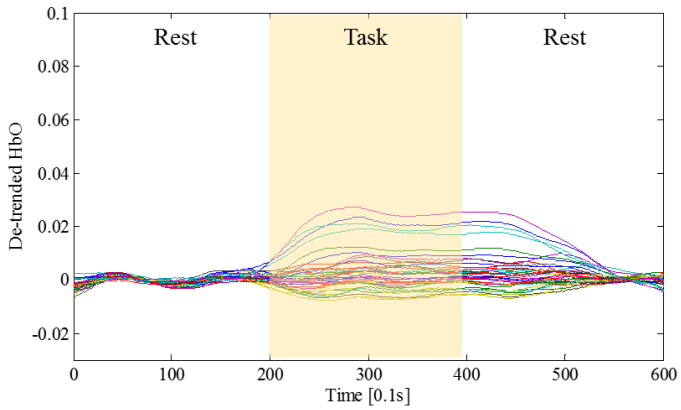
Figure 2. BD detection result from test data 1, (a) *BI* on sorted channel, (b) fNIRS signal on each channels, and (c) the result of BD detection.

To evaluate the proposed BI, the result of BD detection is presented in Fig. 2. The change of BI on sorted channel and a threshold of BD are shown in Fig. 2 (a). As can be seen Fig. 2 (b) and (c), the BI of channel 6, 33, 36, 42, and 43 have more high score than the threshold, and baseline drifted channels for detrending can be detected.

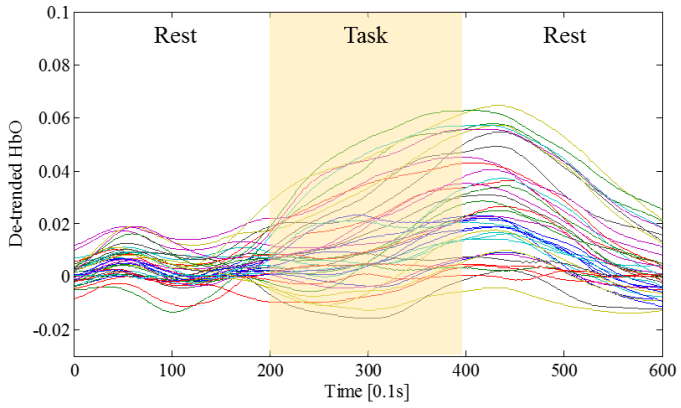
The obtained fNIRS signal is analysed by HRF (hemodynamic response function) smoothind and wavelet-MDL. HRF smoothing and wavelet-MDL have good performance for denoising and detrending, and the detrending of wavelet-MDL can adjust BD. However, wavelet-MDL can often distort a NIRS signal at a specific experimental environment of only single task stimuli. The graphical results of fNIRS detrending are shown in Fig 3 to compare with wavelet-MDL. In order to evaluation performance of the detrending, task-dependant test data 2 that is obtained from general walking motions in a block design (1 repetitions with 20 s task and 20 s rest)



(a)



(b)



(c)

Figure 3. Detrending of test data 2, (a) the measured original fNIRS signals, (b) the result of detrended fNIRS signal using HRF smoothing and wavelet-MDL, and (c) the result of detrended using proposed method.

Fig. 3 (a) is the measured original fNIRS signals of 40 channels which measured on a whole brain. (b) shows the result of detrended fNIRS signal using HRF smoothing and wavelet-MDL on all channels, and can be confirmed that it has too much signal distortion to compare with Fig. 3 (a). However, Fig. 4 (b) shows the result of detrended fNIRS signal using proposed selective detrending method, it keeps original characteristic and hemodynamic response of fNIRS signals on Fig. 3 (a).

In order to evaluate performances of the algorithms, the contrast-to-noise ratio (CNR) is used to the fNIRS signals. If large difference of each part and small variation of one part, the CNR has high value. The CNR indicate that the higher CNR value of fNIRS signal, the better performance of the algorithm. Table 1 shows detailed CNR of real measured whole brain fNIRS signals of 40 channels that used on Fig. 3.

Table 1 The performance of fNIRS detrending obtained using CNR.

		Original	Wavelet-MDL	The proposed method
CNR (dB)	Measured noise	0.231	0.128	0.327
Improvement rate		-	55 %	142 %

As can be see Table 1, the proposed method has high CNR than both of the original fNIRS signal and the wavelet-MDL. Moreover, wavelet-MDL has low CNR than the original signal because of the signal distortion. It shows that the proposed method has a better detrending performance than conventional algorithm on the task-oriented fNIRS signals.

4. Conclusions

This paper dealt with detrending of globally drifted fNIRS signal. The baseline drift detection method was suggested to selectively extract the drifted fNIRS channels by quantifying objective indicator of baseline drift. It was determined by quantitatively manipulating wavelet coefficients based on a stability of the baseline. The proposed detrending highly performed the identification of selective drifted channels and enhancement of fNIRS singal. This method will be carried out in advance of global detrending of fNIRS signals for enhancing quality of task-dependant fNIRS signal post-processing including neuro-cortical mapping, brain signal decoding, etc. The autonomous optimal baseline index determination and following noise elimination should be further discussed.

Ethical Approval

This study was reviewed and approved by the institutional review board at the Ethics Committee of Daegu Gyeongbuk Institute of Science & Technology (DGIST_151211_HR-020-06).

ABSTRACT

In this paper, we propose a novel control method for autonomous-odor-source localization using visual and odor sensing by micro air vehicles (MAVs). Our method is based on biomimetics, which enable highly autonomous localization. Our method does not need any instruction signals, including even global positioning system (GPS) signals. An experimenter simply blows a whistle, and the MAV will then start to hover, to seek an odor source, and to keep hovering near the source. The GPS-signal-free control based on visual sense enables indoor/underground use. Moreover, the MAV is light-weight (85 grams) and does not cause harm to others even if it accidentally falls. Experiments conducted in the real world were successful in enabling odor source localization using the MAV with a bio-inspired searching method. The distance error of the localization was 63 cm, more accurate than the target distance of 120 cm for individual identification. Our odor source localization is the first step to a proof of concept for a danger warning system. These localization experiments were the first step to a proof of concept for a danger warning system to enable a safer and more secure society.

1. Introduction

As the performance of sensors is improved and as the internet of things (IoT) is expanded, new social systems utilizing sensors are being designed to improve safety and security. Although odor sensing is one of the most important kinds of information for living things, the sensitivity of gas sensors in the past could not come close to that of a living thing, such as dogs, which can respond to a parts-per-trillion (ppt) odor [1]. Gas sensors with parts-per-quadrillion (ppq) sensitivity have been reported [2]. As gas sensors are improved, new safety systems and disease-detection systems are being designed using gas sensors [2, 3].

This paper is an extension of work originally presented in 2016 23rd International Conference on Mechatronics and Machine Vision in Practice (M2VIP 2016) [4]. We challenged to discover issues and consider countermeasures for constructing a danger warning system to enable a safer and more secure system utilizing autonomous odor source localization by experiments. The results of the experiments were mainly presented in the previous paper.

Micro air vehicles (MAVs) are promising carriers of gas sensor devices in safety systems because these vehicles can move quickly enough to chase dubious characters and fly over pedestrians without any interference. In safety systems, plural MAVs will work in a coordinated manner and communicate with other systems such as security cameras and audience guide systems. If a MAV detects danger, the MAVs will give a warning of the danger using an alarm bell and/or notification to other security systems to call a security guard. While the MAVs need a lot of information, central control computer and network performance is limited. To enable robust control in complex situations, an autonomous-MAV-control system is required. Therefore, we studied autonomous-MAV control.

Odor source localization has been studied widely for detecting explosives, for narcotics control, and for detecting gas leaks to ensure social safety and security [5–12]. Odor source localization using MAVs is a challenging task due to the non-uniform dispersion of odor, low sensitivity of commercially-available-gas sensors, and constraints of MAVs. Odor from its source is moved by the wind and is divided into many odor filaments. Localizing the source by following the concentration gradient of odor is difficult. In addition, MAV control is difficult due to unstable flight performance, low performance cameras for self-localization,

small payload, and limited flight time. Therefore, a robust control method for odor source localization is needed. Many algorithms for odor source localization have been proposed. The first algorithm uses geometric control such as spiral patterns [6]. The second one is based on Bayesian inference theory [8]. The third mimics biological models such as cells [14], bacteria [9], insects [15], moths [10, 11], and ants [12]. Insects and animals use their olfactory senses with ingenuity for collecting food, avoiding enemies, and finding mates [10]. In this study, a bio-inspired algorithm, specifically a bacterium model, was utilized to achieve stable odor source localization in difficult circumstances. We thought that simple and effective control of bacterium model is valid as the first step in biomimetic control for odor source localization.

In addition, mobile robots—including MAVs—must have a self-localization method so that they can determine their position with respect to known locations in the environment in order to navigate effectively and to reach the goal region. For self-localization, two methods have been proposed. One is vision-based control, and the other is global positioning system (GPS) based control [5]. The safety system has applicability to large facilities, such as sports stadiums, stations—including underground train stations—and airports. The aforementioned places may be out of reach of the GPS-based control. Therefore, we selected a method that is GPS signal free and that has vision-based self-localization. This approach enhances the independence of the MAV.

2. Micro-Air-Vehicle Platform

2.1. Micro Air Vehicles

The Phenox 2 (Phenox Lab, referred to as MAV in this article) MAVs were selected because they are light-weight, they have high computing performance for vision-based self-localization, and they can be extended by attaching odor sensors and enabling control program flexibility [13, 16]. Figure 1 shows the Phenox 2, which flies using four electric motors and has a diameter of 176 mm. The specifications of the MAVs are summarized in Table I. The light-weight MAVs were designed so as not to cause harm to others even if they accidentally fall. One of them weighs 85 grams, including the odor sensor module, LiPo battery, and propeller guard. In some countries, there are regulations for drone whose weight is above standard (e.g. 200 grams in Japan). The MAV is lighter than the standard and easy to use. The controller chip is Zynq 7000 (Xilinx, XC7Z010), which consists of FPGA and dual-core CPUs. The FPGA conducts fast image processing for controlling self-positioning. The CPUs are Cortex-A9 667 MHz dual-core CPUs based on the ARM architecture. One CPU (CPU1) is used for real-time operation such as low-level-flight control. The other (CPU0) runs an odor-source-localization program written in C language on the Ubuntu/Linux OS. 256 MB DDR3 memory and a 4 GB microSD card are mounted on the MAV for working memory and storage.

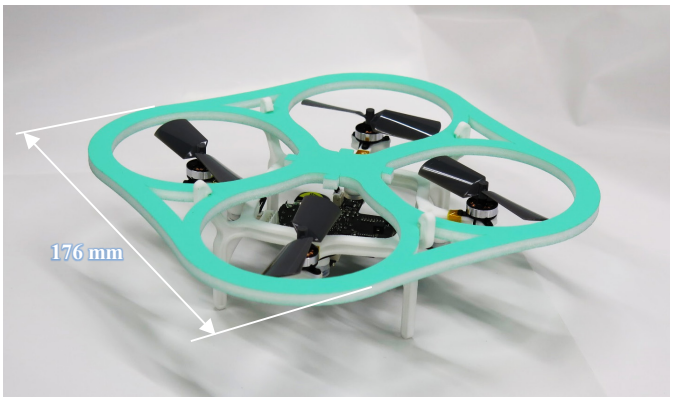

Figure 1. Photograph of the MAVs.

Table I. Specifications of the MAV

MAV name	Phenox 2
Developer by	Phenox Lab
Microprocessor	Xilinx Zynq XC7Z010 (Dual core Cortex-A9 processer + FPGA)
Camera	CMOS Image Sensor (320×240)

The flight control relies on cameras, an onboard inertial measurement unit (IMU, 9-DOF), range sensor, microphone, and gas sensor. The front and bottom cameras are CMOS cameras with 320×240 pixels, respectively. In this experiments, we use only bottom camera. The IMU consists of a three-axis accelerometer and a three-axis rotation rate sensor. In addition, a sonar sensor is used to control the altitude of the MAV. The MAV has a mounted microphone that receives a 3 kHz whistle signal blown by the experimenter. Communication is established using a Wi-Fi to send flight logs to the ground station. The MAV supports I^2C communication to extend the hardware capabilities. We used I^2C communication to connect to an odor sensor module board.

Figure 2 shows a block diagram of the MAV. The bottom camera mounted on the MAV collects image data. The front camera is unused for controlling the MAV. The FPGA conducts image processing of feature point detection based on the FAST algorithm [13, 20] and feature point description based on the BRIEF algorithm [21]. CPU1 calculates the *current position* based on the feature points for self-localization, and it notifies CPU0 of the *current positio*n. CPU0 determines the *target position* based on

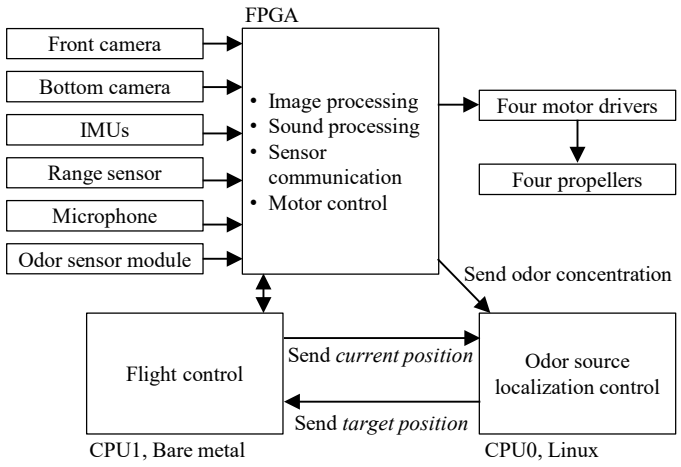

Figure 2. Block diagram of MAV control system based on vision and odor sensing.

the *current position* and current odor concentration, and it notifies CPU1 of the *target position*. CPU1 calculates the parameters of the four motor drivers based on the *current position*, the *target position*, and information on the IMUs and range sensor. The FPGA controls the motor drivers to enable propellers to move the MAV.

2.2. Odor sensor module board

The odor sensor module board was designed for light-weight, low-power consumption. A photograph of the odor sensor module is shown in Figure 3. The gas sensor (Figaro Engineering, TGS8100) converts the concentration of odor to the current magnitude. We selected a MEMS-type gas sensor, which makes the sensor small and light-weight and enables it to have low-power consumption. A constant voltage is applied to the gas sensor. If hydrogen or alcohol is present, the resistance of the gas sensor is reduced, and the current flows more. For example, the current magnitude of 10 ppm ethanol is five times higher than that of clean air. The sensitivity of the commercially-available gas sensor is much lower than the nose of living things. For example, dogs can respond to a parts-per-trillion (ppt) odor [2]. Light-weight odor sensor modules with low-power consumption were fabricated

The analog front-end (Texas Instruments, LMP91000) converts the current magnitude to voltage magnitude. The analog-digital converter (Texas Instruments, ADS1100) converts the voltage magnitude to a digital signal and transmits to MAV's CPU through the I/O. The I/O consists of four pins. Two pins are used for I^2C communication. The other two pins are used for a voltage supply at 3.3 volts. The linear regulator (Texas Instruments, LP5907MFX-1.8) converts the supply voltage (3.3 volts) to voltage for the heater of a gas sensor (1.8 volt).

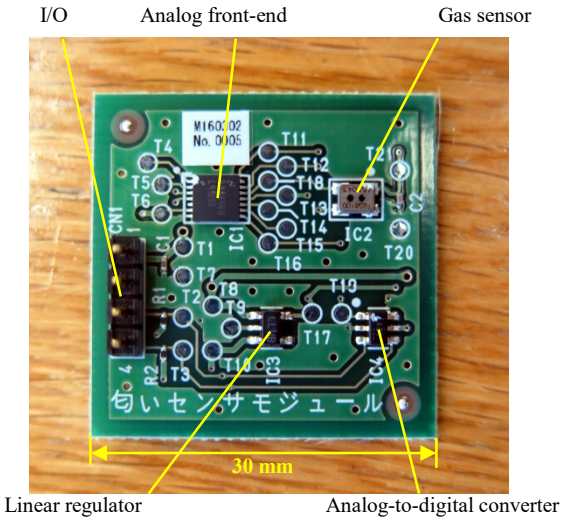

Figure 3. Photograph of odor sensor module.

If the odor concentration increases, the magnitude of the current flow in the gas sensor and the output voltage of the analog front-end increase. Threshold output voltage V_T for deciding how to finish the odor source localization is determined as follows:

$$V_T = V_I + 0.7 \text{ mV} \quad (1)$$

Initial voltage V_I was measured at the start of the experiment; namely, the V_I means the voltage of the clean air.

2.3. MAV arena

Reproducible experimental conditions are required to compare different odor source localization methods. Figure 4 shows a real-

Figure 4. Real MAV arena used for the experiments.

world experiment that was carried out in a 7 × 12 m training room without special lighting. A fabric (Asahi Kasei, Bemcot) sprayed with ethanol for disinfection (ethanol 76.9–81.4% v/v) was set on the top of a light stand as the odor source. Plural markers 30 cm in diameter were put into place to help the image feature extraction and to stabilize flight.

The MAV was placed on the floor at a position 1.8 m away from the odor source. Two external cameras were set outside of the arena. One camera with a fisheye lens was placed on the floor to take a movie. After the experiment, the trajectory of the flight was calculated. Another camera with a normal lens was set on a tripod to take a movie of the experiment. No signals were sent to the MAV for controlling it.

3. Bio-Inspired-Search Algorithm

3.1. Algorithm

We utilized a bio-inspired algorithm, specifically a bacterium model, to achieve stable odor source localization in difficult circumstances due to the limited power of the MAV's onboard computer, the low image quality of the camera, and the low sensitivity of the gas sensor.

The cells undergo chemotaxis to get close to acceptable circumstances [19]. Some bacteria, such as E. coli, have several flagella, which can rotate in two ways. One is counter-clockwise (CCW) rotation, which aligns the flagella into a single rotating bundle, causing the bacterium to swim in a straight line (Straight swim). The other is clockwise (CW) rotation that breaks the flagella bundle apart, causing the bacterium to tumble in place (Tumbling). The chemotaxis is controlled by switching the rotation depending on the concentration gradient.

Figure 5 shows a pseudocode of the firmware for controlling the MAV. At the start of the experiment, the MAV was placed on the floor. The MAV started its takeoff after recognizing the whistle signal blown by the experimenter (pseudocode line 1). The cruising altitude was controlled to 1.2 m. After the whistle, the MAV flew autonomously, and the experimenter did not control the MAV. In addition, the MAV did not receive any external control signals, including a GPS signal. Next, the MAV hovered for eight seconds (line 2 and 3), and measured the initial odor concentration based on the output value of the analog-digital converter. The initial odor concentration determined the threshold odor concentration for finishing the odor source localization.

Also, the MAV randomly decided the *traveling direction* (line 5) from 360° to start odor source localization. If the odor concentration was less than the threshold, the processes of lines 7 to 23 were repeated. In these processes, the *target positions* were updated based on the *traveling direction*. The value of *Speed* was constant. Next, the MAV measured the odor concentration (line 9). If the odor concentration decreased (line 10), the MAV turned back with a probability of 20% (lines 11–15) (tumbling). However, if the odor concentration did not decrease, the MAV went forward (lines 16-19) (straight swim). Please note that the *traveling direction* made a small change with a probability of 5% (line 17). If the MAV became likely to fly out of the arena based on self-position localization using onboard camera and onboard CPUs, the MAV changed the *traveling direction* (line 20, 21) randomly from 180°. The size of the arena was limited to 400×700 pixels in the MAV camera, which corresponds to about 3×6 m in real space. The MAV was controlled to travel to the *target position* (line 22).

```
1  MAV waits for the whistle
2  MAV hovers
3  MAV waits 8 seconds
4  MAV measures the initial odor concentration
5  traveling direction ← random
6  while (Concentration of odor is lower than threshold)
7      target_x_position += Speed * Sin(traveling direction)
8      target_y_position += Speed * Cos(traveling direction)
9      MAV gets odor concentration
10     if (Concentration of odor decreased)
11         // Tumbling
12                 if (random < 20%)
13             // Go backward
14             traveling direction += 135º–225º
15     else
16         // Straight swim
17         if (random < 5%)
18             // Change pathway
19             traveling direction += -45º–45º
20     if (MAV_position == outside)
21         traveling direction ← random
22     lead MAV to (target_x_position, target_y_position)
23     MAV waits 80 msec
24 MAV continues hovering
```

Figure 5. Pseudocode of MAV firmware to detect odor source.

These processes were repeated every 80 ms (line 23). If the odor concentration exceeded the threshold, the MAV continued hovering in the position (line 24), and notified the experimenter that the MAV found the odor source. The *flight time* was defined as the search time duration from finishing the initial hovering in eight seconds to starting the hovering near the odor source.

3.2. Comparison in simulation

The bio-inspired algorithm and random-walk algorithms for MAV's control were compared in a simulation. The time required for odor source localization varied significantly and randomly. Therefore, many trials were required for studying the algorithms. Computer simulations, enabling results to be obtained in a short time, were useful.

In the simulation, the flight area of the MAV was 5×5 m, and the speed was 0.4 m/s. The distance between the MAV and the odor source was set to 1.8 m. We assumed the MAV could detect an odor concentration within 150 cm of the odor source and that the device succeeded in the odor source localization if it approached within 63 cm of the odor source. These values of the distances were determined experimentally.

The bio-inspired algorithm is shown in Figure 5. The random-walk algorithm is based on the bio-inspired algorithm excluding the "Go backward" process (tumble in place). A total of 19 trials were conducted for each algorithm.

The simulation results are shown in Figure 6. The results show the search time based on the bio-inspired algorithm was shorter. The median time required for odor source localization was 17 seconds in the bio-inspired algorithm and 36 seconds in the random-walk algorithm, respectively. The search time based on the bio-inspired algorithm was as much as 47% shorter than that based on the random-walk algorithm. The efficient bio-inspired algorithm was utilized for a real-robot search using the MAV.

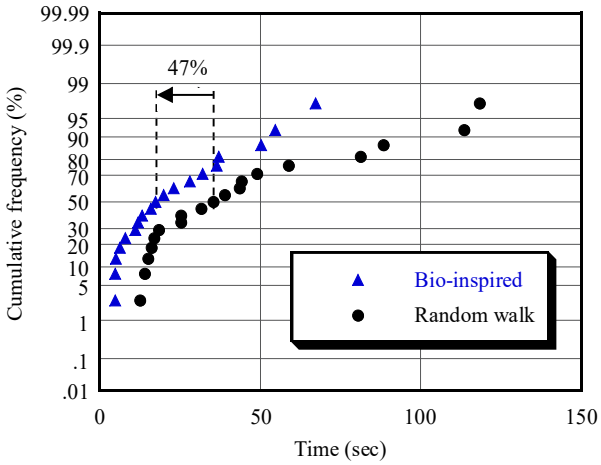

Figure 6. Simulation results of odor-source-localization time based on the control of bio-inspired algorithm and random-walk algorithm.

4. Results

The results of the experiments are shown in Table II. In the four experiments, the MAV succeeded in finding the odor source. In the 5th experiments, the MAV flied away from arena. The median distance of the MAV from the odor source was 63 cm. The median *flight time* required for searching the odor source was 35 seconds.

The results of the first trial are described in detail using Figures 7 to 9. The trajectory of the MAV is shown in Figure 7. The *actual position* was calculated using the recorded movie taken by the external camera with fisheye lens. The MAV took off from the placed position with various inclination angles due to deviation from the center of gravity in the MAV. The start position shows the position in which search began after taking off and hovering for 8 seconds. The MAV moved from position 1→2→3→4→5 and hovered, which shows that the MAV found the odor source. Figure 8 shows the time variation in the trajectory of the MAV. From 8.2 to 15.5 seconds, the MAV flew over the horizon of the external camera. Figures 8-(c) and (d) show the *target position* set by the MAV autonomously and the *current position* recognized by the MAV. At 5.7 seconds, the MAV finished hovering and started to search for the odor source.

Table II. Experiment results for odor source localization

# of trials	Distance from odor source to MAV's goal (cm)	Flight time (sec)
1	73	34
2	42	36
3	79	29
4	53	77
5	Fly away from arena	
Median	63	35

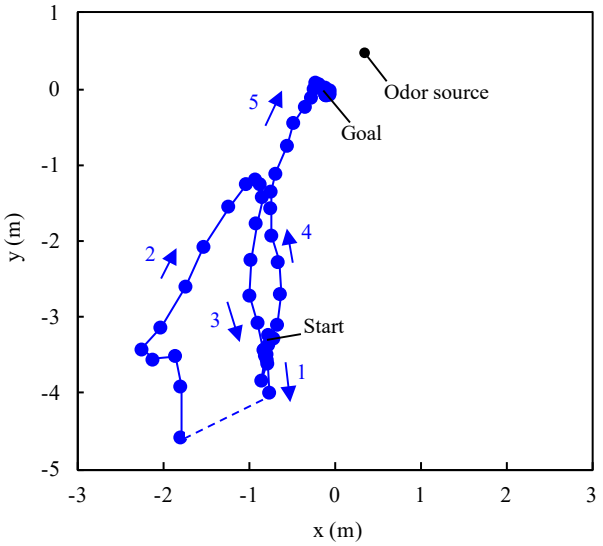

Figure 7. MAV flight trajectory. The *actual position* of the MAV was determined using the external camera.

Figure 8 shows the *actual position*, *target position*, and *current position*. The *actual position* in Figure 8-(a) and (b) was calculated from the footage taken by the external camera. The *target position* and *current position* in Figure 8-(c) and (d) were logged by the MAV. Figure 8 shows that the *actual position*, *target positio*n, and *current position* were attuned to each other.

Figure 9 shows the variation in time of the output voltage of the analog front-end, which indicates the odor concentration. The initial voltage V_I at the start of the odor source localization, namely the voltage of the clean air, was 919.3 mV. Therefore, the threshold voltage V_T for finishing the search was set to 920.0 mV. Figure 9 shows the time of the MAV turn. The MAV operated the change pathway three times and the go backward three times. At 40.2 seconds, the output voltage exceeded the threshold voltage V_T and notified the MAV to finish searching and started hovering.

The deviation distance of 63 cm means this localization method can achieve personal identification because the distance was lower than the personal space of 120 cm [17]. Most people feel discomfort, annoyance, or some level of anxiety when someone or something else encroaches on their personal space. In addition, the deviation distance allows for people to escape from danger found by a MAV. Our results are the first step towards improving social safety and security systems. The reasons for the deviation between the odor source and the position specified by the MAV can be stated as follows: (1) Odor diffusion by the wind; (2) A searching algorithm that terminates the search if the odor concentration exceeds a threshold and does not find the position with highest odor concentration; and (3) Utilization of a proportional and derivative (PD) control method that excludes integration (I) control.

In this experiment, the deviation between the *target position* and *current position*, which depends on the *travelling direction*, was observed. For example, Figure 8-(d) shows that if *target position* y was larger than the *current position* y, the deviation increased. The reason is that the estimated center of gravity in the MAV is located behind the ideal position, i.e., the device is weight biased. Therefore, forward moving, which decreases the *current position*, is slower than backward moving.

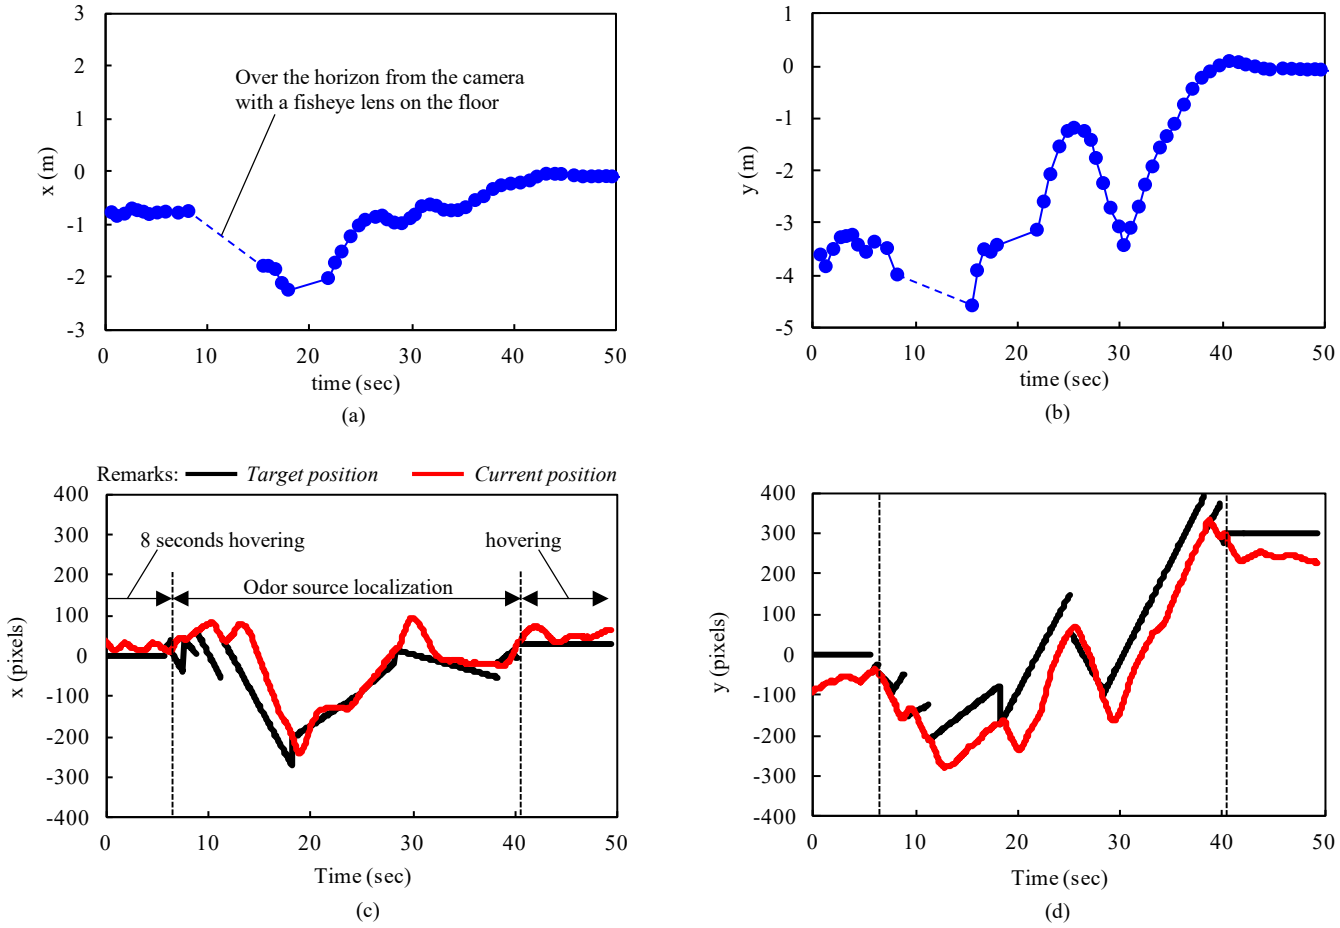

Figure 8. x/y MAV flight paths. The *actual position* of the (a) and (b) was determined using the external camera. The *current position* of (c) and (d) was calculated and logged by onboard CPU using the onboard camera. The *target position* of (c) and (d) was determined and logged by the onboard CPU.

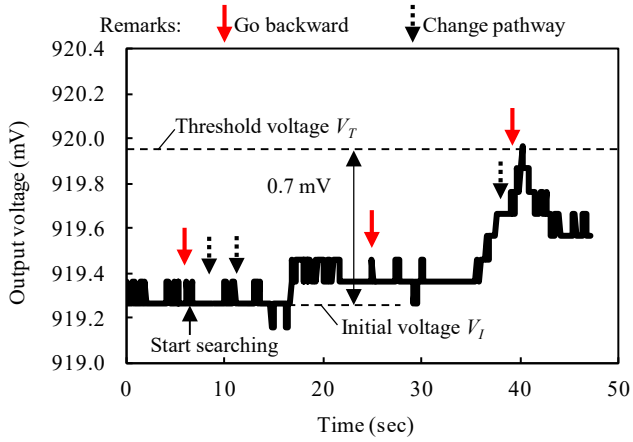

Figure 9. Time – output voltage plot. The odor concentration was measured by the gas sensor and converted to the output voltage using the analog front-end.

The search time in the real-MAV-experiment results was longer than that in the simulation results. The reason for that was presumed to be the simulation assuming that the velocity of the MAV was constant, whereas the real-MAV-experiment took sufficient time to turn around due to the PD control.

5. Discussion

The issues obtained by this experiment for constructing a danger warning system to enable a safer and more secure society with MAVs are summarizes below:

- Vision sensing
- MAV's balancing
- Odor sensing
- Swarm control

In the vision sensing, we used the markers. In the actual safety system, the markers often blocked by pedestrians. Therefore, more robust self-positioning method will be required. Dynamic detection method of crowd was reported [22]. In addition, the 5th experiment was failed by flying away from arena. This reason was the MAV lost the self-positioning estimation. The arena was illuminated by a strong afternoon sun. The bottom camera did not take photo of marker. The sun is thought to have disturbed photography of the pattern of the marker by the bottom camera of the MAV. Therefore, cameras with a larger dynamic range are required. A CMOS imaging array with wide dynamic range pixels was proposed [23]. It is necessary to examine the control method of the wide dynamic range camera for the MAVs.

In the MAV's balancing, the MAV was attached self-produced odor sensor module and adjusted the balance by battery position. However, it was difficult to achieve a balance it as if the speed was different depending on the direction of movement. Therefore, improvement in exercise performance of MAVs is required.

In the odor sensing, the size of the arena was 7 × 12 m. In the actual system, the size will be much larger (e.g. 100,000 square meters in sports stadium). Therefore, ultra-sensitive odor sensors will be required. Gas sensors with parts-per-quadrillion (ppq) sensitivity have been reported [3].

In the swarm control, in large covered areas without any omission and robust exploration, swarm flight will be required.

In the future, we will improve the location accuracy of the odor source localization using person recognition and increase the amount of information collected to enable MAVs to search for suspects using their built-in cameras [18].

6. Conclusion

Localization of odor source using a MAV with vision and gas sensing was achieved. The MAV used vision and odor localization with ingenuity and succeeded in localizing odor sources like living things can. Our approach does not even require GPS-based control. The location accuracy of odor source localization based on a bio-inspired localization method was 63 cm, enabling individual identification. The MAV was controlled with highly autonomously. An experimenter just blows a whistle, and the MAV starts to hover, to seek odor sources, and to keep hovering during flight near the odor source. The MAV is light-weight and does not cause harm to others even if it accidentally falls. These localization experiments were the first step to a proof of concept for a danger warning system. These results will be applied to the system to enable a safer and more secure society.

ABSTRACT

Conformal metalization on mold compound offers new possibility for IC package design to improve features such as rigidization of the flexible core, heat sink capability, 3D-circuit patterning and the electromagnetic interference (EMI) shielding. With the unique processes, the fabrication technology had enabled to achieve the high reliable performance and had passed the electrical test. Following research after the reliability concern, this paper further study the shielding effectiveness of varying coating thickness with respect to laboratory simulated EMI condition, using radio frequency from 10MHz to 5.8 GHz. Different metal namely pure nickel, nickel-phosphorous and pure plated copper are studied for their effectiveness of EMI sheilding. Our first result showed over 35-40dB of shielding effectiveness is achievable on high frequency 868-5800MHz. Nevertheless on low frequency of 10MHz, the shielding effectiveness achievement is below than 25dB. To overcome the shielding need for lower frequency, we further expanded our test by choosing ferromagentic material Nicke/Ironl-alloy in combination with thick copper plating. With this new metal combination, EMI shielding effectiveness for lower frequency is improved to 40dB.

1. Introduction

This paper is an extension of work originally presented in conference name electromagnetic interference (EMI) Shielding Performance by Metal Plating on Mold Compound [1]. EMI shields work as isolation of components, minimizes crosstalk, and reduce EMI susceptibility without impacting system speed. Electromagnetic shielding is the practice of reducing the electromagnetic field in a space by blocking the field with barriers made of conductive or magnetic materials. To achieve good EMI shielding on integrated circuit (IC) assembly, manufacturer is switching from metal capping to other methods such as conductive painting, sputtering or chemical vapor deposition (CVD) on top of mold compound with the intention to miniaturize electronic device. Printing is an easy and fast method, however to control the thickness of the shielding layer within 50-150um is challenging; on the other hand on thin film solution , sputtering or CVD can be a better option.

Plating was not a preferred process in the past due to its difficulty in achieving good adhesion between the plated metal over the surface of a mold compound. Adhesion was greatly improved recently with the introduction of adhesion promoter developed by Atotech, which have achieved a peel strength up to 4-5N/cm complied with industrial standard of moisture sensitivivity level 1 (MSL1) and thermal cycling 1000 (TC1000) [2]. Plating approach offers lower cost solution, ease of thickness control on thin layer (1-10um), and more important, provides uniform coating coverage on all the surfaces of a mold compound with a thickness variation of <20% regardless of the shape, even on structure of high aspect ratio (Figure 1).

The inevitable trends for the circuits inside the modules are fast edge rates and high clock frequencies, which may cause significant electromagnetic interference (EMI) and radio frequency interference (RFI) problems. Recently mobile phone manufacturers have started in applying EMI shielding technology to a variety of digital chips, radio frequency (RF), connectivity (wireless LAN, Bluetooth) chips and others that also include AP (application processor) and modems. Although the use of this

* Corresponding Author: Min Fee Tai, Atotech (M) Sdn Bhd, Malaysia
Email: mftai@yahoo.com

technology on printed circuit boards (PCB) and connectors is not novel, however it is the first time whereby the application of plating technology is extended to most of the major chips [3]. The decision to use this technology stems from interference in wireless communication. The use of that fabrication technology for others components such as those with sensitive clock signals of digital chips have also increasing recently. EMI shielding by metal plating is an important measure to improve device performance whilst decreasing electromagnetic interference to major chips and to relieve consumer fear of electromagnetic waves from smartphones. As EMI is an increasingly important source of unreliable functionality of all electronic technologies, EMI is rapidly becoming a major functional safety issue. Malfunctions caused by EMI in safety-related electronics can lead to serious safety risks for people or the environment in general as well as financial risks for manufacturers and service providers [4].

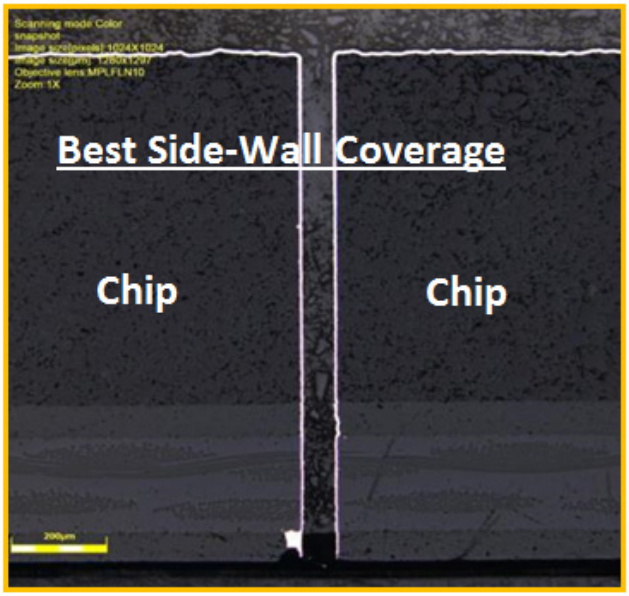

Figure 1: Excellent Throwing Power of Coating by Plating Technology.

Figure 2 shows the process flow of plating on mold compound which is proposed by Atotech's standard process. Theoretically, shielding effectiveness of a material is contributed from three main loss mechanisms: reflection, absorption, and multi-reflection. When an incident wave travels to the shielding material, it is partially reflected with a portion of the wave penetrating into the material. The penetrated wave can propagate inside the material and get attenuated due to the absorption of the material. Once the remaining transmitted wave arrives at the other surface of the shielding material, the second reflection occurs and the wave gets bounced back, resulting in multiple reflections between the two surfaces of the shielding material.

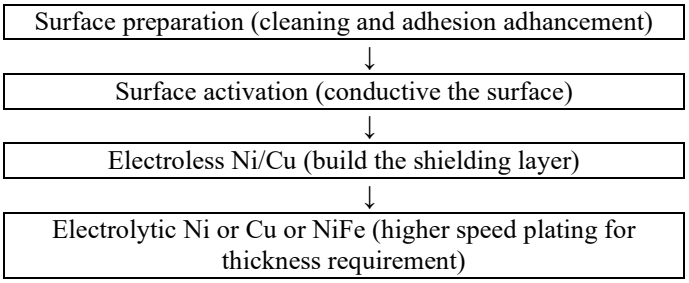

Figure 2: Process Flow of Plating on Mold Compound Shielding Effectiveness

Due to the fact that the wave is attenuated to $1/e$ at one skin depth, the multi-reflection loss can be ignored for the cases where the shielding thickness is much larger than the skin depth. In summary, the shielding effectiveness in dB, SE_{dB} is expressed in equation 1,

$$SE_{dB} = R_{dB} + A_{dB} + M_{dB}, \qquad (1)$$

where R_{dB} is the reflection loss, A_{dB} is the absorption loss, and M_{dB} is the multi-reflection loss. Equation is further explained by Figure 3 [5].

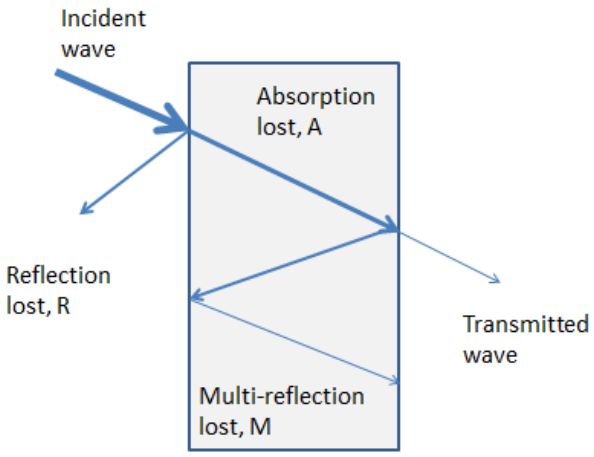

Figure 3: Electromagnetic Shielding Schematic Diagram

The reflection loss is

$$R = 20log_{10}\left|\frac{(Z_0+Z_1)^2}{4Z_0Z_1}\right| \qquad (2)$$

where Z_0 represents the wave impedance of air and Z_1 represents the wave impedance of the metal sheet. As

$$Z_1 \approx \sqrt{\frac{\mu_1\omega}{\sigma_1}}(1+j) \ll Z_0 = 120\pi\omega \qquad (3)$$

$\mu_1$and σ_1 are the relative permeability and conductivity of the metal sheet, respectively, formula (2) can be estimated as

$$R = 20log_{10}\left|\frac{Z_0}{4Z_1}\right| = 20log_{10}\left|\frac{30\pi}{1+j}\right|\sqrt{\frac{\sigma_1}{\mu_1\omega}} \qquad (4)$$

The reflection loss is directly proportional to the conductivity of the metal sheet but inversely proportional to the relative permeability of the metal sheet.

The absorption loss is

$$A = 20log_{10}e^{\frac{L}{\delta}} \qquad (5)$$

where L is the thickness of the metal sheet and

$$\delta = \sqrt{\frac{2}{\mu_1\omega\sigma_1}} \qquad (6)$$

is the skin depth. Formula (5) can be estimated as

$$A = 20log_{10}e^{\sqrt{\frac{\mu_1\omega\sigma_1}{2}}L} \qquad (7)$$

The absorption loss is directly proportional to the thickness, conductivity and relative permeability of the metal sheet.

The multi-reflection loss is

$$B = 20log_{10}\left|1 - \frac{(Z_0 - Z_1)^2}{(Z_0 + Z_1)^2} e^{-2(1+j)\frac{L}{\delta}}\right| \quad (8)$$

As Z>>Z1, formula (8) can be estimated as

$$B = 20log_{10}\left|1 - e^{-2(1+j)\frac{L}{\delta}}\right| \quad (9)$$

If the thickness of the metal sheet is much larger than skin depth, incident wave will be attenuated significantly so that the multi-reflection loss will be negligible [6].

The EM shielding capability of a shield is escribed as shielding effectiveness, *SE*, which is defined as the ratio of the electric fields and magnetic field at a point without and with the shield as equation 10a and 10b,

$$SE = 20log_{10}\frac{E_1}{E_0} \quad (10a)$$

$$SE = 20log_{10}\frac{H_1}{H_0} \quad (10b)$$

where E_1, H_1 is the electrical and magnetic field at an arbitrary point without the shield, and E_2, H_2 is the electrical and magnetic field at the same point with the shield [7].

The shielding effectiveness value depends on the shielding material, its thickness, size of the shielded volume, grounding structures, and the frequency of interest.

2. Preparation of Test

In order to investigate the performance of metal plating on EMI sheilding, test matrixes are prepared with electrolytic plated nickel (pure nickel), electroless plated nickel (nickel-phophorous, P at 7-10%), and pure plated copper as the shielding layer on top of mold compound. For measurement of the electromagnectic field, a copper circuit is designed with substrate material Isola IS410, whereby the spiral flow is made on top of dielectric according to the specifications of ASTM D3123 (Figure 4).

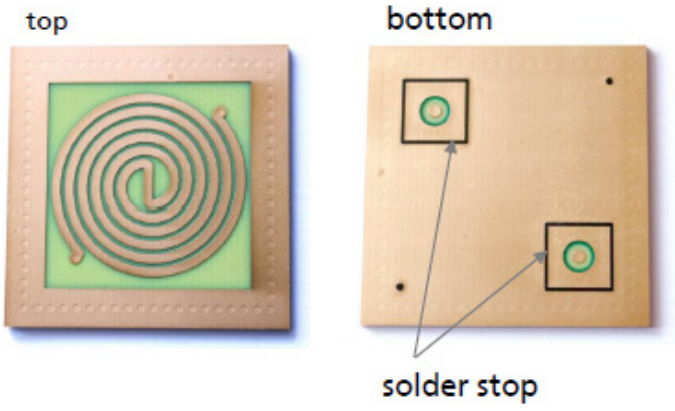

Figure 4: Spiral Circuit formed for near field EMI shielding test

Circuit is then encapsulated by mold compound Sumitomo EME_G770H Type F, with the leg connected to power input is located in opposite side of the dielectric. After that, the sample will go through the process as illustrated in Figure 5.

3. Experimental Results and Analysis

A series of samples with increasing thickness of plated Cu from lower to higher side, as indicated on Table 1 are fabricated and tested.

Table 1: Metal Thickness DOE

Material	Thickness, um
Electroless Cu	1
Electrolytic Cu	5, 10, 15

All data recorded by the plated samples with different thickness and materials is compared versus a control sample (sample without any plating on mold compound). The ratio of 2 readings is used for calculation of shielding effectiveness. Formula 10b is applied on these calculations.

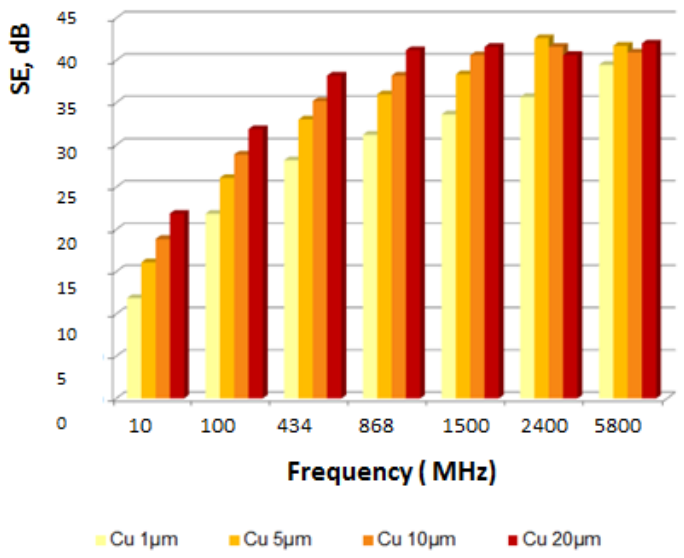

Figure 7: Shielding Effectiveness on Copper with various frequency test

On data analysis of metal shielding by copper (Figure 7), 4 samples are prepared, which are 1 um Cu sample plated by electroless Cu, 5um, 10um, 20um, samples are plated by electrolytic Cu. Higher electroless Cu thickness (> 1um) s not prepared considering its high running cost and high leadtime during mass production. Signal input with frequency 10MHz, 100 MHz, 434 MHz, 868 MHz, 1.5 GHz, 2,4 GHz, and 5.8 GHz are tested. The experimental results show that shielding performance is improved by increasing the metal thickness, especially in lower frequency (< 1 GHz). At higher frequency, 5.8 GHz, thickness of Cu shows little impact on EMI shielding effectiveness. Hence further increasing is not helping to improve shielding effectiveness (*SE*) at high frequency range.

Similar test matrix is applied with nickel, shows in Table 2. Samples with electrolytic Ni 1 um, 3 um, and 5 um; as well as electroless NiP 5um have been evaluated (5um NiP is reasonable in cost and can be plated within 25 min). Same signal input with frequency 10MHz, 100 MHz, 434 MHz, 868 MHz, 1.5 GHz, 2,4 GHz, and 5.8 GHz are applied to allowed the direct comparison. NiP is selected as matrix of study due to it is electroless process which required non conductive point. Besides, NiP with physical property of high hardness and good corrosion resistance make it suitable to be used as final surface.

Table 2: Metal Thickness DOE

Material	Thickness, um
Electroless NiP	5
Electrolytic Ni	1, 5, 10

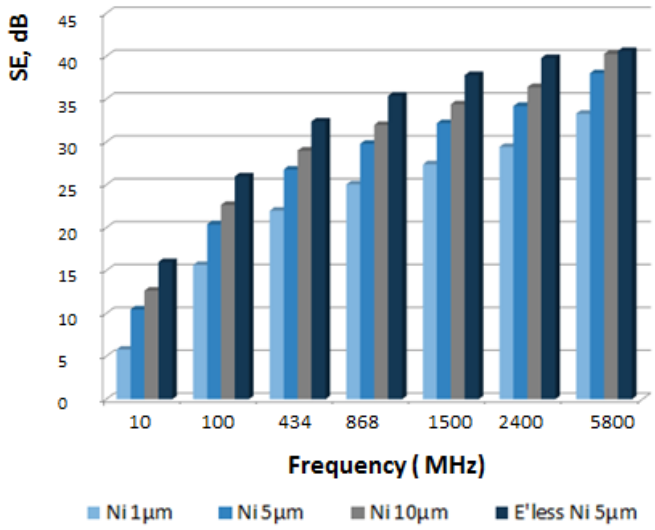

Figure 8: Shielding Effectiveness on Nickel with various frequency test

In gerenal, result from Figure 8 shows a more consistent trend for shielding effectiveness improvement over the thickness increase. Nickel alloy with phosporuos content is showing relatively better perfomance on *SE* versus pure nickel.

Comparing 1um and 5um of pure copper vs pure nickel at high frequency 5800 MHz, we see copper has higher SE (40dB) compare to nickel. As from equation 7, the absorption loss is directly proportional to the thickness, conductivity and relative permeability of the metal sheet. Electromagnetic radiation from the high frequency penetrates only at the near surface region of conductor layer. From equation 6, the skin depth, δ, decreases with increased frequency and increase conductivity and permeability. For copper, when relative conductivity, $\mu_r = 1$, and $\sigma = 5.8 \times 10^7\ \Omega^{-1}m^{-1}$, $\delta = 2.43 \times 10^{-9}$ at 5800 MHz; and for nickel, when relative conductivity, $\mu_r = 100$, and $\sigma = 1.15 \times 10^7\ \Omega^{-1}m^{-1}$, $\delta = 0.547 \times 10^{-9}$ at 5800 MH.

Table 3: Electrical conductivity relative to copper (σ_r) and relative magnectic permeability (μ_r) of selected material. [8]

Material	σ_r	μ_r	$\sigma_r\mu_r$	σ_r/μ_r
Silver	1.05	1	1.05	1.05
Copper	1	1	1	1
Gold	0.7	1	0.7	0.7
Aluminum	0.61	1	0.61	0.61
Brass	0.26	1	0.26	0.26
Bronze	0.18	1	0.18	0.18
Tin	0.15	1	0.15	0.15
Lead	0.08	1	0.08	0.08
Nickel	0.2	100	20	2×10^{-3}
Stainless steel (430)	0.02	500	10	4×10^{-5}
Mumetal (at 1 kHz)	0.03	20,000	600	1.5×10^{-6}
Superpermalloy (at 1 kHz)	0.03	100,000	3,000	3×10^{-7}

Lower frequency shows a more challenging task to shield. In copper material, a maximum 40 dB can be obtain at frequency 5.8GHz at 5um thickness, but for 10mHz, the best shielding performance is only 22 dB at 20um thickness. By taking 5 um as benchmark to compare the material performance, Ni or NiP and Cu show close SE result at 5.8 GHz; but in lower frequency mode (10MHz) Cu and NiP are performing better than pure Ni; which Cu and NiP SE is 15 dB, versus pure Ni SE at 10 dB.

Our target to fulfill industrial requirement is to achieve minimum 30dB SE for varies high and low requency applications. Higher frequency interference is normally shielded by a thin conductive metallization layer. Simple electrically conductive layers however are transparent to low frequency magnetic fields, as shown in Figure 7. This low frequency magnetic interference can be emitted from sources such as switches, motors, power supplies, and transformers and is typically a challenging EMI shielding problem. If low frequency magnetic shielding is required ,it is normally achieved through the use of special ferromagnetic metal alloys with high magnetic permeability (see Figure 9). In order to further improve the SE on lower frequency signal device (such as radio), additional Ni/Fe alloy (Ni75/Fe25 in weigh percentage) is plated on top of Cu. Ni/Fe alloy with high ferromagnetic property can improve electromagentic shielding in low frequency mode.

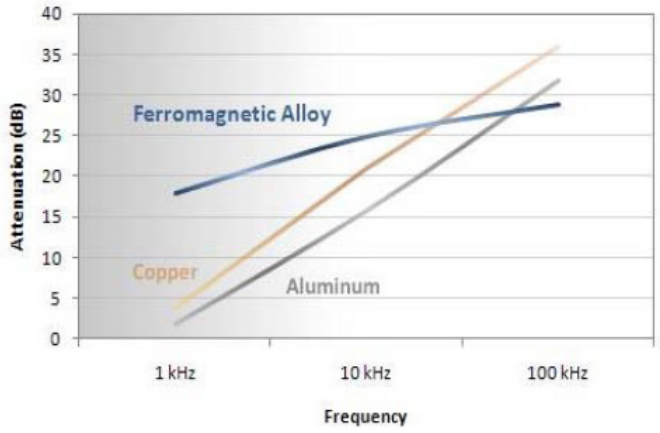

Figure 9 - Magnetic shielding ability at different frequencies [8]

Materials with high magnetic permeability protect sensitive devices from the electrical noise caused by magnetic fields by redirecting the magnetic field through the shielding material and away from the protected device. In the same way, the devices that emits low frequency magnetic fields can also be isolated through the use of materials with high magnetic permeability. [9]

Table 4: Additional Metal Thickness DOE

Matrix	Metal combination, um
1	1um electroless Cu seed + 20um Electrolytic Cu + 4um Ni/Fe
2	1um electroless Cu seed + 10um Electrolytic Cu + 4um Ni/Fe
3	1um electroless Ni seed + 10um Electrolytic Cu + 4um Ni/Fe
4	1um electroless Ni seed + 20um Electrolytic Cu + 4um Ni/Fe
5	1um electroless Ni seed + 20um Ni/Fe

New results showed that plated Cu in combination with ferromagnetic Ni/Fe gives significant improvement on shielding over low frequency signal (Figure 10). Combination of 1um electroless Cu seeding, plus 20um electrolytic Cu and with final finishing layer 4um of Ni/Fe could achieve 40dB of SE over the 10MHz wave. From the seeding method selection between electroless Cu and Electroless Ni, we notice electroless Cu gives slight better SE performance compare to electroless Ni, with around 3-4dB extra of SE. Plating 20of Cu give extra 6-7 dB SE compare to 10um Cu. Plating 20um Ni/Fe alone will give only 20dB of SE.

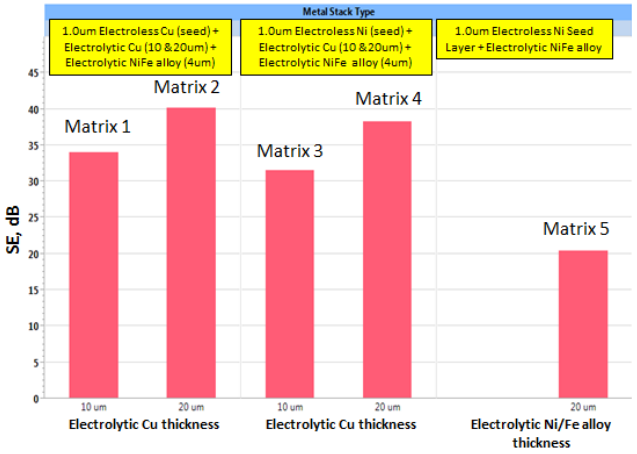

Figure 10: Shielding Effectiveness of Cu Plating combined with Ni/Fe alloy plating on Lower Frequency 10MHz

4. Conclusions

Plating on mold compound provides alternative option on EMI shielding with the proven reliability performance. The solution show features such as thin film coating capability, high throwing power in multiple dimension and high cost advantage compare to sputtering process. Selection of material and metal coating thickness are factors of EMI shielding effectiveness. Experiments show at high frequency of 5.8 GHz, shielding effectiveness as high of 35-40dB can be obtained by plating of

elctrolytic Ni, electrolytic Cu or electroless NiP. Meanswhile, for lower frequency signal down to 10MHz, 35- 40dB SE can be achieved by electrolytic Cu plating and capped by 4um Ni/Fe alloy. With the correct combination on metals and thicknesses, conformal metal plating performs a good solution meeting EMI shielding's requirement over high and low frequency.

ABSTRACT

A comparative study between adaptive consensus control of multi-agent systems composed of fully actuated mobile robots which are described as a class of Euler-Lagrange systems on directed network graphs based on the notion of inverse optimal H_∞ control criterion (Controller I), and the similar control strategy without H_∞ control criterion (Controller II), is given in this paper. Controller I is deduced as a solution of certain H_∞ control problem, where estimation errors of tuning parameters are considered as external disturbances to the process. Asymptotic properties, stability and robustness to unknown parameters are discussed for Controller I and Controller II.

1 Introduction

Motivated by crowd behaviors of animals, birds and fish, cooperative control problems of multi-agent systems are active research fields, and plenty of control strategies have been proposed in those areas, such as formation control, task assignment, traffic control, and scheduling *et al.* (for example, [1]-[11]). Among those, distributed consensus tracking of multi-agent systems with restricted communication networks, has been a basic and important issue, and various research results have been developed for various processes and under various conditions such as [1], [12]-[21]. In those works, adaptive control methodologies were also investigated in order to deal with uncertainties of agents, and stability of control systems was assured via Lyapunov function analysis. Furthermore, robustness properties of the control schemes were also examined. However, so much attention does not have been paid on control performance such as optimal property or transient performance in those research works, and especially, the case of multi-agent systems composed of processes with unknown and different system parameters on directed information network graphs, does not have been investigated in detail in the previous works.

The purpose of the paper is to provide a comparative study of two types of adaptive consensus control schemes (Controller I and Controller II) of multi-agent systems composed of fully actuated mobile robots which are described as a class of Euler-Lagrange systems [22] on directed network graphs. Controller I is constructed based on the notion of inverse optimal H_∞ control criterion [23], [24], and Controller II is synthesized without H_∞ control criterion. Controller I is derived as a solutios of certain H_∞ control problem, where estimation errors of tuning parameters are considered as external disturbances to the process. Asymptotic properties, stability and robustness to unknown parameters are discussed for those two control strategies (Controller I and Controller II).

The proposal of Controller I is an extension of our previous work [25], [26], in which the first-order or second-order linear or nonlinear regression models on directed network graphs were considered. This manuscript is also an extended version of the conference paper [1] (proposal of Controller I), and especially the present paper adds a comparative study of the two types of adaptive consensus control strategies (proposal and comparison of Controller I and Controller II), and highlights robustness properties of Controller I.

2 Multi-Agent Systems and Network Graphs

Mathematical preliminaries on information network graph of multi-agent systems are summarized [17], [20], [21]. As a model of interaction among agents, a weighted directed graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ is considered,

*Corresponding Author : Yoshihiko Miyasato, Email: miyasato@ism.ac.jp

https://dx.doi.org/10.25046/aj0203147

where $\mathcal{V} = \{1, \cdots, N\}$ is a node set which corresponds to a set of agents, and $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ is an edge set. An edge $(i, j) \in \mathcal{E}$ means that agent j can obtain information from i, but not necessarily vice versa. In the edge (i, j), i is called as a parent node and j is called as a child node, and the in-degree of the node i is the number of its parents, and the out-degree of i is the number of its children. An agent which has no parent (or with the in-degree 0), is denoted as a root. A directed path is a sequence of edges in the form (i_1, i_2), (i_2, i_3), $\cdots$ $(\in \mathcal{E})$, where $i_j \in \mathcal{V}$. The directed graph is called strongly connected, if there is always a directed path between every pair of distinct nodes. A directed tree is a directed graph where every node has exactly one parent except for a unique root, and the root has directed paths to all other node. An directed spanning tree $\mathcal{G}_S = (\mathcal{V}_S, \mathcal{E}_S)$ of the directed graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ is a subgraph of $\mathcal{G}$ such that $\mathcal{G}_S$ is a directed tree and $\mathcal{V}_S = \mathcal{V}$.

Associated with the edge set $\mathcal{E}$, a weighted adjacency matrix $A = [a_{ij}] \in \mathbf{R}^{N \times N}$ is introduced, and the entry a_{ij} of it is defined by

$$a_{ij} = \begin{cases} > 0 & : \ (j, i) \in \mathcal{E}, \\ 0 & : \ \text{otherwise.} \end{cases}$$

For the adjacency matrix $A = [a_{ij}]$, the Laplacian matrix $L = [l_{ij}] \in \mathbf{R}^{N \times N}$ is defined such as

$$l_{ii} = \sum_{\substack{j=1 \\ j \neq i}}^{N} a_{ij},$$
$$l_{ij} = -a_{ij}, \ (i \neq j).$$

Laplacian matrix has at least one zero eigenvalue and all nonzero eigenvalues have positive real parts. Especially, the Laplacian matrix has a simple 0 eigenvalue with the associated eigenvector $\mathbf{1} = [1 \cdots 1]^T$, and all other eigenvalues have positive real parts, if and only if the corresponding directed graph has a directed spanning tree.

In this manuscript, a consensus control problem of leader-follower type is considered, where y_0 is a leader which each agent $i \in \mathcal{V}$ should follow (i is called a follower). Concerned with the leader, a_{i0} is defined such as

$$a_{i0} = \begin{cases} > 0 & : \ \text{leader's information is available} \\ & \quad \text{to follower } i, \\ 0 & : \ \text{otherwise,} \end{cases} \tag{1}$$

and from a_{i0} and L, the matrix $M \in \mathbf{R}^{N \times N}$ is defined by

$$M = L + \mathrm{diag}\,(a_{10} \cdots a_{N0}). \tag{2}$$

It is shown that $-M$ is a Hurwitz matrix, if and only if 1. at least one a_{i0} $(1 \leq i \leq N)$ is positive, and 2. the graph $\mathcal{G}$ has a directed spanning tree with the root $i = 0$.

Hereafter, we assume that

1. The graph has a directed spanning tree with the root $i = 0$.
2. At least one a_{i0} $(1 \leq i \leq N)$ is positive, that is, the information of the leader y_0 ($\dot{y}_0$, $\ddot{y}_0$), is available to at least one follower i.
3. For the leader, y_0, $\dot{y}_0$, $\ddot{y}_0$ are uniformly bounded.

In the following, two adjacency matrices $A = [a_{ij}]$, $C = [c_{ij}] \in \mathbf{R}^{N \times N}$ are introduced for a directed graph $\mathcal{G}$, and the corresponding matrices are denoted as L_a, L_c (Laplacian matrices), and M_a, M_c, respectively.

3 Problem Statement

A multi-agent system composed of N fully actuated mobile robots which are described as a class of Euler-Lagrange systems [9], [10], are considered such that

$$M_i(y_i)\ddot{y}_i + C_i(y_i, \dot{y}_i)\dot{y}_i = \tau_i, \quad (i = 1, \cdots, N), \tag{3}$$

where $y_i \in \mathbf{R}^n$ is an output (a generalized coordinate), $\tau_i \in \mathbf{R}^n$ is a control input (a force vector), $M_i(y_i) \in \mathbf{R}^{n \times n}$ is an inertia matrix, and $C_i(y_i, \dot{y}_i) \in \mathbf{R}^{n \times n}$ is a matrix of Coriolis and centripetal forces. Each component has the next properties as a Euler-Lagrange system.

Properties of Euler-Lagrange Systems [22]

1. $M_i(y_i)$ is a bounded, positive definite, and symmetric matrix.
2. $\dot{M}_i(y_i) - 2C_i(y_i, \dot{y}_i)$ is a skew symmetric matrix.
3. The left-hand side of (3) can be written into

$$M_i(y_i)a_i + C(y_i, \dot{y}_i)b_i = Y_i(y, \dot{y}_i, a_i, b_i)\theta_i, \tag{4}$$

where $Y_i(y_i, \dot{y}_i, a_i, b_i)$ is a known function of y_i, $\dot{y}_i$, a_i, b_i (a regressor matrix), and θ_i is an unknown system parameter vector.

The control objective is to achieve consensus tracking of the leader-follower type for the unknown multi-agent system (unknown θ_i) such as

$$y_i \to y_j, \ (i, j = 1, \cdots, N), \tag{5}$$
$$y_i \to y_0, \ (i = 1, \cdots, N), \tag{6}$$

under the limited communication structure $\mathcal{G}$ among agents.

Remark 1 More generalized Euler-Lagrange systems including damping terms and gravitational forces, can be also considered in the present framework. However, for simplicity of notations, the description (3) is to be adopted hereafter, since the generalized Euler-Lagrange systems are written in the similar form to (4).

4 Control Law and Error Equation

As the first step of the design of Controller I and Controller II, an estimator of $\dot{y}_0$ (the leader's information) is developed via available data from the follower i. A similar estimation procedure was presented in [16].

$$\dot{\hat{z}}_i(t) = -\beta \sum_{\substack{j=1 \\ j\neq i}}^{N} c_{ij}\{\hat{z}_i(t) - \hat{z}_j(t)\} - \beta c_{i0}\{\hat{z}_i(t) - \dot{y}_0(t)\} + n_{i0}\ddot{y}_0(t), \tag{7}$$

where $\hat{z}_i$ is a current estimate of $\dot{y}_0$, and is synthesized from the data available to the follower i. $c_{ij}(1 \le i \le N, 0 \le j \le N)$ is defined as the entry of the adjacency matrix C and (1) deduced from the directed graph $\mathcal{G}$, and $\beta > 0$ is a design parameter. Associated with c_{i0}, n_{i0} is defined such as

$$n_{i0} = \begin{cases} 1 & : \quad c_{i0} > 0, \\ 0 & : \quad \text{otherwise.} \end{cases} \tag{8}$$

By employing the estimate $\hat{z}_i$, the control scheme is constructed as follows:

$$\dot{y}_{ri}(t) = \hat{z}_i(t) - \alpha \sum_{\substack{j=0 \\ j\neq i}}^{N} a_{ij}\{y_i(t) - y_j(t)\}, \tag{9}$$

$$s_i(t) = \dot{y}_i(t) - \dot{y}_{ri}(t), \tag{10}$$

$$\tau_i(t) = Y_i(t)\hat{\theta}_i(t) + v_i(t), \tag{11}$$

$$Y_i(t) \equiv Y_i(y, \dot{y}_i, \ddot{y}_{ri}, \dot{y}_{ri}), \tag{12}$$

where $a_{ij}(1 \le i \le N, 0 \le j \le N)$ is defined similarly from the entry of the adjacency matrix A and (1) deduced from $\mathcal{G}$, and $\alpha > 0$ is a design parameter. $\hat{\theta}_i$ is denoted as a current estimate of unknown θ_i, and v_i is a stabilizing signal which is to be determined later based on the notion of inverse optimal H_∞ control criterion (Controller I), or without H_∞ control criterion (Controller II). An estimation error between the leader $\dot{y}_0$ and the estimate $\hat{z}_i$ is defined by

$$\tilde{z}_i(t) \equiv \hat{z}_i(t) - \dot{y}_0(t), \tag{13}$$

and the following relations are deduced for s_i and $\tilde{z}_i$.

$$\dot{\tilde{z}}_i(t) = -\beta \sum_{\substack{j=1 \\ j\neq i}}^{N} c_{ij}\{\tilde{z}_i(t) - \tilde{z}_j(t)\} - \beta c_{i0}\tilde{z}_i(t) + (n_{i0} - 1)\ddot{y}_0(t), \tag{14}$$

$$M_i(y_i)\dot{s}_i(t) + C_i(y_i, \dot{y}_i)s_i(t) = v_i(t) + Y_i(t)\{\hat{\theta}_i(t) - \theta_i\}. \tag{15}$$

Then, the overall representations of the multi-agent system are given as follows:

$$\dot{\tilde{z}}(t) = -\beta(M_c \otimes I)\tilde{z}(t) + \{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0(t), \tag{16}$$

$$M\dot{s}(t) + Cs(t) = Y(t)\{\hat{\theta} - \theta(t)\} + v(t), \tag{17}$$

where

$$\tilde{z} = [\tilde{z}_1^{\mathsf{T}}, \cdots, \tilde{z}_N^{\mathsf{T}}]^{\mathsf{T}}, \tag{18}$$

$$s = [s_1^{\mathsf{T}}, \cdots, s_N^{\mathsf{T}}]^{\mathsf{T}}, \tag{19}$$

$$M = \text{block diag}(M_1, \cdots, M_N), \ (M_i \equiv M_i(y_i)), \tag{20}$$

$$C = \text{block diag}(C_1, \cdots, C_N), \ (C_i \equiv C_i(y_i, \dot{y}_i)), \tag{21}$$

$$Y = \text{block diag}(Y_1, \cdots, Y_N), \tag{22}$$

$$\theta = [\theta_1^{\mathsf{T}}, \cdots, \theta_N^{\mathsf{T}}]^{\mathsf{T}}, \tag{23}$$

$$N_0 = [n_{10}, \cdots, n_{N0}]^{\mathsf{T}}, \tag{24}$$

$$\mathbf{1} = [1, \cdots, 1]^{\mathsf{T}}, \tag{25}$$

$$v = [v_1^{\mathsf{T}}, \cdots, v_N^{\mathsf{T}}]^{\mathsf{T}}, \tag{26}$$

and $\otimes$ denotes Kronecker product.

5 Adaptive H_∞ Consensus Control for Euler-Lagrange Systems (Controller I)

In this section a design scheme of adaptive consensus control based on inverse optimal H_∞ criterion (Controller I) is provided. Stability analysis of the overall control system and deduction of Controller I are composed of four steps. As the first step, for stability analysis of s and the related terms, a positive function W_0 is defined such as

$$W_0(t) = \frac{1}{2}s(t)^{\mathsf{T}}Ms(t). \tag{27}$$

Then, the time derivative of W_0 along its trajectory is derived as follows:

$$\dot{W}_0(t) = s(t)^{\mathsf{T}}[Y(t)\{\hat{\theta} - \theta(t)\} + v(t)]. \tag{28}$$

By considering the evaluation of $\dot{W}_0$ (28), the next virtual system is introduced.

$$\dot{s} = f + g_1 d + g_2 v, \tag{29}$$

$$f = 0, \tag{30}$$

$$g_1 = Y, \ g_2 = I, \tag{31}$$

$$d = (\hat{\theta} - \theta). \tag{32}$$

The virtual system is to be stabilized via a control input v based on H_∞ criterion, where d is considered as an external disturbance to the process. For that purpose, the following Hamilton-Jacobi-Isaacs (HJI) equation and its solution V_0 are introduced.

$$\mathcal{L}_f V_0 + \frac{1}{4}\left\{\frac{\|\mathcal{L}_{g_1}V_0\|^2}{\gamma^2} - (\mathcal{L}_{g_2}V_0)R^{-1}(\mathcal{L}_{g_2}V_0)^{\mathsf{T}}\right\} + q = 0, \tag{33}$$

$$V_0 = \frac{1}{2}s^{\mathsf{T}}s, \tag{34}$$

where q and R are a positive function and a positive definite matrix respectively, and those are deduced from HJI equation based on the notion of inverse optimality for the given solution V_0 and a positive constant γ. The substitution of the solution V_0 (34) into HJI equation (33) yields

$$\frac{1}{4}s^{\mathsf{T}}\left\{\frac{YY^{\mathsf{T}}}{\gamma^2} - R^{-1}\right\}s + q = 0. \tag{35}$$

From (35), R and q are obtained such as

$$R = \left(\frac{YY^{\mathsf{T}}}{\gamma^2} + K\right)^{-1}, \tag{36}$$

$$q = \frac{1}{4}s^{\mathsf{T}}Ks, \tag{37}$$

where K is a diagonal positive definite matrix (a design parameter), From R, v is derived as a solution of the corresponding H_∞ control problem as follows (Controller I):

$$\begin{aligned} v &= -\frac{1}{2}R^{-1}(\mathcal{L}_{g_2}V_0)^{\mathsf{T}} = -\frac{1}{2}R^{-1}s \\ &= -\frac{1}{2}\left(\frac{YY^{\mathsf{T}}}{\gamma^2} + K\right)s. \end{aligned} \tag{38}$$

Then, via HJI equation, the time derivative of W_0 (28) is evaluated as follows:

$$\begin{aligned} \dot{W}_0 &= -q - v^{\mathsf{T}}Rv \\ &\quad + \left(v + \frac{1}{2}R^{-1}s\right)^{\mathsf{T}} R\left(v + \frac{1}{2}R^{-1}s\right) \\ &\quad + \gamma^2\|d\|^2 - \gamma^2\left\|d - \frac{Y^{\mathsf{T}}s}{2\gamma^2}\right\|^2, \end{aligned} \tag{39}$$

and it follows that s is bounded for bounded $\hat{\theta}$ and for the stabilizing signal v (38).

Next, for stablity analysis of the estimation error $\tilde{z}$, a positive function V_1 is introduced such as

$$V_1 = \tilde{z}^{\mathsf{T}}(P_c \otimes I)\tilde{z}, \tag{40}$$

$$P_cM_c + M_c^{\mathsf{T}}P_c = I, \ \ (P_c = P_c^{\mathsf{T}} > 0). \tag{41}$$

There exists a positive definite and symmetric matrix P_c satisfying (41), since $-M_c$ is Hurwitz. Then, the time derivative of V_1 along its trajectory is evaluated as follows:

$$\begin{aligned} \dot{V}_1 &= -\beta\|\tilde{z}\|^2 - 2\tilde{z}^{\mathsf{T}}(P_c \otimes I)\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0 \\ &\le -\frac{\beta}{2}\|\tilde{z}\|^2 + \frac{2}{\beta}\|P_c \otimes I\|^2\|\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0\|^2, \end{aligned} \tag{42}$$

and it is shown that $\tilde{z}$ is bounded for bounded $\ddot{y}_0$.

Thirdly, for stability analysis of the control error $y_i - y_0$ and the related terms, $\tilde{y}_i$, $\tilde{y}$ are defined by

$$\tilde{y}_i = y_i - y_0, \tag{43}$$

$$\tilde{y} = [\tilde{y}_1^{\mathsf{T}}, \cdots, \tilde{y}_N^{\mathsf{T}}]^{\mathsf{T}}. \tag{44}$$

Then, the following relation holds

$$\dot{\tilde{y}} = s + \tilde{z} - \alpha(M_a \otimes I)\tilde{y}, \tag{45}$$

and $-M_a$ is shown to be Hurwitz because of the assumption of the network graph $\mathcal{G}$. From that property, a positive function V_2 is defined by

$$V_2 = \tilde{y}^{\mathsf{T}}(P_a \otimes I)\tilde{y}, \tag{46}$$

$$P_aM_a + M_a^{\mathsf{T}}P_a = I, \ \ (P_a = P_a^{\mathsf{T}} > 0). \tag{47}$$

Similarly to the previous case (M_c), there exists a positive definite and symmetric matrix P_a satisfying (47), since $-M_a$ is Hurwitz. Then, the time derivative of V_2 along its trajectory is evaluated as follows:

$$\begin{aligned} \dot{V}_2 &= -\alpha\|\tilde{y}\|^2 + 2\tilde{y}^{\mathsf{T}}(P_a \otimes I)(s + \tilde{z}) \\ &\le -\frac{\alpha}{2}\|\tilde{y}\|^2 + \frac{4}{\alpha}\|P_a \otimes I\|^2(\|s\|^2 + \|\tilde{z}\|^2). \end{aligned} \tag{48}$$

From the three stages of stability analysis (the evaluations of $\dot{W}_0$, $\dot{V}_1$, $\dot{V}_2$), the next theorem is obtained.

Theorem 1 *The nonlinear control system composed of the control laws (7), (9), (10), (11), (12), (38) (Controller I) is uniformly bounded for an arbitrary bounded design parameter $\hat{\theta}_i$, and bounded y_0, $\dot{y}_0$, $\ddot{y}_0$, and v is an optimal control input which minimizes the following cost functional J.*

$$\begin{aligned} J(t) \equiv \sup_{d_i, d_2, d_3 \in \mathcal{L}_2} \Bigg[&\int_0^t \{q + v^{\mathsf{T}}Rv\}d\tau + W_0(t) \\ &-\gamma^2 \int_0^t \|d\|^2 d\tau \Bigg]. \end{aligned} \tag{49}$$

Also the next inequality holds.

$$\begin{aligned} &\int_0^t \{q + v^{\mathsf{T}}Rv\}d\tau + W_0(t) \\ &\qquad \le \gamma^2 \int_0^t \|d\|^2 d\tau + W_0(0). \end{aligned} \tag{50}$$

Theorem 1 denotes the properties of the proposed nonlinear control system (7), (9), (10), (11), (12), (38) (Controller I), where the tunings of $\hat{\theta}$ is not included (or not necessarily required).

Next, the tuning law of $\hat{\theta}$ is determined as follows:

$$\dot{\hat{\theta}}(t) = \mathrm{Pr}\left\{-\Gamma Y(t)^{\mathsf{T}}s(t)\right\}, \tag{51}$$

where $\mathrm{Pr}(\cdot)$ is a projection operation in which the tuning parameter $\hat{\theta}$ is constrained to a bounded region deduced from upper-bounds of $\|\theta\|$ [27]. As the fourth step of stability analysis of the overall control system, a positive function W_1 is defined by

$$W_1(t) = \frac{1}{2}s(t)^{\mathsf{T}}s(t) + \frac{1}{2}\left\{\hat{\theta}(t) - \theta\right\}^{\mathsf{T}}\Gamma^{-1}\left\{\hat{\theta}(t) - \theta\right\}, \tag{52}$$

and the time derivative of W_1 along its trajectory is evaluated such as

$$\dot{W}_1(t) \le -\frac{1}{2}s(t)^{\mathsf{T}}R^{-1}s \le 0. \tag{53}$$

From the four stages of stability analysis (the evaluations of $\dot{W}_0$, $\dot{W}_1$, $\dot{V}_1$, $\dot{V}_2$), the next theorem is obtained.

Theorem 2 *The adaptive control system composed of the control laws (7), (9), (10), (11), (12), (38), and the tuning law of $\hat{\theta}$ (51) (Controller I), is uniformly bounded for bounded y_0, $\dot{y}_0$, $\ddot{y}_0$, and it follows that*

$$\lim_{t\to\infty} s(t) = 0. \tag{54}$$

Especially, if $\ddot{y}_0(t) = 0$ or the information of the leader $\ddot{y}_0$ is available for all followers ($\{(N_0 - \mathbf{1}) \otimes I\}\dot{y}_0 = 0$), then it follows that

$$\lim_{t\to\infty} \tilde{y}(t) = \lim_{t\to\infty} \dot{\tilde{y}}(t) = 0, \tag{55}$$

and the asymptotic consensus tracking is achieved. Otherwise, when $\ddot{y}_0(t) \neq 0$ and the information of $\ddot{y}_0$ is not available for all followers ($\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0 \neq 0$), then the next relation holds.

$$\|\tilde{y}\| \sim \text{const.} \cdot \frac{1}{\alpha\beta}\|\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0\|, \tag{56}$$

$$\|\dot{\tilde{y}}\| \sim \text{const.} \cdot \frac{1}{\beta}\|\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0\|. \tag{57}$$

Theorem 2 denotes the properties of the proposed adaptive control system (7), (9), (10), (11), (12), (38), (51) (Controller I), and states that the asymptotic consensus tracking is achieved under the specified condition ($\{(N_0 - \mathbf{1}) \otimes I\}\dot{y}_0 = 0$), and also shows that the approximate consensus tracking with the ratios of $1/(\alpha\beta)$, $1/\beta\,(>0)$ is still assured, even if that condition is not satisfied ($\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0 \neq 0$).

Remark 2 It should be noted the proposed control scheme and the adaptation scheme (Controller I) are all implemented in a distributed fashion, where availabilities of signals for each agent i are highly restricted and prescribed by the directed graph $\mathcal{G}$.

Remark 3 The objective of the design of Controller I, is to obtain an adaptive control structure whose stability is not seriously affected by the adaptation scheme, or whose performance is not significantly degraded by the estimation errors of the tuning parameters. For that purpose, in order to attenuate the effects of the estimation errors, the control scheme is to be deduced as a solution of certain H_∞ control problem, where L_2 gains from the estimation errors of tuning parameters to the generalized output is prescribed by a positive constant γ (design parameter).

Remark 4 Of course, J in **Theorem 1** is a fictitious cost functional, since d is not an actual disturbance but an estimation error of the tuning parameter, and since it is not generally included in $L^2[0,\infty)$. Nevertheless, v, which is derived as a solution for that fictitious H_∞ control problem (Controller I), attain the inequality in **Theorem 1**, stabilize the total system, and it means that the L^2 gain from the disturbance d to the generalized output $\sqrt{q + v^T R v}$ is prescribed by the positive constant γ.

6 Adaptive Consensus Control for Euler-Lagrange Systems without H_∞ Criterion (Controller II)

The adaptive consensus control strategy without H_∞ control criterion (Controller II) is easily deduced by setting $\gamma \to \infty$ in the synthesis of v (38) such that

$$v = -\frac{1}{2}Ks. \tag{58}$$

In this case, the tuning scheme of $\hat{\theta}$ (51) is required to assure uniform boundedness of the total control system. The time derivative of W_1 (52) with the tuning law (51) gives

$$\dot{W}_1(t) \leq -\frac{1}{2}s(t)^{\mathsf{T}}Ks \leq 0. \tag{59}$$

Then, by applying the same stability analysis via the evaluations of $\dot{W}_1$, $\dot{V}_1$, $\dot{V}_2$, the following theorem is obtained.

Theorem 3 *The adaptive control system composed of the control laws (7), (9), (10), (11), (12), (58), and the tuning law of $\hat{\theta}$ (51) (Controller II), is uniformly bounded for bounded y_0, $\dot{y}_0$, $\ddot{y}_0$, and it follows that*

$$\lim_{t\to\infty} s(t) = 0. \tag{60}$$

Especially, if $\ddot{y}_0(t) = 0$ or the information of the leader $\ddot{y}_0$ is available for all followers ($\{(N_0 - \mathbf{1}) \otimes I\}\dot{y}_0 = 0$), then it follows that

$$\lim_{t\to\infty} \tilde{y}(t) = \lim_{t\to\infty} \dot{\tilde{y}}(t) = 0, \tag{61}$$

and the asymptotic consensus tracking is achieved. Otherwise, when $\ddot{y}_0(t) \neq 0$ and the information of $\ddot{y}_0$ is not available for all followers ($\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0 \neq 0$), then the next relation holds.

$$\|\tilde{y}\| \sim \text{const.} \cdot \frac{1}{\alpha\beta}\|\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0\|, \tag{62}$$

$$\|\dot{\tilde{y}}\| \sim \text{const.} \cdot \frac{1}{\beta}\|\{(N_0 - \mathbf{1}) \otimes I\}\ddot{y}_0\|. \tag{63}$$

Remark 5 Asymptotic properties of the adaptive consensus control without H_∞ criterion ((60), (61), (62), (63) (Controller II)) are the same as the adaptive H_∞ consensus control version ((54), (55), (56), (57) (Controller I)). However, it should be noted that uniform boundedness of the overall control system via Controller II is not assured for arbitrary bounded design parameters $\hat{\theta}$. Instead, the tuning of $\hat{\theta}$ (51) is necessary to attain the stability of consensus tracking by Controller II. Furthermore, Controller II in Theorem 3 does not contain an optimal property for the cost functional (49), and the inequality (50) does not hold.

7 Numerical Example

In order to show the effectiveness of the two types of adaptive consensus control schemes, numerical experiments for Euler-Lagrange systems are performed.

A multi-agent system composed of simple Euler-Lagrange systems is considered as follows:

$$m_i\ddot{y}_i(t) = \tau_i(t), \quad (i = 1, 2, 3),$$
$$(y_1(0) = 1, \ y_2(0) = 0, \ y_3(0) = -1),$$

where $y_i \in \mathbf{R}$, $\tau_i \in \mathbf{R}$, and $m_i \in \mathbf{R}$ is an unknown system parameter. Associated with the information network structure (Fig.1), the adjacency matrix $A = [a_{ij}]\,(= C)$ and $a_{i0}\,(= c_{i0})$ are chosen such that

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix},$$
$$a_{10} = 1, \ a_{20} = a_{30} = 0.$$

The control objective is to achieve consensus tracking

$$y_i \to y_j,\ \dot{y}_i \to \dot{y}_j,$$
$$y_i \to y_0,\ \dot{y}_i \to \dot{y}_0,$$
$$(i, j = 1, 2, 3),$$

where the virtual leader y_0 is determined such as

$$\ddot{y}_0 + 2\dot{y}_0(t) + y_0(t) = \sin t.$$

The design parameters are chosen as follows:

$$\Gamma = 10I,\ K = 5I,\ \alpha = \beta = 10,$$
$$\gamma_i = 1.$$

As system parameters m_i $(i = 1 \sim 3)$, we consider both time-invariant and time-varying cases such that

$$m_1 = 1,\ m_2 = 2,\ m_3 = 3,\ \text{(time – invariant case)},$$
$$m_1 = f_m(t),\ m_2 = 2f_m(t),\ m_3 = 3f_m(t),$$
$$\text{(time – varying case)},$$

where

$$f_m(t) = \begin{cases} 2 & 0 \le t < 2.5,\ 5 \le t < 7.5,\ \cdots, \\ 1 & 2.5 < t \le 5,\ 7.5 < t \le 10,\ \cdots. \end{cases}$$

Numerical simulations were carried out by utilizing MATLAB and Simulink of the MathWorks, Inc., and the solver is Dormand-Prince method with the adaptive step-size integration algorithm (ode45).

The simulation results of Controller I (Theorem 2) are shown in Fig.2 (time-invariant case) and Fig.4 (time-varying case). For comparison, the cases of Controller II (the adaptive control systems which do not contain H_∞ control scheme), are shown for both cases; Fig.3 (time-invariant case) and Fig.5 (time-varying case). In those figures (Fig.2 $\sim$ Fig.5), the plots were response curves of y_1, y_2, y_3 and y_0 (vertical axises) versus time t (horizontal- axises).

From those results, it is seen that Controller I (H_∞ adaptive control strategy) achieves better tracking convergence property together with robustness to abrupt changes of the system parameters compared with the non-H_∞ control scheme (Controller II), and those are owing to disturbance attenuation properties of Controller I, since the performance of Controller I is not significantly degraded by the estimation errors of the tuning parameters in the settings of both time-invariant and time-varying cases (see also Remark 3).

8 Concluding Remarks

The comparative study of two types of adaptive consensus control (Controller I and Controller II) of multi-agent systems composed of fully actuated mobile robots which are described as a class of Euler-Lagrange systems on directed network has been given in this paper. Controller I is deduced based on the notion of inverse optimal H_∞ control criterion, and is derived as a solution of certain H_∞ control problem, where estimation errors of tuning parameters are considered as external disturbances to the process. On the contrary, Controller II is synthesized without H_∞ control criterion. Asymptotic properties, stability and robustness to unknown parameters are discussed for those two control strategies (Controller I and Controller II). Although asymptotic properties of those two controllers are similar to each others, Controller I achieves better tracking convergence property together with robustness to abrupt changes of the system parameters compared with Controller II, and those are owing to disturbance attenuation properties of Controller I and the problem setting of H_∞ criterion.

Future rolling

ABSTRACT

In futures markets, a single asset is generally represented by several contracts with different maturities. The selection of specific contracts is an inevitable task that also creates new opportunities, especially in terms of speculative trading. Evaluating immediate and upcoming trading costs for all considered contracts might lead to a significantly improved performance. Among that, even possible market inefficiencies might be taken into consideration. This research introduces and evaluates a new algorithm for the contract selection. The results are benchmarked and compared with established methods using a Monte Carlo simulation on different commodity and index futures.

1 Introduction

Contractual agreements over prospective commodity flows already were established in the ancient. The commitment of transanctions to a fixed maturity reliably enabled long-term planning and reduced risks. The standardization of these so-called forwards to exchange-traded futures therefore only has been a question of time. Accordingly, futures have quickly spread after their first release at the Chicago Board of Trade in the 1860s. Modern futures markets offer high volumes and attractive trading conditions for numerous assets. This situation generates a highly interesting trading environment for speculative investors.

This paper is an extension of work originally presented in SSCI 2016 [1] in which different contract selection strategies have been introduced and tested in commodity markets. This research deepens the findings and improves the presented algorithm by refining the selection process. For this purpose, the new algorithm separates the ask and bid price structure to furtherly improve a case-dependent trading cost analysis. The results are evaluated by Monte Carlo simulations on sets of arbitrary trading instructions on three future classes in both, commodity and index futures. The analysis is settled on a broad fundament of historical data that enables a wider range of benchmarks than the previous paper. The results allow the conclusion of market inefficiencies in the analyzed markets.

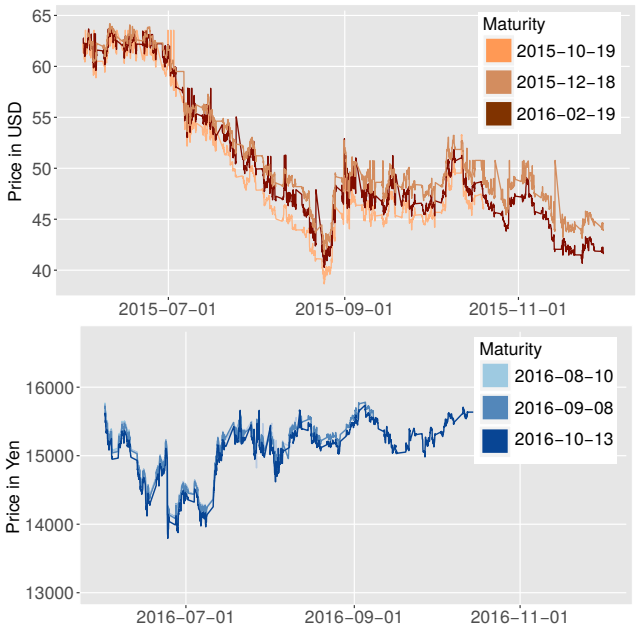

Figure 1: Prices of three WTI future contracts (top chart) and three Nikkei future (bottom chart) contracts with different maturities

Among other properties, every future class is defined by a fix maturity interval in which corresponding contracts expire (typically one or three months). The life span of a contract however is an issue of supply and demand and generally considerably longer. Consequently, there are several coexistent contracts with different price structures and liquidities – all for

*Vasco Grossmann, Kiel University, Germany, vgr@informatik.uni-kiel.de

https://dx.doi.org/10.25046/aj0203148

the same asset, but with different maturities. Due to individual risks and demand changes, different underlyings may exhibit significant disparities in their term structure properties. While consumer goods futures like natural gas show strong seasonal fluctuations, differences of index futures tend to more constant deviations [2]. Figure 1 exemplarily shows quotes for different WTI future contracts during the period from June to December 2016.

The application of conventional trading strategies in futures markets mandatorily generates the challenge of defining a strategy for the contract selection. As advantageous properties of a contract systematically result in other properties being unfavorable, the selection is always a nontrivial compromise with the objective of the best possible balance.

Of course, the prices of future contracts are significantly influenced by the current price of the underlying asset. However, an adequate model requires several additional factors to be taken into consideration. The definition of a formal relationship between future and spot price has been researched precisely and several models have been proposed [3–5]. The cost-of-carry model explains the price $F_{t,\tau}$ of a future contract with maturity τ at time t as a function of the spot price S given by

$$F_{t,\tau} = S_t \cdot e^{(r+s-c)\cdot(\tau-t)}. \quad (1)$$

The interest rate is divided into three parts: the risk-free interest rate r and storage cost s. Arising inaccuracies are explained by the so-called convenience yield c that covers all movements that are created by changing market expectations. Thereby, market situations like contango and backwardation can be constituted.

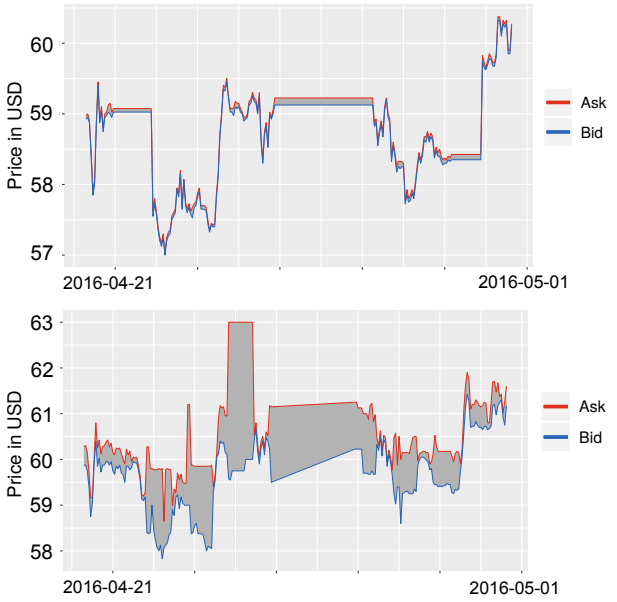

Figure 2: Ask and bid quotes from two WTI Mini contracts with maturities July (above) and September (below) 2016 show huge differences in market liquidity and estimated trading costs

Figure 4 shows ask and bid quotes for two WTI Mini future contracts with maturities July and September 2016 during April 2016. Obviously, the spread highly depends on the time left to the maturity. The lower and much more persistent spread of the near contract yields favorable conditions. The notably smaller liquidility of contract markets with a more distant maturity generates an averagely higher spread. As the trading volume tremendously rises with a decreasing time span to the maturity, spreads tend to be the lowest for the nearest future contracts. While commissions follow a plain pattern, spreads between ask and bid prices strongly depend on market capitalization.

However, the acquisition of contracts with short-term maturities for long-running positions require an extension of the expiry by re-opening positions for the same underlying asset. This procedure is called future rolling and results in additional trades and accordingly trading costs.

So, a suitable future contract selection strategy for speculative investments should balance the contracts in a way that the benefit from low trading costs is as high as possible. Besides, the chance of upcoming future rollings should be as low as possible to avoid additional costs.

One established selection strategy is the so called front month rolling strategy [6]. The method restricts itself to the trade of the nearest future contract whose maturity is more than one month in the future. After exceeding that point in time, contracts are rolled to the subsequent maturity. Of course, the month interval might be scaled depending on average trading intervals. Next to the benefit of most likely addressing liquid markets, it is simple to use and backtesting requires only the two nearest future contracts to be considered.

However, the constant period may be to rigid to fit the needs of the underlying system. Especially highly varying holding times or partial reorganizations of a long-running portfolio may cause the necessity of future rolls. The front month strategy disregards these factors and also ignores several information that might improve the selection process. Even if more distant contracts suffer from higher trading costs in general, their evaluation might depict situations in which transactions of distant contracts create new opportunities. Besides, current portfolio positions have a significant impact during the liquidation process and should be evaluated – their consideration can result in a better contract selection. Also statistical parameters of the trading strategy might be taken into consideration. Correspondingly, this research introduces a procedure that optimizes the selection of futures by investigating the influence of a larger set of parameters. The described problem will be formalized in the following section.

2 Optimal contract selection

The application of a trading strategy based on a conventional non-expiring asset in futures markets is non-trivial due to the additional task of selecting maturities. This research addresses this contract selection problem and introduces algorithms that assign trading decisions for non-expiring assets to expiring contracts. It is searched for the optimal selection of specific contracts for a given future class $\mathbb{F}$ in a defined environment. The objective of the presented method is to allocate contracts in a way that maximizes the overall wealth. As the selection process should work on arbitrary trading strategies on a future class, the latter are sufficiently characterized by deviated trading decisions.

Let a future class $\mathbb{F}$ be a set of related future contracts $F_{\tau_1}, F_{\tau_2}, \ldots, F_{\tau_n}$ that only differ in their maturities $\tau_1, \tau_2, \ldots, \tau_n \in \mathbb{T}$.

Let $(\mathcal{D}_t)_{t\in\mathbb{T}}$ with $\mathcal{D}_t \in \mathbb{Z}$ be the sequence of trading decisions. $\mathcal{D}_t$ contains the number of positions to be bought or sold (depending on sign) at time t – the value 0 represents no transactions.

Let Ω be the set of all possible market scenarios and the finite sequence $(\mathcal{F}_t)_{t\in\mathbb{T}}$ be a filtration on the space Ω, so that the element $\mathcal{F}_t$ represents the known and relevant information at time t.

Let $q : \mathcal{F} \times \mathcal{D} \to \mathbb{F}$ be a selection strategy that returns a specific future contract F_τ by evaluating the known information set $\mathcal{F}_t$ for a given trading decision $\mathcal{D}_t$. Let Q be the set of all selection strategies.

Let $w : \mathcal{D} \times Q \to \mathbb{R}$ be the wealth function that calculates the return after the application of all trading decisions in $\mathcal{D}$ with a selection strategy in the set Q. Thereby, the function gives a measure that enables the comparison of different selection strategies.

The problem is then to find a contract selection strategy $\hat{q} \in Q$ at time t that maximizes the expected wealth after the execution of all trading decisions:

$$w(\mathcal{D}, \hat{q}) = \max_{q\in Q}(w(\mathcal{D}, q)) \tag{2}$$

The optimal selection strategy $\hat{q}$ depends on several factors. The variety of contracts creates an opportunity of lesser trading costs – providing that trading costs (and possible future roll costs) are at least rateable. Thus, the analysis of observed spreads is a mandatory step for a suitable prediction that is discussed in section 3.2. Statistical information of the underlying trading strategy is then included to estimate the temporal uncertainty of trading decisions. These distributions are introduced to identify the time window in which a prospective order may be created by a trading strategy so that emerging costs can be predicted as precise as possible 3.4. In a final step, the overall minimum trading costs are evaluated by the analysis of all discrete trading paths over all possible combinations (section 3.5).

3 Minimizing trading costs

The identification of a selection strategy that maximizes the overall wealth not only depends on minimal trading costs but as well on the question whether the underlying market is efficient in regard to the market-efficiency hypothesis [7]. While cointegrated processes may be used to furtherly improve trading results in inefficient markets, the following section focuses on the minimization of trading costs.

As there is a strong connection between distance to the maturity and the spread of a contract, trading costs can be predicted quote precisely. Figure 3 shows the average development for six WTI contracts during the last 180 trading days (maturities from July to December 2015) and clearly reveals this correlated relation. Not only the value but its volatility decreases for near maturities which is the typical evolution for the price structure [8]. The convergence to a spread of 1‰ of the base price and enables almost exact estimates for the spread during the last months. The spread oscillation is a result of liquidity discrepancies between regular and irregular trading hours. As these tremendous differences may generate a huge impact on the overall performance of the trading strategy, the contract selection is a crucial topic .

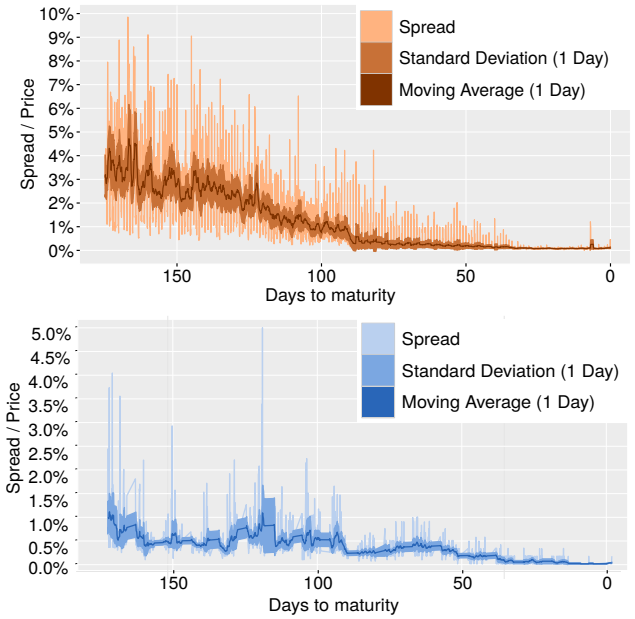

Figure 3: Spread over the last six months to maturity for WTI Mini contracts (top chart) and Nikkei contracts (bottom chart)

Figure 3 clearly displays the advantage of short-term contracts. However, as one contract per month exists for WTI, it also reveals that at least the last three contracts may have similar spreads at times. Considering long-term trading strategies, the acquisition of near contract positions create a high probability of necessary future rolls. This effect appears even stronger for different Nikkei contracts. Although there are frequently high spreads for distant futures, the high fluctuation may yield opportunities as well.

3.1 Spread composition analysis

High spreads are a symptom of market illiquidity. However, they do not automatically represent a similarly disadvantageous situations for both, buyers and sellers. For example, it is absolutely possible that a high spread of a future contract is an expression of a low supply for either long or short positions in comparison to other contracts. Still, the other side may offer attractive prices anyhow. That is the reason why an alignment of spread structures of all contracts is a reasonable step to identify trading opportunities. Therefore, a robust estimation for evolutions of the log prices is applied that generate the least absolute residuals.

Let $A_t^{F_\tau}$ and $B_t^{F_\tau}$ be the ask and bid log prices of F_τ at time t. The evaluation of the estimated log price X_{t+1} is given by

$$\begin{aligned} \mathrm{d}X_{t+1} =& \min_{\epsilon\in\mathbb{R}} \sum_{F\in\mathbb{F}} \max\left(X_t - A_{t+1} + \epsilon, 0\right) + \\ & \min\left(B_t - X_{t+1} + \epsilon, 0\right). \end{aligned} \tag{3}$$

Figure 4 shows the application of the robust quote estimation for the two presented WTI contracts. By interpreting all current contracts, price evolutions are computed that are placed between ask and bid prices. This creates comparable quotes for all future contracts. The differences of ask, bid and robust estimation enables the separate rating of supply and demand. For instance, the significant increase of the spread at April 24 for the December contract is primarily generated by an unfavorable ask price that cannot be traced back to a general movement. The bid price does not show any illiquidities in this case.

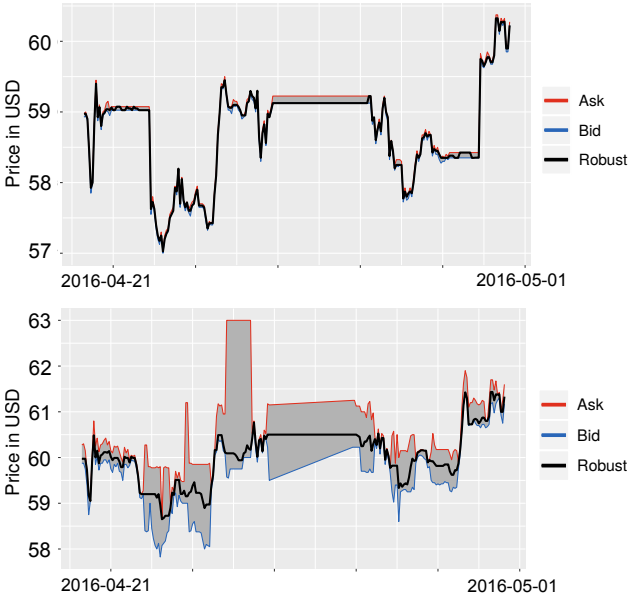

Figure 4: Robust quote estimation

The resulting time series is mandatorily less volatile than both, ask and bid quotes. It only contains the minimum movement that both time series make and is robust concerning every one-sided break. This also enables to separate non-exploitable mean reverse tendencies from real mispricings. This property will be used to evaluate under- and overvaluations in chapter 4.

3.2 Relation between spread and maturity

To formally include the remaining time span of a contract, let $\mathbb{D} \subset \mathbb{Z}$ be the set of durations. Let $d_\tau : \mathbb{T} \to \mathbb{D}$ with $d_\tau(t) = \tau - t$ be the remaining time span between a time t and the maturity date τ of a future contract F_τ.

Let $\mathrm{d}\tau \in \mathbb{D}$ be the time interval between maturities of two consecutive future contracts. It is assumed to be constant for a future class (e.g. 1 month for WTI).

Let $c\colon \mathbb{D} \to \mathbb{R}$ with $c(d), d \geq 0$ then be the average observed trading costs that incur d time steps before the maturity.

Further, let

$$c(d) = \underbrace{c(0) + c(\mathrm{d}\tau)}_{\text{Future roll cost}} + \underbrace{c(d + \mathrm{d}\tau)}_{\text{Liquidation cost}} \qquad \forall\, d < 0. \tag{4}$$

be the trading costs for an exceeded maturity. Future rolls consist of two trades: closing the expiring position at the last valid point before the corresponding maturity ($t = c(0)$) and re-opening the same position in a the consecutive contract ($c(\mathrm{d}\tau)$). The actual liquidation itself must be included as well and is delayed by $\mathrm{d}\tau$. Therefore, the overall trading cost is a sum of three values as shown in equation 4. Figure 6 illustrates these additional future roll costs for exceeded maturities.

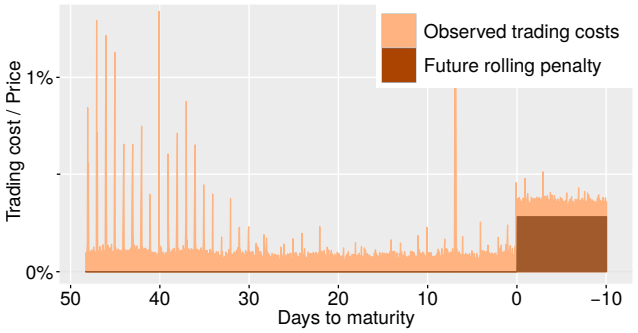

Figure 5: The average trading costs $c(d)$ over the last 50 days for WTI Mini contracts are displayed. An exceeded maturity results in additional trades by future rolling. Therefore, the expected trading costs increase considerably for $t < 0$.

It can be summarized that the a low future roll probability opposes low trading costs – the least costs will generally arise in a balance between these objectives. The probability of future rolls not only depends on maturities but is primarily based on the relationship between maturity and trading frequency. Therefore, statistical information about the trading strategy must be evaluated.

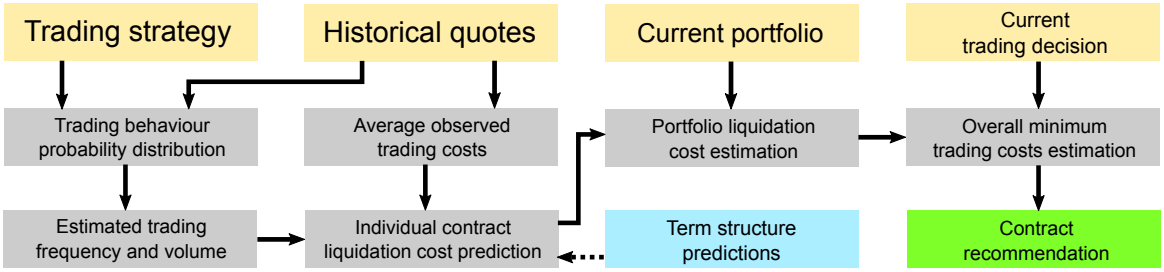

Figure 6: Overview over the evaluation pipeline that leads to a contract recommendation for a given trading decision.

3.3 Statistical trading strategy evaluation

Depending on the trading strategy, prospective trading times may be perfectly predictable. Even if there are no temporal connections, statistical methods allow the estimation based on past observations. Thus, it is assumed that a probability density function of the number of trades per time interval can be computed. In this case, it is assumed to be normally distributed with an average interval between two trades μ and a standard deviation σ. These values enable the calculation of the number of trades up to a prospective point in time. The time of the n-th upcoming trade is then represented by a random variable $t_n \sim \mathcal{N}(t + n\mu, n\sigma)$ for the last observed trading time t. The expected number of trades in an interval from s to t is $\frac{t-s}{\mu}$ with a standard deviation of $\frac{t-s}{\mu} \cdot \sigma$.

3.4 Portfolio liquidation costs

Next to immediate trading costs, the attractivity of contracts is strongly connected to the question how expensive the liquidation of the acquired position will be. This section focuses on the prediction of these costs. A minimization procedure is introduced with regard to the contract selection problem. It is based on the evaluation of the following information:

- future contract positions in portfolio
- estimation of spread fraction (section 3.1)
- estimation of trading cost function c (section 3.2)
- statistical information frequency and volume of the underlying trading strategy (section 3.3)

To connect the trading cost function c with the statistical information, we define $v : \mathbb{T}\times\mathbb{T}\times\mathbb{T} \to \mathbb{R}$ to be expected trading costs. The value $v(\tau, t, s)$ displays the trading cost estimate for a future contract F_τ at time t at calcuation time s with $s < t$. These costs are independent from s for this first researched method and directly arise from the average observed trading costs:

$$v(\tau, t, s) = c(\tau - t). \tag{5}$$

The future trading costs can be predicted by convoluting the probability density function f (in this case a normal-distributed approximation) and a given estimate v. The temporal uncertainty rises with increasing variance of the distribution for larger distances. This effect reduces the accuracy for more distant predictions that reveals itself by observably smoother movements representing the convolution kernel. The function $C_\tau : \mathbb{T} \to \mathbb{R}$ illustrates this relationship and enables the estimation of transaction costs of prospective trades at an approximate time t with the information of time s by

$$\mathbb{E}(C_\tau(t) \mid \mathcal{F}_s) = (f * v)(t) \tag{6}$$

$$= \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi\left(\frac{t-s}{\mu}\cdot\sigma\right)^2}} \cdot \exp\left(-\frac{x^2}{2\left(\frac{t-s}{\mu}\cdot\sigma\right)^2}\right) \cdot v(\tau, t+x, s)\ \mathrm{d}x. \tag{7}$$

In summary, statistical information about the trading strategy, observed trading costs and the estimated probability of future roll costs are weighted to calculate the most likely trading costs for a prospective trading decision.

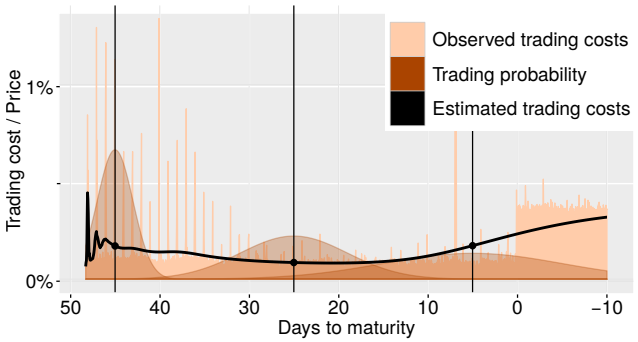

Figure 7: Estimated trading costs $\mathbb{E}(C_\tau(t) \mid \mathcal{F}_s)$ for future F_τ 55 days before its maturity and $\frac{\sigma}{\mu} = \frac{1}{5}$. Normal distributions for three exemplary points (45, 25 and 5 days left) are schematically figured to denote the uncertainty of the effective trading time.

The diverse trading cost effects are exemplarily demonstrated in Figure 7. It shows predictions for uprising trades for a future contract 48 days before its maturity. While the anticipated market liquidity prognosticates averagely lower costs up to 20 days before the maturity, the increased probability of future

rolls yields higher estimates afterwards. While near forecasts apparently embed short-term fluctuations, estimated trading costs for distant trading events are strongly smoothed.

Indeed, these predictions are only suitable to calculate trading costs for discrete future contracts. However, individual estimates can be applied to compare different outcomes in complex scenarios of many consecutive trading decisions. This enables the evaluation of all potential executions and yields the opportunity of a trading cost minimization by prioritizing these estimates. An efficient procedure to calculate the optimal order in such a scenario is introduced in the following.

3.5 Minimizing of portfolio liquidation costs

In the following, the minimum liquidation costs by partial successive trades of a given portfolio iares measured. They are computed by an iterative calculation of optimal liquidation orders for sub-portfolios according to the dynamic programming principle. Starting with the complete portfolio, possible trading decisions are converted to orders that are used to successively remove positions. By comparing each path, an optimal trading path can be evaluated for every sub-portfolio and accordingly, for the empty portfolio. The optimal first liquidation step for the given portfolio is then revealed by the first step of the path with overall minimum trading costs.

Let the set of necessary transactions for the full liquidation of a given portfolio with N futures at time $t \in \mathbb{T}$ be given by $L_t = \{L_t^1, L_t^2, \ldots, L_t^N\} \in \mathbb{N}_0^N$.

Let $\mathcal{C}_s(L_t) \in \mathbb{R}$ at time $s \in \mathbb{T}, s \leq t$ be the estimate of the trading costs for all transactions in L_t.

These transactions will happen at sequent points in future. As described, their order and their costs are predicted recursively. The remaining trading costs are for an empty portfolio have obviously the value 0:

$$\mathcal{C}_s(L_t) = 0 \text{ if } L_t^j = 0 \;\forall\; j \in [1, N]. \tag{8}$$

For every sub-portfolio, there may be up to $N + 1$ actions for each upcoming trading decision:

- if the direction of the order (long or short) is contrary to an existing position of the N given futures, a position of L_t can be reduced (actions will be indexed by $j = [1, N]$)
- choose a different transaction with minimal trading costs that does not contribute to the portfolio liqudation (indexed by $j = 0$)

The latter case might be reasonable if a future provides significantly better trading conditions, but it always increases the probability of future rollings as the number of necessary liquidation steps remains from t to the next trading decision at time $t + \mu$. Therefore, $L_{t+\mu} = L_t$ and accordingly

$$\mathcal{C}_s\left(L_{t+\mu}\right) = \mathcal{C}\left(L_t\right) \text{ if } j = 0. \tag{9}$$

holds. In the other case, contracts of the future with maturity τ_j are liquidated ($j = [1, N]$). The generated trading costs $\mathbb{E}\left(C_{\tau_j}(t) \mid \mathcal{F}_s\right)$ contribute to the overall estimation. They are added to result of the costs for the partial liquidation of the sub-portfolio.

Let the function $\mathcal{L}\colon \mathbb{Z}^N \times F \to \mathbb{Z}^N$ represent contract liquidation. For a given portfolio in $\mathbb{Z}^N$, it returns a portfolio with a reduced position in a specific future of F. The overall trading costs are defined by

$$\begin{aligned}\mathcal{C}_s\left(L_{t+\mu}\right) = \mathcal{C}_s\left(\mathcal{L}\left(L_t, \tau_j\right)\right) \\ + \mathbb{E}\left(C_{\tau_j}(t) \mid \mathcal{F}_s\right) \text{ if } j \in [1, N].\end{aligned} \tag{10}$$

The estimated costs $\mathbb{E}\left(C_{\tau_j}(t) \mid \mathcal{F}_s\right)$ for the liquidation of the specific contract are added to liquidation costs of the residual sub-portfolio $\mathcal{L}\left(L_t, \tau_j\right)$. These cases can be summarized to one evaluation method for the minimum liquidation costs:

$$\mathcal{C}_s\left(L_{t+\mu}\right) = \min_{j \in [0,N]} \begin{cases} 0 & \text{if } L_t^j = 0 \\ & \forall\; j \in [1, N] \\ \mathcal{C}_s(L_t) & \text{if } j = 0 \\ \infty & \text{if } L_t^i = 0 \\ \mathcal{C}_s\left(\mathcal{L}\left(L_t, \tau_j\right)\right) + & \\ \mathbb{E}\left(C_\tau(t) \mid \mathcal{F}_s\right) & \text{else.} \end{cases} \tag{11}$$

Equation 11 contains four cases, three of them are already explained. Only the third case which assigns infinite trading costs to the acquisition of positions for already liquidated contracts has not yet been mentioned. This (obviously wrong) estimate avoids the examination of further transactions after a successful liquidation. Thus, the resulting portfolio is always empty and therefore, the recursive evaluation will always stop its calculation with case one (zero transaction costs for an empty portfolio).

Every sub-portfolio can be reached by a finite number of different order combinations. The dynamic programming principle grants all possible paths to be evaluated. The resulting trading path has the minimum transaction costs according to all intermediate predictions. All in all, $\mathcal{O}(t_{\max} \cdot \prod_{i=1}^{|L|} L_t^i)$ elements must be calculated. The best path can then easily be calculated by backtracking.

The selection of the best liquidation points is unambiguous for a single future when all future costs for its contract are predicted. The best liquidation is directly specified by the order subset with the minimum cumulated trading costs. The complexity arises when several liquidations seem to be optimal at the same time. The best compromise may significantly differ from a greedy selection strategy. As every future generates a new dimension in our evaluation table, such collisions become more probable when more futures

are taken into consideration. The task of finding the optimal path for a single future is trivial, the complexity lies in effecting a compromise between conflicting future liquidations. The resulting path for one future is directly specified by the subset of trades with the minimal cumulated trading costs. However, possible collisions in which several transactions seem optimal at the time yield the problem of selecting specific ones. Therefore, the actual decision is based on the evaluation of all further trading steps as well. It is then given by the first trade of the best trading path.

The process of avoiding liquidations due to better trading costs of other acquisitions extends the time until the portfolio is cleared. Therefore, no finite point in time can be identified and the theoretical number of recursions has no limit. However, as future roll costs cumulate for long-running positions, liquidations of contracts near to their maturity are automatically preferred. The recursive date extension will not exceed $t_{\max} = \max(s + k \cdot \mu, \tau_k)$ with k successive futures for this reason.

4 Mean reverse inefficiencies

The following researches focus on the relationship between a spot price S_t the concerning future prices $F_{t,\tau}$. We expect the future prices to converge to the spot price S_t with a simplified cost-of-carry approach. The differences are explained by specific general interest rates $r_{t,\tau}$, so that

$$F_{t,\tau} = S_t \cdot e^{r_{t,\tau} \cdot (\tau - t)}. \tag{12}$$

Several finance products are only traded as futures, so that spot prices must be approximated by the evaluation of future prices. The following approach averages interest rates between all future combinations. The spot price can be extrapolated to the current time:

$$r_{t,\tau} = avg_{i \neq j} \frac{\ln F_{t,\tau_i} - \ln F_{t,\tau_j}}{\tau_i - \tau_j} \tag{13}$$

The interest rates between spot prices and future prices may strongly fluctuate in short periods. The set of different contract prices is referred to as term structure and several researches concerning its internal systematics have been proposed [9, 10]. As even the smallest under- or overvaluations may be used to enhance the performance of a trading strategy, an ineffiency analysis is a crucial step during the future selection process. For this purpose, it will be analysis whether cointegration between the related price series exist. Different from pure arbitrage strategies, there is no lower limit for the intensity of these inefficiencies. They do not need to be high enough to counterbalance additionally emerging trading costs as all trading decisions are already settled. However, the success of this method does not only require the existence of mean reverse effects but also their persistence to ensure a measurable predictability.

We assume the deviations from the average interest rate $\mathrm{d}r_{t,\tau}$ to be potentially inefficient. In case of over- or undervaluations, mean reverse reactions should be taken into consideration. Therefore, we try to characterize the term evolutions of $\mathrm{d}r_{t,\tau}$ by Ornstein-Uhlenbeck processes with

$$\mathrm{d}r_{t,\tau} = \theta_\tau \left(\mu_\tau - \mathrm{d}r_{t-\mu,\tau} \right) dt + \sigma_\tau dW_t \tag{14}$$

The potential mispricings $\mathrm{d}r_{t,\tau}$ converge to the level μ_τ with the mean reversion speed θ_τ with a standard Wiener process $(W_t)_{t \in \mathbb{T}}$. σ_τ represents the influence of random noise. The parameters of this Ornstein-Uhlenbeck process are fitted with a maximum likelihood estimation [11]. The estimated approximation $\beta_{t,\tau}$ can be used to introduce a future counterbalance of mispricings to the average interest rate in the calculation of $v(\tau, t, x)$ (see Equation 6):

$$\beta_{t,\tau} = F_{t,\tau} \cdot \mathrm{e}^{\mathrm{d}r_{t+\mu,\tau} - \mathrm{d}r_{t,\tau}} \tag{15}$$

$$v(\tau, t, x) = \begin{cases} c((\tau - t) - x) + \beta_{t,\tau} & \text{for a buy} \\ c((\tau - t) - x) - \beta_{t,\tau} & \text{for a sell} \end{cases} \tag{16}$$

By the modification of $v(\tau, t, x)$, the acquisition of a presumably overvalued future contract is penalized in the same way in which a sell of such a future is favored.

5 Results

The objective to reduce trading costs in futures markets by selecting specific futures is targeted by two introduced strategies. They are compared with the established front month rolling strategy for a detailed analysis. This evaluation is based on a Monte Carlo simulation with 10000 tests for each strategy that are based on sets of 100 random trading decisions each. These simulations use real time data from the time period from July 2015 to January 2016.

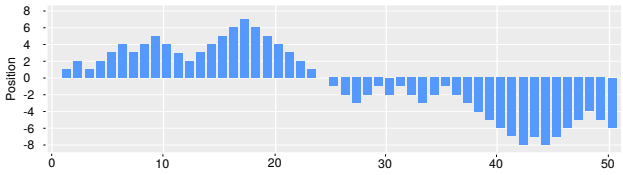

Figure 8: Random portfolio series created by the first 50 trades of an exemplary simulation

Figure 8 shows the resulting portfolio after the first 50 trades of a simulation with a constant volume of one position. Accordingly, the shown portfolio evolution requires 50 contract selections at preassigned times. The result of the front month rolling strategy is shown schematically in Figure 9.

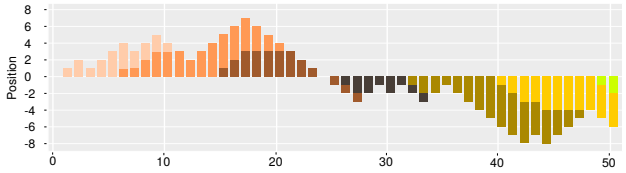

Figure 9: Portfolio evolution of front month rolling strategy

Every color transition represents the change to the subsequent future. Noticeable is the periodic process in which no future is specifically preferred. As every contract is applied for one month, the number of trades is directly dependent from the trading frequency during this period. There are always not more than two different futures in the portfolio. This is induced and without exception, because overlaps directly cause future rollings in this case.

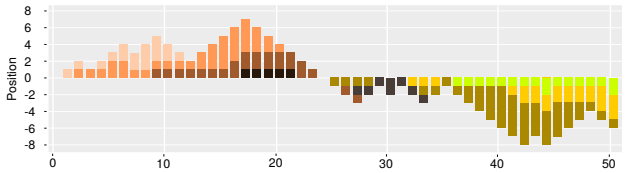

Figure 10: Portfolio evolution of the minimum trading cost contract selection

Figure 10 shows the conversion of trading decisions with the introduced minimum spread approach. The preferred contract changes frequently and yield a more diverse composition with occasional formations with more than two contracts. The expected overall transaction costs are temporary estimated to be the lowest for contracts whose maturity is more than one month in the future, so that transactions partially happen noticeably earlier.

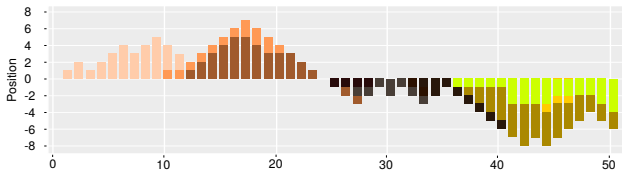

Figure 11: Portfolio evolution of the minimum trading cost contract selection with the Ornstein-Uhlenbeck modification

Mean reverse predictions are added to the selection mechanism in Figure 11. The Ornstein-Uhlenbeck model favors some maturities and leads to situation where some futures are almost skipped. This behavior seems likely as some futures might be seen as under- or overvalued. Even small trading costs might be no compensation in these cases.

The following research examines five different strategies:

1. Front Month rolling strategy
2. Min Spread: strategy that minimizes trading costs as described in chapter 3.5
3. Ornstein-Uhlenbeck: the minimum trading cost estimation (chapter 3.5) with an additional mean reverse expectation term calculated with an Ornstein-Uhlenbeck model
4. Min Spread (SAB): Method 2, but all trading cost evaluations are based on processed spread data according to the ask / bid separation introduced in chapter 3.1. The term *SAB* stands for a separate ask / bid quote analysis during the selection process.
5. Ornstein-Uhlenbeck (SAB): Method 3 with the same ask / bid separation

Table 1: Performance of random sets of trading decisions on three commodities measured in index points.

Return	**Front Month**	**Min Spread**	**Ornstein-Uhlenbeck**
WTI	2.6695	2.5692	3.1958
Natural Gas	-0.1542	0.0245	-0.0625
Silver	0.6951	1.0625	1.4265
Costs	**Front Month**	**Min Spread**	**Ornstein-Uhlenbeck**
WTI	1.4896	1.4126	1.5533
Natural Gas	0.5045	0.3782	0.5913
Silver	1.2405	1.0863	1.5235

Silver	1.2014		1.6495
Costs	**Min Spread (SAB)**		**Ornstein-Uhlenbeck (SAB)**
WTI	1.3840		1.7802
Natural Gas	0.5403		0.4821
Silver	1.2114		1.2247

Table 2: Performance of random sets of trading decisions on three national index futures.

Return	**Front Month**	**Min Spread**	**Ornstein-Uhlenbeck**
S&P 500	-31.8806	-28.4124	-19.1266
Nikkei 225	-760.1611	-680.2393	-580.1591
DAX	-74.1688	-61.5443	-40.5191
Costs	**Front Month**	**Min Spread**	**Ornstein-Uhlenbeck**
S&P 500	35.1198	30.9552	35.9812
Nikkei 225	712.1519	663.0504	634.9534
DAX	80.1419	70.4560	74.2401
Return	**Min Spread (SAB)**		**Ornstein-Uhlenbeck (SAB)**
S&P 500	-5.9915		4.1958
Nikkei 225	-531.0053		-579.5910
DAX	-10.5242		20.5994
Costs	**Min Spread (SAB)**		**Ornstein-Uhlenbeck (SAB)**
S&P 500	32.7817		35.8914
Nikkei 225	649.9088		691.1145
DAX	70.1414		75.0079

The Tables 1 and 2 show the results of Monte Carlo simulations for the different contract selection strategies. Averaged returns and trading costs are depicted for three commodities and three national indices. The cells show cumulated values that are averaged over all simulations with 100 trades each during June 2015 to January 2016.

A return of -760 points with a cost value of 712 points (Nikkei, Front Month) i.e. implies an average

loss of approximately 7 index points per trade that is mainly created by a spread near 7 index points. The loss is expected as the simulations are based on 100 random trades. The corresponding minimum spread approach reduces the cumulated trading costs to 663 points and generated an average loss of 680 points for the same 100 random trading events. The implication of mean reverse tendencies generally increases trading costs, but nevertheless accomplishes higher returns in five cases. These apparently contradicting results encourage the consideration that the term structure temporarily shows mean reverse inefficiencies.

The separation of spreads to supply and demand achieves further trading cost reductions in some cases. These are interestingly more noticeable in the minimum spread approach, the Ornstein-Uhlenbeck method hardly benefits in this category. The return raises clearly in exchange in some cases. The front month rolling strategy averages at a return of -74 points for the DAX index, but generates a win of over 20 points for the improved Ornstein-Uhlenbeck approach. Holding the same positions in different contracts results in a difference of almost 100 index points during the reviewed half year. Especially the newly introduced trading cost separation enhances the result in this case, raising it by approximately 60 points.

6 Conclusion

The selection of specific contracts is a mandatory step in futures markets that may have a huge impact on trading costs and return. Due to a complex spread structure, there are conflictive reasons to acquire contracts with near or distant maturities – the optimal selection depends on many factors. This research opposes five different selection strategies that show considerable disparities in their performance.

The study reveals that a statistical analysis of the used trading strategy and its effects on the portfolio evolution can significantly improve the performance. Therefore, not only detailed analyses of trading times and frequencies but also estimations of upcoming trading costs are contributive. Of course, this advantage requires trading events to be at least approximately predictable. The separate research on ask and bid prices for buy and sell events furtherly improve the trading performance. This holds for commodities as well as for national index futures. The introduction of mean reverse motions after possible over- or underreactions lead to higher trading costs as well as to higher return in the Monte Carlo simulation. On the one hand side, the objective of cost minimization is degraded by the introduction of further influences. On the other hand side, the consideration of over- or undervaluations increases the average return and suggests their existence in the reviewed interval.

ABSTRACT

Line start permanent magnet synchronous motor (LSPMSM) is one of the highest efficiency motors due to no rotor copper loss at synchronous speed and self-starting. LSPMSM has torque characteristics of both induction motor IM and Permanent Magnet Synchronous Motor-PMSM. Using Genetic Algorithm (GA) for balancing magnetic cost and for copper loss minimization, the magnetic sizes and geometry parameter of stator and rotor are found and manufactured for industrial evaluation. This article is also taking account practical manufacturing factors to minimize mass production cost. In order to maximize efficiency, an optimal design method of cage-bars and magnet shape has to be considered. The geometry parameters of stator and rotor can be obtained by an analytical model method and validated by FEM simulation. This paper presents the optimal rotor design of a three-phase line-start permanent magnet motor (LSPM) considering the starting torque and efficiency. To consider nonlinear characteristics, the design process is comprised of the FEM and analytical method. During this study, permanent-magnets and cage bars were designed using the magnetic equivalent circuit method and the barriers that control all magnetic flux were designed using the FEM, and the tradeoff of starting torque and efficiency is controlled by weight function in Taguchi method simulation. Finally, some practical results have been obtained and analyzed based on a LSPMSM test bench.

1. Introduction

Line start permanent magnet synchronous motor (LSPMSM) are well known as high efficiency motor due to outstanding advantages compared to other types of induction motor such as high efficiency [1-3], robust structure and high power density. LSPMSM has rotor cage and permanent magnet to maximum starting torque and efficiency because rotor bar loss will be minimized at synchronous operation. The LSPMSM can apply for many areas of ventilation and fan drives. Most of industrial drive motor can be replaced by LSPMSM high efficiency, it saves from 3 to 5% energy of total electric motor consumption. However, it has some drawbacks of starting torque and efficiency performance based permanent magnet sizes and rotor structure. The stator consists of stacked steel laminations with windings placed in the slots whereas the rotor is made of embedded permanent magnet that can vary from two to eight pole pairs with alternatenorth and south poles. In LSPMSM design, rotor magnetic structure has a significant effect of starting torque performances [4-6]. The torque of rotor cage is to speed up motor reach synchronous operation. The permanent magnet will pull rotor to synchronous speed with high efficiency. To maximize efficiency and starting torque, a practical optimal rotor structure have been implemented by Genetic Algorithm (GA) with different factors of cost, sizes and losses. The practical optimization is material and manufacturing cost of LSPMSM from 2.2kw to 11kW for mass production.

2. Basic parameter of LSPMSM

2.1. Electromagnetic design

In order to determine operation points of permanent magnet circuit, some basic parameters of magnetic circuit have calculated in an analytical model. This point depends on remnant flux density and silicon steel material. In this paper, the magnet of LSPMSM has been carried out by analytical model in fig 1 and NdFeB35 is magnet material used due to its good thermal stability and remnant flux density (~1.3T) allowing its use in applications exposed to high temperature about 180^0C. The flux density is estimated about 0.88 T.

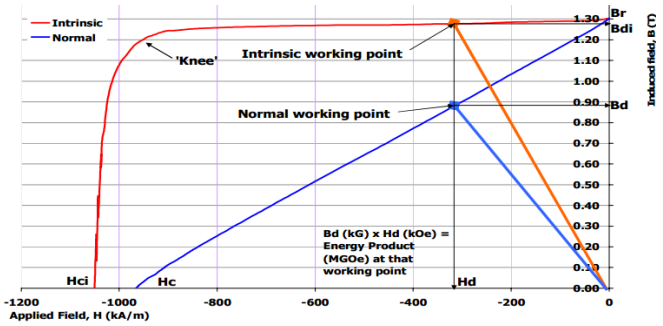

Figure 1 Magnetic properties of NdFeB35

Based on the analytical method, some geometry parameters of stator and rotor can be calculated as follow chart in fig 2. An analytical model was undergone many calculation steps to define basic parameters. Based on torque volume density TVR from 20 to 30 kNm/m3 [5], if we assume rotor diameter equal to rotor length, the rotor diameter D and length L sizes of LSPMSM is determined as follow:

$$D = L = \sqrt[3]{\frac{T}{\frac{p}{4}, TVR}} = \sqrt[3]{\frac{47.75}{\frac{3.14}{4}, 25}} \quad (1)$$

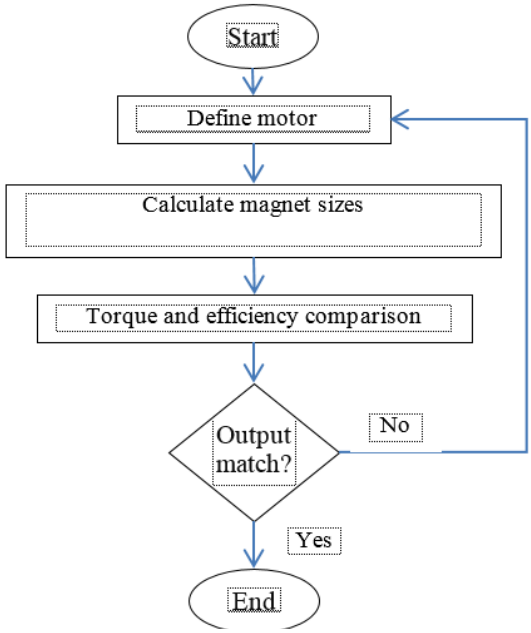

Figure 2 Calculation process

In general, the design process of LSPMSM is similar to that of induction motor. The main parameters (such as outer diameter, rotor diameter, motor length, stator slot, air gap length) are defined by taken into account some practical factors with desired input requirements [3]. The main part of the process is to design the rotor configuration which is embedded permanent magnet. The PM configuration needs to create sufficiently magnetic voltage for magnetic circuit. In fact, there are some possible configurations sorted by the shape and position of PM inside rotor as listed below:

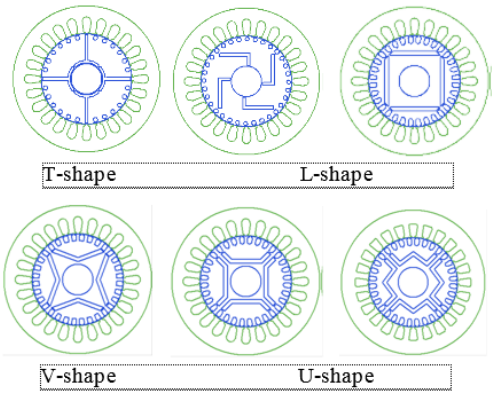

Figure 3 LSPM PM configurations

According to Ilhan Tairimer's research in 2009 [4], the PM configuration has a great influence on motor efficiency. He also pointed out that the V-shape PM gives the highest efficiency. However, the decision on choosing PM configuration depends on the possibility of manufacturing it. In other word, the technique (includes the cost of procedure) and material properties are crucial criteria that impact the configuration selection. By considering them, the I-shape PM is applied in this design.

Table I. Motor parameters

Parameter	Value	Unit
Air gap length	0.5	mm
Stator inner diameter	155	mm
Stator outer diameter	240	mm
Rotor outer diameter	154	mm
Rotor shaft diameter	40	mm
Rotor/stator length	135	mm
PM thickness	8	mm
PM width	60	mm
Number of PM piece	4	-
Stator slot	36	-
Slot space factor	0.48	-
Air gap flux density	0.95	T
speed	1500	rpm

Copper and iron losses are determined efficiency and copper losses in stator winding are biggest, other losses are also calculated and shown in Table II.

Table II. Loss calculation

Loss	Value	Unit
Copper loss	160.5	W
Stator teeth loss	8.1	W
Stator yoke loss	7.6	W
Bearing loss	12.0	W
Windage loss	14.4	W
Additional loss	6.4	W
Total loss	219	W
Efficiency	94.5	%

Some layout of LSPMSM with I-shape are shown in fig 4 due to manufacturing technologies and high flux density in air gap of this rotor configuration.

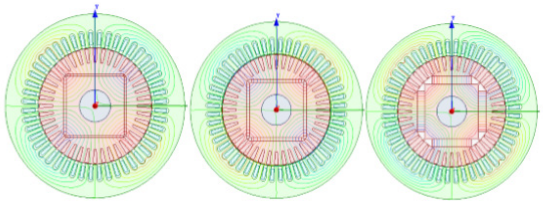

Figure 4 Layout of LSPMSM rpm with different magnet sizes

3. Optimal design of LSPMSM by genetic algorithm

To apply the GA approach, an objective function has to be defined to evaluate how good each motor design is. This objective function may include all the geometrical dimensions of the motor and a large subset of constraints (geometrical constraints) have to be formulated to ensure the physical feasibility of the motor. LSPMSM efficiency is determined as in (2):

$$\eta = \frac{P_{out}}{P_{out}+\sum \Delta P} \quad (2)$$

With: P_{out} is output power which is calculated by:

$$P_{out} = \frac{n_{DC}.M_T}{9.55} \quad (3)$$

n_{DC}: motor speed in steady state (rpm) (determined by FEA)

M_T: load torque in steady state (N.m) (determined by FEA)

$\sum \Delta P$ is total loss in motor.

$$\sum \Delta P = \Delta P_{stator} + \Delta P_{Fe} + \Delta P_{mec} + \Delta P_{add} \quad (4)$$

ΔP_{Fe} core loss in stator and rotor laminations (by FEA)

ΔP_{stator} mechanical loss

ΔP_{stator} additional loss

In order to evaluate efficient objective in 10 scale, the objective function is determined by the following:

$$G_1 = 1 + 9 * (1 - \eta) \quad (5)$$

When $\eta = \eta_{min} = 0$ function value will be 10

$\eta = \eta_{max} = 1$ function value will equal to 1

Second objective function is permanent magnet volume function.

Due to the motor is considered in 2-D planar environment, the permanent magnet (PM) volume calculation is transformed into PM cross-sectional area and PM stacking length is considered constant.

To evaluate this objective in 10 scale, objective function is determined by the following:

$$G_2 = 1 + \frac{9}{S_{max}-S_{min}}.(S_{nc} - S_{min}) \quad (6)$$

Finally, the cost function

$$Cost = \varepsilon_1 \cdot W_1 + \varepsilon_2 \cdot W_2 \quad (7)$$

Where:

$\varepsilon_1 = (G_1 - 1)$ error of efficiency target

$\varepsilon_2 = (G_2 - 1)$ error of magnet volume target

W_1, W_2 weight factors.

Because the permanent magnet cost is more important than other components, the factors are selected W_1=0.8 and W_2=0.2.

4. Optimal results comparison

4.1. Optimized Program Results

Cost factors can be obtained from magnet sizes, based on those results, optimal design parameters will be determined in Table III.

Table III. Cost factor results

No	**Rib (mm)**	**Lm (mm)**	**Wm (mm)**	**Cost**
270	1.35	2.595	54.13	0.57922
323	1.828	2.615	55.03	0.58458
190	1.542	2.5	58.25	0.58826
273	1.756	2.657	54.27	0.58846
157	1.782	2.735	51.98	0.59382
320	1.887	2.57	58.45	0.60239
317	1.497	2.685	49.52	0.60727
327	1.313	2.622	57.71	0.60985
382	1.889	2.913	48.7	0.6134
301	1.281	2.926	49.09	0.61626
245	1.498	2.95	49.11	0.61809
184	1.002	2.92	48.25	0.61933
213	1.666	2.975	48.49	0.62213
123	1.483	3.062	46.76	0.63403
375	1.015	3.06	47.41	0.63436
282	1.923	2.818	55.09	0.63493
251	1.89	2.632	60.08	0.6444
221	1.087	2.785	47.14	0.64621
163	1.822	2.934	53.06	0.64817
244	1.679	3.188	44.48	0.65168

The optimized value distribution results are obtained by the following figure 5.

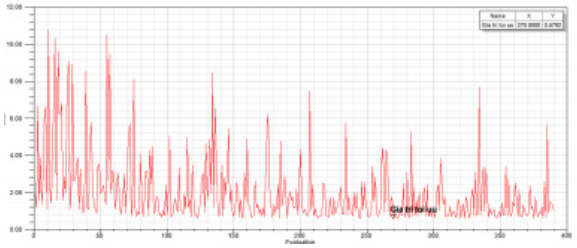

Figure 5 Distribution of optimized value of LSPMSM 7,5 kW

The optimized value is 270 which has the cost valued equals to 0.5792.

4.2. Revaluate optimized results

With the optimized results:

R_{ib} = 1.35 (mm), L_m=2.595 (mm); W_m = 54.13(mm)

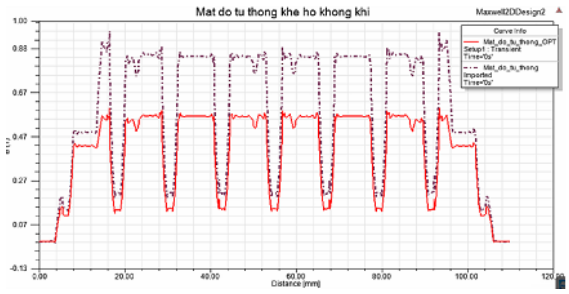
The volume has been decreased 2.5 times compared to original design, notice that PM depth is still unchanged.

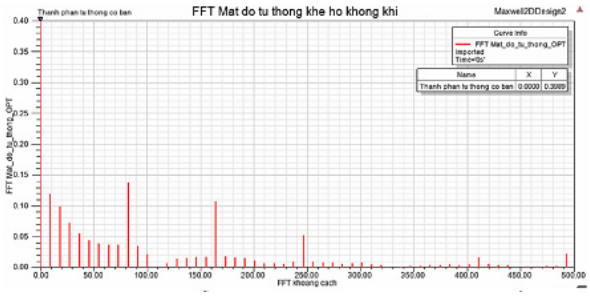
$$V_{nc}^{opt} < V_{nc}$$

In order to be convenient to compare, another results will be shown between before and after running optimization program.

After running simulation by electromagnetic circuit model with optimized parameters, the results are:

a) Flux density and e.m.f





Air gap flux density after optimization is smaller than before due to the decrement of PM width. This proves motor doesn't require large PM energy as before optimized results.

$$W_m^{opt} < W_m$$

$$B_g^{opt} < B_g$$

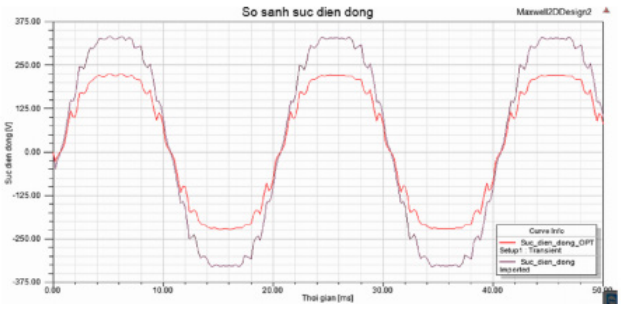


Figure 8 Comparison between e.m.f before and after optimization

Optimized e.m.f is smaller than before optimization corresponding to smaller air gap flux density. Electromagnetic force will cause negative effect of braking torque and dynamic characteristics will be better, faster starting time with the same load torque. In the other hand, peak wave shape will be smoother.

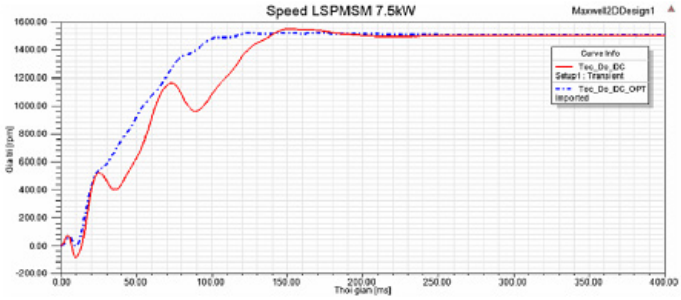

Figure 9 Comparison between speeds starting characteristic before and after optimization

Speed starting characteristic of LSPMSM 7.5 kW after optimization is much better than the previous value with faster stable speed and less ripple.

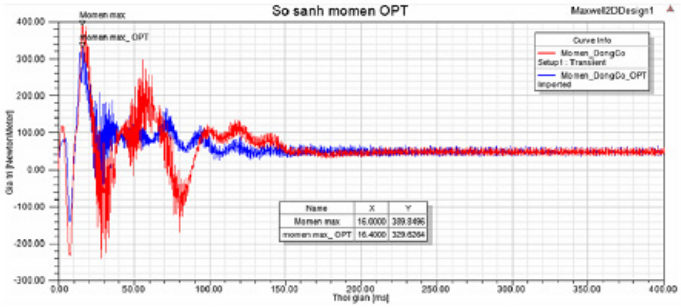

Figure 10 Comparison between speed starting characteristic before and after optimization

Torque starting characteristic of LSPMSM 7.5 kW after optimization is also better than before optimization value, with smaller torque ripple amplitude. It can also be considered from speed starting characteristic.

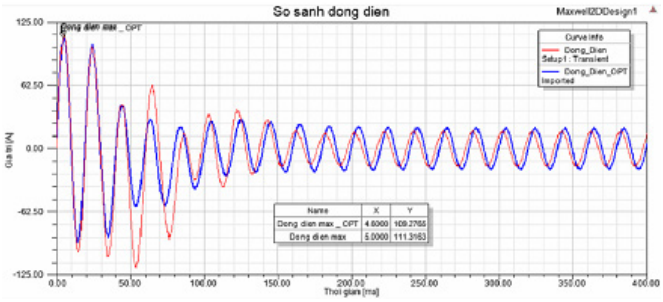

Figure 11 Comparison between starting current before and after optimization

From the figure, it can be seen that the starting current after optimization is smaller than the before value but higher steady-state value due to higher power factor.

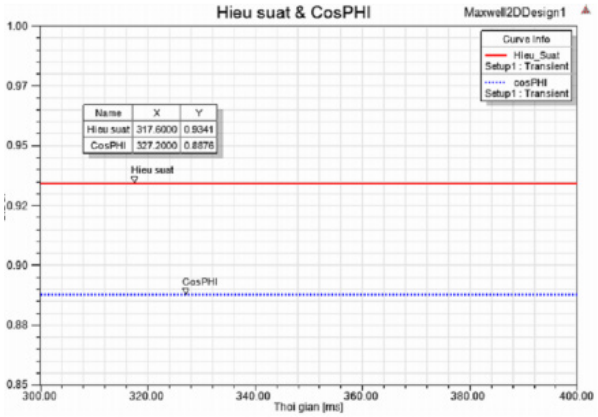

Figure 11 Efficiency and power factor after optimization

According to figure, it can be seen that, after optimization parameters provide higher efficiency. Smaller power factor is caused by the remarkable reduction in PM volume after optimization, however, the new value satisfies requirement that power factor has to be higher than 0.85.

$$\cos \varphi_{rate}^{opt} < \cos \varphi_{rate} \quad (9)$$

5. Calculate temperature rise using thermal model

There are currently some thermal models can be applied to calculate operating temperature of motors. In this research, we chose Lump parameter model [5] to calculate temperature rise of 8 common motor nodes due to its uncomplicated method and rough precision.

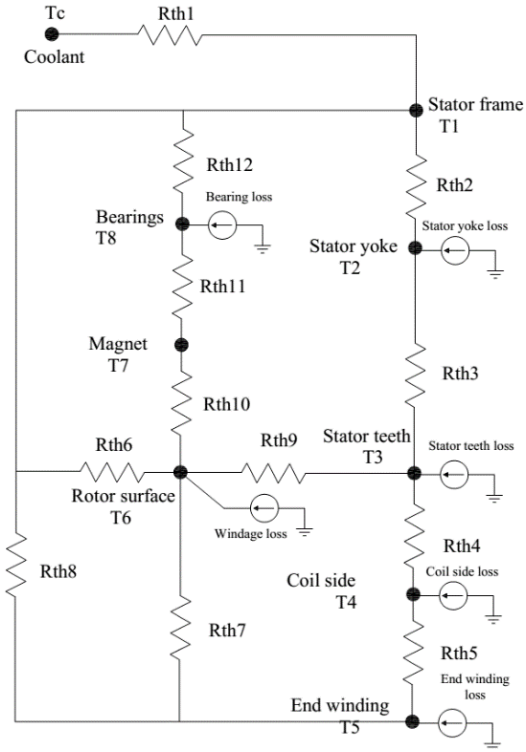

Figure 12 IPM thermal model network

For simplicity, it proposes some following assumptions [3]:

- The heat flows from the slots to the teeth but not directly to the yoke.

- The temperature of copper is assumed constant in every cross-section of the winding, but it varies in the axial direction.

- In the tooth, the temperature is assumed constant in the axial direction.

- Resistive losses are distributed uniformly in the winding.

In order to evaluate the temperature rise, we firstly calculate individually thermal resistance of motor parts, which is affected by its material and parameters. Then by taking them into the following equation with particular losses, we obtain the temperature of each desired node:

Table IV Temperature calculation results

Tc	T1	T2	T3	T4	T5	T6	T7	T8
50	50.0	50.7	51.1	56.0	56.4	68.8	71.0	71.2

If the coolant temperature is assumed to be 50 0C, temperature of the hottest points (usually the permanent magnet and bearings) are under 71 0C. That means with air cooling, the temperature rise is 21 0C at maximum. This result allows the PM to operate well and gets rid of demagnetization.

However, this design is still not really reliable. To validate the design, we'll input all these parameters into RMxprt to see if the output is matched or not.

Using all the calculated parameters and initial input (rated speed, rated voltage, rated output power) as input for RMxprt, we obtained the operating statistic of the motor. Because the design of permanent magnet can have major influence on the motor. An insufficient size of PM could force the magnet to operate in higher flux density which is not recommended or even not adapt the rated output power if the value exceeded remnant flux. Thus, what we must care most about are output power, RMS line current, efficiency and magnetic data.

6. FEM Model Results

FEM has been applied to investigate magnetic performance of LSPMSM design. The flux density of stator and rotor has been validated by FEA model for one pole in fig 5. Flux density curve vs rotor angle is shown in fig 6. Average values are 0.5 tesla in good agreement with calculation.

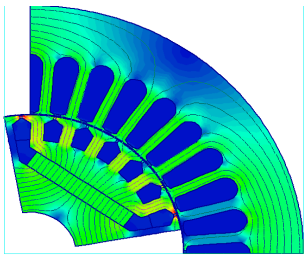

Figure 13 Flux density distribution

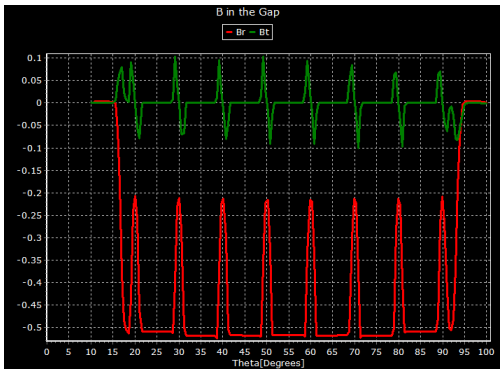

Figure 14 Flux density in air gap results

Magnetic circuit is obviously not saturated and magnet flux density is also adequately high. That allows the motor to operate in overload mode which has not been defined yet.

Torque and efficiency of LSPMSM design play an important role on implementation of this motor. The torque curves of rotor cage, magnet and motor are shown in fig 7.

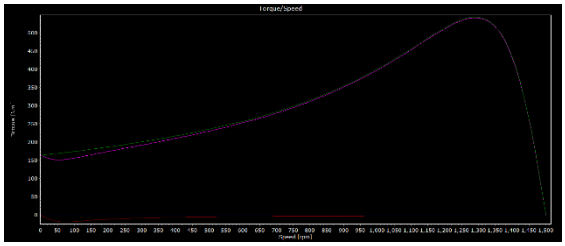

Figure 15 Torque of cage, magnet and motor results

Efficiency of 91% with 10% overload in fig 8. The power shaft is 8 kW started direct from grid. From those results can be concluded that LSPMSM is higher efficiency with IE 2, 3 than induction motor. Total cost of LSPMSM is more expensive than IM but lower operation cost of electric energy can help LSPMSM payback in short time.

Temperatures of rotor and stator tooth, yoke and windings have been calculated under natural convention. The results of analytical and model are good agreements.

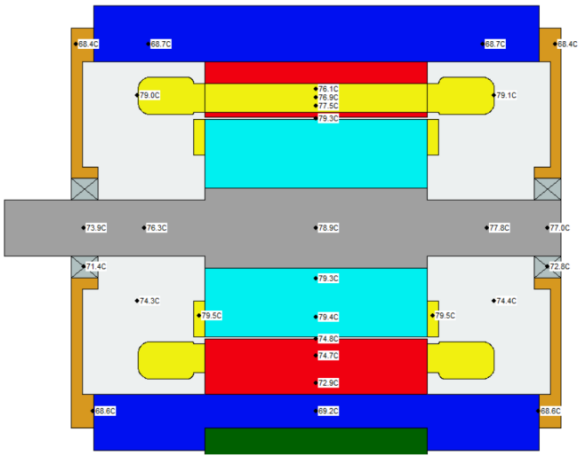

Figure 18 Temperatures of stator and rotor

7. Hardware test bench setup

Rotor magnetic slots have manufacture by wire cutting after die-casting rotor bars and shaft assembly as fig 9.

Figure 16 Rotor magnet slots

The whole hardware of LSPM motor was built together as fig 10.

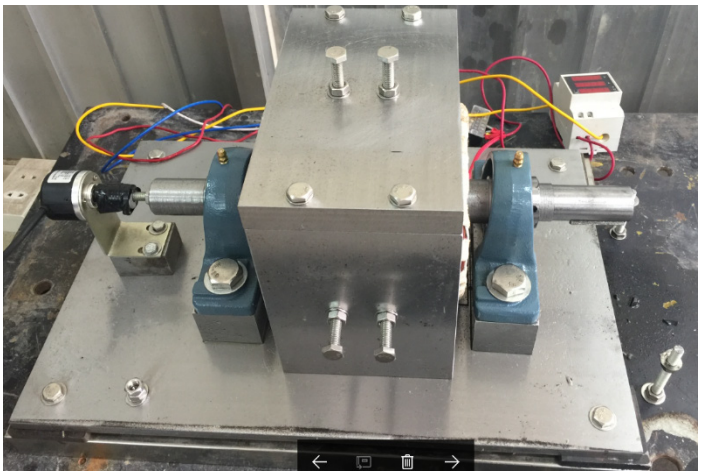

Figure 17 Hardware of LSPM motor

In order to control air gap of rotor and stator, adjustable screw have used to change stator position in three sides. The rotor shaft was connected to encoder to measure speed of motor though NI card and LabVIEW software. Especially, it can measure the dynamic speed performances to validate period of time for speed synchronizing. The LSPM motor was setup to evaluate synchronizing speed under different load and voltage by autotransformer of 10 kW. The transient time for constant speed is less than 0.8 second.

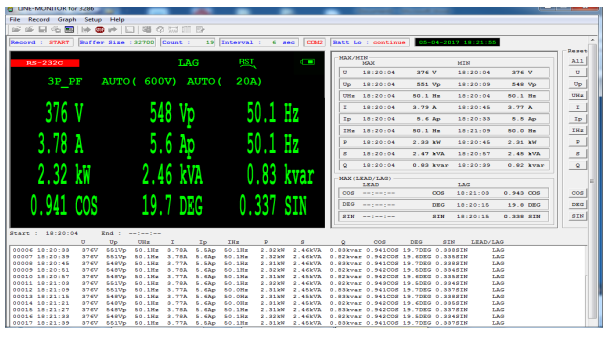

Figure 19 Experiment results of LSPMSM test

8. Conclusion

The paper has presented a comprehensive design of a LSPMSM for industrial applications. The design was calculated by analytical method, validated by Ansysmaxwell software. Particularly, thermal calculation was carried out to assure that the permanent magnet cannot be demagnetized under steady operation. Optimal design parameters have been calculated by GA program. Those results have evaluated by analytical and model methods. The hardware test bench has been built to evaluate synchronizing speed under different loads. The GA program results are LSPMSM design and manufacture cost with lowest price for mass production similar induction motor prices and transfer to industrial companies.

ABSTRACT

Multiprocessor Systems-on-Chip (MPSoC) allow the implementation of heterogeneous architectures with a high integration capacity. In recent years, computational requirements MPSoC are increasing exponentially. This complexity, coupled with constantly evolving specifications, has forced designers to consider intrinsically flexible implementations. Deploying applications typical of multimedia domains is difficult, not only due to the heterogeneous parallelism in the platforms, but also due to the performance constraints that typify these systems. An application can be modeled as a set of cooperative tasks. A task can be implemented in software or in hardware depending on its complexity and the involved cost. Our proposal is a fault tolerance approach which combines the results of a performance model and a technical's fault tolerance. We interest of the dynamic migration task to resolve the Fault-Tolerant for Multiprocessors Embedded System. We exploited an example of multimedia application (MJPEG decoder) to find optimal Fault tolerance systems. Our aim in this paper is to exploit the classic technique of fault tolerance. The solution chosen is the transformation of software processing into hardware processing. And also, exploitation of hybrid models (simulation/analytics). The goal is to have a Fault Tolerant Embedded System.

1. Introduction

This paper is an extension of work originally presented in 11th International Design & Test Symposium, IDT 2016 [1].

Multiprocessors System-on-Chip (MPSoC) is a system that contains several heterogeneous processors interconnected around advanced communication architecture as a Network on Chip (NoC). Nowadays, Multimedia applications use MPSoC architectures in order to achieve high performance. These architectures may include different types of computation units (DSP, Microcontroller...) and use different diagrams of communication.

We distinguish in the literature [2,4] three design approaches for MPSoC: (1) platform based design, (2) components based design and (3) synthesis system. In this paper we are going to focus on the first approach that targets the implementation of an application on configurable prototype architecture.

We follow along our work the MPSoC hardware/software design flow proposed by [5]. The software and the hardware are then gradually refined and simulated on four levels of abstraction. These levels are System Level, Virtual Architecture, Transaction Accurate and Cycle Accurate. System Level (SL) is the highest level of design flow. It provides an environment for parallel execution. The application is described as a set of processes that exchange data only through the FIFO blocking point to point. Virtual Architecture (VA) level is more detailed than the standard SL. The major difference is that it includes information on the architecture. For abstracting the underlying hardware architecture, the code of tasks using APIs known as HdS (Hardware dependent Software). Primitives of these APIs (ex. Send/Receive) access to explicit communication components. Transaction Accurate (TA) level is the second intermediate level. In this level, the tasks are linked to an Operating System (OS) and a library of communication to implement the communication and management services tasks. This software layer uses primitives of Hardware Abstraction Layers (HAL). The data transfer uses explicit addresses. The hardware platform is more detailed, including a communications network, the devices accessed by HAL-API, and an execution model of abstract processor. Cycle

[*]Corresponding Author: Kamel Smiri, Université de Tunis El Manar, Faculté des Sciences de Tunis, Laboratoire LIP2, 2092, Tunis, Tunisie
Email: smiri_kamel@yahoo.fr

Accurate (CA) level is the lowest level. At this level, the HAP-API is implemented. This implementation is done by adding a HAL software layer and a processor for each sub-system (for example, we create an implementation and a model for ARM, MIPS, and SPARC...).

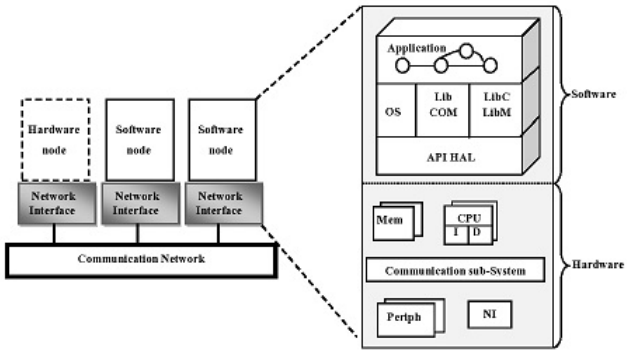

Figure 1 Typical architecture of MPSoC systems

Figure 1 present a typical architecture of MPSoC which is composed by software and hardware nodes connected by a communication network. Hardware nodes are component which does not have the ability of programming. A communication network connects all the nodes together. Software nodes provide the execution environment for applications tasks.

The software node is structured into several layers:

- Application Layer, this layer represents a set of tasks of the application which are carried out in parallel, in order to profit to the maximum of the parallelism offered by architecture multiprocessors. This layer communicates with the software node by calling on primitives of the operating system (OS).

- The Operating System OS, the operating system makes it possible to provide an interface between hardware equipment and the application.

- Libraries, the objective to use the library of communication is to call on the channels of communication and to use the various features of the library C standard and the library of mathematics.

- Hardware Abstraction Layer, this layer makes it possible the operating system to interact with the material peripherals on a level abstract rather than on a detailed material level.

The motivation of the paper is to explore the design space (Design for Space Exploration DSE) by early in the design cycle. We present in this paper a methodology for the migration of a software task in hardware component of a multimedia application at Transaction Accurate level and at Cycle Accurate level. The chosen application to illustrate our approach is the MJPEG decoder that is characterized by its high treatment density and important data exchange. This paper is organized as follows. Section 2 presents the related work. Section 3 gives an overview of Fault-Tolerant in Embedded Systems (MPSoC) approach. Section 4 presents the experimentation of MJPEG Decoder, with the objective to show the efficiency of our approach.

We propose in this paper an extension of the paper conference (IDT 2016) [1]. Mainly, we have added the following parts: a) An advanced synthesis on related works, b) A detailed description of our dynamic migration approach (based on Fault-Tolerant in Embedded Systems (MPSoC)), and c) A series of experiments to illustrate the effectiveness of our approach. We have added some experimentation that shows the effectiveness of our approach. The MJPEG decoder (which is a refresh application) is chosen to get me the dynamic migration efficiency. The IDCT task is chosen to show the gain during dynamic migration of the software to the hardware.

2. Related works

Due to the complexity of multiprocessor systems, the probability of failure is all the more important that it requires special consideration. Indeed, during a failure, a part of the application state disappears and the application may pass in an inconsistent state that prevents it from continuing normal execution. To perform effectively and properly, it must withstand stresses related to the execution environment. It must be able to tolerate the failure of one or more components. Fault tolerance is the property that keeps the smooth functioning and continuity of the system during a failure. So the intensity of the fault is not proportional to the decrease of the system load operation since found contents a very small mistake can cause a total blockage in a system designed.

There are many causes for failures in distributed systems. In [2], the author focused on solving crash failures in GRID computing, their proposal aims to ease the process of recovery when system failures are detected at runtime avoiding the necessity for application restarts. Their proposal works through a set of services that performs transparent task migration over the computing nodes, hiding the complexity related with error handling when a hybrid programming model based on Open MPI and OpenCL is employed.

In [3], the author proposes scheduling algorithm of the adaptive fault tolerant tasks which is a combination of two fault tolerant algorithm TMR (Triple Modular Redundancy) and DMR (Dual Modular Redundancy) and it also benefits from EDF and LLF task scheduling algorithms for decreasing miss rate of tasks. The main goal of these algorithms is to find a proper tasks assignment on the cores and tolerate processing component failures which could either be homogeneous or heterogeneous, so this algorithm is more perform than DMR and TMR methods in average 35% which can guarantee the proper execution of running tasks and reduce the total time of task execution.

In [4], the authors proposes an offline task remapping technique to minimize the communication energy and task migration overhead of an application mapped on a heterogeneous multiprocessor system for all processor fault-scenarios. This technique involves two steps: the first is communication Energy driven Design Space Exploration (CDSE) to select an initial mapping and the second is communication energy and Migration overhead aware Task Mapping (CMTM) for different fault-scenarios. The results show that the proposed CDSE reduces space exploration time of Conception 99% and the reduced energy CMTM 35% average communication and migration over by an average of 20% for all scenarios of single and double faults compared to tolerance techniques existing faults.

In [6], the authors proposes a design flow to explore mapping strategies and shape of the NoC network to improve synchronization performance and the power consumption, then for each step of the flow they used a heterogeneous platform (PC and

FPGA) to fulfill them. The exploration flow is provided to help designers NoC to choose a technique appropriate mapping tasks on a NoC appropriate form for a particular application. The experiments demonstrate that the most appropriate task mapping strategy and the most suitable NoC shape strongly depend on the algorithm used. Depending on the timing latency results obtained and the FPGA resources used, the designer can select the appropriate task mapping strategy on the suitable shape in a short exploration time and with precise timing evaluation.

In [5], the author proposed a methodology to master the migration process at transaction level and they demonstrate the various levels of the design process to deals with the impact of task migration as an alternative to meet performance constraints in the design flow. And, they use a SDF3 tools to provide performance estimation at transaction level. Using the SDF3 tool, the authors model a multimedia application using SDF graphs. Secondly, they target an MPSoC platform. The authors take a performance constraint to achieve 25 frames per second.

In [7], the team of Tahir maqsood are conducted a detailed quantitative evaluation of the selected dynamic task mapping algorithms for NoC based MPSoCs for a wide range of mesh sizes with varying task and communication loads. Comparisons are conducted with varying network load, number of tasks, and network size for constantly running applications. Moreover, they propose an extension to communication-aware packing based nearest neighbor (CPNN) algorithm that attempts to reduce communication overhead among the interdependent tasks. The results indicate that proposed mapping algorithm reduces communication cost, average hop count, and end-to-end latency as compared to CPNN especially for large mesh NoCs. And the proposed scheme achieves up to 6% energy savings for smaller mesh NoCs. Finally, results of formal modeling indicate that proposed model is workable and operates according to specifications.

Synchronous Data Flow SDF is a particular case of the data flow and Petri network. Formalism SDF is often used for the entire predictable systems, in which the number of samples of data consumed and produced by each node with each execution, is specified a priori. Graphs SDF constitute the central element of modeling by SDF3 [8]. Moreover, SDF3 tool integrates several commands, for each one has a precise function. Indeed, the command sdf3flow is most interesting of tool SDF3 since it makes it possible to deploy an application graph with a constraint on architecture graph [9].

System on Chip Library (SoCLib) is an open platform for the virtual prototyping of MPSoC systems. SoCLib is a tool based on the simulation which it allows the development of platforms of virtual prototyping and facilitates the exploration of architectures by means of software tools to conceive embedded applications and of library Open Source is made up of models of high level simulation written in SystemC for the material components, which allow fast simulations [10].

Following our synthesis established in Table 1, we propose to use the contributions proposed in the paper (4) and paper (5), which we will be useful to propose a new fault tolerance approach based on dynamic migration for Embedded Systems.

3. Fault Tolerance Approach for Embedded Systems

Fault tolerance approach for embedded systems multiprocessor (Multiprocessor System on Chip MPSoC), combines the results of a hybrid model (proposed by LIP2 laboratory, in [6]) and a technical fault tolerance that is based on the dynamic migration. This approach provides an effective solution to the current problems of modern embedded systems.

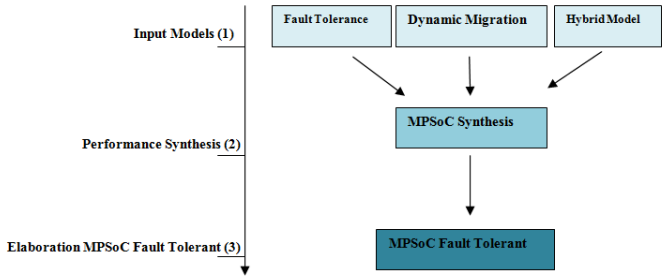

Figure 2 Fault tolerance approach for Embedded Systems

Our Fault tolerance approach for Embedded Systems is structured in three steps: 1) implementation of input models (Hubrid model, Dynamic migration technique, Fault tolerance technique), 2) performance synthesis and 3) Elaboration MPSoC Fault Tolerant.

3.1. First step: Input Models

The first step shows the essentials components of our approach citing hybrid model and fault tolerance techniques based on dynamic migration. The hybrid model (MH) resulting hybridization of two performance estimation methods: Analytical Method (MA) and Method based on simulation (MS). This model allows the exchange of information between the two methods MA and MS through an intermediate bonding layer whose goal is to treat various types of systems and reduce the time estimation and evaluation of performance and a low error rate. So, the aims of the MH model, is to combine the strengths of both MA and MS methods.

Note that the analytical method is characterized by the speed of optimal solution. It is based on the exploitation of SDF graph,

this formalism to model the software applications, hardware and software requirements for deploying tasks on hardware resources. The analytical model used in this approach is a synchronous data stream which is a particular case of the data stream (Data Flow) and Petri network, to generate the mapping of the software application on the hardware platform, not only but also the usage rate of hardware resource which can be regarded as performance indicators.

The simulation-based method is characterized by the precision of the results. So in this model the designer must perform three tasks: Define the structure of the software application, Set the hardware architecture and Check the deployment of the software application on the hardware platform. Concerning technical fault tolerance that is based on dynamic migration, we propose to use migration software / hardware in a multiprocessor architecture, as a solution for fault tolerance.

3.2. Second step: performance synthesis

For the second step is the synthesis step we will make a complete architectural exploration of which will choose a multiprocessor hardware architecture by specifying these settings, A software application and we will follow the simulation and implementation of this application on the architecture while retaining control over the brutal mistakes that makes system failures.

3.3. Tree step: Elaboration MPSoC Fault Tolerant

The last step of our approach that will get a MPSoC fault tolerant. This step involves a component fault monitor CCP noted that the state's objectives of monitoring the system running. This hardware component in two missions which should take care of: detecting hardware failures and handling. CCP's interest is to eliminate any dependency on the rest of the system, consequently control failures will be independent of the processing part or in cases of failures remains functional and it keeps the communication is with the rest of system or with the outside (network). At the end of our proposed approach to fault tolerance in embedded systems multiprocessor allows to restructure the system into two subsystems: the first subsystem dedicated to the execution of the application and the second a dedicated subsystem fault tolerance.

Migration is the solution for fault tolerant problem in MPSoC. The dynamic migration is structured on four steps: (1) modeling software by KPN; (2) mapping and execution; (3) performance evaluation migration.

- *Modeling software by KPN*

First of all, we have modeled a software application on a target multiprocessor architecture. The application is a set of tasks interconnected by communication channels (FIFO) each architecture used contain one or more hardware accelerators where migration can be activated for critical tasks. And, we also fix the performance constraints that must be satisfied.

- *Mapping and execution*

In the second step, we make mapping of the software part on the hardware platform that contains the hardware component. We rely on profiling results of the application to detect the task requiring migration. This task will be transformed into hardware coprocessor to accelerate the processing of the complete system.

- *Performance evaluation of Migration*

To migrate a task from the software to a hardware accelerator, we propose three steps that need to be gone through: (1) Hardware description, it is to design a hardware component and integer throughout the MPSoC system; (2) The instantiation of the task as a hardware task; (3) The deployment of the task as hardware task.

When you decide to execute hardware a task, we start the backup from its current state including the control and the task selected in the shared memory information. Then the task migrated will be deleted or suspended on the source tile.

4. Experimentation: MJPEG Decoder

The figure 3 present Our architecture is formed by two processors ARM, a coprocessor for the TG task, a coprocessor for the RAMDAC task and a coprocessor for the migrate task.

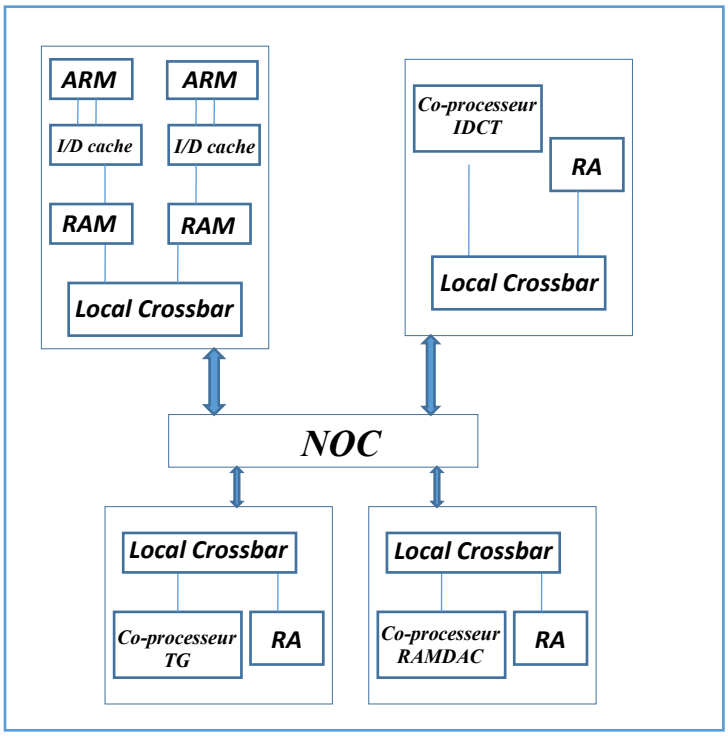

Figure 3 Architecture Hardware Platform for Embedded systems

One has validated the Fault Tolerance Approach for Embedded Systems using a Motion JPEG decoder. One wants to find an implementation of the MOTION JPEG decoder realising 25 frames per second (fps) as a functional constraint and using 50MHz processors as a non-functional constraint. The MOTION JPEG decoder reads a stream of JPEG images from an input peripheral: a traffic generator named TG and writes pixels on an output peripheral: a digital-to-analogue converter named RAMDAC. The first functional bloc DEMUX dispatches the input stream to the other blocs. The decoding chain (Fig. 5.a) begins with the decompression bloc (VLD), then the zigzag rearrangement bloc (ZZ), followed by the inverse quantification bloc (IQ). Finally, the stream passes to the inverse discrete cosine transformation (IDCT).

Based itself on migration diagram presented in Fig. 4, we transform the software task IDCT to hardware component. The validation of hardware IDCT is carried out in two stages. The first is the validation of behavioral IDCT; by comparing the results of the implementation software IDCT in C with the equipment in SystemC. The second step is the validation of the communication interface that interconnects IDCT block with the rest of MPSoC system. The integration is made by adding a software/hardware channel between VLD-IDCT and a hardware/software channel between IDCT-LIBU. We limit ourselves to adapt to existing protocols KPN channels to have a coherent refinement. We have structured hardware IDCT component on three layers: (1) an adapter for easy connection to the rest of MPSoC system, (2) the interface module that manages the exchange of data between SystemC module and the rest of system, and (3) the true behavior of hardware component. The interface module is composed of two SystemC modules *Write* and *Read*, and two FIFO with finite sizes (64 KBytes). *Write* module written in the first FIFO data from the VLD. *Read* module permits to read the data processed by IDCT and sends it to the LIBU. Primitives wait ($t_{_Write}$), wait ($t_{_Write}$) and wait ($t_{_IDCT}$) allow modeling of execution time modules respectively *Write*, *Read*, *IDCT*.

For aim of determining the timing of hardware IDCT and functions Write and Read on target technology (Xilinx, Altera ...), we explored GAUT tool, which is among architectural synthesis tools under constraints. For a cadence = 100ns and period = 10ns, the execution time of the IDCT is $t_{_IDCT}$ = 100ns for the treatment of Macro-Block (8 × 8 pixels). We estimate that the execution time of each module Write and Read are equal and is $t_{_Write} = t_{_Read}$ = 10ns.

2) Performance migration at CA level

The architecture that we synthesize at Cycle Accurate (CA) level is relative to the constraints laid down at the beginning of the problem. The first constraint is the functional constraint on the decoding speed of 25 frames per second (25 fps). The second constraint is the non-functional constraint on the platform that uses MIPS processors running at 50 MHz. The Operating System *Mutek* is a multiprocessor multithread kernel supporting POSIX APIs. This *Mutek* kernel proposes FIFO based communication layer allowing KPN communications. It includes three different schedulers. In the Symmetric Multiprocessor (SMP) kernel, there is only one scheduler allowing the KPN processes to migrate between processors. The Asymmetric centralized Scheduler (Non_SMP_CS) is only one scheduler affecting statically processes to processors. The Asymmetric distributed scheduler (Non_SMP_D) instantiates one scheduler to every processor and the processes are statically affected to processors. The design space exploration synthesis of kernel scheduling policies and software/hardware mapping are presented in Table 1. This table summarizes the performance of implementation of the MJPEG decoder in number of frames per second (fps).

Table 2: Performance implementation of MJPEG decoder (fps)

proc	SMP-CS				Non SMP-CS		SMP - CS		
	Seq	KPN	ZZ + IQ + IDCT	Double IDCT	Double IDCT	ZZ + IQ + IDCT	IDCT hard	IDCT+V LD hard	IDCT+ VLD+I Q hard
1	12,2	6,72	---	6,78	---	---	7,7	17	24,12
2	12,61	12,01	12,16	12,86	---	12,68	11,49	24,07	32,45
3	12,63	14,1	17,65	18,63	20,49	---	11,55	36,73	32,56
4	12,6	13,86	22,35	22,09	25,53	---	---	---	---

We decide to transform IDCT task in hardware component, which allows us to achieve a speed decoding of 24.07 fps with 2 MIPS processors and 36.73 fps with 3 MIPS processors on a simulation platform. The optimal architecture will use 2 MIPS processors configured with 4 KB memory cache, RAM memory, Pi-Bus and an interruption controller. The 2 MIPS processors are dedicated to execute DEMUX, VLD, IQ, ZZ and LIBU processes with an SMP scheduling policy. In addition, an input peripheral is needed for reading video stream TG and an output peripheral for display RAMDAC. For achieving the 25 fps functional constraint, hardware implementation of the IDCT processes is necessary. If the performance is meadows of 25 fps (for example 24 fps), one accepts the solution under condition to optimize the codes of application until to get the performance of 25 fps.

3) Performance migration at TA level

The modeling of the IDCT in hardware, adding time performance metrics ($t_{_Write}$, $t_{_Read}$ and $t_{_IDCT}$) and the integration of the component with the rest of system, allowed us to perform simulations for three different input images (see Fig. 6.). We note that the best performance is obtained for a configuration of two CPU and hardware IDCT. This configuration agrees well with the results obtained at CA level.

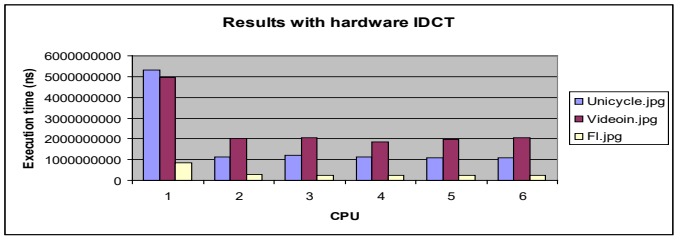

Figure 6 Comparison of simulation Results with IDCT hardware for three different images

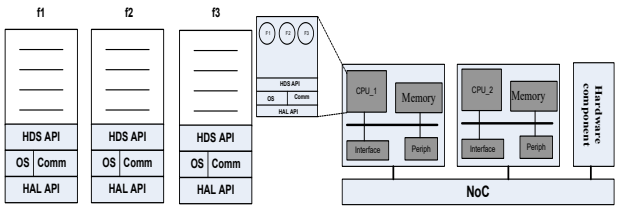
The first stage of our approach is analytical modeling. The latter provide the estimation performance in earlier stage of MPSoC design. In our methodology, analytical modeling is based on the exploitation of graph SDF. This formalism makes it possible to model an application graph, an architecture graph and, it allows to model the constraints (we interested in the throughput constraint as an indicator of performance) under which the deployment will be run (mapping the software tasks on the processors) via SDF3 tool. In order to calculate the throughput constraint, we multiply the number of frames per second by a cycle time.

Throughput = 1/(frequency)(number of frames)*

The first stage of the diagram is the modeling of the application on a target platform at Transaction Accurate level. The Fig. 7.a presents the structure in layers of the software part and the Fig. 7.b shows an example of hardware architecture of a target platform. The application is modeled via the Khan Process Network (KPN) at TA level. The software stack is composed of a set of tasks, HdS-API, Operating System (OS) and HAL-API. Communications at this abstraction level is done through specific addresses by the primitive types *Read()* and *Write()*.



(a) (b)

Figure 7 Transaction Accurate level: (a) software layers, (b) model of the target platform

We are going to try in this section to validate our hybrid model of estimation of the performances for the design of the embedded systems. We begin with the first part which is the analytical modeling and the data, which will be used by this model, can be obtained via tools of profiling either from the traces of a tool of simulation (we choose this method).

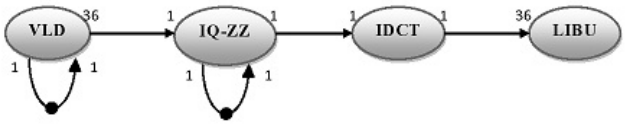


Figure 8 Graph of the MJPEG decoder application

The figure 8 represents the SDF model of the decoder MJPEG which is used during the estimations of performance. The actor VLD produces 36 tokens which correspond to 36 macros block of the image "plane.jpg" with a size of 48 pixels by 48. These are then transmitted to the actor IQ-ZZ, who reorganizes pixels according to the coding inverse zigzag then transmits it to the actor IQ-ZZ, who realizes the inverse quantification. The macro block is then treated by the actor IDCT who makes the inverse discreet transformed in cosine. Finally, the actor LIBU handles the pixels of the image to adapt them to the ring peripheral of exit, it is for it, he requires 36 macro blocks to reconstitute the whole image. Auto-arcs on knots VLD and IQ-ZZ represents respectively the tables of Huffman and quantification auto-passed on executions after execution. Once the actors are modeled, it is necessary to determine the requirements in terms for memory and the execution times of the actors of the graph. These properties are also described in an XML file. This code makes it possible to carry out actor IQZZ on the processor mips0_0 with 174763 cycles like an execution time for this task.

We add the attribute name for the element memory to facilitate the assignment or the allowance of a segment of memory for each actor in the SoCLib simulation tool. The latest information needed for the application description in its XML file is the throughput constraint which must be respectful when the decoder MJPEG mapped on the target platform. This following code presents how can define the throughput constraint in description file.

```
<timeConstraints>
    <throughput>0.0000005</throughput>
</ timeConstraints>
```

In this pseudo code, the objective of constraint is to reach a rate of 25 frames per second. So, the Application must be performed 25 iterations per second and the processor being clocked at 50 MHz (the time unit = 0.2 nanoseconds).

5. Conclusion

In this paper, one presented the technique of Fault-Tolerant in Embedded Systems (MPSoC). We interest of the dynamic migration task to resolve the Fault-Tolerant for Multiprocessors Embedded System. Multiprocessor Systems-on-Chip (MPSoC) allow the implementation of heterogeneous architectures with a high integration capacity. In recent years, computational requirements MPSoC are increasing exponentially. This complexity, coupled with constantly evolving specifications, has forced designers to consider intrinsically flexible implementations. Deploying applications typical of multimedia domains is difficult, not only due to the heterogeneous parallelism in the platforms, but also due to the performance constraints that typify these systems. An application can be modeled as a set of cooperative tasks. A task can be implemented in software or in hardware depending on its complexity and the involved cost. In this paper, our proposal is a fault tolerance approach which combines the results of a performance model and a technical's fault tolerance. Mainly our approach deals with three techniques: 1) Performance estimation in embedded systems, 2) Exploitation of hybrid models (which are based on technical simulation and analytical model), 3) Fault tolerance (based on duplication of software/hardware processing).

This approach has been tested for a Motion JPEG case study, to find out an optimal hardware and software implementation. However, the actual design of MPSoC Fault-Tolerant lacks for a high level performance evaluation model and a technical's fault tolerance. We propose a Fault-Tolerant approach based on the use of three techniques: 1) performance estimation, 2) exploitation of hybrid models (simulation / analytics) and 3) fault tolerances. The goal is to have a Fault Tolerant Embedded System. The limit of our approach is that it will only be applied in the MPSoC design approaches platform based design.

ABSTRACT

Analog layout is created in integrated circuits (IC) computer aided design (CAD) environment and during realization requires a lot of modifications of database objects. Because database objects modification is time consuming, then any improvement and simplification of modification flow in IC CAD environment can increase layout productivity. A proposed new modification concept can speed-up layout work and is very intuitive and easily put into practice. In advance, it allows to apply modern gesture tracking devices for control. By simplifying control of layout object modifications, the productivity of analog layout creation has been improved in the range of 23% to 66%.

1. Introduction

Virtuoso Layout Suite is very universal and user friendly environment for physical implementation of integrated circuits (IC) [2]. This IC computer aided design (CAD) environment supports the Cadence SKILL programming language, which allows implementation of new features [3]. In process of an analog layout creation, engineers spend a lot of time by modifying layout objects properties, inserting accurate values into forms, and confirmation of different windows. Common concept for modification of selected layout objects is through the Edit Properties window as it is depicted in Figure 1.

A width of selected wire can be changed by using a bindkey to call the Edit Properties window, then type a new value for the wire width and press the OK button to apply. This default concept is working well but consist of four steps. If layout object modifications are done very often, then an improvement of the default control concept should speed up the analog layout creation. Considerable effort has been devoted to the creation of a user-friendly and effective interface [4] where principles of IC CAD environment have been described. Since then, evolution of graphic user interface has led to more complex control of CAD systems. This paper introduces a new effective way of IC CAD environment control reducing pop-up windows and forms

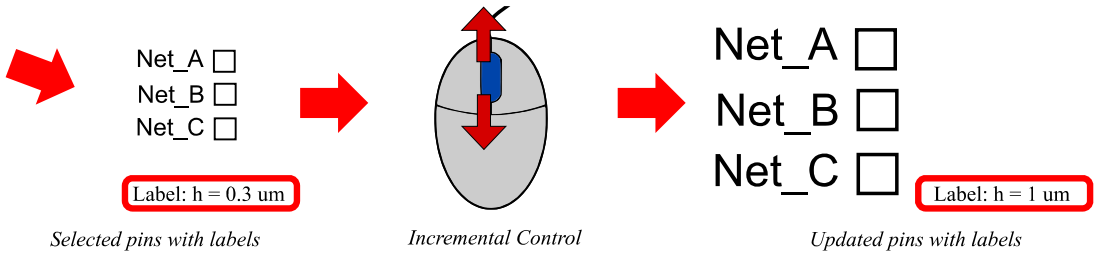

Figure 3 Height modification of pins with labels

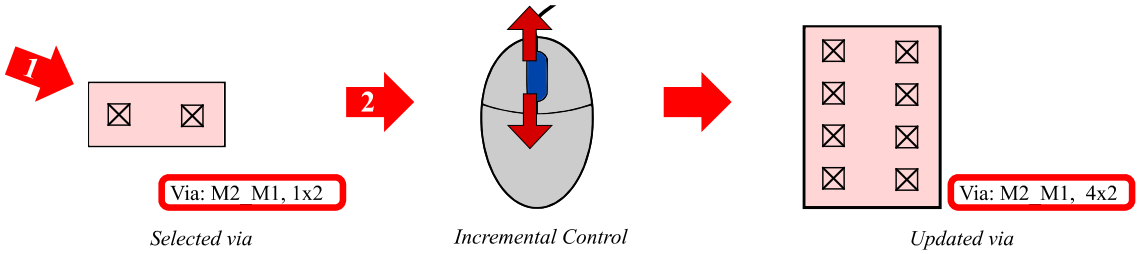

Figure 4 Via modification of rows, columns or both

2. New Incremental Control Concept

A new control concept for changing of layout object properties is defined. The main principles are as follows:

- Replacement of numeric value typing by incremental approach.
- Suppression of the pop-up Edit Properties windows for the most frequent operations.
- Display of changed values in a status bar.
- Application of the same control bindkeys on different layout objects.
- Application of different bindkey modifiers on different layout object properties.
- Possibility of using classic and modern control methods for incremental operations.

This new control concept is called the Incremental Control, where an increment value is applied directly instead of typing a numeric value [1]. After application on a selected wire, the width modification flow is simplified to scrolling of a mouse wheel, which is shown in Figure 2. The exact width value is displayed in the status bar, which allows a user to have all the modifications under control [1].

The same concept of the Incremental Control is also applied on modifications of other layout objects such as pins and their labels (Figure 3). To enlarge or shrink selected pins and their labels, scrolling of the mouse wheel is just needed. In the status bar, the user is informed about pin dimensions or the actual labels height.

The Incremental Control on additional layout objects like vias can be applied (Figure 4). Because the mostly changed properties of via object are rows and columns, control of two independent parameters is needed. To do so, a different bindkey modifier is used to differentiate between rows and columns increment. For example bindkey "*Ctrl + mouse wheel*" is used to change via columns while bindkey "*Shift + mouse wheel*" is used to change via rows.

In the status bar, the user is informed about via array dimensions to immediately know the exact count of rows and columns. Information in the status bar is for the Incremental Control very important because it contains accurate actual values.

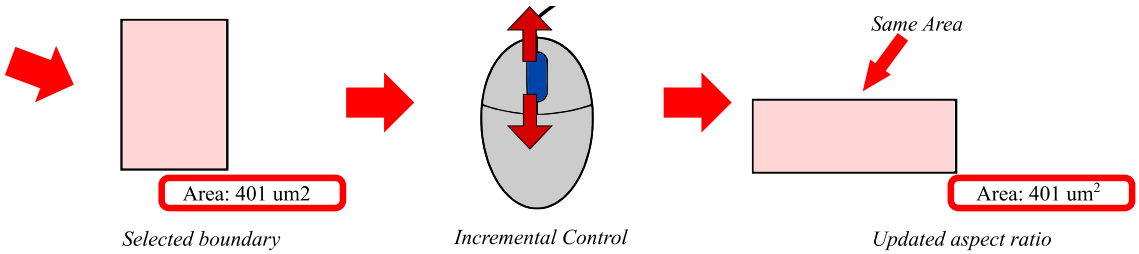

Figure 5 Aspect ratio modification of rectangular objects

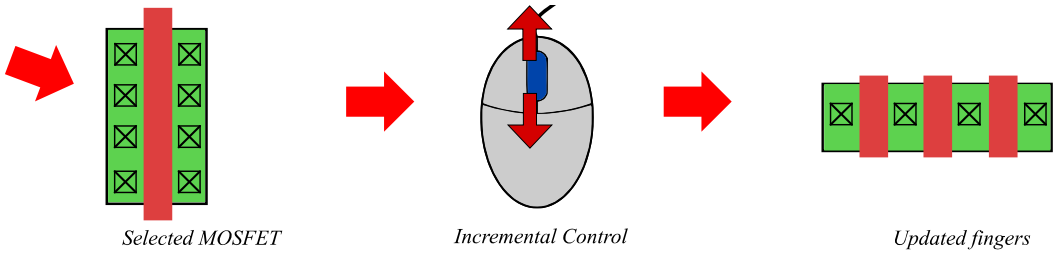

Figure 6 NGF modification of MOSFET

Another practical case for use of the Incremental Control is ability to reshape rectangular layout objects while keeping fixed area. This helps especially during floorplan tasks when the user is able to very quickly modify the aspect ratio of boundaries or rectangles circumscribed to sub-cells to fit expected area. The Incremental Control approach with mouse scrolling is very effective way how to do so (Figure 5).

The Incremental Control allows layout engineers to get simple access to a reshape utility which keeps a rectangular object area and thus has positive influence on productivity of floorplaning as layout engineers can quickly browse among all variants of a rectangle shape to find an optimum. Each modification of the rectangle aspect ratio with the Incremental Control is from user point of view ergonomic and intuitive. In the status bar, the user is informed about an area of the selected rectangle. Such information is very important for floorplaning and is available after each transformation with the Incremental Control.

Now main analog layout objects are discussed. The most important ones are metal-oxide-semiconductor field effect transistors (MOSFETs). Even if there are a lot of different MOSFETs in a process design kit (PDK), there is one common parameter a number of gate fingers (NGF) which is very often modified to allow a MOSFET transformation. The Incremental Control applied on MOSFET allows layout engineers to quickly browse among all possible variants which speeds up the time needed to find an optimal MOSFET shape with the relevant "number of gate fingers" (Figure 6). The Incremental Control applied on MOSFET does not change length and width of a transistor channel but only adjusts the "number of gate fingers" parameter.

Other often used analog layout objects which can be modified by the Incremental Control are capacitors. Goal is to change the aspect ratio of a capacitor while a capacitance or an area is fixed. Generally a capacitor object usually consists of multiple layers, each with different design rules. Due to rounding after each modification, the capacitance of the capacitor is usually slightly changed. This capacitance rounding error has cumulative behavior and for the uncompensated Incremental Control flow can produce a significant shift of the value. Without a correction mechanism the Incremental Control would not be able to precisely keep the existing capacitance value. (Figure 7).

The Incremental Control concept can be used on any other layout object and its properties. If a requested value of a layout object property is very far from current value an adaptive increment or a predefined list of allowed values is used to speed up transformations and improve user experience.

There is an additional constrain influencing user experience. Robustness against a human error. If a way of modifications is very simple, then immunity is lower, for example in a case that all layout object are selected and the mouse wheel is scrolled. Therefore to prevent unwanted modifications, the bindkey modifier such as "*Ctrl*" is combined with the mouse wheel, in the terms of "two hand control".

3. Status Bar for Effective Incremental Control

The status bar is used to retain simplicity and precision of modifications performed by the Incremental Control [1]. In the status bar the user is informed about a current value of a modified property. Information value of the status bar is significantly improved by displaying electrical properties of selected layout objects. For example for a wire or a path the status bar displays not only actual width but even more useful electrical quantities such as resistance, maximum electromigration current (EMC) for direct current (DC) or for root mean square (RMS) and also connectivity. Similarly for vias the status bar displays not only array dimensions but also useful electrical properties like electrical resistance or maximum DC or RMS EMC and connectivity. The status bar is shown in Figure 8. Refreshing all these values is done after each modification and improves productivity.

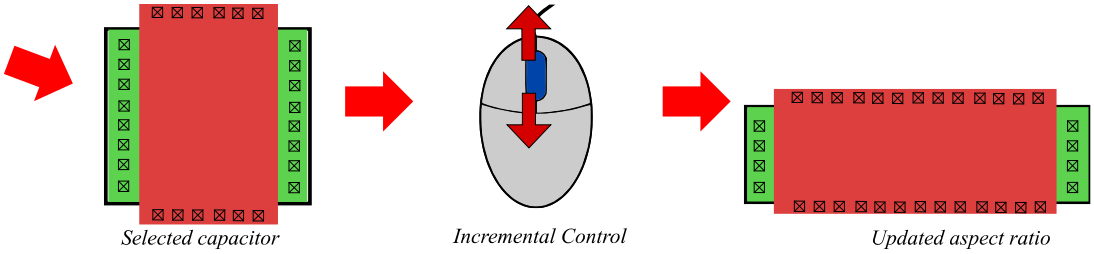

Figure 7 Capacitor transformation

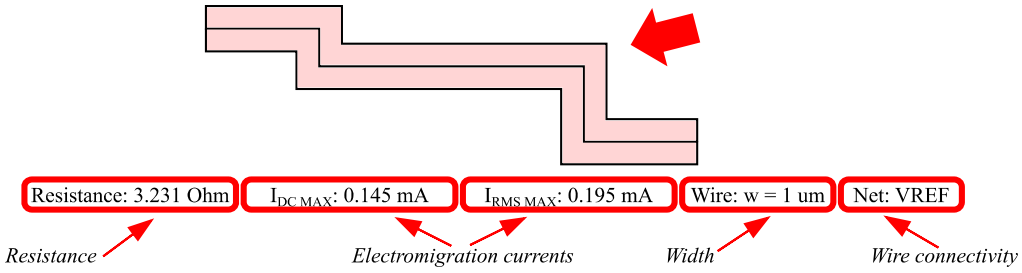

Figure 8 The selected wire electrical and physical properties displayed in the status bar [1]

Figure 9 Gesture control mapped to the incremental interface

4. Gesture Control with Incremental Control

Discussed new control technique is compatible with the IC CAD environment and with current control devices such as keyboard, mouse, or track-ball. In addition to it is also compatible with new gesture tracking systems similar as in [5] and [6]. The Incremental Control is usually mapped to mouse wheel but has been experimentally mapped to gesture recognition camera Creative Senz3D using [7].

By using camera gestures “thumb up” and “thumb down” mapped to Incremental Control bindkeys, a wire width is updated as shown in Figure 9. Based on experience, when gestures were swapped or not recognized and had to be repeated, precision improvement of tested device must be put in place to be suitable for real analog layout application [1].

5. SKILL Implementation of Incremental Control

A flow chart describing the Incremental Control implementation in the programming language Cadence SKILL is shown in Figure 10. SKILL provides direct database access and allows environment customization as described in [3].

The program starts with a user action when the user selects a request type (RQT) by pressing a modifier and performs an increment or a decrement by the mouse wheel. Then the program detects the request type and information about the increment. After the request type and the increment detection, the check is performed, if objects are selected. When not, the program ends. When objects are selected, the program detects object IDs from the CAD (Computer aided design) database (CAD-DB) and reads the Incremental Control Database (IC-DB) which contains a list of changeable properties of each object type and determines the way of all possible modifications. For case of continuous values to be entered, the IC-DB also contains a list of predefined values which the program reads incrementally. If selected objects are members of the IC-DB, then the program loads actual values of the changeable properties from layout objects and loads technique of layout object modification from the IC-DB.

In some cases during layout object modification, an actual value of a changeable property can be slightly different than desired value in order to align layout objects to design grid. After repeated modifications, the actual value can shift from the desired value and a noticeable error can occur. Hence, an initial value of the changeable property is introduced. It allows that the actual value to be always calculated from the original correct value. Hereby the maximal possible accuracy of incremental changes done by the program is ensured. If the initial value is required and not yet set, the program stores the initial value as a parameter of the modified layout object and together with this also creates a record of the last updated value, which serves as a decisive criterion, whether the layout object has been changed in different way by this program.

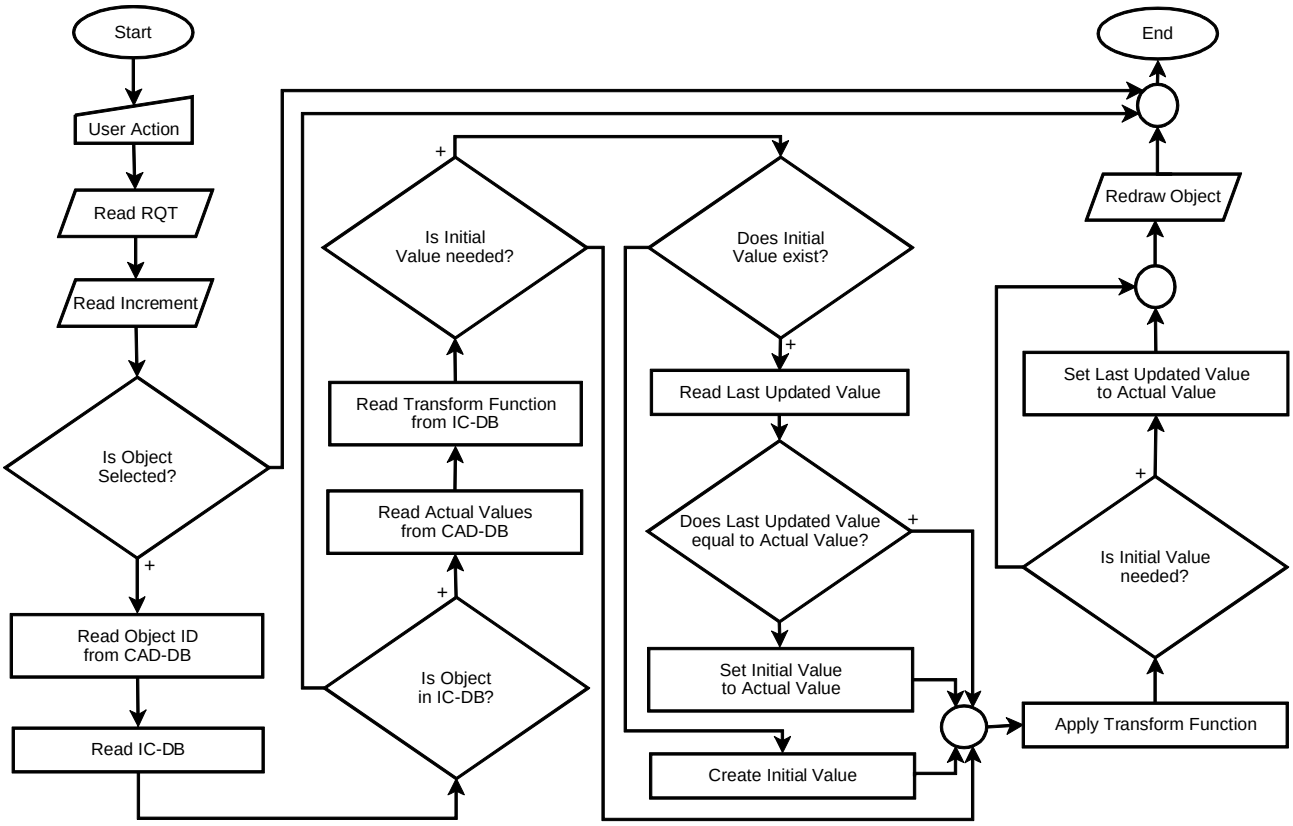

Figure 10 The flow chart of the Incremental Control

Table 1 Layout productivity measurement results [1]

Layout object	t_{SC} (s)	t_{IC} (s)	$(t_{IC} - t_{SC}) / t_{SC}$ (%)
via	5.6	2.0	-64.7
wire	4.6	3.5	-23.4
pin	7.0	4.5	-36.1
label	5.8	3.5	-39.9
pin + label	15.1	5.0	-66.7
rectangle	5.2	3.2	-38.5
transistor	5.6	3.7	-33.6
capacitor	5.4	3.5	-35.2

When the initial value is set, then is read and compared with the actual value. If these values equal, the layout object has not been modified by an external intervention and the initial value is untouched. If these values are different, the external intervention has been performed and the initial value is set to the actual value [1]. It means that the program respects the external intervention.

After these steps, update of a current state is executed based on obtained parameters and the function which has been read from the IC-DB. When the layout object initial value is mandatory, the last updated value is set to the actual value. So, the last updated value is the parameter of the layout object which allows that its value to be used in another run of this program. In the last step, the layout object is redrawn and the actual values are printed into the status bar. By cyclic applications of this program, the layout object is controlled incrementally. This program is able to operate with the OpenAccess and also with the CDBA databases.

6. Layout Productivity Gain

As already mentioned, the Incremental Control allows variety of different layout object modifications by intuitive common control concept. This concept reduces the number of actions needed to reach optimal result. To quantify layout productivity gain value, the average time of standard control modification t_{SC} and of Incremental Control modification t_{IC} to reach target value of layout objects are introduced. The measurement was performed under the same conditions and by a very experienced analog layout engineer with 14 years of experience. At least ten objects of each type were modified. Initial values of properties, which were changed, were set randomly for all objects. Then, the property values were modified to reach the target value by the both ways and the introduced durations t_{SC} and t_{IC} were measured.

Relative difference of t_{IC} and t_{SC} was used for calculation of average layout productivity gain for each layout object type. Based on measurement which is noted in Tab. 1, we can say that layout productivity time saving for the Incremental Control is in the range of 23 % to 66 %. From Tab. 1., it is evident that higher efficiency is reached when different objects are modified simultaneously.

7. Conclusion

The Incremental Control technique was developed to modify various database object properties. This control concept is very intuitive, hence it can be easily put into practice. The Incremental Control can be applied on different properties of database objects such as wires, pins, labels, vias, rectangles, MOSFETs, capacitors or other, which is the main advantage. Incrementally modified properties of objects can be controlled using keyboard, mouse or gesture tracking devices.

Main simplification of IC CAD modification flow is achieved due to removing of typing in object property window and replacing it by value increment. Additional time saving is achieved by suppression of pop-up Edit Properties windows for the most frequent operations. For additional flow improvement Incremental Control was mapped to mouse wheel. Then, productivity of analog layout has been improved in the range of 23 % to 66 %.

In advance, an alternative control was used experimentally when the Creative Senz3D gesture control camera was mapped to Incremental Control bindkeys. For example, width of wire was changed by “thumb up” and “thumb down” gestures. Based on our testing, the gesture tracking device still needs an additional improvement of precision to be suitable for analog layout creation.

A B S T R A C T

In-elastic recovery behavior of seamless tube material has been investigated by uniaxial tensile tests. Unloading Stress–Strain curves obtained under different passes of cold drawing process shows that the percentage of in-elastic recovery to the total recovery increased with plastic deformation. This paper is an experimental study that shows Young's Modulus decreases with plastic strain for ST 52 material. It is found that with increase in plastic strain, Young's Modulus reduces rapidly initially then reduces more slowly and finally settles to stable value due to increase in plastic deformation and ultimately increased residual stresses. This variation of Young's' Modulus is related to internal stresses, residual stresses, micro cracks, dislocations during plastic deformation. Similarly, Scan Electron Microscopy (SEM) and Micro-hardness testing reveals that mechanical properties are better in the first pass sample of multiple cold drawing passes. The results of this study reveals that 10-20% degradation occurs in Young's Modulus for 5-7% plastic strain and better mechanical properties are achieved in the first pass sample.

1. Introduction

This paper is an extension of work that was originally presented in 2016 IEEE International Conference on Industrial Engineering and Engineering Management (IEEM) [1].When a seamless tube is drawn from drawing bench after drawing, the springback phenomenon occurs due to the residual stresses leading to an undesired deformation. This magnitude of springback effect is nearly proportional to the Young's Modulus and strain hardening behavior of material. This phenomenon is particularly critical for high strength steels, which have been increasingly used in the automotive industries in regard to the performance improvement and light-weight design. Generally, the springback strain is an elastic strain.

It is well known that the elastic strain recovery is present during loading and unloading a steel sample and it leads to a hysteresis behavior or energy loss of the material. Thus, description of the elastic behavior strongly affects the springback prediction of a forming simulation. One of the most troublesome problems facing the tubing production industry is springback in the tube making process. With the ongoing miniaturization of products, springback is a dominant effect because material behavior greatly varies in this process.

The mechanism behind springback is the release of residual stresses in a work piece after the forming process. A success of the springback prediction strongly depends on the applied materials model. Among various parameters of the model, Young's Modulus is one of the most important factors influencing the calculation accuracy that should be considered as function of strain. It also influences the plastic-forming quality of the formed components, especially springback. Young's Modulus actually is having correlation with plastic strain and its accurate characterization is necessary to improve springback in the cold

drawing process. The purpose of the investigation described here is to study the influences of pass schedule on the mechanical properties and microstructure, since it is necessary, for the development of ultrahigh strength seamless tubes, to characterize variation of the microstructures and to clarify the mechanism how pass schedule affects the mechanical properties.

2. Literature Review

Many researchers have investigated the effect of Young's Modulus, material behavior and microstructure on springback in different manufacturing processes.

The change of Young's Modulus with increasing plastic strain was firstly investigated by [2]. In this research, he found that the actual springback was greater than that calculated with a constant Young's Modulus and independent of plastic deformation. However, a constant Young's Modulus was often used in many commercial Finite Element Methods (FEM) codes because of its simplicity. A simple analytical model was used to describe the relationship between Young's Modulus and plastic deformation based on experimental results. Great efforts have been made to study Young's Modulus and its effect on spring-back in the recent years [3].Researchers concluded that the correct choice of the yield criterion and consideration of the change in Young's Modulus are essential for improving the prediction accuracy of springback in the numerical simulation [4].Young's Modulus decreases with the increase of plastic strain during cyclic tension– compression deformation and proposed an empirical expression to describe the variation of Young's Modulus with respect to plastic strain [5].The material response is calculated under the assumption of fully elastic deformations in the complete model [6, 7, and 8].An alternative method was explained as inverse forming, during which the loads were reversed and the tools gradually retracted. Because of more computational cost, it is least used. At the same time it is more realistic because the contact forces are present during the unloading step [9, 10, 11,12 and 13].The work reported that the major improvements in the critical properties of a double corrode panel can be achieved using variable blank holder process. Springback was significantly reduced and dent resistance increased [14].Retained austenite exits in many hardenable steels and its presence induced both positive changes in mechanical engineering properties[15].Mathematical expression describing the relation of Young's Modulus with plastic strain was proposed and this expressions was implemented into LS-DYNA for simulation of U-Channel springback[16].The variation of Young's Modulus during loading and unloading was considered to identify different variables affecting ratcheting simulation [17].The work reveals the influence of pre deformation on the springback of steel AHSS sheets under consideration of the Young's Modulus change and the effect of this change as a function of plastic strength[18].An elasto-plastic model using a kinematic hardening model was made for springback analysis in sheet metal forming. The change of Young's Modulus versus plastic strain was proposed by [19]. Strain recovery after plastic pre-strain and associated elastic and inelastic behavior during unloading and unloading of DQSK steel sheet were measured. Slope of the elastic modulus variation was different during loading and unloading step due to the reciprocal dislocation movement. The amount of springback was calculated by using the process of elastic recovery as well as established values of Young's Modulus and poisson's ratio. Results concluded that inelastic strain released from the formed state was major source of additional strain recovery whose magnitude depends on forming stress state [20].

In spite of ample research conducted on springback dependence on Young's Modulus in different manufacturing processes like sheet metal bending, rolling, forming, drawing etc., still there is scope for the prediction of springback in cold drawing of seamless tubes and its dependence on Young's Modulus.

3. Materials and Methods

Material selection process has utmost importance in engineering applications. The failures arising from bad material selection are not uncommon in many industries.

Materials:

The materials under study for dies-plugs used for cold drawing and seamless tubes are:

3.1. Die and Plug material (D3):

The material for dies and plugs is D3 (high carbon high chromium cold-work tool steel) having chemical composition as shown in Table 1.

Table 1 Chemical composition of D3

Component	Min %	Max %
Carbon, C	2	2.35
Chromium, Cr	11	13.5
Manganese, Mn	0	0.6
Silicon, Si	0	0.6
Phosphorous, P	0	0.03
Sulphur, S	0	1
Tungsten, W	0	1
Vanadium, V	0	1

The physical and mechanical properties for die and plug material are tabulated as shown in Table 2.

Table 2 Properties of D3

Properties	**Value**
Physical	
Density (g/cc)	7.87
Mechanical	
Hardness (RC)	64
Modulus of elasticity (N/mm^2)	207
Poisson's ratio	0.29

3.2. Tube material

The material taken in this work is an uncoated cold rolled ST 52 steel with thickness 5.0 mm. The chemical composition of the tested tube sample is shown in Table 3 and the mechanical properties of mother or hollow tube of 75 mm X 5 mm are listed below in Table 4.

Table 3 Chemical composition of ST 52

Component	Min %	Max %
Carbon, C	0.16	0.2
Iron, Fe	-	-
Manganese, Mn	1.4	1.6
Silicon, Si	0.3	0.5
Phosphorous, P	0	0.025
Sulphur, S	0.01	0.025

Table 4 Properties of ST 52

Physical Properties	Value
Density (g/cc)	7.87
Mechanical Properties	
Hardness (Brinell)	207
Hardness (Rockwell B)	94
Hardness (Rockwell C)	17
Ultimate tensile strength (N/mm^2)	602
Yield strength (N/mm^2)	522
Elongation at break (%)	32.6
Modulus of elasticity(KN/mm^2)	210
Bulk modulus(KN/mm^2)	140
Poisson's ratio	0.3
Shear modulus(KN/mm^2)	80

The actual chemical composition on spectrometer is shown in Table 5.

Table 5 Actual chemical composition of ST 52

C	Mn	Si	P	S	Cr	Mo

4. Experimentation

An experiment is a procedure carried out to support, refute or validate a hypothesis. Experimentation is carried to draw a mother or hollow tube through three passes to get the final desired dimensions.

4.1. Cold Draw Reduction

Since a high area reduction is required, multiple drawing passes are generally necessary to avoid fracture of the tubes during the drawing process. To study the effect of Young's Modulus, reduction passes as shown in Table 6 are considered.

Table 6 Reduction passes

Pass Schedule	Outer diameter (mm)	Thick-ness (mm)	Inner diameter (mm)	Reduction on outer diameter(%)
Mother tube	75	5	65	--
First pass	68	5	58	9.3
Second pass	60	5	50	11.8
Third pass	50	5	40	16.7

4.2. Universal Testing Machine (Tensile Test)

Uniaxial tension specimens were cut from the as received tube in the longitudinal direction. The dimensions of each specimen were in accordance with ASTM E370 with the gauge length of 50 mm as shown in Figure 1.In order to minimize the influence of machining forces, linear cutting of the specimens was used. Uniaxial tensile test was carried out on UTM with a precise extensometer. For tensile properties, tensile specimens were loaded in UTM TUE-C-600.Load-elongation data were recorded and converted into stress-strain graphs. Yield strength, Ultimate Tensile strength, Young's Modulus and ductility (% elongation and reduction) were determined in accordance with ASTM standard test procedures (ASTM E18, ASTM E23, ASTM E8).

Figure 1 Test specimens for Tensile Test (Sample photograph)

Tensile test was carried out at each stage of cold draw pass to study the varying mechanical properties. The different mechanical properties measured are Yield Strength (YS), Ultimate Tensile Strength (UTS), Elongation (% E) and Hardness.

4.3. Hardness Testing

For hardness testing, the oxide layers formed during heat treatment were removed by stage-grinding and then polished. The average Brinell Hardness Number (BHN) readings were determined by taking two hardness readings at different positions on the samples, using a Brinell hardness tester. Micro hardness examination was carried out on Vickers hardness tester-MacroMann technologies with load 200 gm on scale HV 0.2 with dwell time of 20 seconds.

4.4. Microstructure Examination

Microstructure examination of all the samples were carried out in Olympus metallurgical microscope. Each sample was carefully grounded progressively on emery paper in decreasing coarseness from grit size 120, 320, 400, 600, 800.The grinding surface of the samples were polished using diamond paste. The crystalline structure of the specimens were made visible by etching using solution containing 3% nitric acid and 97% methanol on the polished surfaces. Microscopic examination of the etched surface of various specimens was undertaken using a metallurgical microscope with an inbuilt camera through which the resulting microstructure of all the samples were photographically recorded with magnification of 100 X and 500 X.

4.5. Scan Electron Microscopy (SEM)

A scanning electron microscope (SEM) is a type of electron microscope that produces images of a sample by scanning the surface with a focused beam of electrons. The electrons interact with atoms in the sample, producing various signals that contain information about the sample's surface topography and composition. For SEM, sample preparation was carried out by polishing and etching the sample as in case of metallurgical microscope. Machine used was Field Emission – SEM Model – Sigma.

5. Results and Discussions

5.1. Tensile test:

The results obtained by tensile test on universal testing machine (UTM) are provided in Table 7 for mother or hollow tube, intermediate passes and final pass.

Table 7 Properties obtained on UTM

Stage	Yield Strength (N/mm^2)	Ultimate Tensile Strength (N/mm^2)	Elongation (%)	YS/ UTS	Strain	Young's Modulus (N/mm^2)
Mother tube	451.20	520.41	18	0.87	0.180	199
First pass	484.10	550.00	17	0.88	0.175	207
Second pass	564.20	620.12	16	0.91	0.160	214
Third pass	630.51	685.21	14	0.92	0.14	222

From this it is clear that mechanical properties are found increasing with the rise in degree of cold working. Also, there is an effect of pre-existing strain of tube on Young's Modulus after cold drawing. It is found that there is inverse proportion between pre-strain and Young's Modulus. Springback prediction and compensation are the major challenges in the modern tube manufacturing industry. In spite of plenty of developments and a certain amount of progress in the field of simulation of tube making processes, the industrial needs for accurate numerical prediction of springback are not yet being met. Springback, a phenomenon that is related to the elastic strain recovery after removal of forming loads, is physically governed by the stress state achieved at the end of forming process and by elastic response of formed parts. The elastic response of the parts is associated with the removal of forming tools. Despite all that, several times it was reported that Young's Modulus drops with the increase in plastic pre-strain in a material which is found in this research work. Table 8 shows the same.

Table 8 Readings of pre-strain against Young's Modulus.

Sr. No.	Pre-strain (mm)	Young's Modulus(N/mm^2)
1	0.160	222
2	0.175	214
3	0.180	207

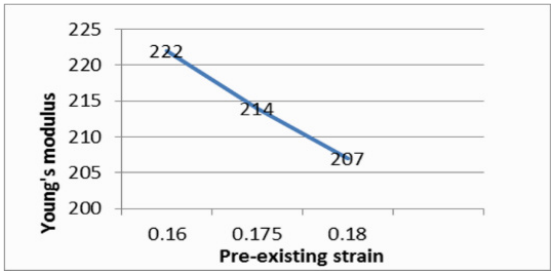

Figure 2 Graph of pre-existing strain vs. Young's Modulus

From Figure 2, it is found that degradation of Young's Modulus was found with increase in degree of plastic pre-strain in a material. Ten readings are taken at 5 different locations (Table 9) for outer diameter of the drawn tubes with digital micrometer of 1 micron accuracy to find the springback. Springback is the deviation from targeted dimension. The results are taken to co-relate the relation of Young's Modulus and springback in cold drawn tubes as shown in Figure 3 and Table 10.

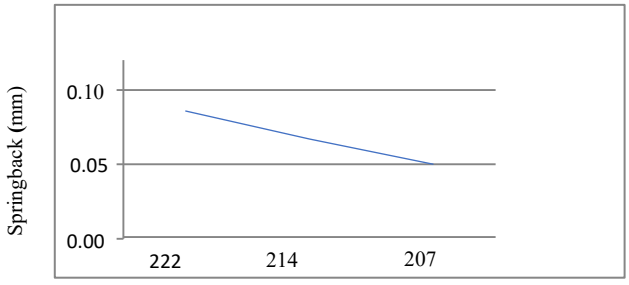

Figure 3 Graph of Young's Modulus vs Springback

Table 9 Tube outer dimensional inspection after each pass of drawing

Tube Size (mm)	Pass	Die size (mm)	Tube outer diameter dimensions (mm)						Spring back (mm)
			1	2	3	4	5	Average	
70 X 5	Mother tube	--	--	--	--	--	--	--	--
68 X 5	First pass	68	68.070	68.087	68.093	68.089	68.091	68.086	0.086
60 X 5	Second pass	60	60.071	60.060	60.063	60.071	60.068	60.067	0.067
50 X 5	Third pass	50	50.045	50.051	50.048	50.055	50.049	50.0496	0.050

Table 10 Young's Modulus against Springback

Sr. No.	Young's Modulus(N/mm^2)	Springback(mm)
1	222	0.086
2	214	0.067
3	207	0.050

From the results; the degradation of Young's Modulus is directly correlated to the degree of plastic pre-strain in tubes. Further, the actual springback is directly co-related to the degradation of Young's Modulus. Based on the studies, the degradation of Young's Modulus have significant effect on final elastic strain recovery and final shape of the product**.** Hence, a control over close dimensional tolerances can be achieved by optimizing the degradation on Young's Modulus which can be optimized by selecting degree of pre strain in tube and reduction ratio.

Table 11 Results of micro hardness test

Pass	Micro hardness readings (200 mg,20 sec dwell)			Average
Mother tube	131	128	130	129.66
First pass	140	140	134	138.00
Second pass	184	185	184	184.33
Third pass	184	198	200	194.00

Table 11 shows that the hardness values increases as number of passes increases.

5.2. Microstructures and grain growth

Microstructures of the tested ST 52 steel samples were examined with Metallurgical Microscope. The specimens for optical microscopy were etched using 3% Nital. The microstructures obtained under microscope are shown in Figures 4-7.

Average grain size in µm : 16.96

Grain size No.: 8.61

Grain size in µm : 17.74 (l)

Figure 7 (j), (k), (l) Microstructures of third pass tube

From the observed microstructure it is found that grain size is decreasing with the rise in reduction. This is due to the increased deformation with simultaneous passes. Further the effect of grain deformation before cold drawing on springback cannot be neglected. Grain refinement is an effective means for improving the strength and lowering the ductile-brittle transition of structural alloys. The improvement can often be expressed in an equation of the Hall-Patch form. However, the appropriate use of grain refinement requires an understanding of the effective grain size that actually governs the mechanism of yielding or failure. Grain size has a measurable effect on most mechanical properties. At room temperature hardness, yield strength, tensile strength, fatigue strength and impact strength all increases with decreasing grain size. Machinability is also affected; rough machining favors coarse grain size while finish machining favors fine grain size. The effect of grain size is greatest on properties that are related to the early stages of deformation. Yield stress is more dependent on grain size than tensile strength. Fine-grain steels do not harden as deeply and have less tendency to crack than coarse-grain steels of similar analysis. There is also an equation expressing the relationship between grain size and yield strength.

5.3. Scan Electron Microscopy (SEM):

SEM scans a high-energy electron beam across the surface of a specimen and measures one of a number of signals resulting from the interaction between the beam and specimen.

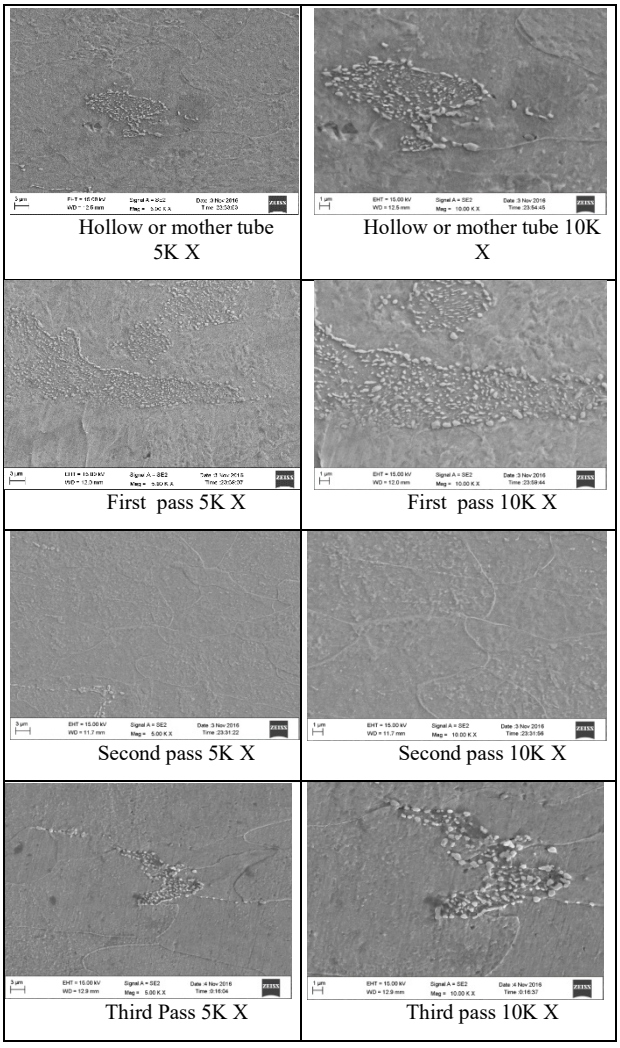

Figure 7 SEM images of all four samples

SEM microstructure shows elongated lamellar boundary structure and equiaxed grain structure. Microstructure reveals size of deformation microstructure gradually increases with increase in pass schedule. The results indicate that slight coarsening of microstructure happens at initial stage due to recovery. Few more samples are tested for mechanical properties and the results are tabulated as shown in Table 12 and Figures 8-12.

Table 12 Results of samples

Pass	Tensile strength (N/mm^2)	Hardness (BHN)	Percentage elongation (%)	Percentage reduction (%)	Young's Modulus (N/mm^2)	Yield strength (N/mm^2)
Mother tube	415.226	129.66	22.80	59.23	393225	208.774
First pass	610.530	136	8.53	32.89	248678	568
Second pass	555.659	184.66	10.94	39.78	165781	547.206
Third pass	378.219	194	37.55	59.53	131342	203.035

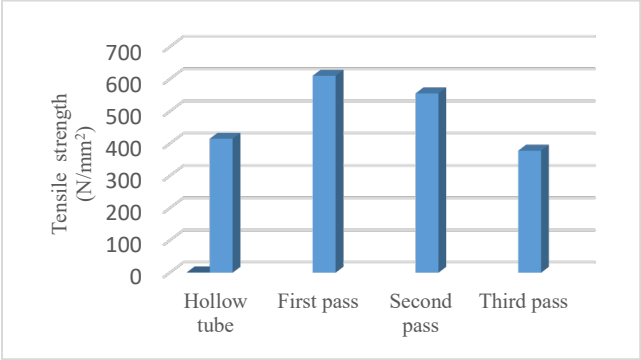

Figure 8 Tensile strength of four tube samples

Tensile strength is more in first pass sample. Greater plastic deformation induced by cold drawing introduces greater strain hardening.

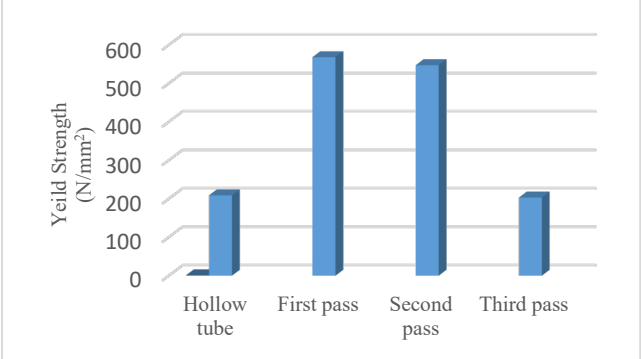

Figure 9 Yield strength of four tube samples

Yield strength is more in first pass sample as shown in Table 9.The reason is that plastic deformation occurs due to the motion of crystal lattice dislocations through the material. The result at large scales is work-hardening: as strain increases, stress needed to cause continued flow increases. Additionally, strain-to-failure decreases.

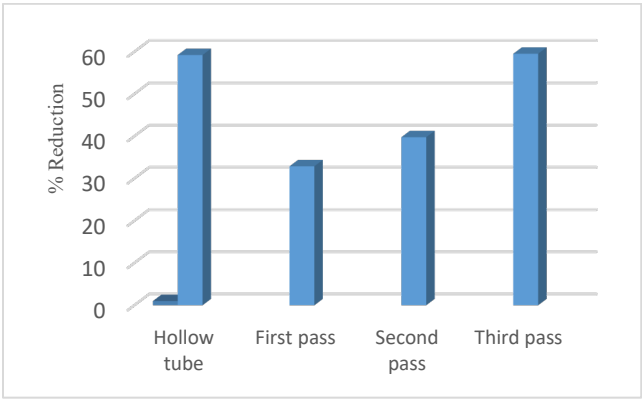

Figure 10 Percentage reduction of four tube samples

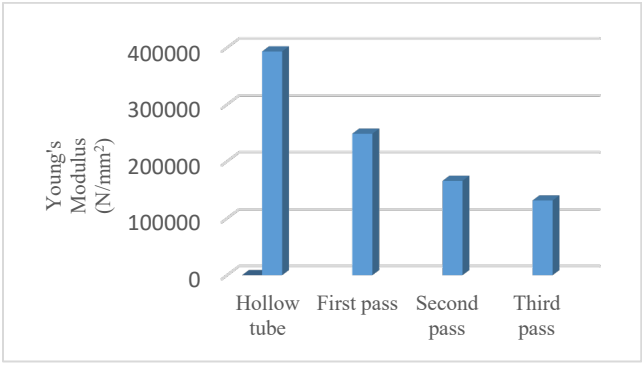

Figure 11 Young's Modulus of four tube samples

Figure 11 shows that Young's Modulus is found to be decreasing as the number of passes increases.

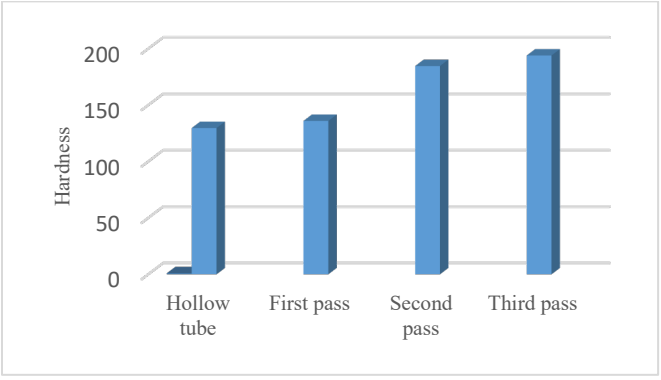

Figure 12 Hardness of four tube samples

From Figure 12, hardness is found highest in last sample due to large plastic deformation.

6. Conclusions:

The influence of pass schedule on mechanical properties, microstructures and micro hardness of cold drawn seamless tubes were studied by preparing samples viz. mother or hollow, first pass, second pass and third pass. The results indicates that both mechanical properties and microstructures were altered during deformation. Based on the experimental results and discussions in the present work, following conclusions can be drawn:

1. The mechanical properties of cold drawn seamless tubes are sensitive to pre-strain deformation, which was attributed to the reduction of boundary strengthening accompanied by the fragmentation of cementite lamellae which is introduced by pre-torsion.
2. Plastic deformation during cold drawing not only result in the variation of the microhardness but also an inhomogeneous microstructure which is responsible for the difference in microhardness behavior between the surface layer and the center layer.
3. Tensile strength, yield strength, hardness increases with plastic deformation.
4. The mechanical properties can be altered by varying heat treatment schedule.

To measure effective Young's Modulus degradation as a function of equivalent plastic strain which is for uniaxial stress case, tubes of various sizes were cold drawn with varying degree of cold working and plastic pre-strain. Further mechanical properties and Young's Modulus were checked for those samples from varying degree of cold working and plastic pre-strain.

From the results of investigation on the effect of pass schedule on mechanical properties and microstructure of ST52 steel, the following conclusions can be made:

a) Tensile strength, yield strength and hardness of ST 52 steel increased with plastic deformation. Maximum hardness is found 86-87 HRB in first pass .Maximum UTS is found in the same sample.
b) Microstructure reveals ferrite + pearlite in all phases. Elongated grains observed with the increase in number of passes.SEM photographs also validated these observations with grain size evaluations.
c) Micro hardness value is found maximum in final pass with value 162-165 and the grains are found highly stressed. Variation in mechanical properties (UTS, hardness) depends on % reduction in cold drawing. Also the heat treatment temperature and soaking time of stress relieving plays a vital role in determining the properties.
d) Vickers hardness test may vary from surface to core. Increase in reduction sample will have high micro hardness on the surface as compared to the core. The micro hardness evaluation is phase specific. Ferrite will reveal lower hardness as compared to pearlite. Finally we can choose the processing path with varying % reduction and stress relieving temperature and soaking time to obtain the required mechanical properties as per specifications.
e) Initial value of Young's Modulus is anisotropic which depends on the material in plane direction and the percentage reduction during col drawing process.In addition to it, the variation of the Young's Modulus during the deformation process is another important reason of usual underestimation of springback. It was found through this research that elastic Modulus of a material decreases by 10−20% during the plastic deformation reaching the saturation value after 5-7% of plastic strain.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The build-in internet-controlled functions of smart devices such as smart phone, smart television, home healthcare gadget, etc., have made them quite attractive to many segments of consumers. In recent years mankind has witnessed an upsurge usage of such devices for numerous purposes. In this paper, the author is going to show how previously forecasted security challenges of these devices are becoming realities in the present day life. The paper initially provides some introductory information about the topic, mostly by means of survey and citations of previous work. It then highlights the devastating effects of October 21, 2016 DDoS attack which mainly utilized IoT devices. It emphasizes the danger of recently revealed Mirai IoT botnet which serves as the basis for the DDoS-for-hire 'booter'/ 'stresser' service. In terms of counter measures, after highlighting IoT security implementation challenges, numerous approaches are presented. As a long-term solution, an architecture wherein security issues are managed through universal home gateway by network operators in a product based fashion is emphasized. The author shows its technical feasibility and demonstrates its partial materialization in proprietary manners. It then explains why and how numerous stake holders are needed to get together for its wide range commercial implementation. Some immediate necessary safeguard actions and intermediate schemes which include soft infrastructures are also presented for the purpose of risk reduction.

1. Introduction

Advancement in technology has been changing our way of life and digital information has become a social infrastructure. Since the expansion of the Internet in 1990s, network infrastructure has become an indispensable part of social life and industrial activity for mankind.

We are now surrounded by Internet enabled smart devices and there are computer technologies in our cars, phones, watches, entertainment systems, and home appliances. The idea of making use of their existing electronics devices and connecting them to the Internet in conjunction with some specialized software have been leading mankind to a new era of technology known as the "Internet of Things" and commonly referred to as IoT. Their build-in internet-controlled function has made them quite attractive to many segments of consumers. Adoptions of cloud computing, mobile applications and virtualized enterprise architectures have led to a tremendous expansion of applications that are connected to internet resources [1].

Japanese audio visual equipment has been Internet enabled for over a decade now. This has enabled people to enjoy network based services, such as Video on Demand (VOD), Music on Demand (MOD), remote update, e-commerce, remote control, and other similar services. Samsung's 'Family Hub' fridge can order food, play films, and even let you see inside of it remotely [2]. Researchers around the world have come up with an abundance of resourceful ideas on how to effectively use microprocessors and the Internet in other everyday household appliances. According to a study conducted by International Data Corporation, 212 billion "things" will be installed based on IoT with an estimated market value of $8.9 trillion by 2020 [3]. Those "things" will be nothing special but daily used appliances ranging from watch, light bulb to smart television, refrigerator and so on.

Commercial advertising has also greatly benefitted from Internet services and online advertising can even be considered as the foundation of web economy. Unlike conventional forms of advertising, the system of online advertising even allows its target to receive something in return for viewing the advertisement [4]. In other words, our daily life, social activity, industrial and

*Corresponding Author: Davar Pishva, Address: APU, 1-1 Jumonjibaru, Beppu, Oita 874-8577 Japan, Tel: +81-977-78-1261, Email: dpishva@apu.ac.jp

business governance highly depend on information systems. In an industrialized country like Japan, most enterprises use information technology to establish their management governance and every enterprise has its own information for its business. 'IT governance' enables them to improve their efficiency and cost performance. The impacts of information systems on their operations are quite significant. It can be said that information assets have become valuable commodities for business and information systems are the key factors to ensure the growths of enterprises.

The Internet has created new markets around the globe by means of breaking physical barriers and connecting people and organizations of similar interests together. We are now progressing towards collaborative intelligence, something which will impact our connected life and business. The era of Collaborative Internet of Things (C-IoT) is approaching wherein improvement of life quality will have a direct impact on business efficiency enhancement. Furthermore, the process of sensors generating data, data producing knowledge and knowledge driving actions is creating a new direction. The introduction of smart phones has generated wide acceptance and adaption by business, consumer and general population. This is mainly because of their conveniences and many added values like navigation, location based services, etc. Today, we see higher growth in mobile traffic than landline. Introduction of tablets and growth of ecosystem for mobile applications will cause gradual decline in the growth of PCs and rapid end of desktop equipment. People are now equipped with remote access and control capabilities to manage their home environment (energy, safety and security). They can have access to gadgets that help track their physical condition and wellbeing and generate necessary proactive course of action. For instance, there are devices that can monitor driving behaviors, children's actions and elderly people's routine life and generate multiple alerts when deemed necessary.

In other words, smart connected digital life which is composed of smart homes, offices, factories, hospitals, transports, etc., will contribute to better quality of life, generate business efficiency and additional source of significant revenues. Through cyber-physical and social data, we can better understand events and changes in our surrounding environment. Such information can enable us to monitor and control buildings, homes and city infrastructures. They can also provide better healthcare and elderly care services among many other things. However, in order to make effective use of cyber-physical and social data, integration and processing are necessary since their data come from various sources. IoT includes every device that is connected to the Internet, ranging from home automation products like smart thermostats, security cameras, refrigerators, microwaves, to home entertainment devices such as TVs and game machines, to smart retail shelves that know when they need replenishment, to industrial machinery and many more.

Nonetheless, as the value of connectivity and information continue to increase, so does the management complexity, vulnerability and attractiveness to malicious attacks. Considering that traditional approach security mechanism does not work on IoT and consumers have little knowledge or incentive to make them more secured, cybercriminals can make use of IoT for their distributed attacks. It is therefore essential to consider security in their design process, development cycle and in the effective usage of their information systems [5]. This paper is a follow up of recently published work [5] and the author would like to highlight sequence of events which have happened since then. The aim is to emphasize the danger of devastating attacks via IoT devices and numerous challenges that exit in equipping them with appropriate security. It then underlines the importance of previously proposed universal home gateway based security approach and shows some progress in its implementation process. Finally it explains why and how numerous stake holders are needed to get together for its wide range commercial implementation and urges policy makers and big players to take the security issues of IoT devices more seriously.

The rest of the paper is organized as follows: Section 2 discusses vulnerability of Internet connectivity, including those due to the operating nature of Internet Protocol (IP) and the ones originating from various Internet services. Section 3 presents some details on IoT, their vulnerability, including devastating effects of October 21, 2016 DDoS attack which mainly utilized IoT devices, and the danger of recently revealed Mirai IoT botnet. Section 4 explains why traditional security approaches do not work on IoT and highlights the main causes that make IoT attractive weapon for professional attackers. Section 5 presents a comprehensive long-term security implementation strategy, an immediate necessary and implementable safeguard action, and some intermediate schemes. Finally, summary conclusion and practical recommendation are highlighted in section 6.

2. Vulnerability of Internet Connectivity

For various reasons, today's networks are vulnerable to numerous risks, such as information leakage, privacy infringement and data corruption. Operating nature of communication protocol used in the Internet domain, availability of many free software that can carry out numerous attacks and users' unawareness about such issues are some of the main contributing factors.

2.1. Operating Nature of Internet Protocol

Internet protocol suite which is commonly known as TCP/IP (Transmission Control Protocol and Internet Protocol), is used for most Internet applications. Its IP serves as the primary component for carrying out the task of delivering packets from a source to a destination using the IP addresses contained in the packet header. Proper operation of such transaction worldwide requires source and destination to have unique IP address and included in the packet header of their information packets. The fact that each IP address gets associated with a unique entity, enables attackers to trace IP address of each holder through the packet headers.

What makes security implementation more challenging is the fact that Internet has 256 protocols and TCP is just one of them. Other commonly known Internet protocols are UCP (Universal Computer Protocol), and ICMP (Internet Control Message Protocol). Most experts who try to prevent attacks just consider these three protocols in their implementations. Many skilled attackers, however, use less known protocols in their attacks to bypass system security and such trends have been increasing during the past decade. In most cases, their attacks initially succeed until the defenders could figure out what was going on. What makes it worse is the fact that skilled attackers experiment with their new attack methodologies for years before they weaponize them via automation in order to create high volume impacts.

2.2. Vulnerability of Various Internet Services

As mentioned earlier, Internet services have their associated risks and a few them are intentionally created by service providers. Although at superficial level, they are supposed to be for better

service purposes, but are often abused for the sake of business expansion at the expense of their users' victimization. The rest are carried out by attackers, the purpose of whom may range from adventurism at individual level to financial gain at individual/group/corporate level, all the way to socio-political competition at much wider scale. This section will highlight vulnerability of some services which are used by a wide public, most of whom being technology-unaware people.

As we all know, most Internet services, e.g., web browsing, email, social networking, navigation and location services, etc., are provided for free. But most of such service providers are private companies and for their source of income, they mainly rely on online advertisement. Under the pretext of better service, most of these service providers use what is called tracking cookies, to keep track of their users' activities. For example, if they know your location, they can show you what are available in your surroundings. If they know your eating habit, they can guide you to pertinent restaurants. If they know your shopping habit, they can show you similar products, etc. When a user visits multiple websites with the same ad provider, since the same cookies are employed, the ad provider can track the user's activity in numerous sites just by compiling the information via tracking the cookies without the user's knowledge. The bottom line is to identify users, deliver targeted advertisement and persuade them do things which they may not have done under normal condition. Furthermore, since payments of most online advertisement is established on per click basis, just persuading the user to click the ad, automatically generates income for its host.

Other Internet service vulnerability can include e-commerce and social networking. We all know the convenience of online shopping and social networking. The fact that we can buy anything from any part of the world without leaving our home or connect to our networks and anyone in the world free of charge from our pc/tablet/smart phone etc., is a good evidence of such realities. Today, nations are using social networking for their election campaigns and super powers are using it to influence elections or create revolutions, etc.

It is, however, a well-known fact that privacy is implicated in e-Commerce because it requires us to disclose our personal information, such as email address, credit card information, etc., to complete the transactions. After the transaction, the retailer can use the info for their next targeted advertisement and bombard us with spam emails. What is more dangerous is the scenario of data transfer (e.g., when customer database information is sold to third parties or stolen) since it results in identity or credit card theft [6]. Furthermore, when such transactions are done via less secured networks, professional attackers can use numerous techniques to steal our credit card information and use it up to its maximum limit before we realize it. During the past decade, this approach has also penetrated to e-banking and huge amount of money have been stolen from peoples' accounts. [7-8].

At a bigger scale, security experts claim that North Korean cyber attackers have targeted banks in 18 countries for the purpose of Pyongyang using the money to boost its nuclear program [9-10]. Using cyber-attacks on nuclear power plant is even more concerning. On October 10, 2016, Reuters reported that according to Yukiya Amano, the International Atomic Energy Agency director, a nuclear power plant had been disrupted by a cyber-attack in the past two or three years [11]. Although additional details, including where the incident took place were not provided, Amano had said: "This issue of cyber-attacks on nuclear-related facilities or activities should be taken very seriously. We never know if we know everything or if it's the tip of the iceberg."

Vulnerability of social networking services is another example that the author would like to mention in this paper since it is mostly used by non-technical people. It is a scenario similar to IoT and combined utilization of different social networking services has dramatically increased, surpassing nine billion users as of April 2017 [12]. As can be guessed, this has lead cyber threats originating from social-engineering technique to also significantly increase. A study conducted by Verizon Enterprise in 2013 showed that it increased by 4 folds within the single year that they carried out the investigation [13]. Considering its rapid development, its adoption for online advertising and marketing, and its utilization by big powers even in political games, it can be foreseen that intrusions through social networking services will continue to increase in the coming years.

3. IoT and their Vulnerability

As mentioned in the introduction section, IoT includes every device that is connected to the Internet, including those ranging from home automation products like smart thermostats, security cameras, refrigerators, microwaves, to home entertainment devices such as TVs and game machines, smart retail shelves that know when they need replenishment, to industrial machinery and many more.

3.1. Some Elaborations on IoT

The term IoT was invented by a British entrepreneur Kevin Ashton in 1999 and was initially used to refer to a global network of Radio-frequency identification (RFID) connected devices [14]. Although the usage of the term IoT in its present context is less than a decade old, most of the present day IoT devices have existed for decades but they were called under different names such as smart devices, smart systems, smart home appliances, etc. Smart has been a common keyword for such devices before the invention of the term IoT.

Recent rapid expansion of IoT has been due to miniaturization of integrated circuit (IC) chips, tremendous increase in their processing/storage capabilities and huge drop in their production cost. Readily available fast, reliable and free/cheap Internet connection around the globe can be considered another major factor in the rapid expansion. Such developments have made it possible to embed various devices with electronics, software, sensors, and network connectivity and enable them to collect and exchange data. The process of sensors generating data, data producing knowledge and knowledge driving actions has enabled automation, remote sensing and remote control in many areas.

3.2. Vulnerability of IoT

As mentioned earlier, convenience of connecting to the Internet has its associated risks and IoT are no exception in this context. However, threat likelihood level of IoT for a particular type of attack would depend on its function. For example, a healthcare monitor device will be less vulnerable to data alteration attack than a security camera device.

On the other hand, huge number of IoT combined with their weak/no security, make them quite attractive for distributed denial of service (DDoS) attack, regardless of their specific functionality. Although no serious DDoS attack originating from IoT network had been reported until recently, the next section will highlight some devastating recent attacks. Nonetheless, its possibility and

upward trend had been predicted based on simple calculation and projection many years ago. If we assume that only 0.01% of the IoT network gets compromised by 2020, this could lead around 20 million appliances vulnerable to cyber-attacks. Even granting that most of the IoT will only transmit relatively small amounts of data, considering their enormous size, the attack can easily bring down a domain name system (DNS) server, or any another host. This is mainly because DDoS attack uses an integrated effect of its compromised devices. Furthermore, because each compromised element has its own unique IP address, blocking a DDoS attack becomes extremely difficult after it takes place.

3.3. Emergence of Thingbot

Traditional DDoS attack took place via a huge network of compromised PCs. Each PC in the network is transformed into a slave by means of malware. Such network is called botnet which is an abbreviation for words "ro**bot**" and "**net**work". This type of attacks occur without awareness of Internet users. Thingbot is an abbreviation similar to the word botnet, but comprised of the words "**thing**" and "ro**bot**". It indicates a huge network of compromised IoT for launching cyber-attacks. The first large scale thingbot based attack was discovered by security researchers from Proofpoint in early 2014. It consisted of more than 750,000 phishing and spam emails which were launched from thingbot. The network contained more than 100,000 hacked IoT devices, ranging from smart TVs, refrigerators and other smart household appliances [15].

Presence of huge vulnerable IoT devices and introduction of DDoS-for-hire 'booter'/'stresser' service have significantly changed and increased the risk. It enables attackers to launch DDoS attacks against target(s) of their choices in exchange for monetary compensation which usually comes in form of Bitcoin. On October 21, 2016 a DDoS attack utilized at least 150,000 hacked IoT devices and created devastating effects. It resulted in a 1 Tbps traffic, 40 to 50 times higher than normal, and brought down much of the America's internet for few hours [16]. The compromised IoT consisted of digital video recorders (DVRs), surveillance cameras and other smart devices that had weak default passwords. The created huge amount of bogus traffic targeted a major DNS service provider (Dyn) and others. This is the largest of its kind in the history as of today and its origin is traced to Mirai-based thingbot from where a significant volume of the attack traffic was originated.

The Mirai IoT botnet which was revealed in August 2016 has been launching multiple high-profile, high-impact DDoS attacks against numerous Internet properties and services worldwide. Even 2016 Rio Olympics and their associated organization were targeted by sustained and large-scale DDoS attacks, but due to their advance preparedness, they were able to minimize the impact. The botnet serves as the basis for the so called 'booter'/'stresser' service and its nodes are scattered around the world. Their concentrations are, however, higher in Spain, Brazil, Indonesia, Thailand, South Korea, Taiwan, Macau, Hong Kong, and China [17-18]. The botnet has been expanding by incorporating vulnerable IoT devices through automated continuous scanning using well-known, hardcoded administrative credentials that are present in the IoT devices.

4. IoT Security Implementation Challenges

Like other Internet enabled devices, IoT are also prone to numerous risks. Although threat likelihood level of IoT for a particular type of attack depends on its functionality, none of such threats are new. There are established security measures for most of them. However, peculiar characteristics of IoT make implementation of such security measures in a traditional way quite challenging and this section highlights some of its major causes.

4.1. Limited Resources

Unlike traditional computers, IoT are designed to serve only a specific purpose and marketability factors such as low cost, portability, tinier size, etc., prevent them from having powerful processing capabilities. It does not make sense to incorporate several hundred dollars' worth of security and processing capability in IoT devices like smart watch, smart LED, smart toaster, etc., the sale value of which are few tens of dollars. As such, most IoT end up having toy CPUs that cannot handle computationally expensive cryptographic computations and with battery power that prohibits long-lasting or high-peak computations. Hence, built-in full cryptography capability which is common for most computers becomes infeasible for most IoT devices.

4.2. Technology-Unaware Users

Even in those IoT devices, such as smart TV, smart refrigerator, healthcare monitor, etc., into which incorporation of powerful processing capabilities are feasible (cost wise, size wise, etc.), such incorporation does not produce positive results in most cases. This is mainly because most of their users are technology-unaware people, unable to take advantage of such functionality, consider their usage and requirements user unfriendly and additional burden both in terms of their cost and utilization. Hence, our competitive market makes vulnerable IoT devices more attractive in terms of their low cost and user friendliness. It also discourages makers to build secured devices in the production stage.

4.3. Around-the-clock Availability

Traditional computer users, in addition to being more technology aware people in comparison with typical IoT users, turn off their computer after they accomplished their tasks. Furthermore, they stay at their computer most of the time while it is on. In other words, Internet connectivity of traditional computers is enabled while their users actively use them and are disabled when they finish their tasks. In contrast to human-controlled computers, most IoT e.g., smart refrigerators, security cameras, gas/fire sensors, etc., are connected to the Internet 24 hours. Hence, their around-the-clock availability on the Internet, weak/no security make them quite attractive for attackers to continuously experiment their attack techniques. As mentioned earlier, skilled attackers experiment with their new attack techniques for years before they employ them at large scale via automation for high impact achievement.

5. Possible IoT Security Solutions

As we can see, despite the necessity and high importance of equipping IoT with appropriate security measures, its achievement is not that easy. The author originally got involved with investigation of security of smart home appliances over a decade ago and has recently extended it to the broader field of IoT. In this section, the author would like to share his findings in form of a comprehensive long-term security implementation strategy, an immediate necessary and implementable safeguard action, and some intermediate schemes.

Considering the existence of theoretical security measures for most threats against IoT, impracticability of incorporating such measures within each individual IoT inform of powerful security processing capability, the author would like to emphasize the importance of securing the local area network to which they are connected. The fact that most IoT rely on locally available Internet in their vicinity, e.g., home, office, etc., existence of more than one IoT in every home or office and stationary nature of most IoT, the approach can be considered as the most practical one.

5.1. Appropriate Security Model

A decade ago, the author after thoroughly investigating vulnerability of smart home appliances and existence of numerous challenges in equipping individual appliance with appropriate security, came up with the idea of "universal home gateway" (UHG) approach. The idea was to connect all Internet enabled gadgets of a house through a single gateway, build the necessary security processing capability into the gateway and let network operators and service providers to remotely manage the required security via the gateway [19-20]. The purpose was to avoid built-in security features for each gadget and embed all the security related processing capability into the gateway instead. The operation involved channeling of all local and remote access to a family area network (FAN) via the gateway by means some user-friendly authentication schemes. Its required security management was envisioned to be carried out remotely by service related third party experts in exchange for a reasonable overhead cost. The logic was, since vulnerability comes from the Internet connection, if we channel all of our devices' Internet access through a single gateway and secure the gateway, everything gets secured without requiring any of our devices to have its own built-in security related processing capability or us to perform technical security management tasks. This approach will definitely work for IoT devices like smart thermostats, security cameras, refrigerators, microwaves, etc. which are used at a fixed location. However, a different security scheme will still be needed for non-stationary IoT like smart watch, smart phone, tablet, etc. when they utilize Internet from outside the FAN.

The problem was that existing gateways were not compatible with all smart home appliances since they required different wireless technologies and protocols. The author, however, gave detailed functional requirements of such UHG, how to initiate its construction, as well as pertinent responsibilities and commitments of its numerous stakeholders. The proposed idea may have sounded like a far reachable dream and some people even wondered about the viability of being able to control many different devices by means of a single gateway. Nonetheless, even at that time, there were some vendors whose products were marketed with a central controller that could link their smart home appliances together in a FAN environment and offered some limited security and exclusive digital services [21-22]. History has shown that propriety approaches are prone to fail and the author was hopeful that in the near future, a universal controller could control various smart gadgets that are manufactured by many different companies.

5.2. Current State of the Envisioned Security Model

At present, commonly used communication methods for IoT devices include Z-Wave, Zigbee, Powerline, Bluetooth 4.0 and other radio frequency (RF) protocols. Among these, Z-Wave, Zigbee and Powerline are the most common ones for home automation devices. Z-Wave protocol seems to also have better backwards and forwards compatibility, widely adopted as it is easier to find Z-Wave compatible devices from different manufacturers. Figure 1 shows a commercial product of Z-Wave which is compatible with 1,500 products that are produced by 375 companies [23].

Figure 1 Z-Wave Wireless Technology (Z-Wave Alliance, May 2017).

5.3. Long Term Security Strategy

For a comprehensive long-term security implementation strategy, the author would still recommend the originally proposed UHG approach since no other scheme can handle the numerous challenges that exit in equipping IoT with appropriate security measures in a better way. The fact that in less than a decade, compatibility from a few single company based products has grown to 1,500 products that are produced by 375 different companies, shows that it is not a far reachable dream and we are indeed moving in that direction. Unfortunately, however, Z-Wave protocol is still a proprietary standard.

The remaining gaps are to get rid of proprietary standards, involve cooperation of manufacturers, network operators and service providers more widely, arrive at a consensus on minimum security requirements among main stakeholders and involve policy makers on the legal implementation. The size and impact of October 21, 2016 shows the urgency of the matter and an unsuccessful 2016 Rio Olympics attack should not be allowed to turn into a perfect success in a foreseen 2020 Tokyo Olympics attack. The most effective way to achieve this is to:

- Engage a network operator to build dedicated but nonproprietary universal home gateways and become the preferred trusted third party.
- Motivate IoT manufacturers to develop device drivers and application software that can run on such UHG for their control and operation.

This will, however, require support for security-driven business models and involvement of policy makers on the legal aspects of utilizing IoT. It is worth mentioning that thingbots are used against third parties rather than their IoT owners. Furthermore, consensus on minimum security requirements among main stakeholders (e.g., IoT manufacturers, third-party developers, service and solution providers and electronic communications providers) will be essential.

Therefore, design and development of an open system and involvement of big and experienced players like network operators

are vital to the successful adoption of the technologies. This way, their users can enjoy security without having to be aware of the underlying mechanisms. UHG may even be provided free of charge, like the way that cell phone sets and broadband modems are being given away by their respective service providers in Japan. Security pricing may also be implemented on a product (functional group) based scheme.

There are standards bodies which specify how to build these devices and meet their various requirements, e.g., OSGi Alliance [24-25]. It is essential to conform to these standards when building, managing and providing services for IoT in the future. Such an approach will encourage more vendors/manufacturers to conform to these standards, and the standards themselves will evolve as needs arise. The best way to proceed is to develop the security model around IoT and network components that conform to certain standards.

5.4. Immediate Necessary Safeguard Actions

Considering our globalization trends and increase in competition, the levels of bureaucracy that exist in many governments when making new policies, and their difficulties when trying to implement created policies, immediate implementation of the proposed security scheme may be difficult. Nonetheless, through some immediate safeguard actions, one can at least reduce vulnerabilities of IoT for their involvement in possible attacks. The following such actions are therefore recommended to be carried by IoT owners, their sellers or service providers:

- Change their default passwords since attackers usually penetrate through such settings.
- Disable their Universal Plug-and-Play features since they create security loopholes and are enabled by default.
- Disable their Telnet based remote management as Telnet can be used to control them remotely.
- Keep their software up-to-date so as to protect them against the known attacks.

5.5. Some Intermediate Schemes

Let us not forget that achievement of ultimate security goal requires both hard and soft infrastructures. The author has so far mainly focused on the hard infrastructure but soft infrastructures inform of appropriate education, training, guidelines, policies and governance systems are equally important. The fact that thingbot adversely affects third parties rather than their respective IoT owners, implies moral, social and "hopefully in the near future" legal obligation for their possessors. Now that the Internet is an indispensable part of our social life and business activity, security awareness and pertinent education for the common people is also quite important. Furthermore, no security will work when a user does not properly select/protect his/her passwords for various Internet services or does not know what Phishing/Pharming is, clicks such links and provide the requested information. In some collaborative work, the author has explained some relevant incidents which have taken place in online advertising and social networking services [4, 26]. Unfortunately, even in a highly industrialized country like Japan, information security awareness is not part of general education even at university level!

Considering slow progress in the UHG approach and dramatic increase in the use of social networking platforms by many non-technical people, its adoption for online advertising and marketing and victimization of many users, the author also investigated the employment of anonymous communication and its adoption to IoT network. Implementation of TOR (the Onion Router)-based anonymous communication into the IoT network as an effective alternative way to help smart home appliance users protect their privacy and make the smart home appliance system more secure from aforementioned cyber-attacks was the main objective of the work [27]. Such approach can also be effective, particularly for technology-aware users and could even be utilized for non-stationary IoT devices.

6. Conclusion

This paper explained numerous conveniences of IoT and its projected huge market in the near future. It also showed that like other Internet enabled devices, IoT are also prone to numerous risks but there exist theoretical security measures for most of them. Nonetheless, peculiar characteristics of IoT make implementation of such security measures in a traditional way quite challenging and their huge number make them quite attractive for DDoS attack. It highlighted the devastating effects of October 21, 2016 DDoS attack and emphasized the danger of Mirai IoT botnet which serves as the basis for the DDoS-for-hire 'booter'/'stresser' service and enables attackers to carry out DDoS attacks against targets of their choice in exchange for monetary compensation that usually comes in the form of Bitcoin payments. An architecture wherein security issues are managed through universal home gateway by network operators in a product based fashion was cited. It emphasized support for security-driven business models, consensus on minimum security requirements among main stakeholders and involvement of policy makers on the legal aspects of IoT environments. Some immediate necessary safeguard actions and intermediate schemes which included soft infrastructures were also recommended for the purpose of risk reduction. It is hoped that policy makers and big players take the security issues of IoT devices quite seriously and maintain the October 21, 2016 DDoS attack as the largest of its kind in the history forever.

Conflict of Interest

ABSTRACT

Mobile robots can be used to perform transportation tasks for different objects. These tasks have to be implemented carefully. Therefore, an accurate approach for object recognition and position estimation is required. This work presents a concept for identification and position estimation of multiple labware. These labware, which contain chemical and biological components, have to be manipulated and transported in life science laboratories using H20 mobile robots. The H20 robot has dual 6-DOF arms with 2-DOF grippers. Different marks are used to be attached with the labware lid for identification process. The Kinect sensor V2 is used to recognize and localize the mark of the required labware on a wide workstation. The difference of performance between the Kinect V1 and V2 is illustrated. SURF algorithm (Speeded-Up Robust Features) is used to recognize the target according to its local features. Some preprocessing steps are applied to the RGB frame to enhance the image features. The effects of strong lighting condition are eliminated by using polarization and intensity filters which are attached to the Kinect camera. The position estimation step is performed by applying a mapping process form the color frame to the depth frame of Kinect. The communication procedure between the Kinect platform and other robot platforms is done using client-server model. An efficient performance with high success rate is obtained under different lighting conditions.

1. Introduction

This paper is an extension of work originally presented in the international symposium on computational intelligence and informatics (CINTI 2016) [1]. This work shows an approach to identify required labware for mobile robot transportation in life science laboratories. In general, the realization of objects transportation using mobile robots leads to an increase of the productivity and saving human resources in the working environment. This requires several prerequisites like object recognition with position estimation, arm control, and a robot navigation system. The navigation system includes the path planning, mapping, and robot localization in the working environment. Related to the object manipulation, the robotic arm has to be guided to the target pose. The object pose can be acquired visually using a suitable sensor with a proper recognition algorithm. The Kinect V2 sensor fixed on the H20 robot is used in this work to identify and localize multiple labware. The H20 robot is a wireless networked autonomous humanoid mobile robot. It has a PC tablet, dual arms, and an indoor GPS navigation system. A Kinect holder is installed on the H20 body in a way that the labware on the workstation can be visualized clearly. Some technical achievements have been developed at the Center for Life Science Automation (celisca, University of Rostock) to improve the transportation system of the H20 mobile robots [2]-[4]. The H20 mobile robot with different labware and tube racks is shown in Figure.1. The Kinect sensor provides color frame and depth frame of the view. The RGB frame has to be processed to find the required target. This process includes the extraction of meaningful features from the image that lead to the identification of the object. Different target features can be used for this procedure such as color, shape, edges, size, and local features. Some algorithms use

Email: mohammed.myasar.ali@celisca.de

multiple features related to the target to create a robust strategy for recognition process.

Figure 1. H20 mobile robot with different tube racks.

In order to identify the required object using visual sensors, it is necessary to apply different techniques to the captured image. There are several features which can be extracted from the image to find the target. In general, these features are divided into two categories. The first is the appearance features of objects such as the color and intensity. The second is local features of the target itself. The local features have to be extracted and matched with the features in the database related to the object of interest. Image segmentation using color feature is one of the easiest methods to find the required target in the view. This method is suitable for real-time applications because it does not require a detailed prior information about the target. Color detection can be performed using different representations of color system such as RGB, HSV, and YCbCr. The HSV (hue, saturation, value) color system is more robust in dynamic lightness conditions because it is insusceptible to illumination. Sanchez-Lopez et al. used the HSV color system to track the target for service robot applications [5]. The edges detection can also be used to extract the edges of the target. Some filters are commonly used for this purpose such as Canny, Sobel, and Laplace filters. Furthermore, a set of rules of shape primitives can be applied for shape recognition such as circles, triangles, and rectangles. Yamazaki et al. used edges and shape detection with HSV color segmentation to recognize some foods and kitchen tools [6]. The success rate of object recognition can be improved by using multiple features related to the target at the same time.

In order to use specific local textures of the target as an identification reference, feature matching algorithms can be used. SIFT (scale invariant feature transform), SURF (Speeded-Up robust features), and FAST (Features from Accelerated Segment Test) are the most common algorithms for local feature descriptors to perform object recognition [7]-[9]. Theses algorithms are somehow independent to the changes in scale, illumination, and orientation. Collet et al. extracted the local descriptors for the registration and recognition of learned metric 3D models of house-hold objects using a multi-view system [10]. Marchand et al. used the features like corners and contours of known objects to perform a visual tracking method [11]. The speeded-up robust features (SURF) algorithm can be considered as an efficient object recognition method with a fast scale- and rotation-invariant detector and descriptor. The object tracker decreases the required time by providing the full region which is occupied by the target in the image at every frame. The target region is jointly estimated by iteratively updating the region information and location obtained from the previous frame. The region of interest (ROI) which contains the target is obtained using the object position in the image coordinates. In the successive images, only the interest points in this updated ROI are extracted and matched to find the object. Anh et al. proposed an object tracking method based on SURF for safe grasping tasks [12]. Zickler et al. used humanoid robots to achieve detection and localization of multiple objects on the kitchen desk [13]. Katsuki et al. attached specific marks on the required objects to handle various objects in home or office environments using robot system [14]. For the localization process of the object in the real environment, 3D visual sensor like Microsoft Kinect is more preferable. Chung et al. used the Kinect sensor installed on a service robot to help humans in object transportation [15]. Ramisa et al. used the Kinect for cloth grasping by finding the manipulation points in the depth frames [16].

In this work, the approach of recognition and position estimation of different labware is presented. Several concepts and challenges are taken into the consideration to realize an efficient performance. The visual feedback is necessary to perform a high precision manipulation of the labware that contains chemical and biological components. The strong and glossy lighting conditions in addition to the appearance of the labware affect the identification process. Therefore, a specific mark is attached to each labware to be to be distinguished from each other on a wide workstation. Speeded-Up robust features algorithm (SURF) and HSV color segmentation are used to recognize different marks. Some preprocessing steps are applied to the image to enhance its features for the recognition step. The Kinect V2 is used for this work. The difference of performance between the Kinect V1 and V2 is illustrated. Polarization and intensity filters are attached to the Kinect to reduce the effects of strong and glossy light. The connection between the Kinect platform and other robot platforms is established through a client-server model.

This paper is organized as follows: in section 2, the problem definition is presented. The proposed methodology is given in section 3. Section 4 shows the labware identification and localization process which will be followed by the system integration. Finally, the results are concluded and discussed.

2. Problem Definition and Restriction

The future of life sciences laboratories depends significantly on the innovations of automated solutions in the entire scope. Different scientific tasks, like biological testing and sample preparation, are performed in the laboratories by using automation equipments. This leads to realize high throughput, workflow optimization and reliable measurement results. Robots and especially mobile robots are very important in the life science field. Mobile robots increase the productivity and save human resources by connecting all workstations in different laboratories. For labware transportation, an intelligent procedure to grasp the target object and placing it at the right position on the workstation is required. The success of this procedure depends significantly on the success of recognition and position estimation for the required

labware. Fig. 2 shows the wide workstation which consists of 8 positions of labware containers. The required labware and its position on the workstation have to be identified and the H20 robot has to change its position to manipulate it. The laboratories and the workstations have strong lighting conditions especially with sunny weather. The glossy ceiling light blinds the visual sensor which affects the identification process since it changes the labware appearance. Also, the workstation can be affected by the sunlight if it is close to a window or is surrounded with objects which reflect some light.

Figure 2. Eight locations of labware containers on the workstation.

According to this situation, a proper visual sensor has to be located in a suitable pose on the robot with a specific height to provide an adequate view for the workbench. Moreover, the view angle of the visual sensor related to the workbench plays a role in the identification process by reducing the light effects. The H20 robot has stereo cameras in the head. The stereo vision system is fixed on a pan-tilt joints module for object tracking. The head cameras are not appropriate for labware identification task because of the limited height and distance between the head and the workstation. The cameras don't provide a clear view for the whole workbench especially at the ends of left and right sides of it. Moreover, several complex steps have to be performed in stereo vision systems to obtain the depth data. The images of stereo cameras have to be processed by steps such as undistortion, rectification, correspondence, and reprojection. It is important to correspond the video quality, resolution, and contrast in the both cameras. The two cameras have to be mounted accurately to guarantee that all their axes are parallel. Also, the kinematic solution of the head joints has to be derived and the target has to be tracked to be seen by the two cameras. To avoid these complex issues, the Kinect sensor can be considered as a proper choice for this work. It can be used to provide a sufficient and clear view for the whole workstation after fixing it in a suitable pose over a holder. Also, the Kinect provides the depth data directly without the need of performing all the complex steps which are previously mentioned for the stereo vision system.

3. Proposed Methodology

In the Center for Life Science Automation, different automation islands are connected with each other by the cooperation of stationary and mobile robots. This cooperation requires an appropriate hierarchical management systems. The mobile robots are used for maneuvering between the adjacent laboratories for transporting multiple labware and tube racks. The overall workflow starts with the user or with the hierarchical workflow management system (HWMS) to decide which target has to be manipulated and transported [17]. The manipulation system can be splitted into two parts, the target localization and the arm controller. The target localization software with the visual sensor is utilized to detect the target and to estimate its pose. The pose information is sent to the arm controller software to guide the robotic arm. The information exchange between the two parts is performed using a TCP/IP socket through client-server communication model. Fig. 3 shows the block diagram of the manipulation process.

The target pose has to be calculated related to the arm base. Then, an accurate kinematic model has to be used to control the arm joints. The kinematic analysis is how to describe the arm links motion without considering its forces. There are two terms related to the kinematic analysis, forward kinematics (FK) and inverse kinematics (IK). Using the forward kinematics model, the end-effector pose relative to the arm base can be found according to the given joint angles. On the other hand, the inverse kinematics model describes how to find the required joint angles for the given end-effector pose. The analytic solution of IK problem has been found and applied physically on the H20 arms to guide them to the target [18][19][20].

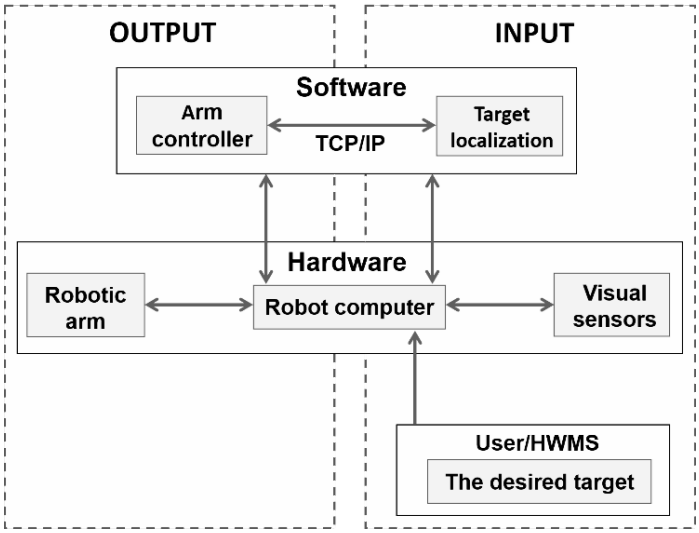

Figure 3. Block diagram of manipulation process.

The Kinect sensor can be considered as an appropriate choice for the labware manipulation approach. The Kinect provides a high quality color and depth information which is directly obtained without applying some complicated steps on the image as in the stereo vision. Both versions V1 and V2 of the Kinect sensor have been used for this work. The Kinect V2 has a wider horizontal and vertical view than V1. The RGB and depth cameras have a higher resolution and the depth measurements are more accurate. Also, the Kinect V2 uses the time-of-flight principle, whereas the Kinect V1 is based on structured light to provide the depth data [21]. Fig. 4 shows the two versions of Kinect and Table 1 shows the differences between them.

(*A*) (*B*)

Figure 4. Microsoft Kinect sensor, A: V1, B: V2.

Table 1: Differences of features between Kinect Sensor V1 and V2.

Features	Kinect V1	Kinect V2
RGB camera	640 X 480	1920 X 1080
Depth camera	320 X 240	512 X 424
Max depth	~ 4.5 M	~ 4.5 M
Min depth	40 cm in near mode	50 cm
Horizontal FOV	57 degrees	70 degrees
Vertical FOV	43 degrees	60 degrees
Tilt motor	Yes	No
USB standard	2.0	3.0
Supported OS	Win 7, Win 8	Win 8, Win 10

A holder has to be installed on the H20 body for fixing the Kinect sensor. The height and tilt angle of the holder have to be appropriate to realize a wide and clear view for all the labwares on the workstation. The distance between the Kinect and the workstation has to be suitable to obtain the target position where the minimum depth value of Kinect V2 is 50cm. Also, the FOV of the RGB camera and depth camera are not compatible. This leads to the fact that not every point in the RGB frame has a related 3D position value since the FOV of the RGB camera is wider than the FOV of the depth camera. The Kinect holder should not obstruct the head movement. In addition, the FOV of stargazer, which is located behind the H20 head, has not to be affected by the holder or the Kinect (see Fig. 5). The stargazer module is used to detect passive ceiling landmarks for mobile robot localization [22]. Moreover, any kind of changes in the Kinect position and orientation has to be avoided during the robot movements. The Kinect sensor has been supplied with the required power using a 12V battery with stabilizer. Furthermore, the interfacing between Kinect V2 and H20 robot is set through a USB-3 port of the H20 tablet. SURF algorithm for local features description and recognition is used to identify multiple labware and tube racks. This can be performed by extracting local features from the reference image to be identified with the current image. C-sharp programming language has been used to develop the manipulation system of the H20 robots. Fig. 6 shows the structure of the labware manipulation system.

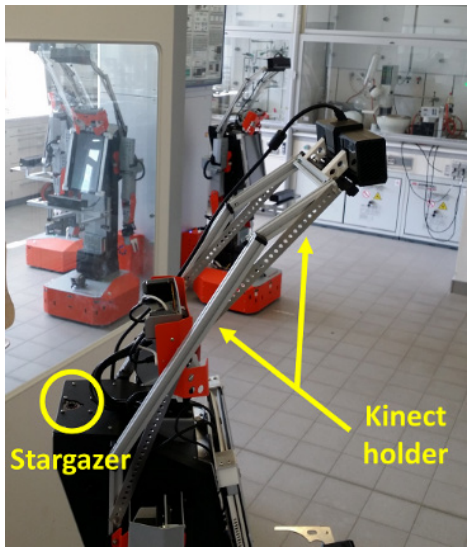

Figure 5. Frame of Kinect holder.

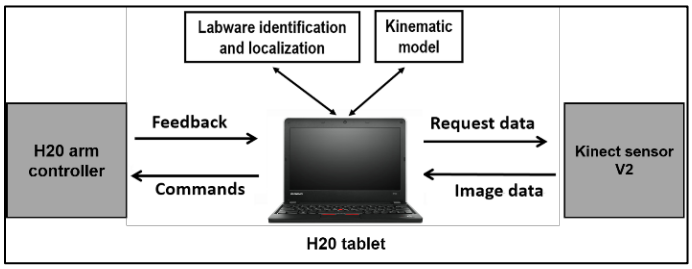

Figure 6. Structure of labware manipulation system.

Arm gripper design plays an important role in the realization of secure manipulation tasks. Several models of arm grippers and labware containers have been designed for arm manipulation [18]-[20]. Fig. 7 shows the final 3D model of the gripper with container. The goal of this design is to handle heavy labware by decreasing the lever arm of the wrist joint. This brings the labware weight center closer to the wrist. In this case, less torque is required from the wrist joint for lifting the labware. The maximum payload which can be handled with this design is 700g. To implement the visual manipulation, the labware itself has to be recognized and localized. Different object recognition algorithms can be used such as SIFT, SURF, and FAST, which are widely used for object recognition applications. The next section illustrates the process of labware recognition and position estimation using SURF algorithm with Kinect V2 sensor.

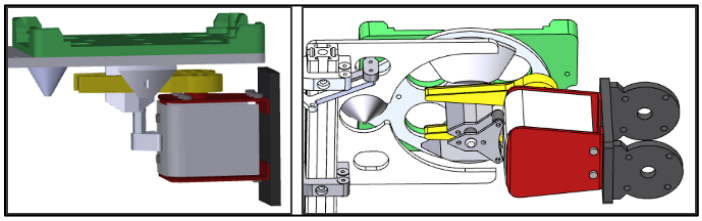

Figure 7. 3D design of labware container with gripper.

4. Labware Identification and Localization

Since the H20 robots deal with different kinds of labware, a reliable technique is required to recognize them. Different tests have been performed to show the performance of identification and localization for labwares at different positions on the workstation and under different lighting conditions. The identification tests have been performed using Microsoft Visual Studio 2015 with C# programming language. SURF algorithm is the most appropriate method that can be implemented using this programming language. The project is running on a Windows 10 platform in the H20 tablet. The process starts with an offline step by capturing an image of the target to be saved in the database as a matching reference. Strong and glossy light as well as sunlight may affect the recognition process. Therefore, to start with the online process and to decrease the light effects, some pre-processing steps have to be applied on the live image to ensure a better performance with SURF algorithm. Different procedures have been applied such as contrast with brightness correction, histogram equalization, HSV conversion, grayscale conversion, etc. The average required time for recognition process is about 3 seconds, which is long according to the application perspective. This long time is related to the features extraction and identification from a high resolution image of Kinect (1920X1080). To cope with this issue, the region of interest (ROI) can be extracted from the image using a cropping technique. The cropping process for the area of workstation with labwares is performed in the Y-axis of the image only as shown in

Fig. 8. The cropping area can be estimated according to the error range of the distance between the robot and the workbench which is about ±3cm. The resolution of the image after the cropping step is (1920X400). The recognition process requires about (1.1~1.5 sec.) using the cropped image. Thus, the required time has been decreased to the half after using the cropping image.

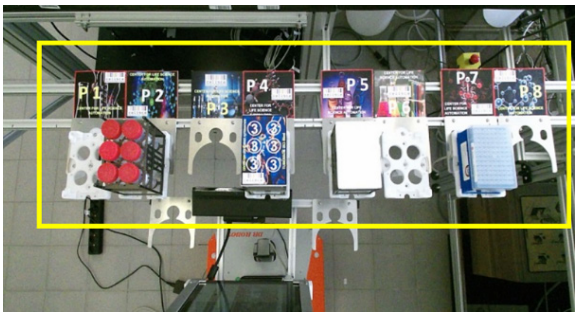

Figure 8. ROI area after cropping step.

4.1. Labware Identification Process

The recognition procedure has been performed for some tube racks without lid. In general, the lids are entirely either white or transparent. These lids are necessary to protect the tubes components from cross contamination and evaporation. Fig. 9 shows the 6-tubes rack which has different top views at different positions on the workstation. The variation in the top view are related to the 3D features of the tubes and also related to the angle of Kinect view. The lighting conditions play an effective role in the appearance of tubes rack at different positions.

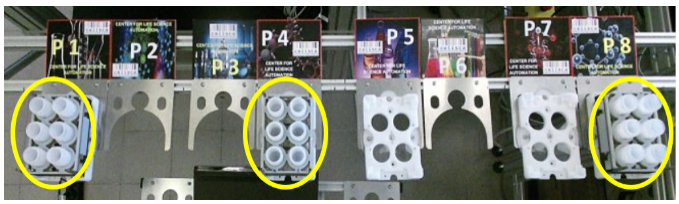

Figure 9. 6-tubes rack at different positions on the workstation.

The 6-tubes rack has been placed at 8 different positions on the workstation for the recognition process. The 8 positions are ordered from left to right in the sequence of P1-to-P8. Fig. 10 shows the recognition outcome of the 6-tubes rack by drawing a polygon around it with cross to specify the center point.

Figure 10. Identification of 6-tubes rack on the workstation.

Fig. 11 shows the success rate of the recognition process which has been tested 20 times at each position using different preprocessing steps and under different lighting conditions. The first test has been done without turning on the glossy ceiling light. The image acquired from Kinect has been used directly without applying any preprocessing steps. The identification results of the first test at each position are titled with (N) in Fig. 11. The success rate at P4 is 100% (20/20) since the top view of the tubes rack is very clear at this position. At P3, the success rate is 65% (13/20) while it is zero at the rest positions. The overall success rate for the first test is~20% (33/160). This rate is related to the 3D features of the tubes top view which gives different appearance at each position according to the angle of Kinect view. The second test has been done after turning on the ceiling glossy light. The overall success rate of the second test (N_L) is~19% (31/160) as shown in Fig. 11. The third and fourth tests have been performed after applying the brightness and contrast corrections for the Kinect image. The overall success rates are~9% and~22% respectively. The fifth and sixth tests have been performed after converting the Kinect image to grayscale and applying the histogram equalization. The overall success rates are 20% and~ 17% respectively.

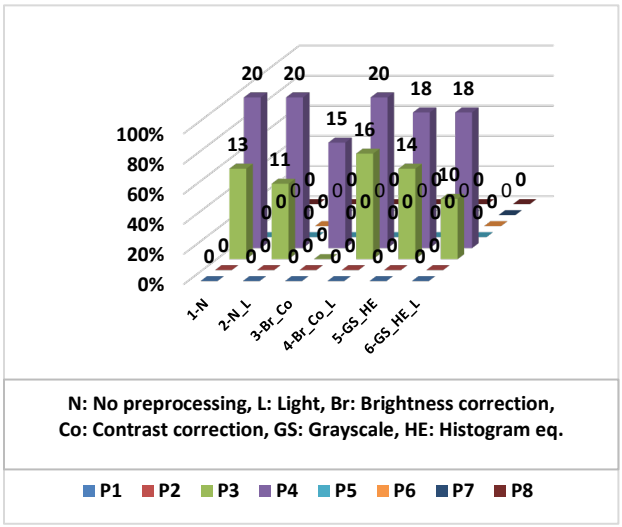

Figure 11. Success rate of 6-tubes rack identification.

The best overall success rate (~22%) has been obtained after applying the brightness with contrast correction and in lighted environment. The false positive rate for this case is about~ 13% (21/160). The false positive condition causes identifying a wrong target in the view which has to be avoided because it affects the manipulation process. As a conclusion from the overall results, it can be realized that the labware without lid has to be located at a fixed position on the workstation to be identified. This can be noticed clearly according to the overall success rate at P4 which is about ~92% (110/120). Table 2 shows the success rates summary of the identification tests for the 6-tubes rack where the term O.S.R.T means the overall success rate for each test and the term O.S.R.P means the overall success rate at each position.

Table 2: Results summary of 6-tubes rack identification.

Test	P1,2	P3	P4	P5,6	P7,8	O.S.R.T
N	0%	65%	100%	0%	0%	~20%
N_L	0%	55%	100%	0%	0%	~19%
Br_Co	0%	0%	70%	0%	0%	~9%
Br_Co_L	0%	80%	100%	0%	0%	~22%
GS_HE	0%	70%	90%	0%	0%	20%
GS_HE_L	0%	50%	90%	0%	0%	~17%
O.S.R.P	0%	~52%	~92%	0%	0%	

Specific marks have been attached to each labware lid to improve the identification process at each position on the workbench. Fig. 12 shows different lid marks which can be used to distinguish different labwares. The mark contains an information like labware name and its type with specified number. The number is used for differentiation and classification purposes. This information with the background picture gives sufficient features to differentiate multiple labware. The more features the mark has, the higher success rate of identification will be realized. Also, it is necessary to select the suitable colors of the background mark which reduce the effects of strong lighting conditions. It is known that the dark colors are much preferable to avoid the light reflection. The Kinect V2 has been used to recognize the required tube rack (6 microwaves tubes) according to the related mark with number 8 as shown in Fig. 13. The marks have been printed using coarse paper since it is more robust against light reflection.

Figure 12. Different designs of marks to distinguish multiple labware.

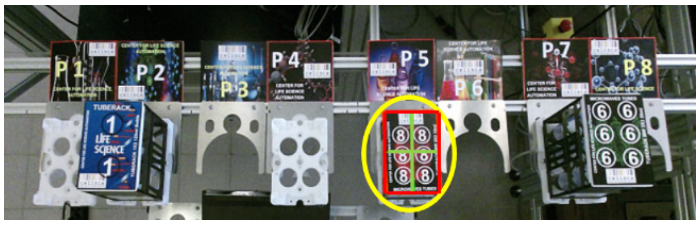

Figure 13. Labware identification according to the related mark.

The identification process has been performed for the lid mark at different positions on the workbench and under different lighting conditions. The test has been repeated 20 times at each position. Different preprocessing steps have been used before applying SURF algorithm on the Kinect image. Fig. 14 shows the recognition success rate of the mark with number 8 at each position. The improvement in the success rate results from the 2D property of mark which is not easily to be influenced by the angle of Kinect view. Also, the adequate features in the mark help to find the required one easily. In comparison with Fig. 11, it is clear that the success rate has been improved at the positions that are located at the horizontal ends of image like P1, P7, and P8. This is related to the reflected light from the mark and to the angle of view at these positions. It can be noticed also that the brightness with contrast correction improves the recognition process that is slightly affected under strong lighting conditions. The overall success rates for this case at all the 8 positions without and with glossy ceiling light are~ 98% and~ 97% respectively. On the other hand, the grayscale conversion with histogram equalization reduced the success rate of mark recognition. Furthermore, the valuable improvement that has been obtained is zero false positive rate. Tables 3 shows the success rates summary of the identification tests for the lid mark.

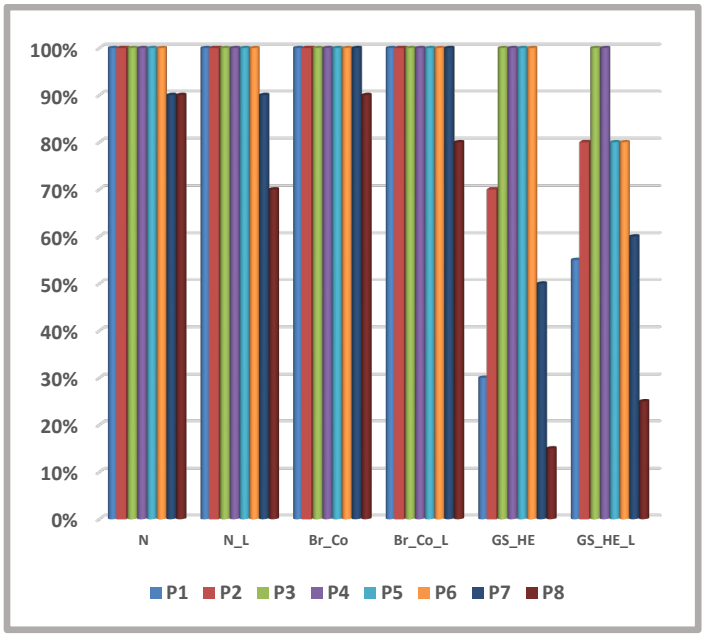

Figure 14. Success rate of lid mark identification.

Table 3: Results summary of lid mark identification.

Test	P1,2	P3,4	P5,6	P7,8	O.S.R.T
N	100%	100%	100%	90%	~97%
N_L	100%	100%	100%	80%	~97%
Br_Co	100%	100%	100%	95%	~98%
Br_Co_L	100%	100%	100%	90%	~97%
GS_HE	50%	100%	100%	~32%	~70%
GS_HE_L	~67%	100%	80%	~42%	~72%
O.S.R.P	~86%	100%	~97%	72%	

The realization of 100% success rate is the goal which has to be achieved especially under strong lighting conditions. The most appropriate solution to deal with lighting effects is to change the camera exposure time. Decreasing the exposure time leads to a reduction of the light effects on the image acquired from the camera. But Microsoft Company has blocked the camera setting of Kinect V2 which prevents the possibility of changing the exposure time or any other camera settings. Therefore, polarization and intensity filters have been affixed on the Kinect V2 camera to decrease the lighting effects as shown in Fig. 15. The intensity filters are used to decrease the brightness in the image and sharpen its edges and features. On the other hand, the polarization filters are used to increase the color saturation and decrease the reflections from glass, metals or other shiny surfaces. The success rate of mark identification under strong and glossy lighting condition is 100% at the all 8 positions on the workstation. Table 4 shows the success rates summary of the identification tests for the lid mark using filters.

Figure 15. Kinect V2 with camera filter.

Table 4: Results summary of mark identification (with filters).

Test	P1	P2,3	P4,5	P6,7	P8	O.S.R.T
N	95%	100%	100%	100%	100%	99%
N_L	100%	100%	100%	100%	100%	100%
O.S.R.P	~98%	100%	100%	100%	100%	

The recognition process requires between 1-1.5 second to be performed after cropping the ROI area. To decrease this time, the unwanted and unimportant features have to be removed from the cropped image. For this purpose, lid marks have been designed with red color features as shown in Fig. 16. Color filters can be used to extract the required color from the image after removing all the unwanted colors. This has been performed by using the HSV color filtering as a preprocessing step for the cropped image. The process of red mark identification starts with applying brightness correction with histogram equalization to increases the color saturation. Then, the color system is converted from RGB to HSV because it is more robust against strong lighting conditions. The next step is to extract the red color by removing all the unwanted colors in the image using color segmentation. The final image is converted to a binary image (black and white) to be prepared for the SURF process. Fig. 16 shows the result of this method which requires about 0.5 sec. The best success rate for this method is ~96% at all 8 positions on the workstation with using the filters in the lighted environment. Table 5 shows the results summary of this test.

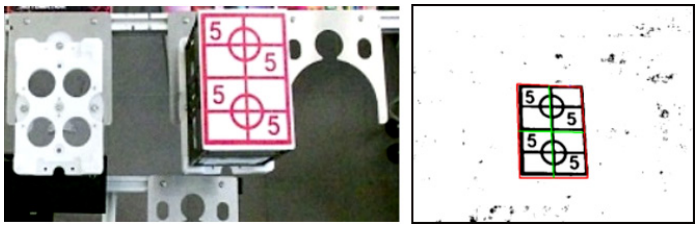

Figure 16. Identification of red-white mark.

Table 5: Results summary of red mark identification.

Test	P1	P2,…6	P7	P8	O.S.R.T
Br_H.E.	85%	100%	85%	80%	~94%
H.E._F	90%	100%	90%	85%	~96%
O.S.R.P	~88%	100%	~88%	~83%	

Table II summarizes the best results of the overall tests after applying the brightness and contrast correction on the raw image and under strong lighting condition.

Table 6: Overall summary of the Best Results.

Test case	Success rate	False pos. rate	Time
Without lid	~22%	14%	1.4sec
With lid mark	~97%	0%	1.3sec
Mark with filters	100%	0%	1.1sec
Red mark with filters	~96%	0%	0.5sec

The using of marks for labware identification and manipulation is very useful. These marks can be recognized even when they are partially occluded by some object as shown in Fig. 17. This can be considered as one of the advantages of using this approach. The mobile robot can still find and grasp the required labware even if the related mark is partially seen by the Kinect.

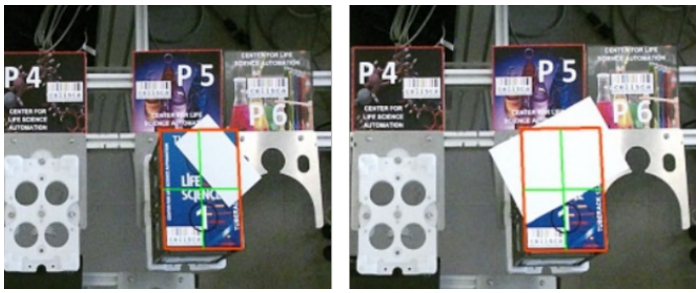

Figure 17. Mark identification with partial occlusion.

4.2. Holder Identification

The required holder has also to be identified and localized for performing the placing tasks visually. To realize that, placing mark has been designed and fixed in front of each holder as shown in Fig. 18. Each placing mark has a number and it is used for recognition and position estimation of the required holder to guide the robotic arm to the right place. In case of existing labware on the workbench, these labwares do not block the placing marks to be seen by the Kinect sensor.

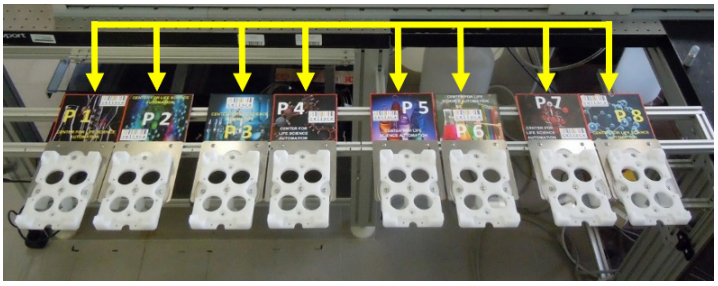

Figure 18. Holders' marks for placing tasks.

4.3. Localization Process

Since the Kinect sensor provides the depth data directly, it is simple to find the position of any point in the view. For labware or holder localization, the related mark is recognized and its center point is found in the image coordinate. The center point can be determined by finding the centroid of the bounding box drawn around the object using the box corners' positions. To find the

position of the center point related to the Kinect, mapping steps are required. The first mapping step for the related point is performed from the image frame to the depth frame. This step is essential because there is a mismatch in the resolution between the depth frame and image frame. The second mapping step for the center point is performed from depth frame to the Kinect space coordinates. The center point position of the mark related to the Kinect is used as reference to locate the position of the manipulating point where the robotic arm has to reach. At the end, the position information has to be transformed to be related to the arm shoulder space. Then, the kinematic model is used to control the arm joints and guide the arm to the target.

5. System Integration

The integration of multiple control software, which are developed using similar or different programing language, into a single one can be complicated. To cope with this issue, an interface can be developed to interact with all coding platforms simultaneously. It is useful to separate the system into multiple platforms to simplify the coding tasks and to facilitate finding the coding bugs. These platforms can communicate with each other in the system using client-server model. The labware recognition and localization part has been integrated and communicates with the multifloor navigation platform [22] and the arm manipulation platform. Using this communication model, these parts can exchange the orders and information between each other. The communication process between the client and the server is described using a sequential diagram shown in Fig. 19. Initially, sockets are created on the server and the client. The client requests a socket connection from the server using a specific port number and IP address. If the requested port is free to use, the server establishes a connection to communicate with the client. Once the connection is established, the client program sends/receives information to/from the server program. Both sockets are closed when the data transfer is successful. The information is exchanged between the client and the server in the form of strings.

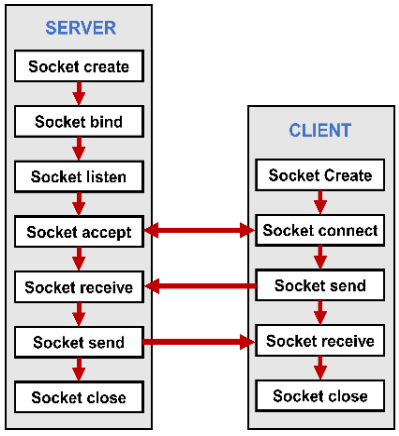

Figure 19. Diagram of client-server model.

In the described system, the multifloor navigation platform sends the work information to the arm manipulation platform whenever the robot reaches the workstation. This information includes the required task (grasping/placing) with the required number of labware or holder. This information is sent to the identification and localization platform (Kinect control). The Kinect platform finds the position of the target and transfers this information to the arm manipulation platform to perform the required task [18]. The process flowchart and the GUI of the identification and localization system are shown in Fig. 20 and Fig. 21 respectively. In the GUI window it can be clearly noticed how the required labware mark has been recognized after cropping the image.The upper part of the GUI represents the server socket which shows the used IP address with the port number. It shows also the received command related to the required target which has been sent from the arm manipulation platform. The bottom of the GUI shows the position information of the target related to the Kinect with the recognition time in milliseconds.

6. Conclusion

Visual based manipulation plays an important role in mobile robot transportation systems. The ability to identify and localize the required object visually is very essential to guarantee successful tasks. In this paper, an approach for multiple labware and holders' identification and localization for manipulation in life science laboratories has been presented. A suitable design of grippers and labware containers is very important to perform a secure transportation for the required labware. The Kinect sensor

V2 with SURF algorithm is used for this work. The Kinect is fixed on the mobile robot using a holder which has been designed carefully. Specific marks have been designed for labware and holder identification. The marks improve the success rate of the identification process for the labware and holders at any position on the workstation. The image acquired from the Kinect has been processed initially to enhance its features and to decrease the execution time. This step improves the identification success rate using SURF algorithm. HSV color filtering has been used with red marks to decrease the identification time. Polarization and intensity filters are used with the Kinect V2 to reduce the glossy lighting effects in the working environment. Kinect V2 provides high resolution image, wide FOV, and accurate position data directly that makes it very desirable for such tasks. The position of the mark related to the robot guides the arm to perform the required task. The client server model has been used to integrate and connect the identification and localization part with the arm manipulation and Multifloor transportation systems.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In automated working environments, mobile robots can be used for different purposes such as material handling, domestic services, and objects transportation. This work presents a grasping and placing operation for multiple labware and tube racks in life science laboratories using the H20 mobile robots. The H20 robot has dual arms where each arm consists of 6 revolute joints with 6-DOF and 2-DOF grippers. The labware, which have to be manipulated and transported, contain chemical and biological components. Therefore, an accurate approach for object recognition and position estimation is required. The recognition and pose estimation of the desired objects are very essential to guide the robotic arm in the manipulation tasks. In this work, the problem statement of H20 transportation system with the proposed methodology are presented. Different strategies (visual and non-visual) of labware manipulation using mobile robots are described. The H20 robot is equipped with a Kinect V2 sensor to identify and estimate the position of the target. The local features recognition based on SURF algorithm (Speeded-Up Robust Features) is used. The recognition process is performed for the required labware and holder to perform the grasping and placing operation. A strategy is proposed to find the required holder and to check its emptiness for the placing tasks. Different styles of grippers and labware containers are used to manipulate different weights of labware and to realize a safe transportation. The parts of mobile robot transportation system are communicated with each other using Asynchronous socket Channels.

1. Introduction

This paper is an extension of work originally presented in the international conference on Mechatronics (Mechatronika 2016) [1]. This work shows grasping and placing operations for labware and tube racks transportation in life science laboratories using mobile robots. Different purposes can be performed using mobile robots such as product transportation [2], teleoperation for the tasks with power tools [3], domestic services [4]-[6], or material handling [7]. The development of laboratories in the field of life science depends significantly on the new techniques of automated solutions in all related areas. Different tasks such as biological testing, samples preparation, and samples analysis are performed in the laboratories using automated equipments. The robots are very necessary in the field of life sciences. All the workstations in the same or in different laboratories can be connected using stationary and mobile robots. This connection ensures a 24/7 operation and reduces tedious and routine work for the employees. Object transportation using mobile robots is one of the most important tasks in the automation field since it increases productivity and saves human resources. For safe transportation, the mobile robots have to perform the object manipulation processes in addition to the path planning, mapping, and localization. H20 robots and Kinect V2 are used in this work to perform a visual manipulation for multiple labware and tube racks. The H20 robot is a wireless networked autonomous humanoid mobile robot. It has a PC tablet, dual arms, and an indoor GPS navigation system. Some technical procedures have been

[*]Corresponding Author: Mohammed Myasar Ali, Center for Life Science Automation (celisca), 18119 Rostock, Germany

implemented at the Center for Life Science Automation (celisca) to develop the transportation system of the H20 mobile robots [8]-[10]. The H20 robot and different labware with tube racks are shown in Fig. 1 and Fig. 2 respectively.

Figure 1. H20 mobile robot.

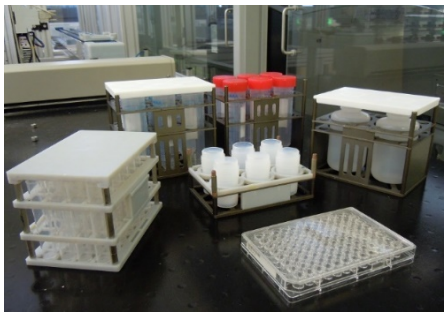

Figure 2. Different labware and tube racks.

For grasping and placing operation of multiple labware, the object identification and localization are very necessary to guide the robotic arm to the target. This requires an arm control based kinematic model to find the joints' values which move the robotic arm to perform the task. The kinematic analysis is the way of describing the motion of arm links without considering the forces causing this motion. The kinematic analysis is classified into two parts: forward kinematics (FK) and inverse kinematics (IK). Using the forward kinematics equations, the end-effector pose relative to the arm base is found according to the given joints' angles. On the other hand, the inverse kinematics equations are used to find the required joints' angles for the given pose of the end effector with respect to the arm base. The joints' limits and workspace of the robotic arm have to be taken into consideration in the manipulation process. In general, the FK solution is easier to be found than the IK solution especially for serial arms. The IK problem can be solved using two approaches: analytic and numeric. The analytical solution is more preferable to be applied in real time applications because it is computationally faster than the numerical approach. Also, all possible solutions can be found using the analytical approach. But, the IK analytical solution can only be derived for manipulators with a particular structure. For example, if 3 consecutive joints' axes are parallel, or intersect at a single point, then the analytical solution can be found. This solution often cannot be generalized to other robotic arms. Ali et al. proposed a reverse decoupling mechanism method to solve the IK problem analytically for a 6-DOF (degree of freedom) robotic arm [11]. O'Flaherty et al. developed the same method to find the closed-form solution of IK problem for a HUBO2+ humanoid robot arms [12]. The reverse decoupling mechanism method has been used to find the analytical solution of the IK problem for the arms of the H20 robot [13].

The visual approach of grasping and placing requires the use of a suitable visual sensor with a suitable object identification algorithm to realize a successful operation. Various features can be extracted from the image to find the target in the view. Color, edges, corners, shape, and local features can be considered as target characteristics for detection task. The detection of multiple characteristics related to the target improves the success rate of the process. Some applications depend on the object color as a feature to be found in the image. Different color systems can be used for this task such as RGB, HSV (hue, saturation, value), HSL (hue, saturation, lightness), etc. HSV color system can be considered as the more reliable in color segmentation in comparison with other systems [14], [15]. The HSV system is more powerful against dynamic lightness and brightness conditions. Additional information has to be used such as the target shape and area in case of presenting different objects with the same color in the view. Sanchez-Lopez et al. proposed a fast method for object tracking using HSV color segmentation and service robot [16]. Yamazaki et al. used HSV color with edges and shape for manipulation of foods and kitchen tools with daily assistive robot [17]. To recognize the required object which has a specific textures, feature matching algorithms have to be used. Generally, the local features recognition requires an off-line step to save the images of the targets in a data base as references. Then, the matching algorithm is performed by extracting local features from the reference image related to the target to be identified with the current live image. Visual matching based on local feature descriptors such as SIFT (scale invariant feature transform), SURF (Speeded-Up robust features), and FAST (Features from Accelerated Segment Test) are very popular algorithms in this field [18]-[20]. These algorithms are somehow independent to changes in orientation, scale, and illumination. Chen et al. presented an identification approach for textured objects using SIFT algorithm [21]. Grundmann et al. recognized household items using object classification based on SIFT algorithm [22]. Anh et al. proposed an object tracking method based on SURF algorithm for safe grasping operations [23]. To estimate the target position, stereo vision and 3D cameras are considered the most appropriate solutions. A 3D camera such as the Kinect sensor is more preferable for this task. Kinect provides directly the depth data without implementing any steps in image processing as in the case of stereo vision. Chung et al. proposed an intelligent service robot equipped with Kinect sensor to help humans in object transportation [2]. Stueckler et al. described a strategy for objects segmentation and manipulation using the depth frame of the Kinect sensor [24]. The design of arm grippers and labware containers is one of the most important issues which plays a main role to achieve a safe grasping and placing operation. Some factors have to be taken into consideration to design a suitable style of grippers like the task quality, the end effector structure, and the characteristics of the target like its weight, shape, etc.

In this work, a grasping and placing operation is presented to achieve labware transportation in life science laboratories. Five H20 mobile robots are used for maneuvering between the adjacent labs and workstations for transporting multiple labware and tube racks which contain chemical and biological components. Local features matching based on SURF algorithm is used to identify

multiple labware. The navigation and arm control systems of the H20 robots are developed using C-sharp programming language. SURF algorithm is the most appropriate method that can be implemented using C-sharp. The inverse kinematics solutions for the head and arms of H20 robot are listed in this work. This paper is organized as follows: in section 2, the problem statement and proposed methodology are discussed. The head and arm structures of the H20 robot with IK solutions are given in section 3. Different designs of grippers and labware containers are described in section 4. Visual (using Kinect) and blind (using sonar sensor) manipulation for the labware are presented in sections 5 and 6 respectively. Section 7 shows the target localization followed by the labware transportation process. Finally, the paper concludes the current results.

2. Problem Statement and Proposed Methodology

The future of life science laboratories depends significantly on the innovations of automated solutions in the entire scope. The stationary and mobile robots play an important role in the automated environment. In the Center for Life Science Automation, different automation islands are connected with each other by the cooperation of stationary and mobile robots. For transportation task, mobile robots usually follow a predefined path from the starting station to the ending station using a guidance control system. The H20 mobile robots use the Stargazer sensor with ceiling landmarks (see Fig. 3) for maneuvering between the adjacent labs (Hagisonic Company, Korea) [25]. This guidance system is not accurate enough and causes positioning errors in the range of ±3cm and ±2cm in the X and Y axes respectively in front of the workstation. The glossy lighting and sunlight blind the Stargazer to recognize the ceiling landmarks which leads to positioning errors. Also, the odometry system, that updates the robot pose, accumulates errors for different reasons such as different wheel diameters, wheel-slippage, and wheel misalignment. Therefore, the mobile robot transportation requires a reliable grasping and placing operation for the labware which contain chemical and biological components. This operation depends on 3 main factors as shown in Fig. 4. The identification and localization process for the desired labware has to be performed. The other essential issue is to calculate the arm joints to guide the end effector to the desired pose by solving the inverse Kinematics problem. Also, the design of arm gripper and labware containers has to be taken into consideration to realize a secure manipulation.

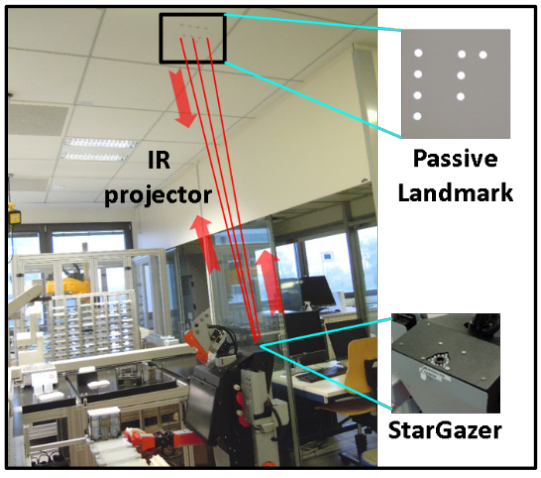

Figure 3. Stargazer sensor with ceiling landmarks.

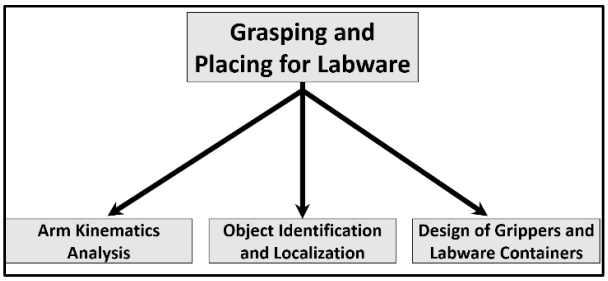

Figure 4. Requirements of grasping and placing operation.

The transportation of multiple labware between different workstations and labs requires an appropriate management systems. This is important to perform the automation of individual areas in such a way that comprehensive life science processes are realized. The hierarchical workflow management system (HWMS) controls the workflow between the stationary and mobile robots [26]. Related to the mobile robots, the management system sends the plan to the transportation system as shown in Fig. 5. The plan information includes the starting position, end position, and the required labware to be transported. The transportation system of the mobile robots includes 3 main parts: the robot remote center, the navigation system, and the grasping/placing system. The grasping/placing system is splitted into two parts, object identification and localization and the arm control. The object identification and localization software with the visual sensor is utilized to recognize the target and to estimate its pose. The pose information is sent to the arm kinematic control to guide the robotic arm.

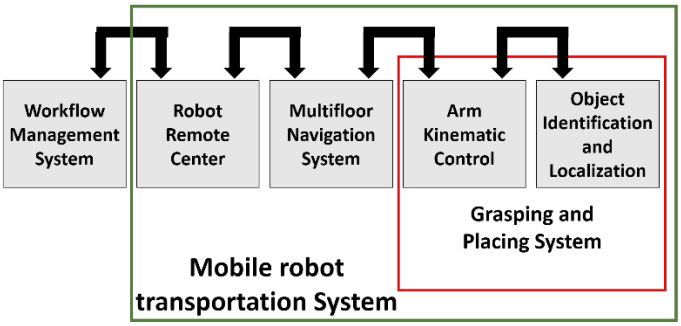

Figure 5. Overall structure of the mobile robot transportation.

3. Kinematic Analysis of H20 Robot

The H20 mobile robot has dual 6-DOF arms with 2-DOF grippers. It has also a head with 2 revolute joints (2-DOF). Fig. 6 shows the joints structure of the head and arms. According to Fig. 6, the values of d3 and d5 are 0.236m and 0.232m respectively. Also, there is a distance of de=0.069m between the wrist joint and the end-effector (E). The Denavit-Hartenberg (D-H) representation is used to describe the translation and rotation relationship between the arm links. According to this D-H representation, there are four parameters to analyze the manipulator: the link length (ai-1), the link twist (αi-1), the link offset (di), and the joint angle (θi) where (i) refers to the joint number [27]. By following the D-H rules, the homogeneous transformations between adjacent links are defined. The D-H parameters and the rotational limit for each joint of the H20 arms are described in Table 1.

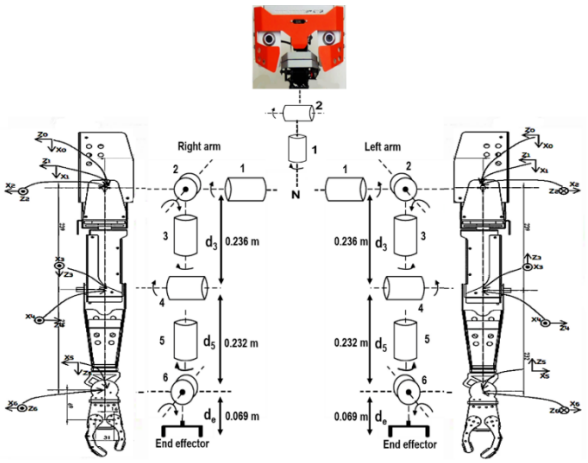

Figure 6. Arms and head structures of H20 robot.

θ_6	-90°	90°	0	0	0	-60°~85°

The solution of the IK problem for the H20 arms has been found using the reverse decoupling mechanism method [11]. The inverse matrix of the FK solution has been found which is considered the first step to solve the IK problem. Eq. (1) shows the inverse matrix of the FK model where (in_x , in_y , in_z) is the orthogonal vector, (io_x, io_y, io_z) is the orientation vector, (ia_x , ia_y , ia_z) is the approach vector, and (ip_x , ip_y , ip_z) is the position vector.

$$ {}^{E}_{0}T = {}^{E}_{6}T \cdot {}^{6}_{5}T \cdot {}^{5}_{4}T \cdot {}^{4}_{3}T \cdot {}^{3}_{2}T \cdot {}^{2}_{1}T \cdot {}^{1}_{0}T = \begin{bmatrix} in_x & io_x & ia_x & ip_x \\ in_y & io_y & ia_y & ip_y \\ in_z & io_z & ia_z & ip_z \\ 0 & 0 & 0 & 1 \end{bmatrix}. \quad (1) $$

The equations below are the solution of the IK problem where (*C*) and (*S*) are the abbreviation of angle cosine and sine respectively, (R) and (L) are related to the right and left arms respectively, and (atan2) is the two argument arc tangent function. The equation of joint 4 is the first step that has been found. The other joints' equations are followed sequentially as follows [13] [28]:

$$ \theta_{4(LR)} = \text{atan2}\left(\pm real\left(\sqrt{1 - C_4^2} \right), C_4 \right), \quad (2) $$

$$ C_{4(LR)} = \frac{(ip_y + d_e)^2 + (ip_x)^2 + ip_z{}^2 - d_3{}^2 - d_5{}^2}{2 d_3 d_5}. $$

In case that the target is outside the arm workspace, complex numbers are generated in the solution. Therefore, a (*real*) function is used to keep the real part and ignore the imaginary part for realizing the closest solution to the target position [12].

$$ \theta_{5(LR)} = \text{atan2}\left(S_5, \pm real\left(\sqrt{1 - S_5^2} \right) \right), \quad (3) $$

$$ S_{5(L)} = \frac{ip_z}{S_4 d_3}, \; S_{5(R)} = \frac{-ip_z}{S_4 d_3}. $$

$$ \theta_{6(LR)} = \text{wrapToPi}(\text{atan2}(d_3 C_4 + d_5 \; , -d_3 S_4 C_5 \;) - \gamma), \quad (4) $$

where γ = (atan2 (ip_y+d_e,ip_x)), and (wrapToPi) function is used to wrap the angle to the interval between –π and π [12].

$$ \theta_{2(LR)} = \text{atan2}\left(\pm real\left(\sqrt{1 - C_2^2} \right), C_2 \right), \quad (5) $$

$$ C_{2(L)} = ia_y (C_4 C_6 - C_5 S_4 S_6) + ia_x (C_4 S_6 + C_5 C_6 S_4) - ia_z S_4 S_5, $$

$$ C_{2(R)} = -ia_y (C_4 C_6 - C_5 S_4 S_6) - ia_x (C_4 S_6 + C_5 C_6 S_4) - ia_z S_4 S_5. $$

$$ \theta_{3(LR)} = \text{atan2}\left(S_3, C_3 \right), \quad (6) $$

$$ S_{3(L)} = -ia_y S_5 S_6 + ia_x C_6 S_5 + ia_z C_5, $$

$$ S_{3(R)} = ia_y S_5 S_6 - ia_x C_6 S_5 + ia_z C_5, $$

$$ C_{3(L)} = ia_y (C_6 S_4 + C_4 C_5 S_6) + ia_x (S_4 S_6 - C_4 C_5 C_6) + ia_z C_4 S_5, $$

$$ C_{3(R)} = -ia_y (C_6 S_4 + C_4 C_5 S_6) - ia_x (S_4 S_6 - C_4 C_5 C_6) + ia_z C_4 S_5. $$

$$ \theta_{1(LR)} = \text{atan2}\left(S_1, C_1 \right), \quad (7) $$

$$ C_{1(L)} = in_y (C_4 C_6 - C_5 S_4 S_6) + in_x (C_4 S_6 + C_5 C_6 S_4) - in_z S_4 S_5, $$

$$ C_{1(R)} = in_y (C_4 C_6 - C_5 S_4 S_6) + in_x (C_4 S_6 + C_5 C_6 S_4) + in_z S_4 S_5, $$

$$ S_{1(L)} = io_y (C_4 C_6 - C_5 S_4 S_6) + io_x (C_4 S_6 + C_5 C_6 S_4) - io_z S_4 S_5, $$

$$ S_{1(R)} = io_y (C_4 C_6 - C_5 S_4 S_6) + io_x (C_4 S_6 + C_5 C_6 S_4) + io_z S_4 S_5. $$

The IK solutions of singularity cases have been found too. Three cases of singularity have been determined within the joints limits. The singularity cases occur when one or more degrees of freedom are eliminated because some joint axes are aligned with each other. This leads to infinite number of solutions. The singularity cases of H20 arms are as follows:

A) When θ4 = 0 and θ2 ≠ -π: The axis of the third joint is aligned with the fifth joint axis

B) When θ2 = -π and θ4 ≠ 0: The axis of the first joint is aligned with the third joint axis

C) When θ4 = 0 and θ2 = -π: The joints 1, 3, and 5 are collinear

According to Eq. 2, 3, and 5, there are 8 solutions for the required pose inside the reachable workspace. To choose the suitable solution, a selecting algorithm has to be used [13]. The forward and inverse kinematics solutions have been validated and simulated using MATLAB with robotics toolbox. For the integration of the kinematic model with H20 system, the required angle value of each joint has to be converted to its related servo motors position. This step is very crucial since the H20 arms' joints are weak and they can be easily bent by the effects of gravity and payload.

Related to the H20 head, a stereo vision system is fixed on a pan-tilt module. This module consists of two revolute joints which are used for moving the head to track the desired object. The transformation matrix from the neck to the head is as follows:

$$ {}^{N}_{H}T = \begin{bmatrix} C_1C_2 & -S_1 & S_2C_1 & l_{H2}S_2C_1 \\ C_2S_1 & C_1 & S_1S_2 & l_{H2}S_1S_2 \\ -S_2 & 0 & C_1 & l_{H1}+l_{H2}C_1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (8) $$

Eq. 8 represents the forward kinematic solution of the head for the given joint angles. Related to the inverse kinematic problem, the given ${}^{N}_{H}T$ is in the form:

$$ {}^{N}_{H}T = \begin{bmatrix} n & o & a & p \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (9) $$

Thus, the solution of IK for the 2 joints of head is as follows:

$$ \theta_1 \text{ (H)} = \text{atan2}\left(o_y, -o_x\right) \quad (10) $$

$$ \theta_2 \text{ (H)} = \text{atan2}\left(n_x, a_x\right) \quad (11) $$

4. Design of Grippers and Labware Container

For labware grasping and placing with the mobile robots, different grippers with labware containers have been designed. Since the labware contain chemical and / or biological components, any kind of spilling has to be avoided. Therefore, a specific design of grippers and labware containers is required to guarantee secure grasping and placing operations. Fig. 7 shows the initial designs of the grippers and labware containers which are attached with handles.

(*A*) (*B*) (*C*)

Figure 7. Initial designs of grippers and labware containers [13].

Related to Fig. 7.A, the handle was designed to be detected using RGB color detection [29]. Each handle has a specific single color to be identified from the others. The Kinect sensor V1 was used to detect and localize the required handle to manipulate the required labware. In Fig. 4.B, the gripper and handle designs were improved. Flat panel on the upper side of the handle was resolved for fixing different colored or pictorial marks to distinguish multiple handles. Proper gripper has been designed also to fit this handle. SURF algorithm and HSV color segmentation with area and shape detection were used for identification tasks [28]. The required handle was localized using Kinect sensor V2. 350g is the maximum payload that can be manipulated using the designs in Fig. 7.A, and 7.B. The weak wrist joint of the H20 arms as well as the labware container design play a role to limit the manipulated weight. The manipulation of the handle attached with the container requires high torque due to the long lever arm of the wrist joint. The lever arm here represents the distance between the center of the labware weight and the wrist joint. A vertical handle has been designed to manipulate heavier payload as shown in Fig. 7.C. In this case, the wrist joint is rotated to have a vertical axis on the ground. Thus, the lifting process depends on the elbow joint which has more powerful torque [13]. 500g is the possible payload that can be handled using this design. This manner is still not sufficient due to the tube racks which are heavier than 500g. To cope with this issue, a new manipulation style has been created (see Fig. 8). A new gripper has been designed and the handle has been removed from the container. This brings the end-effector closer to the labware weight center. Thus, less torque is required to handle heavier objects since the lever arm of the wrist joint has been decreased. A rubber has been attached to the gripper to increase the friction for secure manipulation. The maximum payload which can be handled with this style is about 700g. Fig. 8 shows the designs of the gripper, labware container, and its holder.

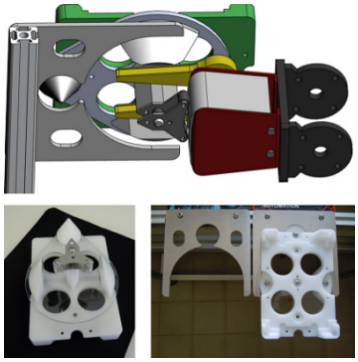

Figure 8. Final design of gripper and labware container.

5. Blind Manipulation using Sonar Sensor

A manipulation strategy has been performed using the developed kinematic model with two sonar sensors [13]. The front base of H20 robot has 3 built-in DUR5200 sonar sensors. One sensor is in the middle and the other two are on the left and right sides. These sensors can detect the range information from 4 cm to 340 cm which can be used for collision avoidance and distance detection. For the grasping and placing operation, the mobile robot has to be straight in front of the workstation. The labware container has a specific posture on the workstation. The pitch and roll orientation of the container related to the robot are fixed. The yaw orientation has to be secured by correcting the robot orientation. This can be done using the two sonar sensors on the base sides (see Fig. 9). The distance (Z) from each channel to the plastic board is checked and the robot rotates till the values of both sensors are equalized. Thus, the distance (Z) between the labware on the workstation and the robot arm base is known. Also, the height (Y) of the workstation related to the robot is fixed and known. Related to the (X) information of the labware position, this can be decided by the workflow management system [27]. Then, the X positioning feedback has to be mapped to be related to the arm base. The X-axis error of the robot position in front of the workstation is about ±2cm. This can be compensated by the design tolerance of gripper and labware container [13].

This strategy is not reliable enough due to some reasons. The positions of holders and boards, which reflect the sonar signals, have to be identical for all workstations. It is not possible in some stations to install this board due to the environment structure. Existence of obstacles leads to wrong estimation from the sonar sensors for the distance and orientation of robot in front of the

workstation. Also, there is no accurate value related to the positon of the required labware in the X-axis due to the lack of positioning feedback in this axis. To cope with all these issues, a visual sensor can be used to identify and localize the target wherever it is located on the workstation.

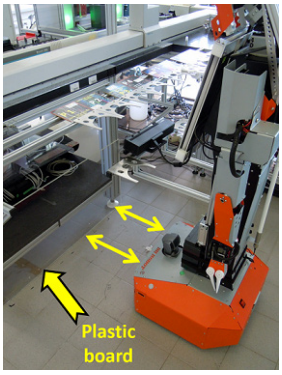

Figure 9. 2 sonar sensors for labware manipulation.

6. Vision based manipulation using Kinect Sensor

It is very crucial to have an intelligent concept to perform a visual grasping for the required labware which then will be transported to the required place. Stereo vision is one of the common methods to detect the target and estimate its position. But, it is not feasible to use the head stereo cameras of the H20 robot for this task because of the head position related to the workstation. This leads to unclear views to the wide workstation which consists of multiple positions for labware containers. Therefore, the Kinect sensor can be considered as an appropriate choice for the visual approach of labware manipulation. It provides a high quality color and depth information which is directly obtained without applying complicated steps on the image as required in the stereo vision. The Kinect V2 has been fixed on the H20 body using a holder with a suitable height and tilt angle to guarantee a clear and wide view for the whole workstation (see Fig. 1). The Microsoft Kinect sensor V2 uses "time of flight" technology to provide the depth information. It relies upon a novel image sensor that indirectly measures the time for pulses of laser light to travel from a laser projector to a target surface, and back to an image sensor. By using the "time of flight" technology, the Kinect V2 can see just as well in a completely dark room as in a well-lit room. The Kinect sensor with its features are shown in Table 2 and Fig. 10.

Table 2: Features of Kinect Sensor V2.

Features	Kinect V2
RGB camera resolution	1920 X 1080
Depth camera resolution	512 X 424
Maximum depth	~ 4.5 M
Minimum depth	50 cm
Horizontal FOV	70 degrees
Vertical FOV	60 degrees
Tilt motor	No
USB standard	3.0
Supported OS	Win 8, Win 10

Figure 10. Kinect sensor V2.

The success of visual manipulation and transportation depends significantly on the success of identification and localization for the required target. The workstation consists of 8 positions of labware holders. According to the arms workspace, the robot can deal with 4 holders (2 for each arm) for grasping and placing operations. Therefore, the robot needs 2 positions in front of the workstation to manipulate all the 8 holders. It is complicated to differentiate the holders according to their appearances. Also, it is not possible to identify the required holder for the grasping task because it will be covered with a labware with its container. To cope with this issue, an initial strategy of grasping and placing operation has been performed. This strategy includes the utilization of 2 marks as a reference for each robot position in front of the workbench. Each mark is centrally located in front of the related robot position to be used as a visual feedback for 4 holders as shown in Fig. 11. Whenever the robot arrives at the required position, the related mark is recognized and localized using Kinect V2 with SURF algorithm. Then, the mark position is modified to find the positions of the 4 holders related to the robot. The workflow management system sends the plan information to the mobile robot transportation system. This information includes the required task (grasp/place) and the holder number. According to the holder number (1-8), the robot moves to the required position (1 or 2) for performing the task. In this case, each mark is considered as a reference for 4 related holder where the holders 1, 2, 5, and 6 belong to a particular robot position. Whereas, the holders 3, 4, 7, and 8 are related to the other robot position. For this strategy, all the holders' positions related to the marks have to be fixed and identical in the other workstations in life science laboratories. To cope with this limitation, a specific mark has been attached to each holder for visual grasping and placing operation as shown in Fig. 12. The required mark is identified and the position of its center point is derived to guide the robot in the grasping and placing operation using the kinematic model.

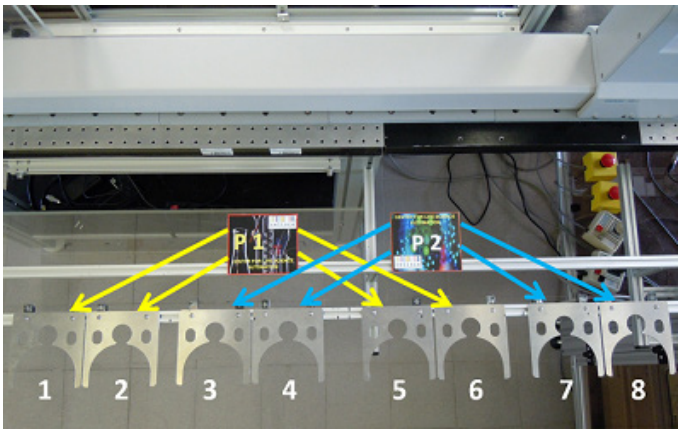

Figure 11. Specific mark for each robot position.

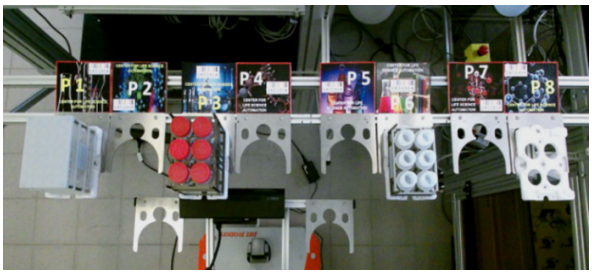

Figure 12. Workbench holders with their related marks.

For grasping the required labware, probable wrong information related to the holder number is sent to the robot transportation system. Also, there is a possibility that the required labware has been moved to another holder by an employee before the mobile robot arrives the workstation. In this case, it is very crucial to identify and localize the required labware wherever it is located on the workstation. Since the labware and tube racks are covered with transparent or white lids to protect the components from cross contamination, it is not applicable to distinguish them on the workbench. Therefore, a specific mark has been fixed on each labware lid for identification process. Fig. 13 shows two tube racks where one of them is covered with a white lid and the other with a mark fixed on its lid. Different marks have been used to identify multiple labwares. The mark contains the labware information with a particular number for classification purposes. The labware information with a background picture in the mark gives adequate features to differentiate multiple labware.

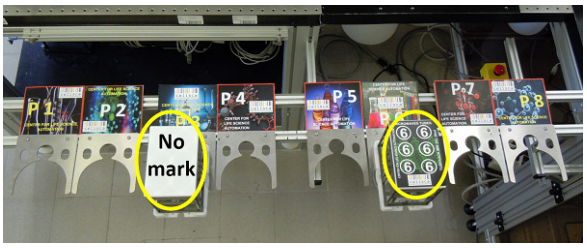

Figure 13. Labware lid with and without mark.

Several methods have been applied to test the performance of object identification and position estimation under different lighting conditions [30]. The tests have been performed for labware identification at the 8 different positions of the workstation. Various procedures have been applied to the Kinect image such as cropping, contrast with brightness correction, and histogram equalization as preprocessing steps before applying SURF algorithm. Histogram equalization process increases the global contrast of the image while the cropping process is used to extract the region of interest (ROI) from the image. The required ROI in this work is the workstation with their labware, holders, and related marks. The cropping step simplifies the recognition process and decreases its required time. The identification of the required labware is assigned by drawing a polygon around its lid mark with cross to specify the center point as shown in Fig. 14.

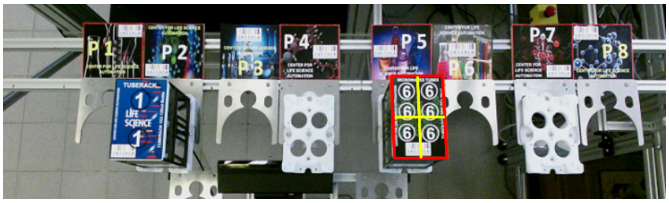

Figure 14. Recognition of the required labware.

For the grasping task, the labware orientation related to the robot can be found using coplanar POSIT algorithm which stands for POSe ITerations. It requires image coordinates of the desired object points (minimum 4 points). It also requires the real model coordinates of these points; the target has to be previously known. Furthermore, the effective focal length of the used camera has to be known [31]. The orientation angle is very important to correct the arm motion in case that the robot is not straight in front of the workstation. This has been done by finding the corners' positions of the lid mark in the image coordinates. Also, the real physical positions of the corners related to the mark center point have to be calculated. This information is inserted to the POSIT algorithm to calculate the difference in orientation between the labware and the Kinect camera or the robot. The orientation angle represents the yaw angle of the robotic arm. Fig. 15 shows the corners of the lid mark which are used to calculate the orientation angle.

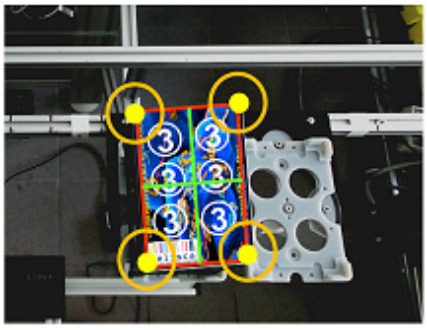

Figure 15. Corners detection of the lid mark.

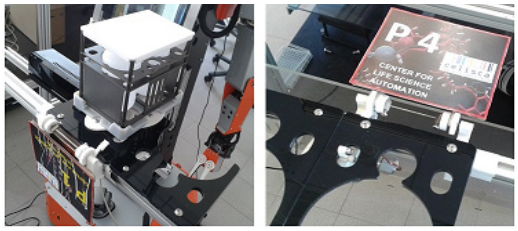
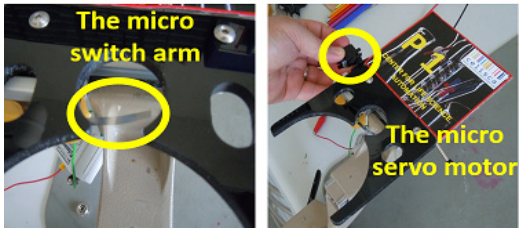
The holders' marks are used for identification and position estimation purposes to perform the placing task. But, it is very necessary for the robot to check whether the holder is already occupied by a labware or not before performing the placing task. Therefore, a checking method has been implemented by fixing the holder mark on a mechanical part. A rotational joint is used to show and hide the mark from the Kinect view to determine whether the holder is empty or not. In other words, if the Kinect cannot identify the mark of the required holder, this holder is already occupied as shown in Fig. 16.A. A second method can be applied using a micro switch, micro servo motor, and servo controller to rotate the holder mark as shown in Fig. 16.B.



(*A*)



(*B*)

Figure 16. Checking the availability of the required holder.

7. Target Localization and Extrinsic Calibration

The identification step enables the identification of the required labware or holder according to the related mark. Then, the position of the center point of the mark in the image coordinate is derived. This can be done using the corners' position of the polygon drawn around the detected mark. In order to obtain the real or physical position of this center point related to the Kinect, mapping processes have to be performed. Since the RGB frame of Kinect is not identical with the depth frame, the center point has to be mapped from the image frame to its related point in the depth frame. Then, another mapping step is performed for the point in depth frame to be related to the Kinect space coordinates. The result of these mapping steps is the real position of the mark center point related to the Kinect sensor. The position information of X-axis determines which arm (left or right) can be used for the required operation. The position information of the center point has to be calibrated to calculate the position of the manipulation point in the labware container. The manipulation point represents the position where the end effector of the robotic arm has to reach during the grasping and placing operation. Fig. 17 shows the effective point of the labware container on the workstation. For the grasping task, there are different kinds of labwares which have different height. Therefore, it is not feasible to depend on the labware height to find the manipulation point position. To cope with this issue, the workstation height, which is fixed and identical for all workstations, can be used as a reference to find the manipulation point height.

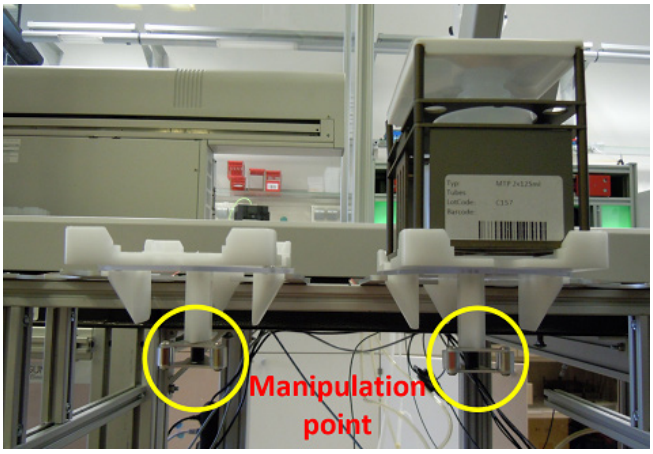


Figure 17. Manipulation point of the labware container.

The position of the manipulation point related to Kinect has to be calibrated to guide the robotic arm to the required point. This can be done by applying the extrinsic calibration step. The purpose of this step is to transform the position information from the Kinect space to be related to the arm shoulder space. Then, the inverse kinematic model is used to find the joints' values of the arm for guiding its end effector to the target. The calibration from Kinect space to arm shoulder space includes the transformation in translation and in rotation. This belongs to the difference in the position and the tilt angle (t) between the Kinect coordinates and shoulder coordinates according to the Kinect holder as shown in Fig. 18. The Kinect holder has been designed very carefully to be suitable for the grasping and placing operation. The tilt angle of the Kinect plays a role in reducing the light effects for the identification process. The holder has to be fixed very firmly to guarantee that there are no changes in the Kinect position and orientation during the robot movements.

Figure 18. Kinect holder.

8. Labware Transportation Process

The transportation process of multiple labware using the mobile robots is based on the following scheme. In the 1st step, the navigation system receives the transportation plan from the workflow management system through the robot remote center. In the 2nd step, the robot moves to the required laboratory and workstation. Then, the robot checks around the workbench to identify the lid mark related to the desired labware which has to be transported to the destination lab. In the 3rd step, the position of the target manipulation point related to the arm shoulder is found. In the 4th step, the robot uses the arm kinematic model to calculate the required joints' values depending on the position information. In the 5th step, the arm moves to the required target and grasps the labware container. After grasping operation, the robot moves to the desired destination to place the labware on the required holder. The mobile robot transportation system has been realized using three main coding platforms which are the multifloor navigation system (MFNS) [25], the arm control system (ACS), and the object identification and localization system (OILS). These 3 systems are connected with each other through a asynchronous socket. The 3 coding platforms exchange the orders and informations between each other using 2 client-server communication models as shown in Fig. 19.

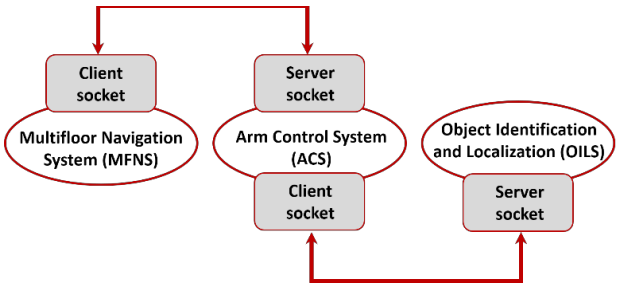

Figure 19. Client-server models for labware transportation.

One of the important information, which has to be sent to the transportation system, is the approximate weight of the manipulated labware. Since the arms of H20 robot are unstable and have weak wrist joint, the weight information helps to calibrate the wrist joint. This step is very crucial to keep the labware straight during the grasping/placing operation to avoid the spilling of its contents. Also, two labware holders have been fixed on the H20 body for the left and right arms as shown in Fig. 20. These holders support to keep the labware in a safe horizontal posture during the transportation tasks. To supply the Kinect sensor with the required

electrical power during the robot movements, a 12V battery with a voltage and current stabilizer has been installed on the robot base. If the grasping operation is performed with a particular arm (right or left), the placing operation for the grasped labware has to be achieved using the same arm. It is not possible to perform the placing operation with the other arm since the labware is positioned on the H20 holder according to the used arm. Therefore, it is very essential to perform the placing task at a position where the required arm can reach. In case that the required labware is not existing in the Kinect view or it is outside the arms workspace, a feedback information is sent to the navigation control. This information includes several decisions such as changing the robot position or skipping to the next task. Fig. 21 shows the overall flowchart of labware manipulation process (grasping/placing). Fig. 22 shows the arm movement steps for grasping the required labware and how the arm places it on the H20 holder.

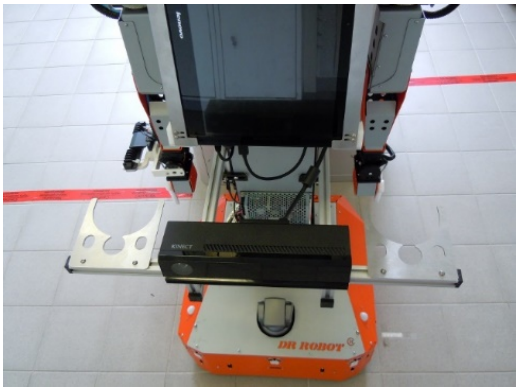

Figure 20. H20 holder frame for labware transportation.

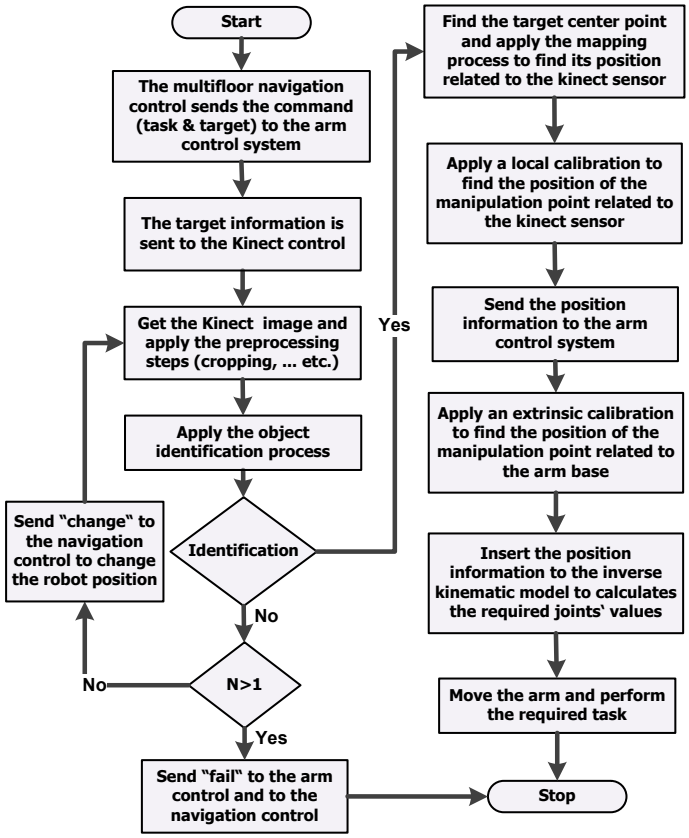

Figure 21. Flowchart of labware manipulation process.

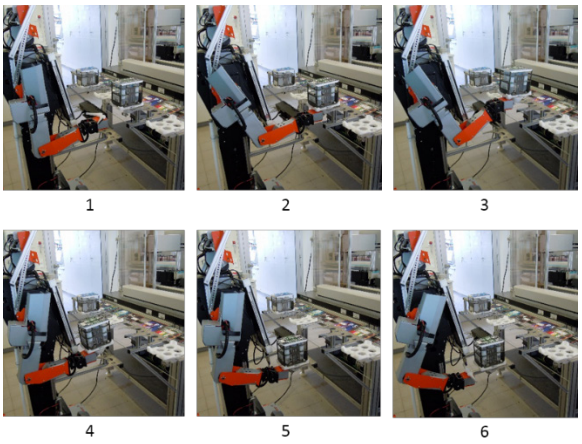

Figure 22. Arm movement steps for grasping operation.

In the grasping operation, the robotic arm moves from the rest configuration to the manipulation point on the labware container. At the rest configuration, the position of the end effector related to the arm shoulder is (X= 0.56m, Y= 0 m, Z= 0m). This position information is according to the shoulder coordinates which is shown in Fig. 6 where X represents the arm length in rest configuration. Fig. 23 shows a chart for the changes in the end effector position during the arm movement from the rest configuration to the manipulation point. In this example, the position of the manipulation point related to the arm shoulder is (X= 0.18m, Y= 0.46m, Z= 0.03m). The approximate time required to reach the manipulation point is about 30 seconds. Fig. 24 shows the path of the end effector in XY plane for the same example. Furthermore, Table 3 shows the changes of arm joints' values in degrees from the rest configuration to the manipulation point.

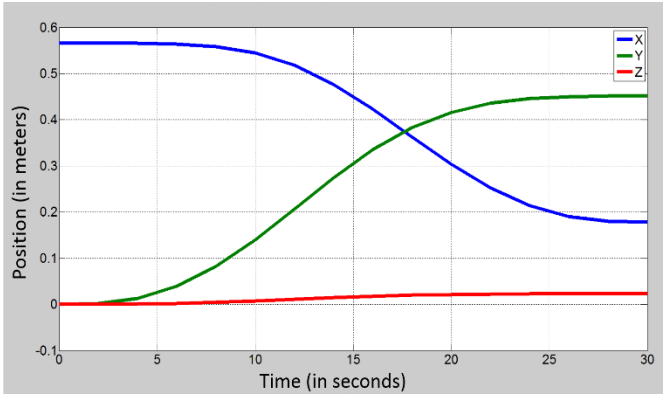

Figure 23. End effector position versus time.

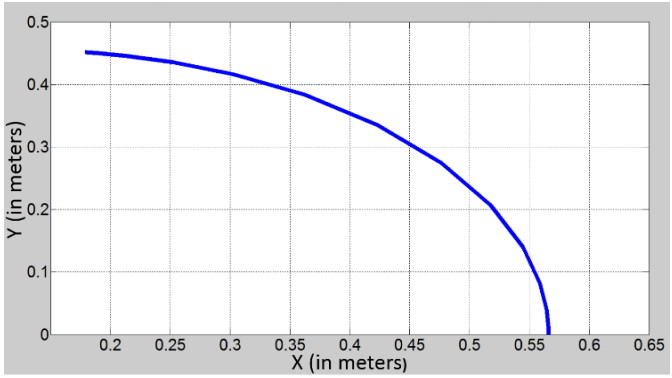

Figure 24. End effector path in XY plane.

Table 3: Joints values in degrees for grasping task.

Configuration	J1	J2	J3	J4	J5	J6
Rest	0°	-90°	-90°	0°	90°	0°
Manipulation point	32°	-95°	-92°	-64°	5°	6°

The required time for performing the grasping operation is about 69 seconds while 59 seconds are required for the placing operation. The work has been developed using Microsoft Visual Studio 2015 with C# programming language. The project is running on a Windows 10 platform in the H20 tablet. Table 4 shows the overall success rate of the grasping and placing operation for 50 attempts of transportation. Fig. 25 shows the GUI of the arm control system.

Table 4: Labware manipulation tests.

Attempts	Successful grasp	Successful place
50	92%	90%

9. Conclusion

The ability to identify and calculate the position of the target in real-time plays an important role in the manipulation process of mobile robots. In this paper, a grasping and placing strategy has been presented to perform multiple labware transportation in life science laboratories. The problem statement with the proposed methodology for the mobile robot transportation system has been discussed. Different labware manipulation strategies have been described which depends on the sonar sensors and Kinect. The identification process of labware and holder, which is based on SURF method, has been integrated to the transportation system. The pose estimation of the labware related to the robot is very significant to guide the robotic arm in the grasping and placing operation. The Kinect V2 can be considered one of the powerful 3D cameras which provide the position information in a fast way. A strategy has been proposed to check whether the required holder is occupied or not for the placing operation. The design of the arm gripper and labware container have been improved to handle heavier payloads and to guarantee a secure manipulation for the labware.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The study is supported by the Federal Ministry of Education and Research (FKZ: 03Z1KN11, 03Z1KI1) and the German Academic Exchange Service (Ph.D. stipend M. M. Ali). The authors would also like to thank the Canadian DrRobot Company for the support of the H20 mobile robots, Mr. Ali A. Abdullah for controlling the multifloor navigation system with the technical collaboration, and Mr. Lars Woinar for his contribution in the 3D modelling and printing designs.

ABSTRACT

Advancement in computer vision technology and availability of video capturing devices such as surveillance cameras has evoked new video processing applications. The research in video face recognition is mostly biased towards law enforcement applications. Applications involves human recognition based on face and iris, human computer interaction, behavior analysis, video surveillance etc. This paper presents face tracking framework that is capable of face detection using Haar fea-tures, recognition using Gabor feature extraction, matching using correlation score and tracking using Kalman filter. The method has good recognition rate for real-life videos and robust performance to changes due to illumination, environmental factors, scale, pose and orientations.

1 Introduction

In recent years, there has been rapid growth in research and development of video sensors and analyzing technologies. Cameras are vital part of security systems used to acquire information from environment. It includes video, audio, thermal, vibration and other sensors for civilian and military applications. The intelligent video acquisition system is a convergence technology including detecting and tracking objects, analyzing their movements and responding to them.

Face recognition system is used to automatically identify a person from an image or a video source. The recognition task is performed by obtaining facial features from an image of the subject's face. The main objective of video-based face recognition and tracking is to identify a video face-track of unknown individuals. It identifies the facial features by extracting features from image of subjects face and analyzing the relative position, size, shape etc. These obtained features are utilized to search corresponding matching features in other images or subsequent frames.

The face recognition system can be divided into three main parts:detection, representation and classification. The face detection from video is challenging task as it needs compensation to distortions arising from motion. The most popular algorithm for last decade is Viola Jones algorithm based on cascaded Haar feature detector [1]. Due to its high computational speed and robustness it is widely used to detect face in still images as well as video frames. Skin color of human being has limited range of chrominance that can be modeled to represent skin color pixels [2]. To overcome the limitation of complex background with skin color like objects it detects feature like shape and appearance to validate face detection [3]. The representation stage extracts distinct and discriminative features that represents face texture and appearance for face classification. The feature extraction stage is an important as the final matching decision is biased to the quality of features. Recognition stage consists of generating reference template by averaging multiple faces and matching with the detected faces. Eigenface method is simple and popular method widely used in this field [4]. Other methods like LBP [5], LDA [6], Gabor Filter [7], etc. Neural Network is efficient method used for classification [8]. It requires large training samples suitable for face recognition in images. The computation time of recognition system depends on the size of feature vector and number of database images. The state-of-art methods are mostly used for still image face recognition. Research is in progress to develop robust methods for face recognition in real-time.

This paper is an extension of work originally presented in IEEE Annual India Conference [9]. The system proposed here is intended to detect and identify the person. The first stage captures the video segments. Pre-processing algorithms like histogram

[*]Swapnil Vitthal Tathe, Sinhgad College of Engineering, Pune, India & swapniltathe7@gmail.com

https://dx.doi.org/10.25046/aj0203156

equalization are employed to remove the unwanted artifacts present in the image [10]. The second stage detects faces in complex backgrounds using Viola-Jones [1] face detector. Next stage is representation of face features using Gabor filter [11] that inculcates directional features. The Gabor features are compared with the database images using correlation coefficients [12]. The later stage tracks the detected face in subsequent frames. Tracking utilizes popularly used Kalman filter [13] that makes use of statistical analysis to predict the location of face. The proposed system identify a person in high security premises to restrict the movements of unauthorized person.

The paper is organized as follows: Section 2 presents state-of-art technologies of the field. Section 3 describes methodologies used. Section 4 presents Results and Section 5 gives Conclusions.

2 Related Work

Recognition of individuals is of high importance for various reasons. The real-time algorithms has hard limitations to overcome as any delay in processing may result in loss of important information. Facial features are used for describing individuals as it has unique nature i.e. no two persons can have same faces. The facial features commonly used in many of the studies are skin color [14], spatio-temporal [15], geometry[16] and texture pattern [17]. Face detection algorithms are computationally intensive, which makes it is difficult to perform face detection task in real-time. As human face changes with factors like facial expression, mustache, beard, glasses, size, lightening conditions and orientation, detection algorithms must be adaptive and robust[18].

The simplest approach to detect faces is to find skin pixels present in frames and then apply geometrical analysis to locate exact position of face. The conventional images or frames in videos are modeled with RGB color space. Skin pixel values for normalized RGB plane are - r plane pixel values are in the range 0.36 to 0.456 and g values in the range 0.28 to 0.363. The second model in representing images is HSV color space. In HSV model pixel is classified as skin pixel if it has values $0 \leq H \leq 50$ and $0.20 \leq S \leq 0.68$ [19]. The third model in color representation is YC_bC_r color space. Skin color pixel has C_r value around 100 and C_b value around 150 [20]. Dhivakar et al. [21] used YC_bC_r space for skin pixel detection and Viola-Jones [1] method to verify correct detection.Skin color based method is sensitive to illumination variation and fails if background contains skin color like objects.

The other complex methods used for face detection are based on geometry and texture pattern that uses depth features to detect face. Face detection using edge maps and skin color segmentation is presented in [22]. Mehta et al. [6] proposed LPA and LBP methods to extract textural features with LDA dimensionality reduction and SVM classification. Lai et al. [23] used logarithmic difference edge maps to overcome illumination variation with face verification ability of 95% true positive rate. Contour based face detection is proposed in [24]. Xiao et al. [25] used eigen faces for face detection using texture and shape information in bi view face recognition system. Viola and Jones [1] proposed haar feature based real-time method for face detection. Many researchers popularly used haar face detection with adaboost classification [8] in face detection.

Face recognition systems are popular in biometric authentication as they do not require the user intervention. Face recognition systems can be classified as sub-class of pattern recognition systems. Eigenfaces and Fisher faces were proposed in the early 1990s by Turk et al. [26]. Bayesian face recognition has better performance compared to eigenfaces [27]. Rawlinson et al. [28] presents eigen and fisher face for face recognition. Feature based methods are robust to illumination and pose variations. SIFT and SURF has robust performance in unconstrained scenarios [29]. Gangwar et al. [30] introduced Local Gabor Rank Pattern method that uses both magnitude and phase response of filters to recognize face. Neural Network is most popular tool of recent days that is used for classification which has outperformed many methods [31]. Meshgini et al. [7] proposed a method with combination of Gabor wavelets for feature extraction and support vector machine for classification. Recognition methods are time consuming as it requires accumulates training and testing phases.

Tracking is of prime importance to monitor activities of individuals in various environments [32]. The location of object in next frame is predicted based on location of object in current or preceding frames. More details for tracking methods can be found in [33]. Elafi et al [34] proposed an approach that can detect and track multiple moving objects automatically without any learning phase or prior knowledge about the size, nature or initial position. Gyorgy et al. [35] proposed Extended Kalman filter for non linear systems. Kumar et al. [36] extracted moving objects using background subtraction and applied Kalman filter for successive tracking. The other popular tracker is mean shift that employs mean shift analysis to identify a target candidate region, which has most similar appearance to target model in terms of intensity distribution. Adaptive mean shift (Camshift) algorithm is popular OpenCV algorithm for tracking [37]. In [38] combined mean shift and kalman filter is used for tracking. Particle filter tracker uses probabilistic approach to estimate position of object in next frame. The particle filter searches for histogram that best matches with reference [39]. Tracking using sparse representation [40] is gaining momentum for fast and accurate tracking.

3 Methodology

Automatic face detection is the very first step in many applications like face recognition, face retrieval, face tracking, surveillance, HCI, etc. Face is vital part of human being representing most information about the individual. Developing a representation model is difficult because face is complex, multi-dimensional visual stimuli. General architecture of proposed system is shown in Figure 1.

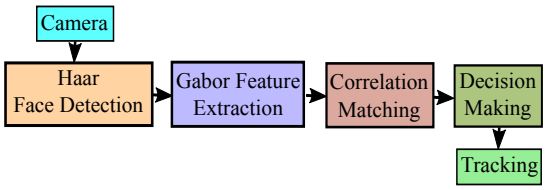

Figure 1: Human detection and tracking system

3.1 Haar Face Detection

This method is most popular method for face detection in real-time applications. Most of mobile platform uses the technique to locate faces in camera applications. Viola and Jones [1] proposed real-time AdaBoost algorithm for classification of rectangular features. The detection technique is based on the idea of the wavelet template that defines the shape of an object in terms of a subset of wavelet coefficients. The different Haar features shown in Figure 2 are used to analyze the intensity variation patterns of face regions. For example the eye region appears darker than the surrounding region that can be modeled using two rectangle feature (black part corresponding to eye region and white part corresponding to surrounding region). Combination of four, six, eight and more features is used in practical face detection to make detection robust. For a given random variable X, the variance value of X is as follows:

$$Var(X) = E(X^2) - \mu^2 \quad (1)$$

where $E(X^2)$ is expected value of squared of X and μ is expected value of X.

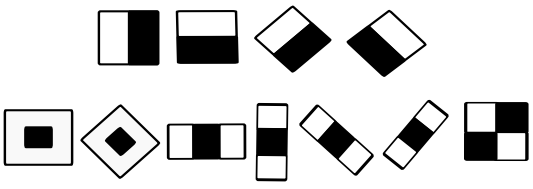

Figure 2: Haar features

Feature value is computed by subtracting the sum of variance of black region from sum of variance of white regions. To increase the computation speed, feature values can be computed using integral image [41]. Each feature is classified by a Cascaded Haar feature classifier. The Haar feature classifier multiplies the weight of each rectangle by its area and results are added together. The cascaded structure helps to speed up the detection process by eliminating non-face regions at every stage of cascade. Figure 3 shows face detection results from a video stream capture using webcam.

Figure 3: Face detection using Haar Features

Haar based method is capable of detecting multiple faces in near real-time and robust to illumination variations.

3.2 Gabor Filter

Feature extraction is one of the most important steps in designing a pattern recognition system. The features must have features have a small within class variation and strong discriminating ability among classes. Gabor filters have band pass performance that emphasizes features in face region that are analogous to scale and orientation of filter. The characteristics of Gabor filters are appropriate for texture representation and discrimination [7]. This method is robust to face pose and illumination changes.

The Gabor filter extracts face features from gray-level images. A two-dimensional Gabor filter is a Gaussian kernel function modulated by a complex sinusoidal plane wave represented as Equation 2.

$$\Psi_{\omega,\theta}(x,y) = \frac{1}{2\pi\sigma^2} exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) exp\,(j\omega x') \quad (2)$$

$$x' = xcos\theta + ysin\theta, y = -xsin\theta + ycos\theta \quad (3)$$

where (x,y) is the pixel position in the spatial domain, x is the central angular frequency of the complex sinusoidal plane wave, h is the anti-clockwise rotation(orientation) of the Gabor function, r represents the sharpness of the Gaussian function along both x and y directions and $\sigma \approx \frac{\pi}{\omega}$.

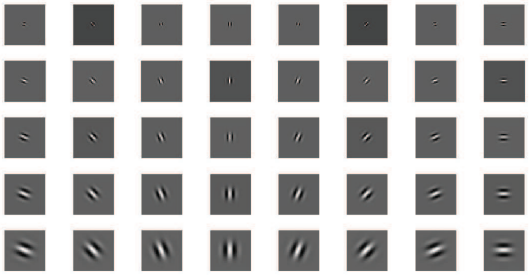

Figure 4: Gabor filters at 5 scales and 8 orientations

To extract useful features from an face image a set of Gabor filters with five frequencies (scales) and eight

orientations is used. Figure 4 shows the Gabor filter bank. The scale and orientation values are obtained using Equations 4 and 5.

$$\omega_u = \frac{\pi}{2} \times \sqrt{2}^u, u = 0, 1, \ldots, 4 \quad (4)$$

$$\theta_v = \frac{\pi}{8} \times v, v = 0, 1, \ldots, 7 \quad (5)$$

The Gabor representation of a face image $I(x, y)$ is obtained as:

$$G_{u,v}(x, y) = I(x, y) * \Psi_{\omega_u, \theta_v}(x, y) \quad (6)$$

where $G_{u,v}(x, y)$ denotes the two-dimensional convolution result corresponding to the Gabor filter at scale u and orientation v. This process can speed-up with the use of frequency domain transformation. Figure 6 and 7 shows the convolution results of a face image shown in Figure 5) with Gabor filters.

Figure 5: Face Image

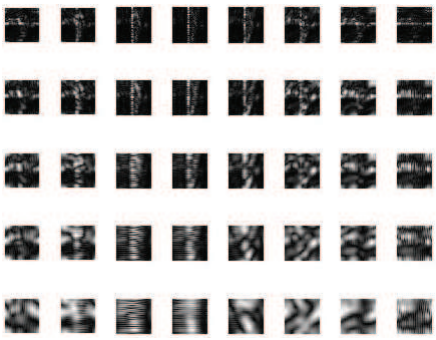

Figure 6: Magnitude of Face

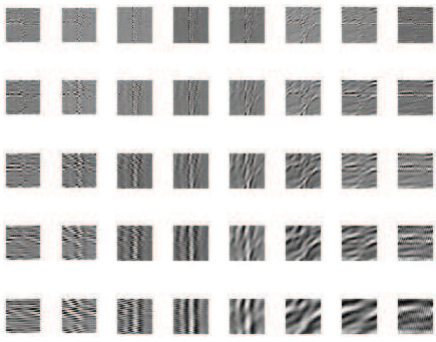

Figure 7: Real Part of Face

Each image $I(x, y)$ is represented as set of Gabor wavelet coefficients $G_{u,v}(x, y)|u = 0, 1, \ldots, 4; v = 0, 1, \ldots, 7$. The magnitude $G_{u,v}(x, y)$ is normalized to zero mean and unit variance and represented as a vector $z_{u,v}$ given by Equation 7 [7].

$$z = \left[(z_{0,0})^T (z_{0,1})^T \ldots (z_{4,7})^T\right]^T \quad (7)$$

Gabor based recognition is robust to pose and illumination variations with additional overhead of processing time and complexity.

3.3 Correlation Score Matching

Matching is a search algorithm that compares the features from query image to the database images to find best match. The comparison is done using correlation coefficients [32] between the Gabor features of detected face and the images present in database. Prior to matching stage all images in database are applied with Gabor filter for efficient feature matching. The 2D images are represented by 1D feature vector that speeds up the matching process. The correlation score is computed as :

$$Score = \sum_{i=1}^{m} f_q(i).f_{db}(-i) \quad (8)$$

where m is size of feature vector, f_q represents query feature vector and f_{db} represents database feature vector. The query image best matches with the database image that results into high correlation score.

3.4 Kalman Filter Tracking

Tracking objects in video sequences is one of the most important tasks in computer vision. The approach is to search target within a region centered on last position of the object. The important facts that should be taken care for effective tracking are: speed of moving object, frame rate of video and search region. These factors are dependent on each other, higher frame rate is used to get hold of faster moving target which on other hand requires faster processing. Tracking is defined as localization and association of features across series of frames. The two major components of tracking system are object representation and data association. The first component describes object and second utilizes the information for tracking.

The location of face from face detection stage is used as apriori estimate or sometimes called as initialization for tracking. Based on this location Kalman filter estimates and updates the prediction behavior of this stage. Initialization is an important stage for the tracker.

Kalman filter predicts the next time state vector based on the movement information in the previous stages. Kalman filter equations are categorized as - time update equations and measurement update equations. The time update equations projects forward the current state and error covariance estimates to obtain the apriori estimates for the next time step. The measurement update equations are the feedback i.e. it incorporates a new measurement into the a priori estimate to obtain an improved aposteriori estimate. The time update equations are predictor equations, while the measurement update equations are

corrector equations. The process for Kalman filter estimation and update is given in Algorithm 1.

Algorithm 1 Kalman Filter

1: Initial Estimates for $\hat{X}_{k-1}$ and P_{k-1}
2: Time Update

- Project the state

$$\hat{X}_k^- = A\hat{X}_{k-1} + Bw_k$$

- Project the error covariance

$$P_k^- = AP_{k-1}A^T + Q$$

3: Measurement Update

- Compute Kalman gain

$$K_k = \frac{P_k^- H^T}{HP_k^- H^T + R}$$

- Update estimate with measurement Z_k

$$\hat{X}_k = \hat{X}_k^- + K_k(z_k - H\hat{X}_k^-)$$

- Update error covariance

$$P_k = (1 - K_k H)P_k^-$$

The state equation is

$$X_k = AX_{k-1} + Bw_k \tag{9}$$

The measurement model is

$$Z_k = HX_k + v_k \tag{10}$$

A and B are the system parameters and are matrix in the multi-model system, H is a parameter in a measure system, which is matrix in the multi-measurement system. w_k and v_k represents the process and measurement noise respectively.

The state vector $X_k = [x_k y_k x'_k y'_k]^T$, x_k, y_k are the object center in the x, y-axis location, x'_k, y'_k are the x, y axis speed. $Z_k = [x_{ck} y_{ck}]^T$ is the observation vector. P_k^- is apriori estimate error covariance and P_k is aposteriori estimate error covariance.

The search for object is carried in a region selected based on the estimated observation matrix Z_k. It fails if image is not properly illuminated. Kalman filter overcomes problem of Kanade-Lucas-Tomasi(KLT) [42]. It can track multiple objects with variations in pose and occlusion. The drawback is that it cannot handle rapid changes in motion of target.

Table 1: Result Comparison

Video	Frames	Face Det.	True Recog.		False Recog.

4 Results

The algorithms are applied on video sequences obtained from NRC-IIT Facial Video Database and our own videos recorded with webcam. Table 1 gives the comparison of proposed method with eigen face method. The values presented in table are the number of frames with true result. Table 2 gives summary of results obtained on the videos. Haar face detector used has robust performance for frontal faces. It cannot handle larger pose variations. Face detection fails if the face is very small in size compared to size of frame and in random pose changes. The second part of algorithm is face recognition that makes use of gabor filters. Gabor filter has robust performance in pose and illumination variations. Once person is recognized Kalman filter keeps track of movements the face in subsequent frames. Kalman filter has good tracking performance in partial occlusions but fails in case of sudden movements. Recognition result is shown in Figure 8. The values in table shows the playback time in sections for videos under test with face detection and recognition stage.

5 Conclusions

The proposed system detects the facial features of human being and verify identity of a person. Haar based face detection is popular and efficient face detection algorithm for real-time applications. Haar based face detector has high accuracy in frontal face detection. Recognition performance depends on the type of images in database. Larger the database more is recognition time. Gabor face recognition is better than many other methods as it compares features at different scale and orientations. Disadvantage of recognition stage is that comparison of large number of features requires more time for recognition that affects real-time performance. Reducing feature set reduces recognition time but affects accuracy of system. Kalman filter gives good performance in complex environment. Future directions can be optimizing algorithms to minimize processing time and achieve real-time performance.

ABSTRACT

This paper examines the efficiency of a fuzzy logic control (FLC) based maximum power point tracking (MPPT) of a photovoltaic (PV) system under variable climate conditions and connected load requirements. The PV system including a PV module BP SX150S, buck-boost DC-DC converter, MPPT, and a resistive load is modeled and simulated using Matlab/Simulink package. In order to compare the performance of FLC-based MPPT controller with the conventional perturb and observe (P&O) method at different irradiation (G), temperature (T) and connected load (R_L) variations - rising time (t_r), recovering time, total average power and MPPT efficiency topics are calculated. The simulation results show that the FLC-based MPPT method can quickly track the maximum power point (MPP) of the PV module at the transient state and effectively eliminates the power oscillation around the MPP of the PV module at steady state, hence more average power can be extracted, in comparison with the conventional P&O method.

1. Introduction

The extracted output power from the photovoltaic (PV) system is affected by the climate conditions represented by a solar irradiation (*G*) and a temperature (*T*). Hence, an effective maximum power point tracking technique is required improve the efficiency of the overall PV system.

In the last years, many MPPT techniques have been proposed to track the MPP of the PV module [1–6]. In [1], the FLC based MPPT is proposed to track the MPP at standard technical condition (STC) and variable resistive load. Where, the change in duty cycle (ΔD) was used as an FLC's output to adjust the duty cycle (D) of the DC-DC converter, in order to meet the load matching between the PV module and the connected resistive load.

This work is an extension of work originally presented in 2016 International Conference on Applied and Theoretical Electricity (ICATE) [1]. In this paper, the efficiency of FLC-based MPPT for the PV system is examined under variable climate conditions (irradiation and temperature) and variable values of connected resistive load. The utilized PV system includes a BP SX150S PV module, buck-boost DC-DC converter, MPPT controller, and resistive load (R_L). The circuit diagram of the PV system is shown in Figure 1.

The rest of this paper is arranged as follows: Section 2 explains the basic modeling of the utilized PV module. Section 3 tackles the MPPT control and the mechanism of load matching through the DC-DC converter. Section 4 describes the details of considered MPPT algorithms: conventional perturb and observe (P&O) and the proposed FLC. Simulation and comparison results obtained by using Matlab software are presented in Section 5. Finally, conclusions of the work are revealed in Section 6.

2. Modeling of the PV Module

In this paper, a single-diode equivalent circuit model is used. This model consists of two resistances (series R_s and parallel R_{sh}) as depicted in Figure 2 [7].

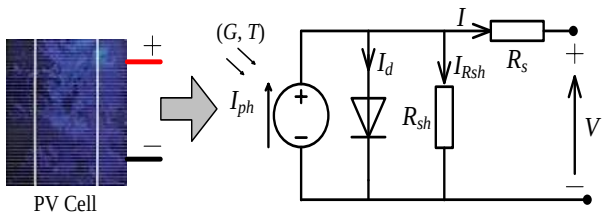

Figure 2. The equivalent circuit of the PV model.

According to the Kirchhoff's law, the characteristic equation of the PV model can be expressed by [8]:

$$I = I_{ph} - I_d - I_{Rsh} \tag{1}$$

By developing the terms of I_d and I_{Rsh}, the PV current can be written as,

$$I = I_{ph} - I_o\left(\exp\left(\frac{q(V + I R_s)}{N_s n K T}\right) - 1\right) - \left(\frac{V + I R_s}{R_{sh}}\right) \tag{2}$$

Where I_{ph} is the light current that is equal to short-circuit current I_{sc}. I_d and I_{Rsh} are the parallel currents through the diode and parallel resistance R_{sh}, respectively. I_o is the cell's reverse saturation current, also known as the "dark current", q is the electron charge (1.602×10^{-19} C), n is the diode ideality factor of a value is between 1 and 2, K is the Boltzmann's constant (1.381×10^{-23} J/K), T is the PV cell temperature (K), and N_s is the number of series-connected solar cells to organize the utilized PV module [1,8,9]. In this paper, the BP SX150S PV of N_s =72 cells is utilized to produce a peak power output of 150 W at standard technical condition (STC). Under STC, the cell temperature T_r is 298 °K which equivalent to 25 °C and the solar irradiation G_r is 1000 W/m^2 at air mass (AM=1.5). Table 1 illustrates the utilized PV module's electric parameters [10].

Table 1. Electrical parameters of BP SX150S PV module

Parameter	Value
Maximum Power (P_{max})	150 W
Voltage at P_{max} (V_{mpp})	34.5 V
Current at P_{max} (I_{mpp})	4.35 A
Short-circuit current (I_{sc})	4.75 A
Open-circuit voltage (V_{oc})	43.5 V
Temperature coefficient of I_{sc}	(0.065 ± 0.015) %/ °C
Temperature coefficient of V_{oc}	– (160 ± 20) mV/ °C

The reverse saturation current (I_o) is dependent on the temperature (T) and can be expressed by:

$$I_o = I_{or} \times \left(\frac{T}{T_r}\right)^3 \times \exp\left(\frac{q E_g}{n K}\left(\frac{1}{T_r} - \frac{1}{T}\right)\right) \tag{3}$$

Where E_g is the band-gap energy of the semiconductor used in the cell.

To determine the module's open-circuit voltage (V_{oc}), we set (I=0 and V=V_{oc}) and assume R_{sh}= ∞ in (2), which results,

$$V_{oc} = N_s n \frac{KT}{q} \ln\left(\frac{I_{sc}}{I_o} + 1\right) \tag{4}$$

The PV module's short-circuit current (I_{sc}) depends on the cell temperature (T) and solar irradiation (G) as,

$$I_{sc} = \frac{G}{G_r}\left(I_{scr} + \alpha(T - T_r)\right) \tag{5}$$

Where α is the short circuit current temperature coefficient.

The PV module's maximum power point (MPP) is the point at which the peak product of V and I is obtained, hence V=V_{mpp}, I=I_{mpp}, and P=P_{max} at MPP. This point changes with the variation of climate conditions as shown in Figure 3 and Figure 4. It can be seen that the current and power of the PV module increase linearly as irradiation increases, while the voltage approximately unchanged as shown in Figure 3. In contrast, for an increasing temperature, the voltage and power decrease while the current approximately unchanged as shown in Figure 4. Different MPPT methods can be used to maintain the PV module's operating point at or near the MPP, thereby, extracting a maximum available output power from the PV module.

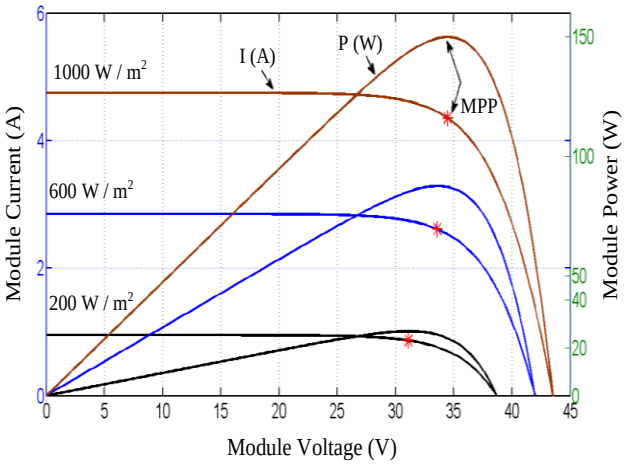

Figure 3. *I-V* and *P-V* Characteristics of the PV module at various irradiations and 25 °C of temperature.

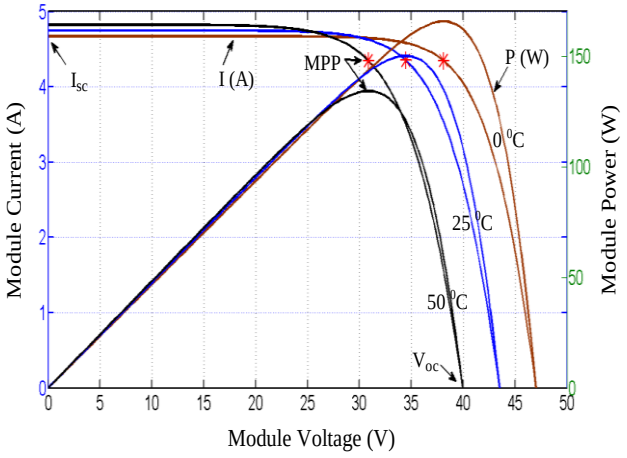

Figure 4. *I-V* and *P-V* Characteristics of the PV module at various temperatures and 1000 W/m^2 of irradiation.

3. MPPT Control and Load Matching

The switch mode DC-DC converter represents a main part of the PV MPPT. The DC-DC converter is used for two purposes; firstly, to regulate the PV operating point at the MPP. Secondly, to maintain the matching between the PV optimal impedance (R_{opt}) and the connected load impedance (R_L), consequently, a maximum power transfer between the PV module and the load can be obtained. The DC-DC converter uses the duty cycle control signal produced by the MPPT algorithm [1].

According to an ideal (lossless) DC-DC converter, the input-output voltage and current relationships can be described by:

$$P_{in} = P_L , \tag{6}$$

$$V \times I = V_L \times I_L , \tag{7}$$

$$\frac{V_L}{V} = \frac{I}{I_L} = \frac{D}{1-D} \tag{8}$$

Where, V_L and I_L are the load's voltage and current, respectively. Whereas V and I are the PV module's voltage and current, respectively. The relationship between the voltage and duty cycle can be expressed as:

- If $0 < D < 0.5$, the converter output voltage does not exceed the input voltage (Buck type).
- If $D = 0.5$, the converter's input and output voltages are identical.
- If $0.5 < D < 1$, the converter output voltage exceeds the input voltage (Boost type).

The DC-DC converter's input impedance (i.e. input impedance seen by the PV module) can be written as:

$$R_{in} = \frac{V}{I} \tag{9}$$

By substituting (8) in (9), R_{in} can be expressed as:

$$R_{in} = \frac{(1-D)^2}{D^2} \times \frac{V_L}{I_L} = \frac{(1-D)^2}{D^2} \times R_L , \tag{10}$$

$$R_L = \frac{V_L}{I_L} \tag{11}$$

From (10), it can be seen that by changing the duty cycle, the value of R_{in} can be matched with the optimal input impedance (R_{opt}) of the PV module at the MPP, where,

$$R_{opt} = \frac{V_{mpp}}{I_{mpp}} \tag{12}$$

At STC, the relationship between the duty cycle and extracted power from the PV module at various values of resistive load (R_L) is shown in Figure 5 [1]. As it is seen in this figure, when R_L is increased, the optimal duty cycle (D_{opt}) is also increased to reach the unique MPP. In this paper, the goal of the two utilized MPPT methods is to maintain D_{opt} under various climate (G and T) conditions and resistive load (R_L).

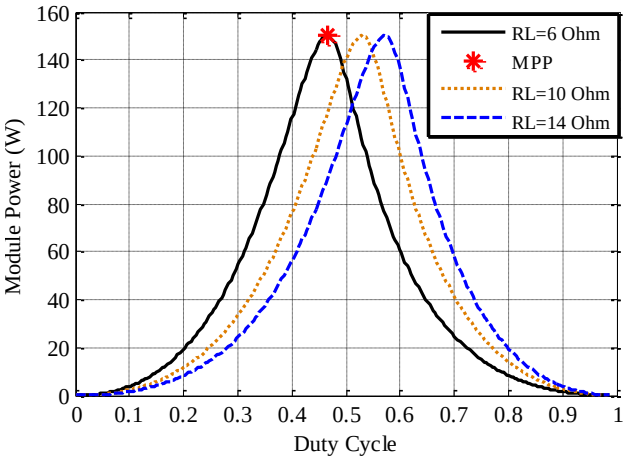

Figure 5. Module power vs. duty cycle at STC and various resistive loads.

4. MPPT Algorithms

4.1. Perturb and Observe (P&O) Method

The perturb and observe (P&O) method, also known as the "hill climbing" method is widely used as an MPPT algorithm for PV systems applications due to its simplicity and ease of implementation and simplicity [11]. The algorithm perturbs the duty cycle by increasing or decreasing it using a constant duty step-size (ΔD) and observes resulting variations in the PV output power (ΔP). If the $\Delta P>0$, that means the new operating point has moved closer towards the MPP, hence the duty cycle is further perturbed in the same direction; otherwise, the direction will be reversed. This process is repeated periodically until MPP is maintained. Unfortunately, by this algorithm, the operating point oscillates around the MPP at the steady state. Consequently, the PV efficiency is slightly reduced. Although the steady state oscillation can be decreased by decreasing ΔD, however, the dynamic response will be slowed. Hence, the tradeoff between these two requires that ΔD is finely tuned. The flow chart of the P&O algorithm is shown in Figure 6.

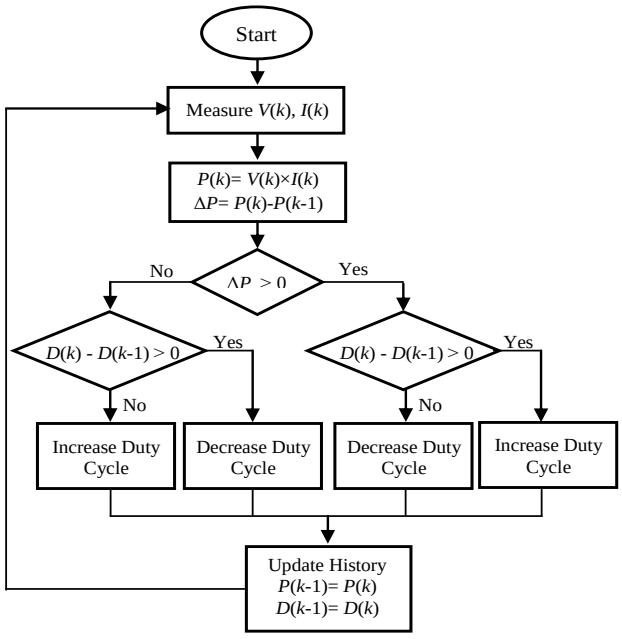

Figure 6. Flow chart of the P&O algorithm.

4.2. Fuzzy Logic Control (FLC) Method

The fuzzy logic was developed by Zadeh in 1965. The FLC is used to convert the human information to the rule-based model that can control a plant with linguistic explanations [12,13].

In this paper, the utilized FLC has two inputs and one output. The inputs are an error (E) and its variation (ΔE), whereas the output is the change in duty cycle (ΔD), as shown in Figure 7.

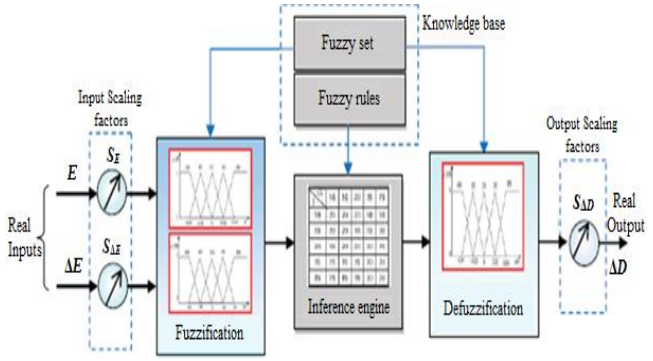

Figure 7. The Structure of a fuzzy logic controller.

The inputs and output, at a sampling instant k are expressed as follows:

$$E(K)=\frac{P(K)-P(K-1)}{V(K)-V(K-1)}, \quad (13)$$

$$\Delta E(K)=E(K)-E(K-1), \quad (14)$$

$$D(K)=D(K-1)+\Delta D(K) \quad (15)$$

Where $P(k)$ and $V(k)$ are the output power and voltage of the PV module at sampling k. $\Delta D(k)$ is the change in duty cycle used as the FLC's output to calculate the DC-DC converter's actual duty cycle $D(k)$ at sampling k.

$E(k)$ is the P-V curve's slope. Consequently, the sign of $E(k)$ indicates the operating point's location at instant k, either on the left or on the right of the MPP on the P-V curve of PV module as illustrated in Figure 8. However, the input $\Delta E(k)$ expresses the moving direction of this point. The typical FLC includes three main components: fuzzification, inference engine, and defuzzification, as shown in Figure 7 [14].

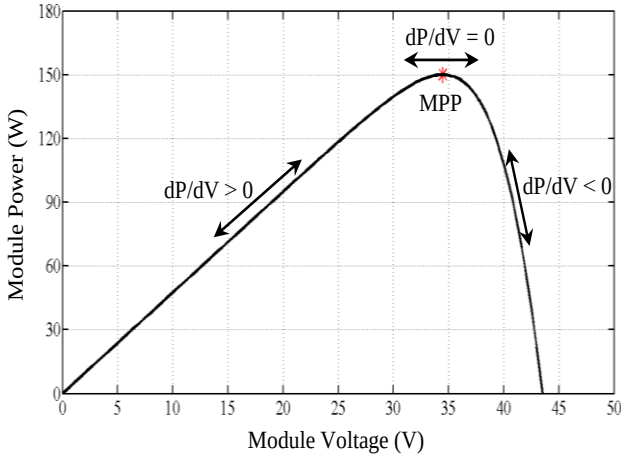

Figure 8. The slope of P-V characteristics of PV module at STC.

I. Fuzzification

After normalizing the actual (crisp) FLC's inputs by scaling factor (S_E) and ($S_{\Delta E}$), as shown in Figure 7, the inputs are fuzzified. The fuzzification process converts the input and output variables from real crisp variables to fuzzy variables which are expressed by linguistic terms such as negative big (*NB*), negative small (*NS*), zero (*Z*), positive small (*PS*), and positive big (*PB*). Figure 9 shows the fuzzy sets for the inputs and output variables used in this paper with triangular and trapezoidal membership functions.

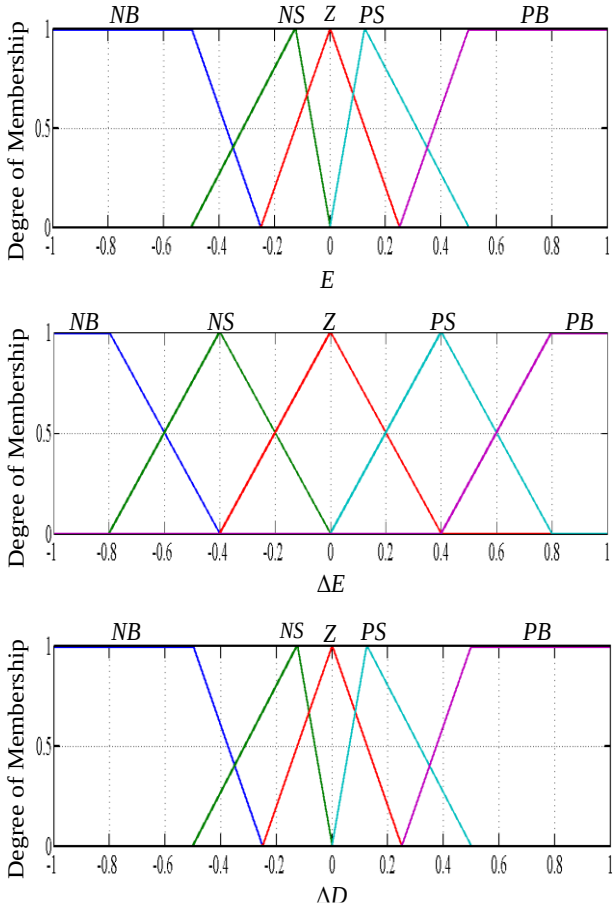

Figure 9. Membership functions: E and ΔE are the inputs; ΔD is the output.

II. Fuzzy Rules and Inference Engine

The inference engine applies the rules to the fuzzy inputs which are produced by the fuzzification process to generate n aggregated fuzzy outputs. In this paper, since each of the input and output has five fuzzy subsets, 25 fuzzy IF-THEN rules shown in Table 2 are used. The rules are used to control the DC-DC converter by a suitable ΔD.

The main concept of the rules is related to the location of the operating point from the MPP. If the operating point moves closer toward the MPP, the ΔD will be increased or decreased to a small extent and vice versa if the operating point diverges away from the MPP. For example, in the shaded rule in Table 2: If E is *NB* AND ΔE is *Z* THEN ΔD is *PB*. This means that if the operating point is located at a distance to the right of the MPP and there is no change in the P-V slope, then the duty ratio is substantially increased.

Table 2. Fuzzy logic controller rules

ΔD		ΔE				
		NB	*NS*	*Z*	*PS*	*PB*
E	*NB*	*Z*	*Z*	*PB*	*PB*	*PB*
	NS	*Z*	*Z*	*PS*	*PS*	*PS*
	Z	*PS*	*Z*	*Z*	*Z*	*NS*
	PS	*NS*	*NS*	*NS*	*Z*	*Z*
	PB	*NB*	*NB*	*NB*	*Z*	*Z*

III. Defuzzification

The defuzzification represents the inverse of the fuzzification process. It is used to transform the output from the fuzzy domain into the single real (crisp) domain, using the well-known center of gravity (COG) defuzzification methods. This method computes the centroid of the final composite area representing the output fuzzy term, which is resulted by the union of all 25 rule output fuzzy sets [15,16], to produce the real value of ΔD as:

$$\Delta D = \frac{\sum_{i=1}^{n} \Delta D_i \times \mu(\Delta D_i)}{\sum_{i=1}^{n} \mu(\Delta D_i)} \quad (16)$$

Finally, this crisp output is denormalized using the output scaling factor ($S_{\Delta D}$) then substituted in (15) to generate the actual duty cycle $D(k)$.

5. Simulation Results

In this paper, the load, irradiation, and temperature variations are presented in Figures 10–12, respectively.

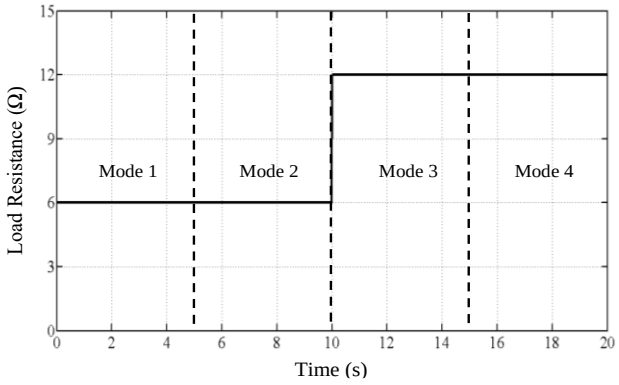

Figure 10. Resistive load variation.

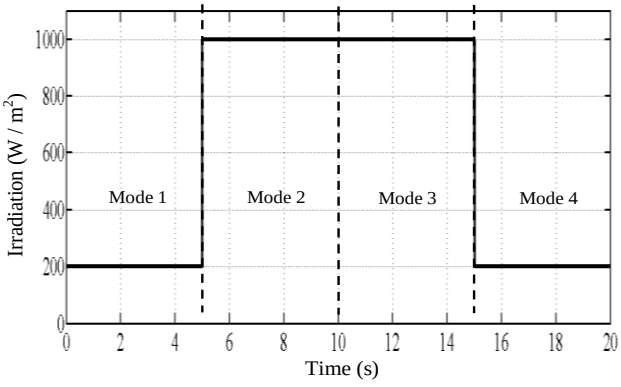

Figure 11. Irradiation variation.

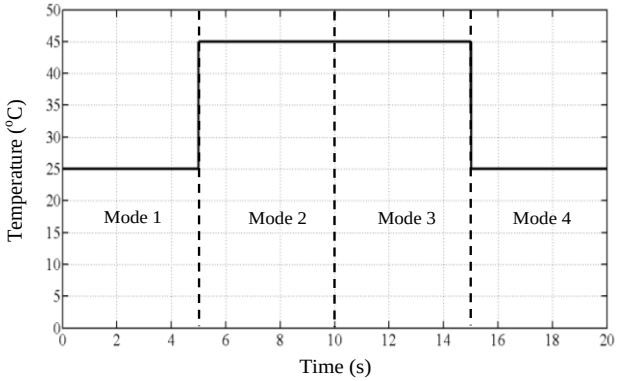

Figure 12. Temperature variation.

The overall operating period can be classified into four different modes:

- Mode 1 is the period where G=200 W/m^2, T=25 °C, and R_L=6 Ω.
- Mode 2 is the period where R_L is kept constant whereas G and T are suddenly increased to 1000 W/m^2 and 45 °C, respectively.
- Mode 3 is the period where the load is changed from 6 Ω to 12 Ω at constant G and T of the previous mode.
- Mode 4 is the period where the load is kept constant whereas G and T are suddenly decreased to the same its values in mode 1.

During the time period of mode 1 shown in Figures 10–12, the MPPT methods increase the duty cycle from initial value (D=0.1) to (D_{opt1}=0.29), as shown in Figure 13 and decrease the converter input resistance (R_{in}) by using (10) to match (R_{opt1}=35.92 Ω), moving the operating point of the PV module from starting point ***A*** to reach MPP at point ***B***, as shown in Figure 14, thereby extracting maximum power (P_{max1}=27 W) from the module as shown in Figures 15–17.

Due to a large increasing in the irradiation at the starting mode 2, the operating point will suddenly jump to point ***C***, as shown in Figure 14 with a small increasing in power to (P=40 W), as shown in Figures 15–17. During this mode, the MPPT methods increase D to (D_{opt2}=0.476), as shown in Figure 13 and decrease R_{in} to match the new (R_{opt2}=7.27 Ω), moving the operating point from point ***C*** to the new second MPP at point ***D***, as shown in Figure 14, thereby increasing the power to (P_{max2}=137.3 W), as shown in Figures 15–17.

At the starting of mode 3, when the load is suddenly doubled, R_{in} is also doubled from 7.27 Ω to 14.54 Ω, thus the operating point will suddenly jump away in the right direction from point ***D*** to point ***E***, as shown in Figure 14 and the power drops from P_{max2} to 95 W, as shown in Figures 15–17. During this mode, the tracking methods try again to recover the operating point from current point ***E*** to the MPP at point ***F*** which is the same location of optimal point ***D***, by moving it in the left direction, by increasing D from D_{opt2} to new (D_{opt3}=0.5624), as shown in Figure 13 and decreasing R_{in} to match R_{opt2} again, as shown in Figure 14, to reach P_{max2} again, as shown in Figures 15–17.

Finally, at the starting of mode 4, when the load is kept constant and the climate conditions drops as the inverse of starting condition of mode 2, the operating point will suddenly jump to point ***G***

shown in Figure 14 with a large decreasing in power from P_{max2} to 7.5 W, as shown in Figures 15–17. During this period, the MPPT methods decrease D to (D_{opt4}=0.3663), as shown in Figure 13 and increase R_{in} to match (R_{opt1}=7.27 Ω) again, moving the operating point in the right direction from point ***G*** to the MPP at point ***H*** which is the same location of optimal point ***B***, as shown in Figure 14, thereby increasing the power and reaching P_{max1} again, as shown in Figures 15–17.

From the different operation modes, it is clear that the FLC provides a fast and effective transient response in terms of tracking and recovering speed and this method also provides an effective steady response with less oscillation as compared with P&O tracking method, according to the responses of duty cycle and extracted power from the PV module shown in Figures 13, 16, respectively.

At variable climate and load operation modes explained in Figures 10–12, Table 3 lists the load matching results of voltage, current, and power of PV module, duty cycle and input resistance of the DC-DC converter, and the corresponding load voltage and current using MPPT.

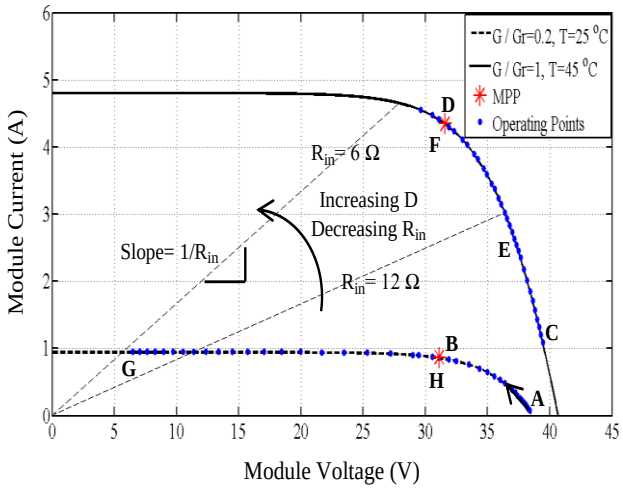

Figure 14. *I-V* Characteristics of PV module and traces of operating point under variable climate and load conditions.

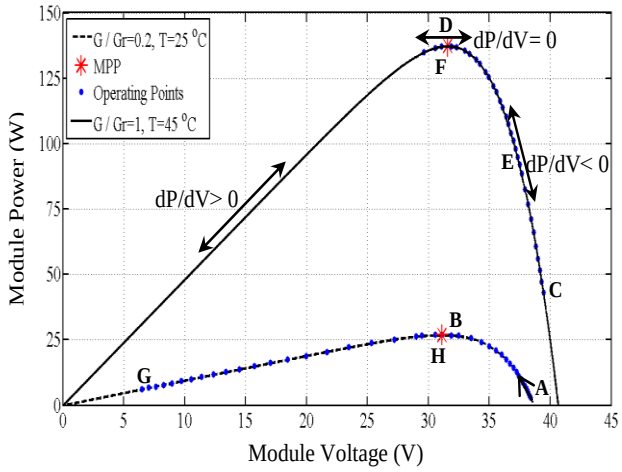

Figure 15. *P-V* Characteristics of PV module and traces of operating point under variable climate and load conditions.

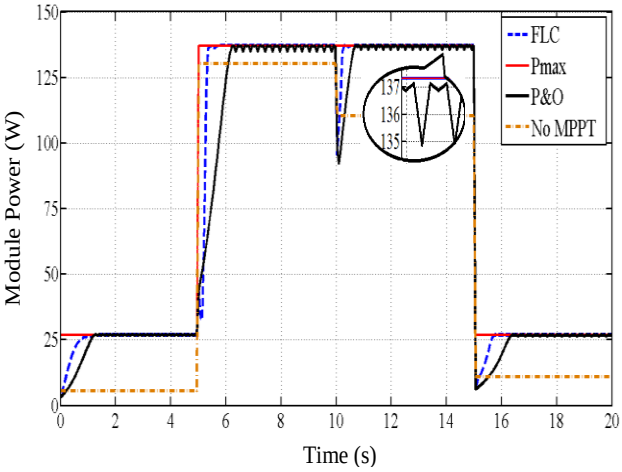

Figure 16. Module power performances using MPPT methods under variable climate and load conditions.

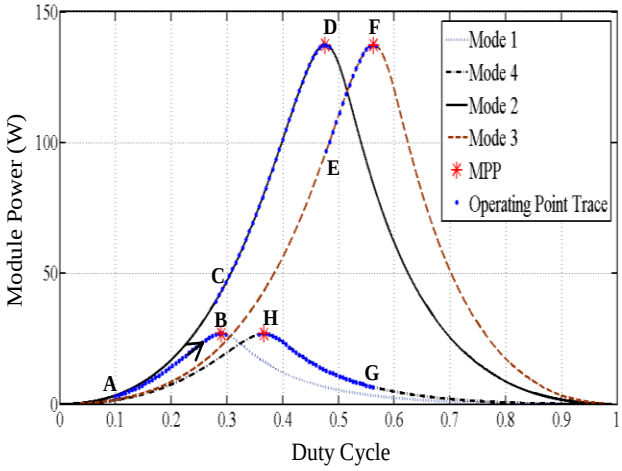

Figure 17. Module power vs duty cycle and traces of operating point under variable climate and load conditions.

Whereas, Table 4 lists the comparison results of MPPT methods in terms of rising time, recovery time, total average power, and MPPT efficiency during the overall operating period.

Table 3. Load matching results under different operating modes

Operating Modes	V_{mpp} (V)	I_{mpp} (A)	P_{max} (W)	R_{opt} (Ω)	D_{opt}	V_o (V)	I_o (A)
Mode 1	31.1	0.86	26.92	35.92	0.29	12.71	2.12
Mode 2	31.6	4.34	137.3	7.27	0.47	28.70	4.34
Mode 3	31.6	4.34	137.3	7.27	0.56	40.59	3.38
Mode 4	31.1	0.86	26.92	35.92	0.36	17.97	1.49

Table 4. Comparison of MPPT methods under different operating modes

MPPT Method	t_r (s)	Recovering Time (s)	Ideal P_{av} (W)	Total P_{av} (W)	Efficiency %
Without (D=0.5)	–	–	82.1137	64.153	78.12
P&O	1.25	0.75	82.1137	76.3	92.92
FLC	0.75	0.25	82.1137	79.66	97.01

6. Conclusions

In this paper, the effectiveness of the FLC and classical P&O based MPPT methods are analyzed by simulation and compared using different operation modes of irradiation, temperature, and load requirement.

In the case of rapid changes in the climate conditions and constant connected load, as represented by starting periods of modes 2 and 4, the simulation results show that the FLC tracking method can quickly reach the new MPP with less rising time (t_r) at transient response and eliminates the power oscillation around the MPP at steady state; thus providing a higher power output efficiency, as shown in Figures 13, 16 and Table 4.

According to a rapid fluctuation of the load, as represented by starting periods of mode 3, also the FLC method has better performances in comparison with P&O method – less recovering time and better steady responses of less oscillation as shown in Figures 13, 16 and Table 4. Consequently, the PV system with FLC-based MPPT control is more efficient due to the fact that allows harvesting more solar power in comparison with the classical P&O tracking methods.

EAST-ADL

ABSTRACT

Safety is becoming more and more important with the ever increasing level of safety related E/E Systems built into the cars. Increasing functionality of vehicle systems through electrification of power train, in future even more by autonomous driving, leads to complexity in designing system, software and safety architecture. ISO 26262 aims to reduce the complexity and to approve the traceability of the different safety activities. This paper presents an approach about model-based development of system, software and safety architecture using Electronics Architecture and Software Technology - Architecture Description Language (EAST-ADL), being in line with the relevant standard ISO 26262. In particular, we briefly discuss how the main safety related activities, such as hazard analysis and risk assessment, developing functional and technical safety concepts and performing safety analysis can be performed model-based and how the activities can be related with system and software development. The state-of-art is also provided and compared with the proposed approach.

1. Introduction

This paper is an extension of work originally presented in Electrical Systems for Aircraft, Railway, Ship propulsion and Road Vehicles & International Transportation Electrification Conference (ESARS-ITEC 2016) [1]. Nowadays, in a premium vehicle up to 100 processing units (ECUs) are installed, which are capable of computing complex algorithms. The embedded software of a premium automobile contains up to 100 million lines of source code. On the contrary, the new “Boeing Dreamliner 787” needs for all onboard systems around 6.5 million lines of code [2].

This comparison shows how complex the software is already in today's vehicles. Complexity and the scale of the software will continue growing [2]. Major reasons for the large amount of software are the electrification of the automobile and already available advanced driver assistance systems. It is believed that the ratio of the cost of electric and electronic components to the total production cost of a vehicle could rise up to 35% by 2020 and up to 50% by 2030 [3]. With the increase of electrification, the proportion of safety-critical systems is also growing. Malfunctions like "unintended blocking of the drive axle while driving", "power assisted steering acts in the wrong direction", or "false tripping of the airbag while driving" are a few examples that can lead to life-threatening injuries [4].

Increasing functionality of existing or new vehicle systems both result in increasing proportion of E/E systems and an increase in complexity of the system, software and safety architecture. Engineers from different fields need to be involved. The system and software architectures have to satisfy the different requirements in any phase of development. At this point the question arises, how the industry is responding to the increase in safety and non-safety related functions without sacrificing the quality of the software.

An approach, how the engineers deal with these challenges, uses model-driven system, software and safety development. This research presents an approach for model-based development of safety critical functions and model-based development of ISO work products. EAST-ADL is used as the basis of this approach. However EAST-ADL should be modified in a way to bring the system architecture and safety architecture together, because ISO 26262 requires consistency and traceability by the development of safety critical systems. But the current EAST-ADL specification is not enough to implement these requirements, because currently the

[*]Corresponding Author: Bülent Sari, Electronics Powertrain Technology, ZF Friedrichshafen AG, Friedrichshafen, Germany | Email: buelent.sari@zf.com

system architecture and safety architecture are separated in different models and there is not direct relation between system architecture models and safety models. The system architecture is developed within the abstraction levels of EAST-ADL and the safety models are realized within the dependability model. It is a big challenge and also requirement of ISO 26262 (Part 4 – Figure 2, Part 10 - Figure 8 and Figure 9) to show the dependencies between hazards and risks, safety goals, functional and technical safety requirements and safety functions. By safety assessments, the developers should be able to show which safety goals are implemented by which safety functions and it should be proven that the safety functions and safety goals have the same Automotive Safety Integrity Level (ASIL). Therefor it was essential to modify EAST-ADL in a way to bring these models together in order to provide consistency check, traceability of safety functions and also generate the ISO26262 work products such as safety concept automatically. The extensions enable to show the relationship between the safety goals and the safety functions in order to prove easily which function is implemented for which safety goal. So it is easier to prove the completeness of the safety activities.

The second main contribution of the paper is to verify and to validate the technical safety concept and functional safety concept as required from ISO 26262-4:2018, Clause 7.4.8 within simulation of safety requirements in the earlier development phase of project. So it is possible to improve the safety concepts earlier and also to find out the systematic errors in the earlier phase of development. The modeling of a complete system is an extensive project and requires domain specific knowledge. Furthermore, knowledge is needed about various tools, because the architecture is described using several tools. Current approach can be replaced within developed approach based on domain-specific language with ADL [6, 7]. By this it is possible now within the extensions and improvements that all information is created within a system model that describes the complete system, safety and software architecture and offers the consistency, traceability between system and safety architecture and enables to verify the safety concepts in the earlier development phase.

Section 2 shows how EAST-ADL is modified for this purpose.

2. Description of the Approach

The developed approach in Figure 1 shows how the system, software, and safety development are combined and thus the complexity of the system is reduced by a coherent architecture.

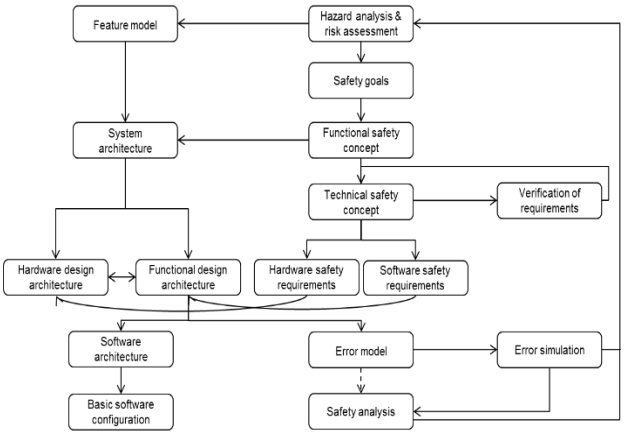

Figure 1 Model driven approach for system, safety and software development

The developed method consists of five main parts, which are shown in Figure 2:

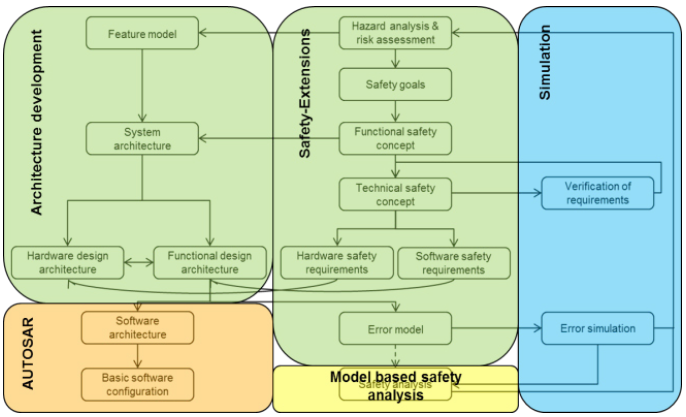

Figure 2 Main parts of the approach

First part is the architecture development [7]. This part is about the creation of feature model, system architecture, functional design architecture (FDA) and hardware design architecture (HDA). It is also possible to allocate the functions from FDA model to the corresponding hardware elements of HDA model. This part is extended within additional safety attributes in order to combine the system architecture and safety architecture and thus it is possible to realize the relationship between system architecture and safety architecture in order to prove traceability and consistency. The further details will be explained by chapter 2.1.

Second part is safety extensions [8, 9]. This part deals with the model-based creation of ISO 26262 work products as an extension to architecture development. Firstly, hazard analysis and risk assessment is performed. Secondly, the safety goals are derived from hazard analysis and risk assessment. In order to fulfill the safety goals, functional safety concept and technical safety concept are created in the following step. This part is also extended with additional safety attributes to realize a relationship between safety model, system model and requirements model. Safety model enables to realize the safety work products model based such as Hazard Analysis and Risk Assessment (HARA), functional and technical safety concept. The extensions enable now additionally to generate these safety work products automatically from the models using the developed scripts. The further details will be explained by chapter 2.2.

Feature model can contain both non-safety-critical and safety-critical properties of the system. After hazard analysis and risk assessment, the safety-critical aspects of the system will be considered as being part of the feature model.

In the system architecture, the safety goals and corresponding safety functions of the system are taken into account. In the functional and hardware design architecture, the safety-critical functions are detailed.

Third part is AUTOSAR [10]. This is about the software architecture and basic software configuration. The software architecture can be created from FDA model, which contains the necessary software features.

Fourth part is model-based safety analysis. In this step, the fault trees (FTA) of fault models are automatically generated from error model of ADL or simulation model with external tools [11] [12].

The last part is simulation and verification. This part is developed within this research. In this step, error simulation and verification of the requirements are carried out and this becomes possible already in the earlier phases of development. On the one hand, the safety requirements are verified with usage of a simulation environment. On the other hand, it is possible to determine the system impacts of causes with error simulation. Thus, the defined top events of the system from hazard analysis and risk assessment can be approved. The further details will be explained by chapter 2.4.

The developed approach allows for consistency and traceability of individual steps. The method also permits the efficient tracing from the software architecture to the feature model and from the safety analysis to the hazard analysis and risk assessment.

In the following subsections the details of the main parts will be described.

2.1. Architecture development and AUTOSAR

The architecture development can be realized with UML, SysML or EAST-ADL. For our tasks, the architecture description language EAST-ADL (Electronics Architecture and Software Technology - Architecture Description Language) is investigated.

The description language EAST-ADL represents an ADL, which was specified initially in research project EAST-EEA (Electronic Architecture and Software Technology – Embedded Electronic Architecture) and developed further to EAST-ADL2 in other research projects ATESST1 (Advancing Traffic Efficiency and Safety through Software Technology), ATESST2 [7] and MAENAD (Model-based Analysis & Engineering of Novel Architectures for Dependable Electric Vehicles) [8], SAFE (Safe Automotive Software Architecture) [9] and Synligare [21]. In addition the language was adapted to AUTOSAR [10], such that AUTOSAR can be used for the detailed description and the implementation of the software architecture. It is used to describe electronic systems in vehicles to facilitate the development of vehicle electronics [5]. Thus EAST-ADL is a domain-specific language.

The purpose of EAST-ADL is to provide the engineers facilitation for the representation and description of electronic systems in vehicles in a standardized form [5]. It can be used during different activities for the modeling of functional requirements, safety work products, as well as for analysis and design purposes [13].

The metamodel of EAST-ADL is organized in four different abstraction levels. Each of them fulfills specific roles. Each level considers a "different phase of vehicle development" [14], represents the complete system and provides different perspectives of the whole EEA [5].

The 4 levels “vehicle level, analysis level, design level and implementation level” are described in detail in the following Fig. 3:

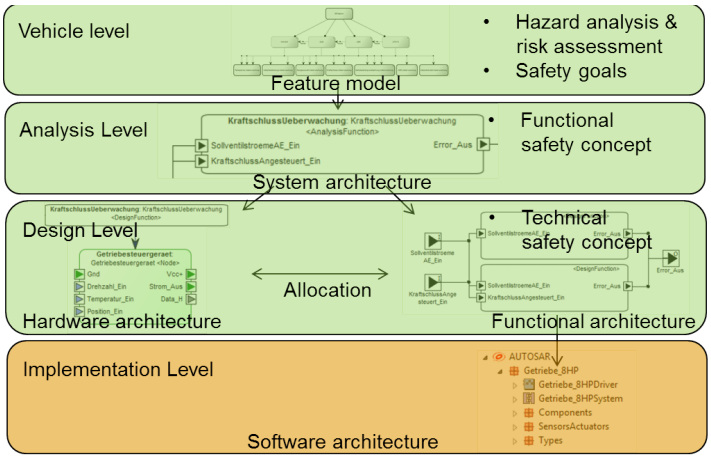

Figure 3 The EAST-ADL levels and safety activities of the approach

As mentioned before, the library elements of these abstraction levels were extended further as follow in Fig. 4. The library elements of EAST-ADL abstraction layer contain the additional information about corresponding safety goal, safety requirements and ASIL classification which enable the relationship between safety model and system model. Additionally the attribute “verified” shows whether the function is already verified in the earlier development phase. This information is very useful for safety case generation and also required from ISO 26262-4:2018, Clause 7.4.8.1.

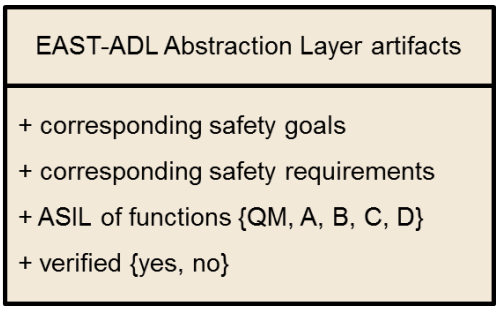

Figure 4 The extensions of EAST-ADL Abstraction layer

At vehicle level, the vehicle or system characteristic is described with a lot of features. In this step, the question 'what' must be realized with the architecture development, but not the question "how". To detect and to eliminate risks as early as possible, it makes sense to perform the hazard analysis and risk assessment in parallel on the same level [15].

The analysis level describes the realization of the features in the functional analysis architecture (FAA) in form of functions. Here we find a top-down decomposition of features on functions and on abstract sensors and actuators [16].

The design level consists of FDA and HDA. The FDA comprises the functions of the FAA, which can be further detailed and decomposed. In addition, an allocation graph is modeled, in which the function blocks of the FDA are allocated to the hardware components of the HDA [18].

The implementation level describes one-to-one the software architecture of the FDA in AUTOSAR [17].

2.2. Safety Extensions

EAST-ADL offers the dependability package with safety extensions, which enable to create the work products of safety development process such as hazard analysis and risk assessment or safety goals, as it is shown in Figure 6.

The dependability model is additionally designed to support the developer in creating safety requirements and performing safety analysis, as well as in the modeling of systematic errors and their propagation, which leads to failures.

As mentioned before, within this research the library elements of dependability model were extended further as follow in Fig 5.

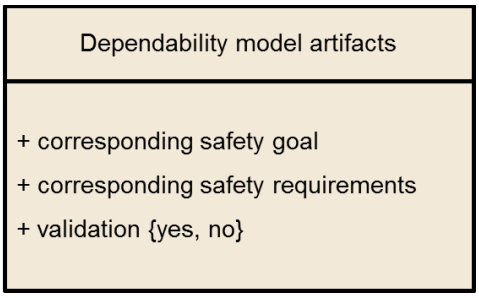

Figure 5 The extensions of EAST-ADL dependability model

The developed extensions within this research enable the generation of safety concepts using the developed automation script. They are created automatically from modified requirements model and dependability model.

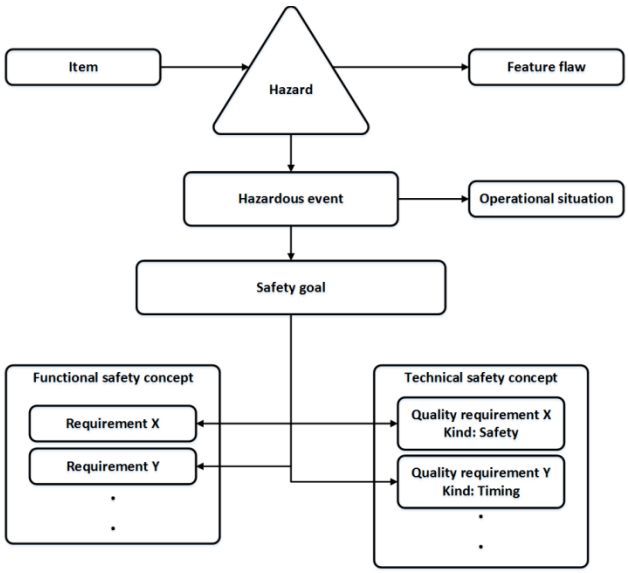

Figure 6 Dependability model

During the development of a system, requirements should be defined, which can be modeled in a separate requirement diagram as shown in Fig 5. Requirements model may include both non-safety-critical and safety-critical requirements. Therefore, it is recommended to begin with the requirements modeling on the system architecture level.

The requirements model in EAST-ADL is based on the SysML (Systems Modeling Language), adapted to the metamodel of EAST-ADL [5]. User-defined features can be added to the requirements, as it is also possible in DOORS (Dynamic Object Oriented Requirements System). Information such as status, author and responsible person are added, in order to achieve better traceability of the changes. Requirements model can be exported in the format ReqIF (Requirements Interchange Format) to facilitate exchanges with other requirements tools. As mentioned before, the requirements model is extended further as in Fig. 7 and 8 with safety related features such as ASIL classification, corresponding safety goal or decomposition relevance.

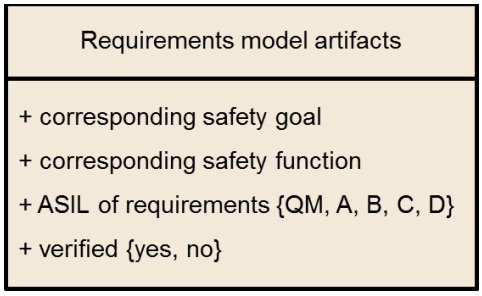

Figure 7 The extensions of EAST-ADL requirements model

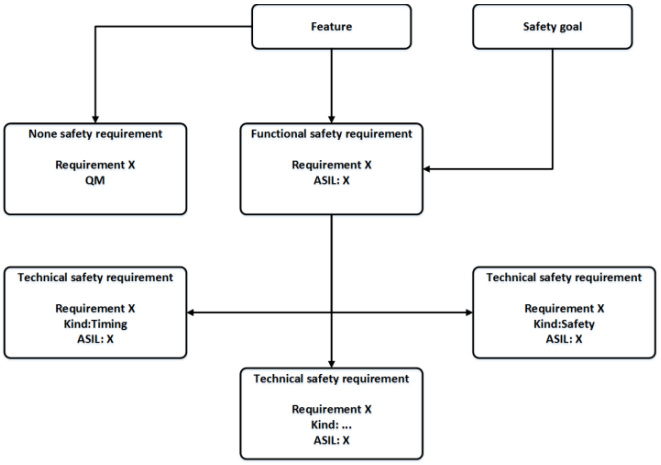

Figure 8 Requirements model

The extensions within this research enable the generation of safety concepts using the developed automating script as follow in Fig. 9.

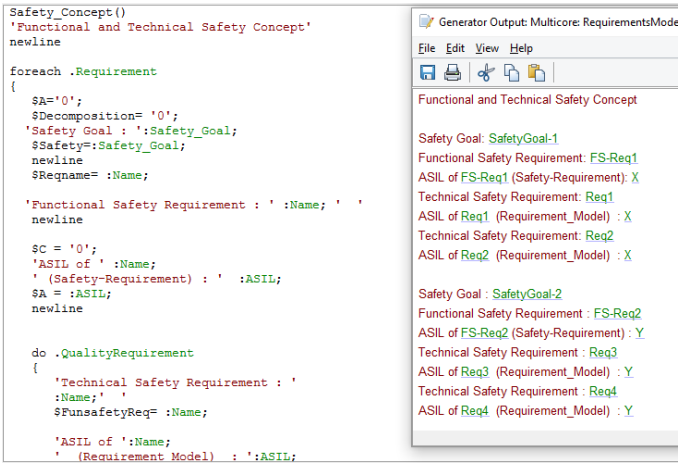

Figure 9 Safety concept script and generated document

It is possible to generate error models automatically from functional design architecture model (FDA). Error description and error logic to the individual subsystems are modeled afterwards.

Because vehicles in general and especially electrical vehicles consist of complex systems, it is very difficult to determine all measures to prevent a hazard. Of course, Original Equipment Manufacturers (OEMs) and their system suppliers are committed to reduce all risks to an acceptable level. This means that for all hazards and risks relevant safety goals, safety concept, safety requirements and safety measures have to be defined. For this reason, ISO 26262 requires to carry out the safety analysis based on fault models in the automotive industry. For example with the help of the fault tree analysis it is possible to find the error causes for a particular hazard [19].

In EAST-ADL, it is possible to model errors and their propagation in an error model to recreate a failure behavior [20]. On the basis of error models, additional tools such as HiP-HOPS [11], ALTARICA [12] can be used to perform model-based safety analysis.

Figure 6 shows how the error model and error logic can be created.

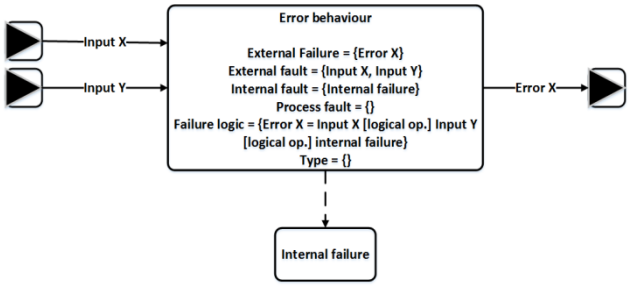

Figure 10 Error Model

2.3. Model based safety analysis

It is possible to use commercial tools such as HiP-HOPS [11] to perform the safety analysis. These tools are capable of generating fault tree analysis (FTA) and failure modes and effects analysis (FMEA) automatically from an error model [11].

Safety analysis enables to find out possible error causes which should be detected and avoided with appropriate safety measures. For this purpose, safety measures and requirements are defined in order to introduce countermeasures. Additionally, functional and technical safety requirements can be defined or extended based on the results of the safety analysis.

2.4. Simulation

For verification of the requirements and error simulation, a simulation environment such as Simulink (Matlab), Dymola, CarMaker, etc. can be used. For instance, the power train of an electric vehicle can be simulated with the help of a simulation environment and error models can be designed and implemented. The behavior of the vehicle can be simulated with error models in a way where the error causes such as failure sensor values can be used as stimulation signal. The simulation is used for the verification of the requirements, for detection of the errors in the earlier phase of development and for detection of the system impacts of errors. If it is found that the safety requirement cannot be implemented as intended, then the requirement should be redefined. This is shown in Figure 11.

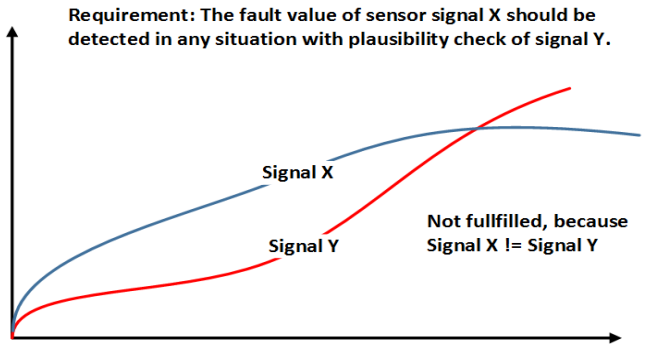

Figure 11 Verification and simulation

Fig. 12 shows the evaluation procedure of the defined hazards. The simulation is performed within the error causes in order to find out the system reaction of these failures. If the vehicle behavior is the same as defined hazards, then HARA is approved, otherwise HARA should be extended further as required from ISO 26262-4:2018, Clause 7.4.8 in order to develop the necessary safety measures to detect and prevent the possible hazards.

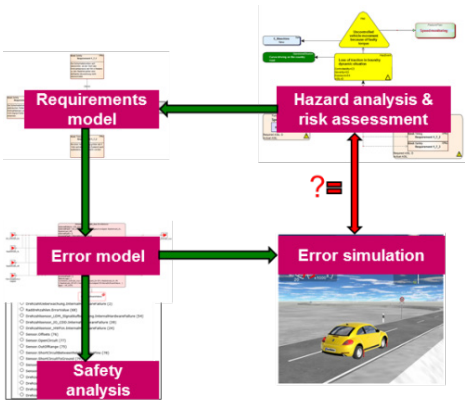

Figure 12 Error simulation

3. Use-Case

In order to show the benefits of the developed model-driven approach, an example is created which shows the safety-critical function development. It starts with hazard analysis and risk assessment and ends with verification of safety goals and safety requirements. Figure 13 shows a typical dependability model of a system. In this concrete case an electrical machine is considered as an item. Hazard is defined as “Uncontrolled vehicle movement because of faulty torque”. ASIL of hazardous event is classified based on the operational situation. In this case the hazardous event “Loss of traction in boundary dynamic situation” leads by driving a curve to a dangerous situation. Therefor the ASIL of this hazardous event is classified as ASIL D (C3, S3, E4). At the next step safety goal “No faulty torque in boundary dynamic situation” is defined with the safe state “Electric machine is torque-free, vehicle is rolling freely” in order to detect and avoid the failure. After this functional safety concept and technical safety concept are created in order to achieve the safety goal. Functional and technical safety requirements are linked from the requirements model and shouldn`t be specified again in the dependability model.

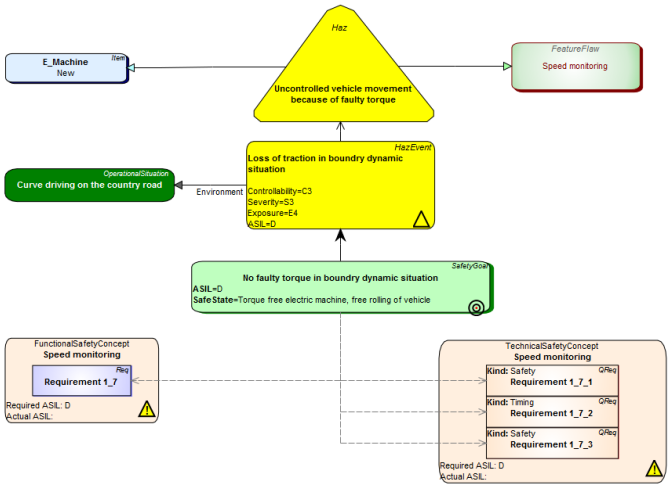

Figure 13 Dependability model – power train example

Functional and technical safety requirements are specified with associated information within the requirements model. Their allocation to architectural elements is realized just by using the satisfy connection. In this case the safety goal is realized with the function “Speed monitoring” (FAA) as shown in Figure 14.

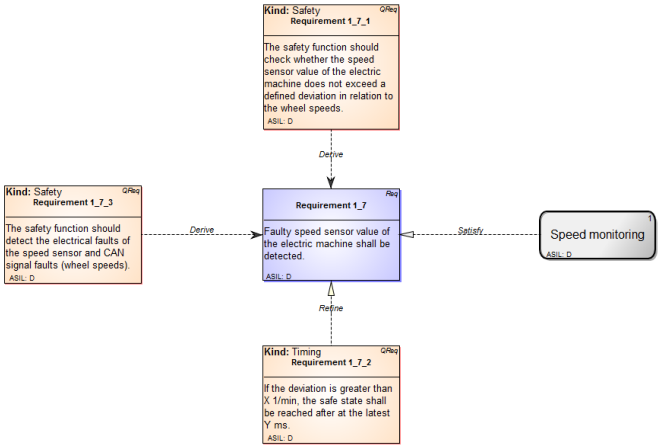

Figure 14 Requirements model – power train example

Functional and technical safety concept can be created automatically from the dependability model and requirements model using the developed script as shown in Figure 15.

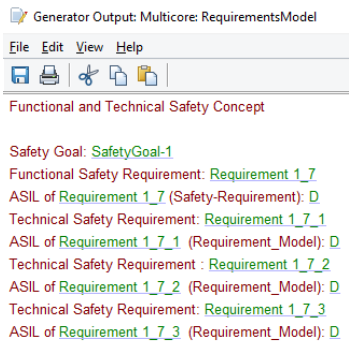

Figure 15 Functional and Technical Safety Concept – power train example

Figure 16 shows the FDA model. The safety requirements are implemented within the subfunctions of the FDA model which are extended within safety attributes to enable consistency and traceability check.

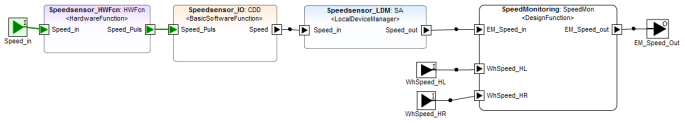

Figure 16 Functional design model – power train example

Error model of the hazard is generated automatically from FDA-Model. Afterwards the error logic of subsystems will be described individually with possible fault causes, considering the error propagation. Error logic contains all possible output failures of every submodule, with regard to internal hardware failures, internal software failures and input signal failures, as it is shown in Figure 17.

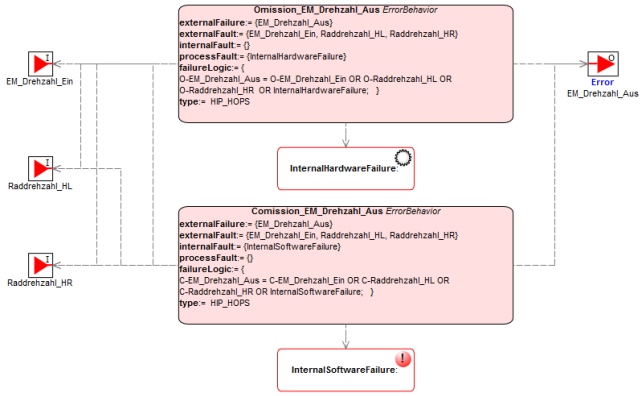

Figure 17 Error model logic – power train example

The additional tool HiP-HOPS enables to perform model based safety analysis automatically from the existing error models. This tool is capable to generate cut sets, fault tree analysis (FTA) and failure modes and effects analysis (FMEA). Figure 18 shows the generated FTA for the top event “faulty torque”. The causes such as sensor failures, internal software failures and internal hardware failures, which lead to the top event, are listed in the FTA. In this case a qualitative safety analysis is realized. The tool also enables to perform a quantitative analysis.

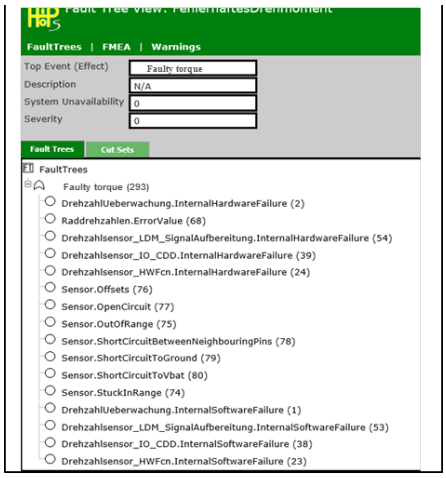

Figure 18 Model based safety analysis with HiP-HOPS – power train example

Finally, the error simulation is performed, in order to verify the system effects (top events) which were defined before within the HARA. For this reason the simulation is stimulated within the error causes (basic events) regarding fault tree analysis. The basic events should lead to the top events. After simulation the results are compared with the HARA results. If they are same, then the defined hazardous events are correct and thus verified. But if the vehicle behavior is other than defined events, the HARA should be extended. If necessary, a new safety goal should then be defined, in order to avoid new detected system impacts. In this example a concrete hazardous event (faulty torque due to E-Machine speed sensor failures) leads to loss of traction, which causes the vehicle to enter an instable state. In the boundary dynamic situations, e. g. when driving a curve, the driver cannot control the vehicle anymore. This may lead to a fatal accident. Figure 19 shows both the verification results of technical safety requirements and validation of safety goals regarding the error simulation.

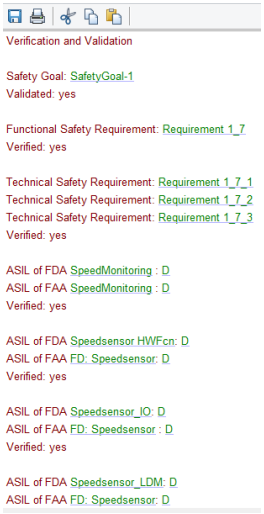

Figure 19 Verification and Validation – power train example

4. Conclusion

The presented approach supports developers in creating a model based system, software and safety architecture of E/E systems. Various tools are used currently for different special development fields. The architecture description language EAST-ADL, the main component of this approach, replaces these tools in a way that the entire development of system and safety architecture can be realized within EAST-ADL. The proposed approach has the advantage to verify the functional safety concept and technical safety concept and also to validate the hazard analysis and risk assessment within the developed simulation environment in the earlier development phase of project.

The biggest advantage of this method is to prove the traceability of the different development steps and safety work products with the help of extended library elements and developed scripts. Once the user became familiar with the method, it is easy for him to understand the overall architecture. Figure 20 highlights the relationship between the various levels and shows the traceability of different steps.

The approach enables to understand the system, software and safety architecture of an item very quickly. When applying this approach, requirement model, dependability model and library elements of EAST-ADL is extended within safety features (such as ASIL classification of requirements) in order to model the safety-critical requirements with necessary attributes and in order to create functional and technical safety concepts automatically using developed script and in order to combine system and safety architecture. The user can thus find out quickly which requirements are implemented for which functions.

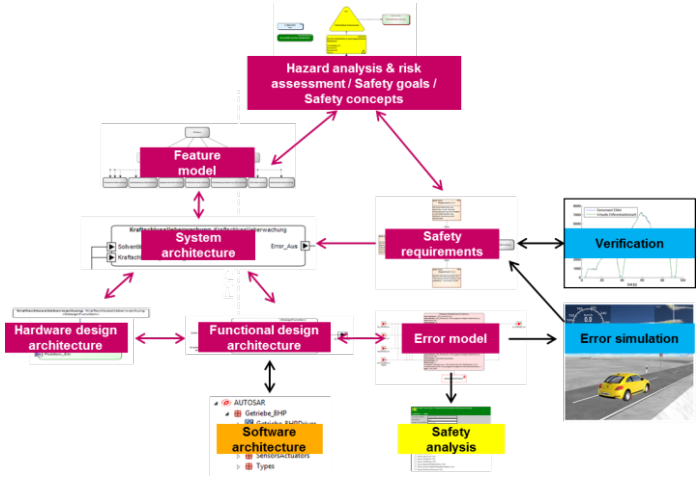

Figure 20 Traceability of the development steps

Another major advantage of the approach is the mapping of the EAST-ADL levels to the work products and requirements of ISO 26262. Already, at the initial phase the relationship between EAST-ADL and ISO 26262 is very significant. With dependability package of EAST-ADL, safety aspects of ISO 26262 can be early considered in the architecture development workflow. Thus, the hazard analysis and risk assessment is performed to find out the safety goals.

Dependability models allow the modeling of the necessary requirements for achieving the defined safety goals. Subsequently, the functional and technical safety concept can be created. So the user gets an overview, which safety concept is formulated for which safety goal. EAST-ADL offers the possibility to generate the error models automatically from FDA-models. With help of the approach and external analysis tools, safety analysis can be performed automatically from error models.

Systematic errors can be detected by the verification of the requirements and error simulation and it is also possible that safety measures are specified early in the development phase.

Finally, advantages of the presented approach can be summarized as follow:

- Modeling of safety-related functions in an architecture description language.
- Achievement of an efficient and consistent model-based development of automotive embedded system.
- Model based automated creation of ISO 26262 work products from hazard analysis and risk assessment to safety requirements using developed scripts.
- Combination of system and safety development to achieve the traceability and to show the relationship between safety goals and safety functions considering ASIL.

• Verification and validation of functional safety concept and technical safety concept in the earlier development phase of project.

• Early detection of systematic errors and system impact of errors.

This paper presents on-chip testing structures to characterize and detect faulty Through Silicon Vias (TSVs) in 3D ICs technology. 3D Gunning Transceiver Logic (GTL) I/O testing is proposed to characterize the performance of 3D TSVs in high speed applications. The GTL testing circuit will fire different data patterns at different frequencies to characterize the transient performance of TSVs. In addition, Different testing schemes based on an oscillation ring testing methodology are proposed to detect TSVs faults such as stuck-at, open, slope and delay degradation, and severe crosstalk TSVs coupling. A parallel ring-based oscillator test structure is proposed and simulated based on a high performance fully tunable electrical circuit pi-model where a single and coupled TSVs with ground-signal-ground (GSG) and ground-signal-signal-ground (GSSG) 3D vias configurations are used as a test vehicle for 3D interconnect characterization and test. Simulation results are presented using the Keysight/Agilent Advance Design System (ADS) and a standard 0.25 µm CMOS process.

1. Introduction

With deep sub-micron silicon processing technology, it becomes more difficult for integrated circuits to achieve higher integration through the scaling down of the transistor feature size. 3D ICs technology stacks multiple dies together and connects them using Through-Silicon Vias (TSVs), which become a promising technology to provide a low cost and high efficient way to increase integration for modern systems [1-2]. However, there are some problems associated with this technology. One of the most important issues is the compound yield loss due to die stacking and TSV failures, which might occur either in the fabrication of the TSV themselves, in the bonding of the TSVs to the next layer, or during the life time of the 3D stack. Thus, to guarantee the stacking yield, the interconnections (TSVs) reliability must be tested. Common TSV defects in this emerging technology can be caused by TSV shorts, opens, delay faults [3], crosstalk induced-delay faults and glitches [4-7].

To insure a low probability of 3D IC failure, integrating embedded test structures in 3D stacked ICs becomes a more attractive solution to avoid traditional probe testing, which becomes an infeasible approach to validate inaccessible nodes after stacking. The embedded test circuits can be integrated during the fabrication process to test a group of TSVs or each TSV individually for different possible defects in the die before stacking. In addition, they can be used to characterize the TSV's signal integrity effects and the impact of TSVs on the 3D circuit performance after fabrication. The results of these test circuits can then be read out off-chip for post processing. In this paper, A 3D Gunning Transceiver Logic (GTL) I/O testing is proposed to characterize signal integrity of TSVs. Additionally, an oscillation ring (OR) 3D test methodology with different circuits testing schemes, based on our work [8], are presented to detect TSVs failure induced by TSVs shorts, opens, delay faults and crosstalk coupling.

The paper is organized as follows: a high performance TSV electrical pi-model, which can be used as DUT for 3D TSV testing, is discussed in Section 2. Section 3 discusses the 3D GTL I/O testing to evaluate TSV performance. Section 4 proposes the ring-based oscillation testing schemes to detect TSVs failures and their induced 3D performance degradation. Section 5 concludes the paper.

2. An Equivalent Electrical Circuit For TSVs

To test and study the effects of TSVs on 3D circuit performance, a high frequency electrical pi-model, commonly used in literature [9-11], is applied for TSV test and characterization, which is extracted from physical configurations of a common TSV structure. Ground-signal-ground (GSG) and ground-signal-signal-ground (GSSG) vias configurations are used to test single and coupled TSVs for different 3D routing topologies. By leveraging these fully parametric TSV models, different TSV designs can be explored to study the impact of TSVs on the 3D performance. In addition, changing the model parameters gives more insight about how these parameters such as induced resistance and capacitance of TSVs affect the 3D circuit. Figure 1(a) shows a schematic drawing of the high frequency equivalent circuit model of a GSG via configuration [12].

The electrical model of the TSV is expressed as an inductor (Lvia) and a resistor (Rvia), while the capacitive coupling between the vias is modeled as coupling capacitors (Cvia_ox, Cox, and Csil). The parameter Cvia_ox denotes the capacitance of the thin oxide layer surrounding the via barrel, and Cox denotes the capacitance of the oxide layer on the silicon surface and the fringing field between the vias. The capacitance of the silicon substrate is denoted by Csil, and the loss property of the silicon substrate between the signal via and the ground via is denoted by Gsil. The model parameters (Rvia=0.22 Ω, Lvia=3 pH, Cvia_ox=1 PF, Cox=5 fF, Csil=4 fF, Gsil=2.92m/Ω) are chosen from [4] as default values for the proposed testing applications. It is worth mentioning that the Rvia and Cvia_ox seem to be the main parameters to consider in order to model the impact of TSVs on 3D circuits. Figure 1(b) shows also the pi electrical model for a GSSG structure. It is assumed that the two outer TSVs are grounded and the other two inner ones are signal TSVs.

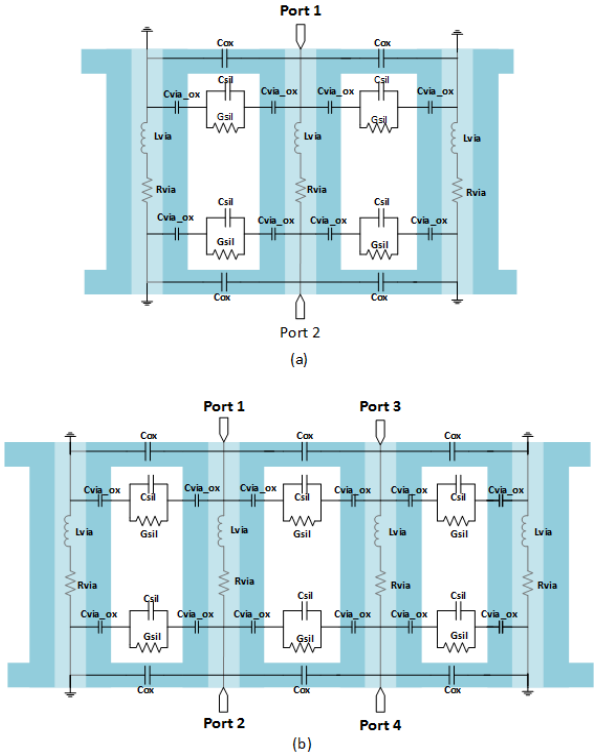

Figure 1: Equivalent Circuit Model of (a) a Standard GSG TSV and (b) a standard GSSG TSV [12]

3. 3D GTL I/O Testing

3.1. Single-Ended Gunning Transceiver Logic (GTL) I/O Design

Single-ended GTL (Gunning Transceiver logic) I/O standard is used in a wide range of applications from ASICs and processors to interface logic devices. A GTL I/O test structure [13] consists of a GTL clock and data receiver, data depths control logic, a serial-to-parallel converter, and GTL I/O drivers as shown in Figure 2. The GTL clock and data can be provided from off-chip using an external test equipment. The data depth control logic controls the depth of the fired data where the control signals come from an external stimulus system. The serial-to-parallel converter loads the serial data from off-chip and fire the parallel data out to the I/O ports. The basic cell consists of a flip-flop and a multiplixer that selects either the serial or parallel data. When the shift register goes to the parallel mode, the register starts firing the parallel data indefinitely with period specified by number of GTL cells. GTL I/O driver is basically an open drain circuit. The circuit has NMOS shunted to ground, and the other end is pulled up to the termination voltage with a 50Ω off-chip resistor.

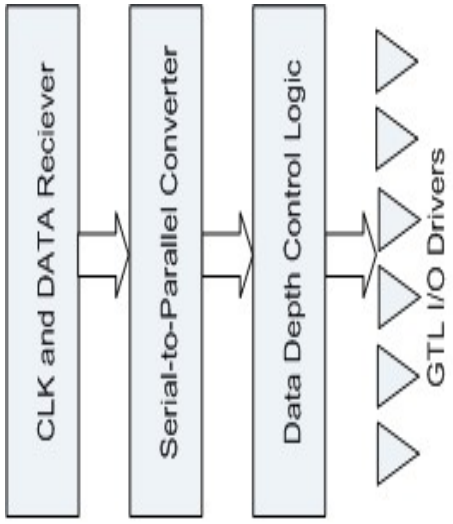

Figure 2: A GTL I/O test structure

3.2. GTL Circuit Architecture in 3D Stacked ICs

A Gunning Transceiver Logic (GTL) I/O test circuit can be utilized to characterize the performance of the 3D TSVs under high speed transient simulation in 3D stacked ICs. The 3D GTL I/O test circuit will fire different data patterns at different frequencies having different data depths across multiple tiers to characterize the impact of TSVs by observing the transient performance through different 3D routes. Figure 3 shows a block diagram of the proposed test structure, where the GTL serial-to-parallel shift registers (SIPOs) are placed in different tiers. A control MUX with Tri-state buffers and control logic can be used to switch between different I/O signals. Figure 4 shows the 3D GTL I/O circuit implementation, where each tier has a 16-bit serial IN-2-bit parallel out GTL test structure. Each I/O driver fires signals out through TSVs from its corresponding tier.

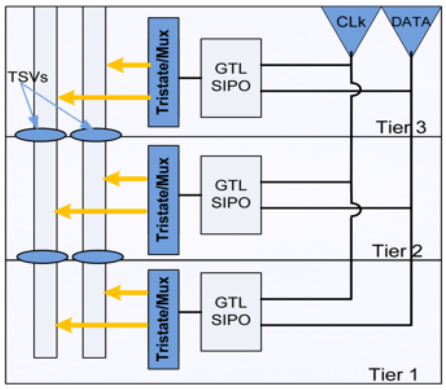

Figure 3: The GTL I/O Test Structure in 3D Stacked IC

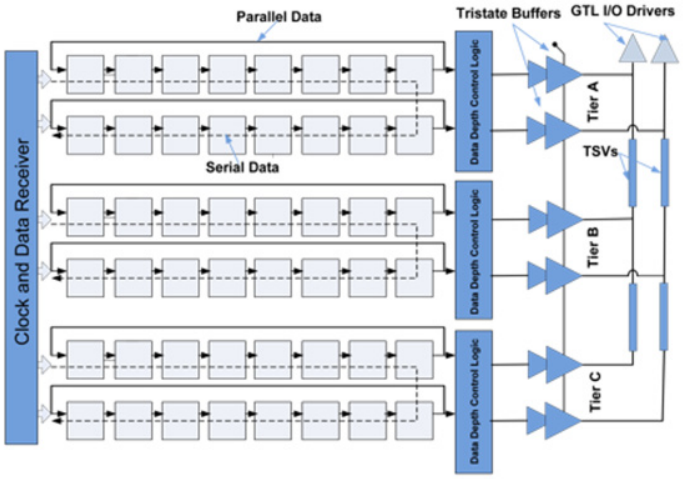

Figure 4: 3D GTL I/O Circuit Implementation

The 3D GTL I/O test structure can be also dedicated to measure the NEXT/FEXT crosstalk between vertical connections by firing high speed signals from different tiers as shown in Figure 5. FEXT and NEXT crosstalk tests can be realized by activating only the I/O signal in tier A and tier C respectively. For example; FEXT crosstalk can be observed by firing high speed signal only at the bottom layer and monitoring the coupling noise at the far-end of the victim line. Similarly, NEXT crosstalk can be observed by firing high speed signal only at the top layer and monitoring the coupling noise at the near-end of the victim line.

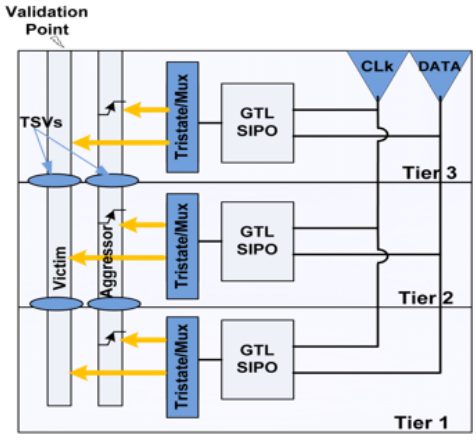

Figure 5: Measuring Crosstalk between TSVs in 3D Stacked ICs

A 2 port GTL I/O test for three tiers system was designed and simulated using the Advanced Design System (ADS) and 0.13 µm UMC CMOS process. Figure 6 shows the simulated results of the GTL test circuit at 1Gb/s data rate.

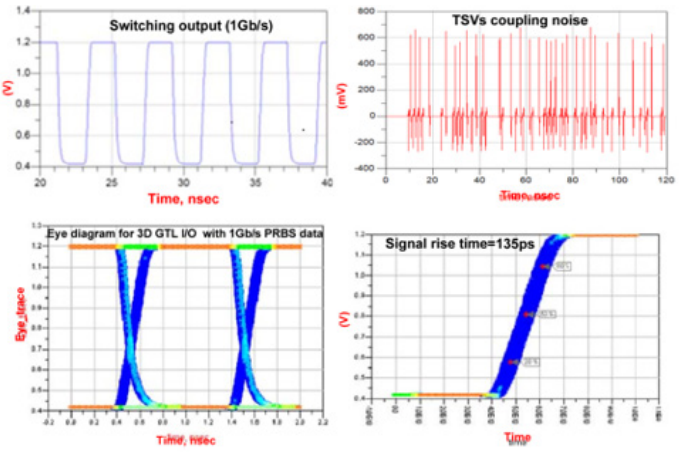

Figure 6: simulated 3D GTL Test Results at 1Gb/s data rate.

3.3. TSV Test Using the GTL I/O Shift Register as Scan Chain

A testing scheme for TSVs in 3D ICs can be realized by using the Gunning Transceiver Logic (GTL) shift register circuit. The GTL serial-to-parallel (SIPO) shift register can be designed where the TSVs are connected serially to form a scan chain structure [14]. In this case, each TSV is connected to a multiplexer and a flip-flop which can be used as scan chain as shown in Figure 7. When the GTL registers are in the data load mode, the registers start loading data serially from the top tier and shifting them down and up between tiers. After loading the data, data starts circulating up and down and vice versa. Circulating data with different patterns can test the reliability of TSVs.

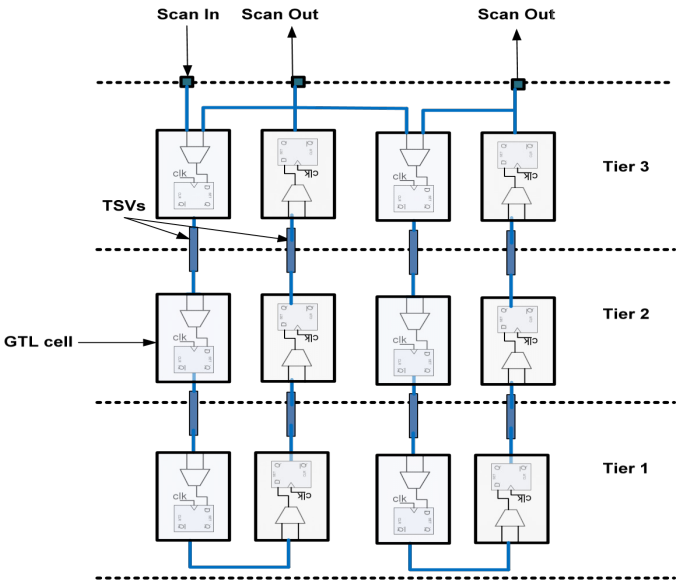

Figure 7: The GTL serial-to-parallel shifts register for 3D TSV test

The GTL scan chain test structure was simulated using ADS and 0.25 µm standard CMOS process. The TSVs connect the GTL cells serially between tiers. The TSVs are tested by injecting test vectors (i.e. data patterns) in one tier (source tier). The test vectors

are then propagated to the destination tier (e.g. the top tier), where they are captured and transmitted off-chip. Figure 8 shows a test vector with data stream ("101010.."), which is injected from the source tier and captured at the destination tier (i.e. top tier). In case of faulty TSVs, the captured data has bit errors as shown in Figure 8(b).

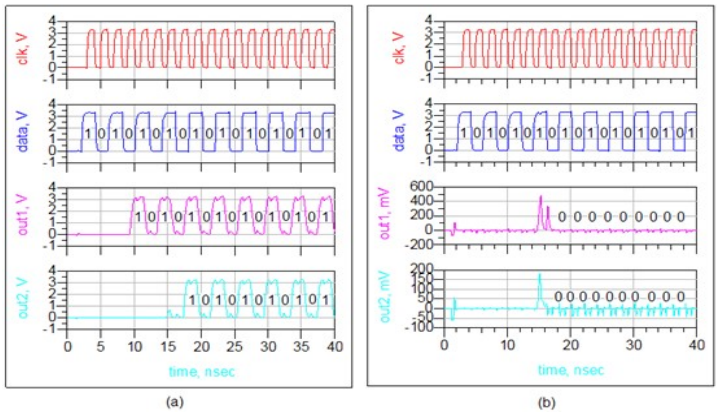

Figure 8: Outputs of the scan chain using the GTL shift register (a) with fault-free TSVs (b) with faulty TSVs.

4. Oscillation Ring-based 3D Testing Schemes

Oscillation ring (OR) test is a useful and efficient method to detect faults in functional circuits and devices [15-16]. An oscillation ring is a closed loop with an odd number of signal inversions. Intuitively, if an oscillation ring fails to oscillate, it implies that there exists stuck-at or open faults in the components of the oscillation ring. The period of the oscillation signal can also be measured to test the delay faults. For example; in a circuit with gate or path delay faults, the oscillation frequency is different from the fault–free circuit. By observing the oscillation signal at the circuit output, one can decide whether the circuit-under-test is faulty or not. To evaluate the impact of a TSV on 3D circuit performance due to the additional delay induced by a TSV, an Oscillation Ring (OR) 3D Built-in Self-Test (BIST) testing schemes, shown in Figure 9, are designed and simulated using the Advanced Design System (ADS) and 0.25 µm standard CMOS process. The target fault models of this testing architecture are TSV stuck-at, open, delay and slope degradation, and TSVs strong crosstalk coupling. If a triggered oscillator fails to oscillate, there exist stuck-at or open faults in the components of the RO. In addition, measuring the TSV delay fault can also be achieved. In this proposed testing scheme, a counter is included at the output of each triggered oscillator to detect TSVs delay faults.

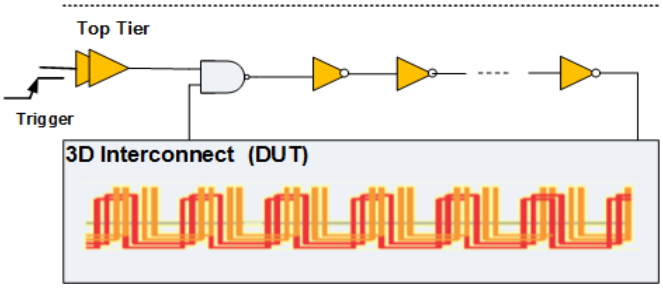

Figure 9: OR Testing Methodology for 3D Stacked ICs

4.1. TSVs Test with Different Configurations

In this testing scheme, a parallel ring oscillators (ROs) testing structure is presented, each RO has different routing TSVs configuration across different stacking tiers as shown in Figure 10. An edge detector circuitry is used to trigger ROs in parallel when the trigger enable signal (OR_TEST) is asserted and a rising edge of the reference clock is detected. This will imply that each one will have a different oscillating frequency and thus a different counting value, which can be scanned out for off-chip testing. Since the frequency of each triggered oscillator is predetermined during the design phase, a delay fault can thus be detected and measured by inspecting the contents of the counters. In this test scheme, let assume that we have m triggered oscillators for different TSV configurations and the oscillation ring test is enabled by the OR_TEST signal. Also let assume that the triggered oscillator unloaded by TSVs is allowed to count only up to n at frequency of f0 and the counter contents of the other triggered oscillators, be n1, n2, …, nm, respectively. An estimation of the ith ring's oscillation frequency fi can be approximated by:

$$f_i = f_0 * \frac{ni}{n} \quad (1)$$

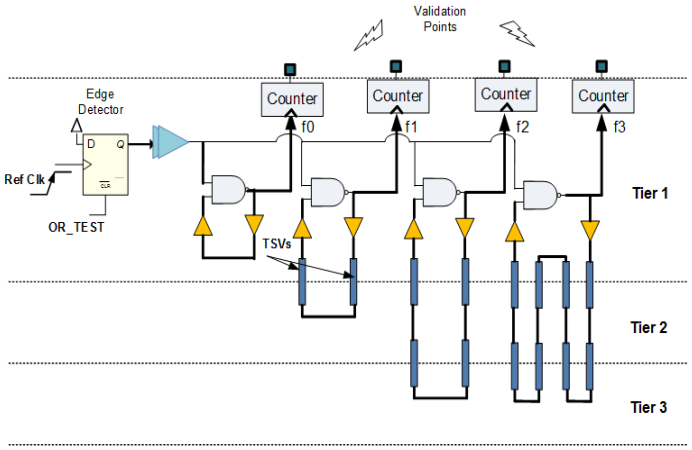

Figure 10: 3D Interconnect Test based on a Parallel triggered ROs Structure

Figure 11 shows simulation results for the triggered oscillators connected with different 3D configurations based on the pi-model which is used to electrically characterize the TSV. Each triggered oscillator has different output frequencies where the triggered oscillator with unloaded TSV has the highest frequency (1.37 GHz) compared to the ones loaded by TSVs. For example; the triggered oscillators loaded by 2 TSVs, 4 TSVs, and 8 TSVs have the following frequencies: 662 MHz, 543 MHz, and 436 MHz respectively. Each output frequency will have a different counter value. Figure 12 shows the counting values 'b111, 'b101, 'b010 for the 2 TSVs, 4 TSVs and 8 TSVs respectively. Obviously, the addition of a TSV is similar to the addition of a short interconnect, thus leading to a degradation of rise time and more induced delay in the ring oscillator and thus slower oscillating frequency.

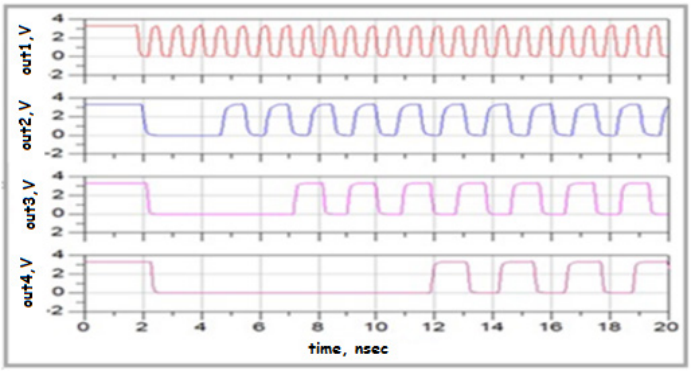

Figure 11: Output frequencies for the triggered oscillators

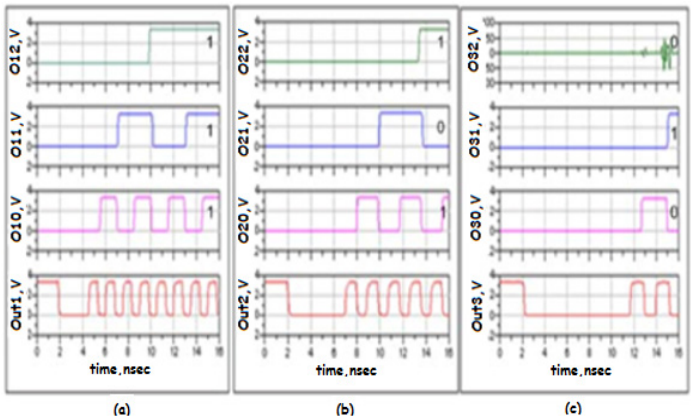

Figure 12: Output Frequencies and Counter Values for Different 3D Configuration (a) TSVs, (b) 4 TSVs, (c) 8 TSVs

4.2. TSVs Rise Time Degradation Test

To characterize the effect of the rise time degradation using the OR test, the capacitance of the thin oxide layer is changed from 10fF to 4pF, which corresponds to 45 ps, and 1.3 ns rise time respectively as shown in Figure 13. This will presents the importance of RC delay caused by the time needed to load TSV oxide capacitance. Figure 14 shows the output frequency and the counter values for triggered oscillators loaded by 2 TSVs for both cases (45 ps, 1.3 ns). The 1.15 Ghz output frequency with counter value of 'b111 corresponds to the 45ps TSV rise time, and the 833 MHz output frequency with counter value 'b010 corresponds to the 1.3 ns TSV rise time.

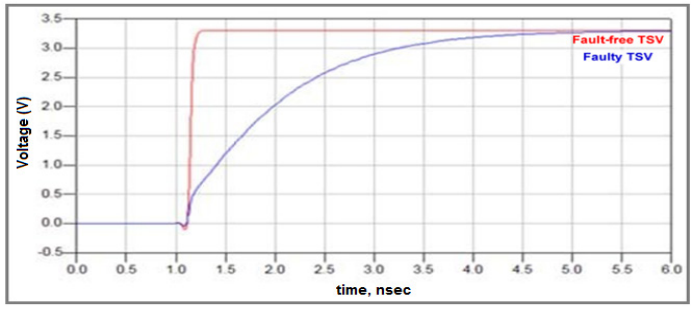

Figure 13: TSV Rise Time (red: 45ps, blue: 1.3ns)

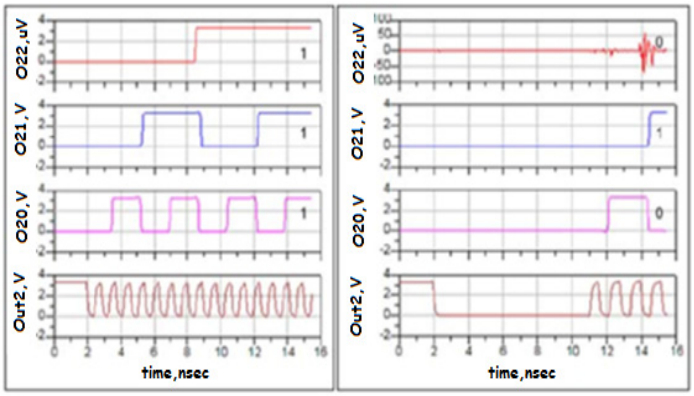

Figure 14: Output Frequencies and Counter Values for (a) 45ps TSV rise time, (b) 1.3ns TSV rise time

4.3. TSVs Crosstalk test

In this test, a consecutive triggered parallel ROs structure running same frequency is used to characterize the crosstalk effect between TSVs. Figure 15 shows four triggered oscillators; two oscillators are crosstalk-coupled and the other two are crosstalk-free. The proposed ROs parallel structure creates a delta phase shift difference between each consecutive triggered oscillators, which is equal to the time difference between the delay buffer chain and the oscillation time period of the triggered oscillators. 3D crosstalk detection can be achieved by observing the frequency of crosstalk-coupled oscillators, which is different from the frequency of the crosstalk-free oscillators.

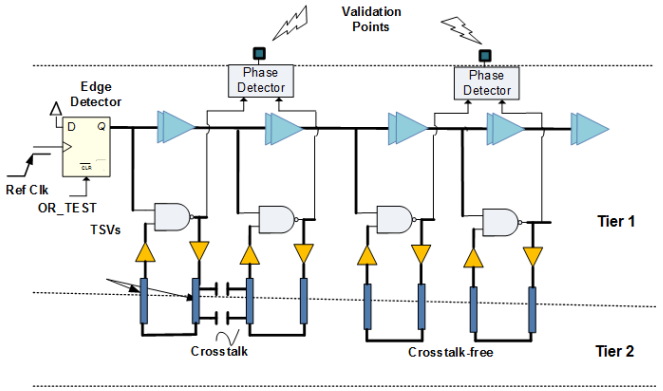

Figure 15: 3D Crosstalk Detection Scheme

Figure 16 shows the output frequency for both crosstalk-coupled (725 MHz) and crosstalk-free oscillators (667MHz).

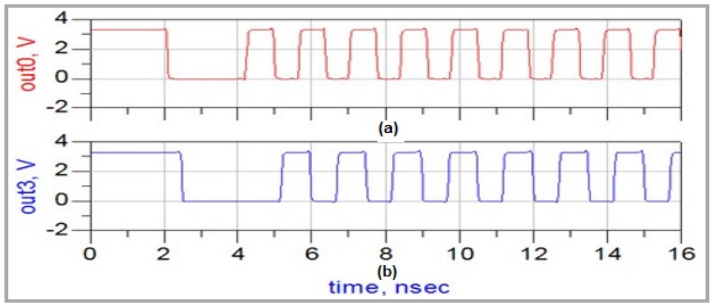

Figure 16: Output frequency for (a) Crosstalk-coupled and (b) Crosstalk-free oscillators

Interestingly, the two crosstalk-coupled triggered oscillators have less oscillation time delay (i.e. faster frequency) than the crosstalk-free oscillators, and the phase difference between the two crosstalk-coupled oscillators diminishes due to the coupling effect as shown in Figure 17. Phase detection at the output of the crosstalk-coupled triggered oscillators can be used as an indicator for strong coupling between TSVs. On the other hand, the edges of crosstalk-free oscillators are still separated by a deterministic phase shift dictated by the time difference between the delay buffer chain and the ring oscillation time period.

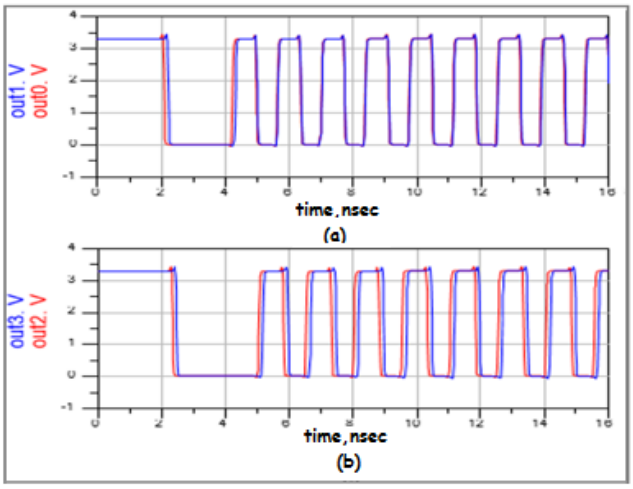

Figure 17: Simulated Results for 3D Interconnect Crosstalk (a) Crosstalk-coupled (b) Crosstalk free

5. Conclusion

In this paper, on-chip testing techniques are presented to test and characterize the signal integrity effects of TSVs after fabrication. Characterizing TSVs using an on-chip 3D testing will provide accurate information since it is closely matches real IC operating conditions, which is very important to evaluate the 3D circuit performance and validate the electrical models of these TSVs. In this paper, 3D testing techniques for TSVs are presented. A Gunning Transceiver logic (GTL) testing structure is utilized to provide a unique way of characterizing crosstalk and Inter-Symbol-Interference (ISI) effects of TSVs. This includes a proposed methodology of characterizing near-end crosstalk (NEXT) and the far-end crosstalk (FEXT) between different 3D routes. A GTL shift register can be also utilized as scan chain test to characterize the reliability of TSVs. Finally, an oscillation ring (OR) 3D testing methodology to detect and identify faulty TSVs and characterize their impact on 3D circuits performance is presented. The proposed OR testing methodology adopt a parallel ROs structure, which is dedicated to detect TSV faults such as stuck-at, open, delay faults and crosstalk coupling between TSVs. The parallel RO structure can be built in different 3D configurations connected through TSVs across different 3D stacking tiers to evaluate and characterize the reliability of TSVs. For open and short faults, the circuit outputs of this test scheme are based on pass/fail criteria. TSVs delay and rise time degradation can be detected based on the counter data for each triggered RO. In addition, the proposed testing structure provides a new way of detecting a strong noise coupling between TSVs. In this test, the outputs of the coupled ring oscillators, which is running at same frequency, will eventually lock in phase due to the coupling noise between TSVs, where a phase detection circuit can be used to indicate a strong TSVs crosstalk noise.

A B S T R A C T

This paper introduces a kind of novel backstepping phase- locked loops (PLL). The paper presents a developed theoretical model of (PLL) frequency synthesizer and provides analytical equations for calculating the desired specification such as phase margin (PM). The proposed model aims to improve the control accuracy, ensure stability and reducing the lock time. Adaptive controller algorithm has been used to design a conventional phase locked loop to operate at 2.2GHz using 0.18 µm CMOS technology. The lock time was reduced by adding nonlinear controller in addition with the low-pass filter (LPF) and the tuning variables of the adaptive control to ensure the control accuracy. The simulation results confirm that the stability of the system has been improved and increase Phase Margin (PM) from 56° to 60°. Furthermore, the simulation results indicate that the performance of adaptive PLL control has greater speed response and smaller overshoot than conventional PLL. The lock time for the conventional PLL was 2.1 µs and it is reduced to 1 µs by adding adaptive controller, showing a reduction of the lock time by 53% over the classical PLL.

1. Introduction

This paper is an extension of work originally presented in conference [1]. The phase-locked loop (PLL) considered as an important part in many applications. Phase-Locked loop (PLL) has been widely used in different applications such as electronic application, communication system etc. [2]. Moreover, it is used for data transmission and are manufactured as integrated circuit [3]. PLL considered as an electronic circuit with voltage driven oscillator that permanently adjust to correspond the frequency of an input signal. PLL has been used to generate, stabilize, filter or recover signal from noisy communication channel [4]. Most application of different system requires the oscillator to be tunable [5]. Therefore, their output frequency will be a function of a control input and frequency can be adjusted or controlled by voltage of the control signal. Stability of the system is a critical issue for many designers. Phase margin consider as one of the stability metrics for assigning system robustness. This paper includes stability analysis of the PLL to remain system unchanged over time from external condition.

2. Modeling PLL

The systematic model of the phase- locked loop (PLL) nonlinear controlled system is shown in Figure 1. Moreover, the linearized model of the PLL and nonlinear controller is illustrated in Figure 2. The PLL consists of the voltage control oscillator, phase frequency detector, charge pump, divider and traditional low-pass filter. The first functional block of the PLL is the PFD (phase frequency detector) which effects on the performance of the PLL where it compares the phase of two input signal one usually comes from VCO [5]. Figure 3 and Figure 4 show the structure of PFD. Secondly, the charge pump works as a switch current source that controlled by the phase difference between oscillator and reference [6]. Figure 5 shows the charge pump. Furthermore, the loop filter and backstepping controller are considered as a one of functional block of PLL. The second order loop filter is shown in Figure 6. The voltage gains of the VCO (voltage-controlled oscillator) is a major parameter in the PLL that effects lock time [7]. An illustration of the three stages current-starved VCO (CS-VCO) is shown in Figure 7. Frequency divider consists of TSPC technique. TSPC employs a true single-phase clock that is the only clock signal needed and never inverted, which avoids the usage of two non-overlapping two-phase clocks and thus increase the speed [8]. The divider based on TSPC is shown in Figure 8.

3. Theoretical Analysis

Backstepping design technique is a motivating topic for many researchers, it is widely used and became as one of the featuring new methods for stabilizing strict-feedback, nonlinear systems [9]. Backstepping control is a nonlinear control that used one of the state as a control input to control the other states [10]. The technique is based on generating a family of global asymptotically stabilizing control laws starting the design procedure by defining stable system and determining controller that gradually stabilize each outer subsystem. The process terminated when the external control is attained [11]. The method basically depends on applying Lyapunov functions in which guarantees the stability of the related system [12].

4. Design Proposed

In this section, we will explain the steps needed to implement the backstepping method. The open loop transfer function of PLL can be defined in Equation (1).

$$G(s) = \frac{sk_b + k_a}{s^2\left(s + \frac{\left(1+\frac{C_1}{C_2}\right)}{R_1C_1}\right)} \quad (1)$$

Where $k_a = \left(\frac{k_{vco}I_{cp}}{NR_1C_1C_2}\right)$, $k_b = \frac{k_{vco}I_{cp}}{NC_2}$,

K_{VCO} is the VCO gain and Icp is the charge pump current. Finding the state space of the system from the transfer function Equation (1).

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & \frac{-\left(1+\frac{C_1}{C_2}\right)}{R_1C_1} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} u \quad (2)$$

$$\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} k_a & k_b & 0 \\ 0 & \frac{k_a}{k_{vco}} & \frac{k_b}{k_{vco}} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \end{bmatrix} u \quad (3)$$

Rearrangement the system is the first procedure of the backstepping controller.

$$V_1 = \frac{k_1}{2}x_2^2 \quad (4)$$

The derivative of Equation (4) is taking.

$$\dot{V}_1 = k_1x_2(\dot{x_2}) \quad (5)$$

Substituting Equation (2) in Equation (5) yields.

$$\dot{V}_1 = (x_2)(k_1x_3) \quad (6)$$

Choosing the controller in Equation (10) to ensure the stability of the system.

$$k_1x_3 = -k_2x_2 \quad (7)$$

$$k_1x_3 + u = -k_2x_2 + \mathrm{u} \quad (8)$$

$$k_1x_3 + \dot{x_3} + \frac{\left(1+{}^{C_1}/_{C_2}\right)}{R_1C_1}x_3 = -k_2x_2 + \mathrm{u} \quad (9)$$

$$u = \dot{x_3} + \left(k_1 + \frac{\left(1+{}^{C_1}/_{C_2}\right)}{R_1C_1}\right)x_3 + k_2x_2 \quad (10)$$

$$\dot{V}_1 = -k_2x_2^2 < 0 \quad (11)$$

The schematic of backstepping controller is shown in Figure 9.

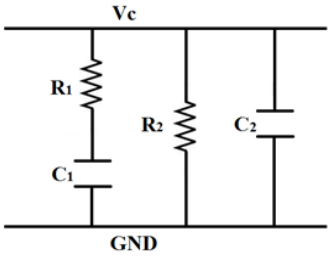

Figure 9: Backstepping Control

5. Stability Analysis

The open loop transfer function of PLL system is shown in equation (12).

$$G(s) = \frac{K_{VCO}I_{CP}}{NC_2\left(1+\frac{C_1}{C_2}\right)}\left(\frac{(s\,R_1C_1+1)(s^2(2C_2R_2R_1C_1)+s(R_1C_1+2R_2C_1)+1)}{s^2(s^2(C_2R_2R_1C_1)+s(R_1C_1+R_2C_2+R_2C_1)+1)\left(\frac{R_1C_1s}{1+\frac{C_1}{C_2}}+1\right)}\right) \quad (12)$$

The magnitude of the G(s) has been plotted with respect to frequency ω as shown in Figure 10.

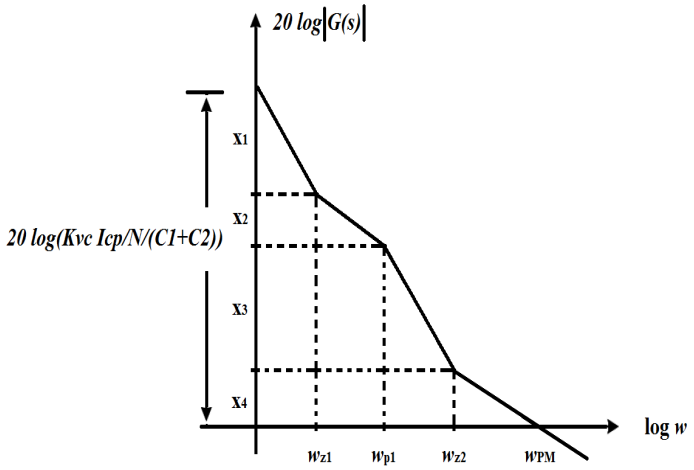

Figure 10: Bode Plot of the G(s)

The crossover frequency (ω_{PM}) has been determined [13].

$$20log\left(\frac{K_{VCO}I_{CP}}{N(C_2+C_1)}\right) = x_1 + x_2 + x_3 + x_4 \quad (13)$$

$$\frac{x_1}{log(\omega_{z1})} = 40 \quad (14)$$

$$\frac{x_2}{log(\omega_{p1})-log(\omega_{z1})} = 20 \quad (15)$$

$$\frac{x_3}{log\left(\frac{1}{R_1C_1}\right)-log(\omega_{p1})} = 40 \quad (16)$$

$$\frac{x_4}{log(\omega_{PM})-log\left(\frac{1}{R_1C_1}\right)} = 20 \quad (17)$$

$$\omega_{PM(with\ backstepping)} \approx \frac{K_{VCO}I_{CP}}{N(C_2+C_1)}\frac{\omega_{p1}}{\omega_{z3}\omega_{z1}} = \frac{\omega_{p1}}{\omega_{z1}}\omega_{PM(without\ backstepping)} \quad (18)$$

Where

$$\omega_{p1} = -\left(\frac{R_2+R_1}{2C_2R_2R_1}\right) + \sqrt{\left(\frac{R_2+R_1}{2C_2R_2R_1}\right)^2 - \left(\frac{1}{C_2R_2R_1C_1}\right)}, \quad (19)$$

$$\omega_{p2} = -\left(\frac{R_2+R_1}{2C_2R_2R_1}\right) - \sqrt{\left(\frac{R_2+R_1}{2C_2R_2R_1}\right)^2 - \left(\frac{1}{C_2R_2R_1C_1}\right)}, \quad (20)$$

$$\omega_{z1} = -\left(\frac{2R_2+R_1}{2R_1C_2R_2}\right) + \sqrt{\left(\frac{2R_2+R_1}{2R_1C_2R_2}\right)^2 - \left(\frac{2}{C_2R_2R_1C_1}\right)}, \quad (21)$$

$$\omega_{z2} = -\left(\frac{2R_2+R_1}{2R_1C_2R_2}\right) - \sqrt{\left(\frac{2R_2+R_1}{2R_1C_2R_2}\right)^2 - \left(\frac{2}{C_2R_2R_1C_1}\right)}, \quad (22)$$

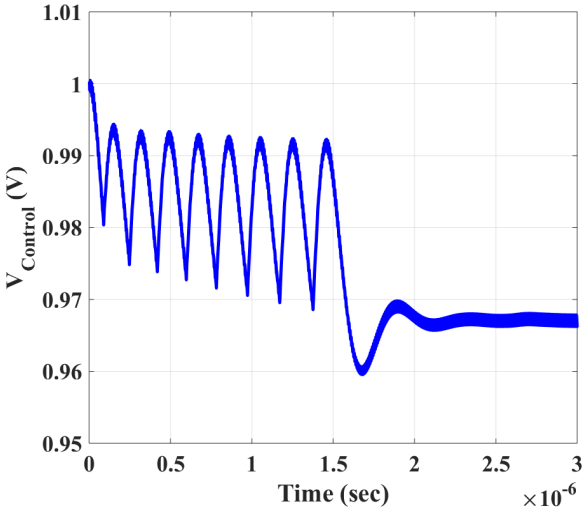
$$\omega_{z3} = -\left(\frac{1}{C_1R_1}\right), \quad (23)$$

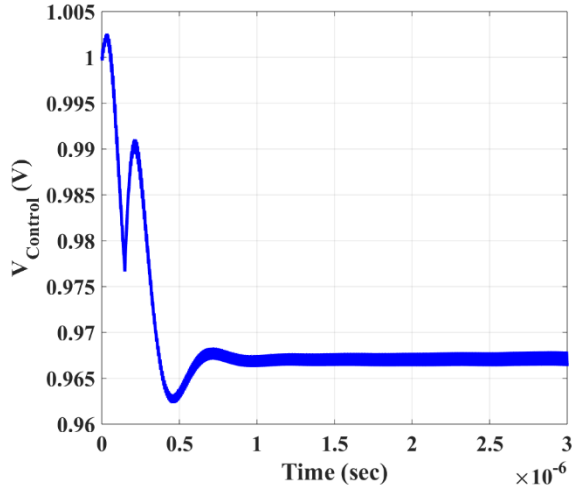
The phase margin can be calculated as shown below:

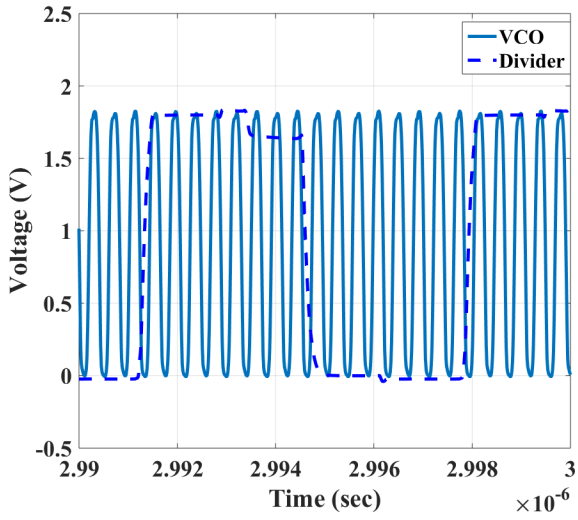
$$PM = tan^{-1}\left(\frac{\omega_{PM}}{\omega_{z1}}\right) + tan^{-1}\left(\frac{\omega_{PM}}{\omega_{z2}}\right) + tan^{-1}\left(\frac{\omega_{PM}}{\omega_{z3}}\right) - tan^{-1}\left(\frac{\omega_{PM}}{\omega_{p3}}\right) - tan^{-1}\left(\frac{\omega_{PM}}{\omega_{p2}}\right) - tan^{-1}\left(\frac{\omega_{PM}}{\omega_{p1}}\right), \quad (24)$$

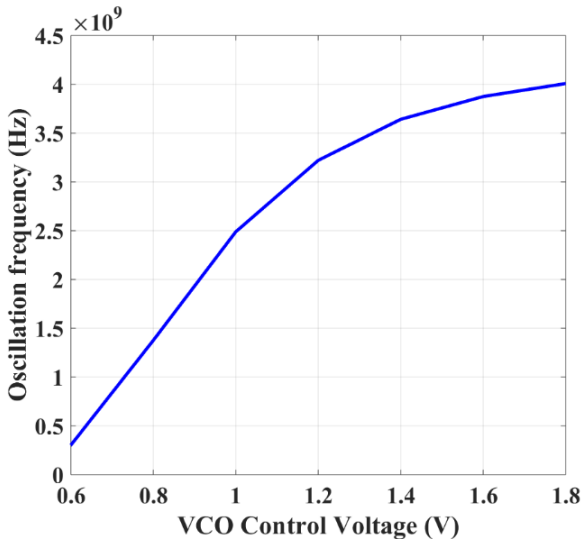
6. System Simulation

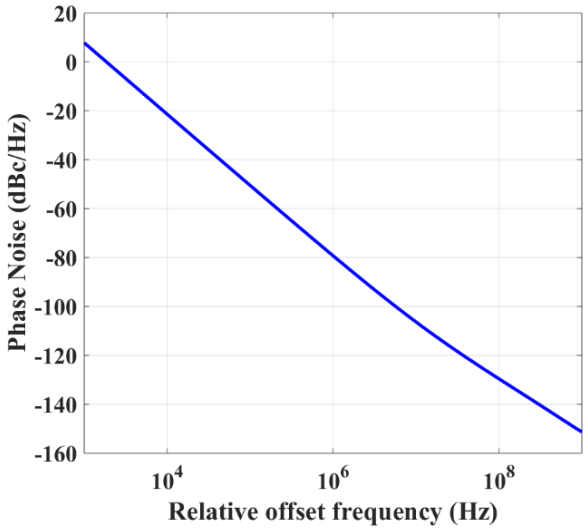
A 0.18µm CMOS technology was used to simulate the proposed design, test and verify the dynamic response of backstepping phase lock loop (PLL). The transistors size of the VCO, Divider, Gates and Charge Pump is shown in Table 1. Maximum overshoot and settling time have been considered as a performance metrics to compare the performance of conventional PLL and backstepping controller with PLL. The comparison between the actual PLL and the implementation of backstepping controller with PLL has been shown in Figure 11 and Figure 12 respectively. The results based on proposed design is showing a smaller overshoot and fast response time with lock time of 1µs where the lock time of the classical PLL was 2.1µs. The new scheme increases the speed and make the system more faster in order to settle the desired voltage where each voltage applying to the VCO represents as a frequency as shown in Figure 12. Figure13 shows Division ratio. The division ratio is 16 when the input and output frequencies are 2.3 GHz and 142 MHz. Figure 14 shows the increased of the measured tuning range of the VCO. The measured tuning range increases from 0.3 to 4 GHz, as the control voltage is increased from 0.6 to 1.8 V. Figure 15 represents that the phase noise is -79.24 dBc/Hz at 1MHz offset. The performance summary of this paper is shown in Table 2.











To insure stability, the phase margin should be at least 45 degree. Typically, the value of C2/C1 is set in the range of 1/10 to 1/6 for conventional PLL that limit phase margin and settling time. By adding backstepping the phase margin is function of R_2 and it is improved as shown Figure 16 and Figure 17. The phase margin without backstepping is 56.4˚ and with backstepping is 60.6˚.The improvement is 7.44%.

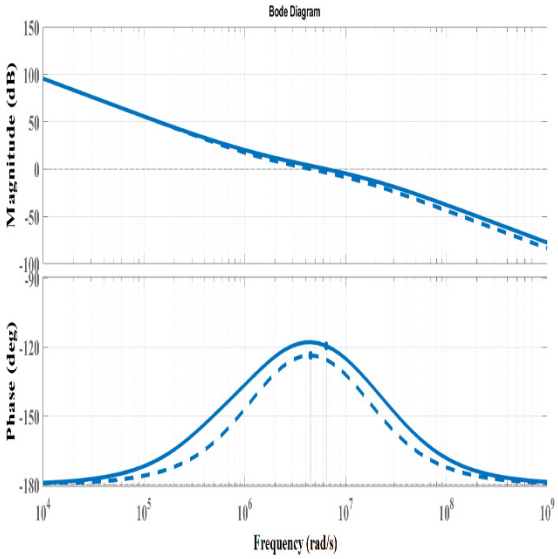


Table 1: Sizing of the Transistors

Device	Transistor	Ratio
VCO	PM1	27.778
	PM2	28.333
	NM1	11.667
	NM2	11.111
Divider	PM	16.667
	NM	11.111
Not Gate	PM	27.78
	NM	11.67
Nand Gate	PM	27.78
	NM	17.78
Nor Gate	PM	66.67
	NM	15.56
Charge Pump	PM1	17.78
	PM2	8.88
	NM2	2.22
	NM1	11.11

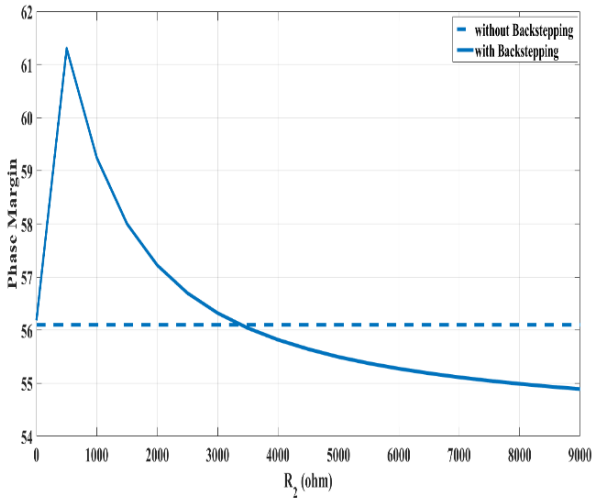

Figure 17: Phase margin as a function of R_2

Table 2: Performance Summery

Technology	CMOS 0.18µm
Voltage supply	1.8 V
Power Dissipation	11.079 mW
Phase noise	-79.24dBc/Hz @1MHz
Tuning Range	300MHz – 4GHz
Lock Time	1µs

In this paper, we present adaptive controller to PLL. The modeling, tuning and simulation of proposed design are presented in this work. In addition, stability analysis is produced by determining phase margin of open loop transfer function of PLL from Bode plot. A 0.18µm CMOS technology was used for circuit designed. In general, it is evident that the established model shows through simulations the superiority and effectiveness performance of the backstepping controlled PLL over the conventional PLL. The proposed controller proved to achieve greater speed response and smaller overshoot when it compared to conventional PLL. The results based on proposed design is showing a fast response time with lock time of 1µs where the lock time of the classical PLL was 2.1µs reducing the lock time by a 53%. Simulation results also confirm that the proposed controller works very well, in which it improved control accuracy and it stability. Furthermore, the phase margin that is considered as one of the stability metrics of system showing an increase from 56° to 60°.

ABSTRACT

Network security is often built on perimeter defense. Sophisticated attacks are able to penetrate the perimeter and access valuable resources in the network. A more complete defense strategy also contains mechanisms to detect and mitigate perimeter breaches. Deceptive systems are a promising technology to detect, deceive and counter infiltrations. In this work we provide an insight in the basic mechanisms of deception based cyber defense and discuss in detail one of the most significant drawbacks of the technology: The deployment. We also propose a solution to enable deception systems to a broad range of users. This is achieved by a dynamic deployment strategy based on machine learning to adapt to the network context. Different methods, algorithms and combinations are evaluated to eventually build a full adaptive deployment framework. The proposed framework needs a minimal amount of configuration and maintenance.

1 Introduction

Several studies suggest that cyber crime and espionage frameworks are flourishing. In the United States of America the monetary loss due to cyber crime is amounted to $1,070,000,000 in 2015 [1]. The European Union was also in the focus of organized cyber crime. 15 reported major security breaches leaked more than 41 million records of sensitive information, such as credit card information, email addresses, passwords and private home addresses [2]. In the context of highly sophisticated cyber crime such as industrial espionage, digital repression and sabotage it is common to not only trust perimeter based network security [3]. Several cyber attacks and developped attack methods such as *AirHopper* [4] proved that even physical isolation can be circumvented. This leads to a permanent and latent threat of successful infiltrations, which are undetectable by state of the art defense mechanisms such as firewalls, antivirus, rule based intrusion detection and prevention systems (IDS/IPS), network separation and user authentication. Deception systems (DS) enable in depth network defense support for the IT security concept. They mimic productive, secret or critical resources in the target system. Intruders can not distinguish between a *DS* and the actual resource. However, defenders easily detect intrusions because no connections, traffic and activities are expected on a *DS*. Any interaction with such a system can be classified as malicious. This technology therefore comes along with no false positive classifications, from which other defense in depth technologies such as anomaly detection often suffer. Typical issues for state of the art network defense are: Inside or insider attacks, encryption, high-throughput traffic, polymorphism and highly fluctuating signatures. Deception systems do not suffer any drawbacks on these issues. More than that, technology changes such as IPv6 do not impact *DS*s. However, there are other drawbacks coming along with *DS*s. A major drawback is the deployment [5]. The *DS* needs to mimic a actual system and additionally fit in the network structure [6]. State of the art for a proper configuration, deployment and maintenance is manual effort [7]. We state that a framework consisting of a scanning engine for context observation, a back-end database for proper storage of context information in combination with an engine for machine learning based on context analysis and a *DS* dependent deployment engine can solve this issue. This enables *DS*s for a broad range of applications and companies. Especially small and medium size companies will profit from manageable *DS*s, because they cannot afford cumbersome manual configuration, de-

ployment and maintenance of network security mechanisms.

This work is structured as follows: Since the idea of machine learning and deception in network defense is around 30 years old, we first identify recent trends and related work in chapter 2. Investigated machine learning methods as well as their advantages and drawbacks are introduced in chapter 3. In chapter 4 we propose our adaptive deployment framework and discuss important modules. The proposed framework is evaluated in chapter 5. Our work is concluded in chapter 6.

2 Related Work

In strategic defense and attack the idea of deception dates back to the 5th century BC [8]. It was first described from Clifford Stoll as digital strategy [9] in 1990 and first implemented from Lance Spitzer as network defense strategy [10].

2.1 Deception Systems

Modern *DS*s provide a vast variety of fake resources to deceive intruders. The most popular concept are server side systems. These systems mimic typical server protocols such as FTP, SSH or SMB. Connecting intruders trigger alarms and are under observation while they try to exploit the server. Other concepts are client side systems, which connect to potential malicious servers and observe the servers behavior. This concept is common to investigate web based attacks such as drive by downloads. A more recent concept employs tokens as trigger for alarms. Tokens impersonate documents, credentials or accounts. Stack canaries can be interpreted as token-based *DS*. Long-term and large scale studies with deception systems enable high quality insight in recent threats and their developments [11][12].

2.2 Deployment Strategies

Except for client-side *DS*s all need to be implanted in an existing and often fluctuating context. This context can be a IP-based network, a file system or any other architecture to defend. In this work we will focus on IP-based networks. There are two major groups of deployment modes: Research and production. In research mode the *DS* is directly connected with the Internet. In this mode its main purpose is the collection of threat intelligence, botnet observation and other trends. For non IT security companies this mode is not relevant. The production mode deploys *DS*s behind the perimeter. *DS*s in this mode typically have less interaction. However, in this mode any interaction is a strong indicator for perimeter breaches or internal misuse. In the production mode, six basic deployment concepts are prevalent [13][14]: Sacrificial lamb, deception ports on production systems, proximity decoys, redirection shield, minefield, zoo. In table 1 the different concepts are described.

State of the art deployment strategies do not employ automated deployment. Our adaptive framework supports all deployment concepts except for deception ports, since access to the production machines is not natively available. Furthermore, we argue that manipulation of software on production systems is not acceptable for most operators and vendors. This restricts the usage of the deception port concept in industrial scenarios and proprietary systems. We also argue that sacrificial lamb and zoo deployment suffer from lower attraction to intruders and less knowledge about the actual network security state. Both are implications of the deployment in a different subnetwork. Minefield deployment is a good choice to detect intrusions in an early state, but if an intruder circumvents the minefield there are no more defense in depth mechanisms. We focus on proximity decoys, since we think it is the most promising deployment concept for defense in depth strategies. Please note that redirection shield is a special case of all other concepts, where the *DS*s hardware is not located in the internal network, but the malicious traffic is tunneled out to an external environment.

2.3 Artificial Intelligence for Deception based Network Security

Artificial intelligence enables context-awareness. In network security this is crucial, since modern networks are heterogeneous and entities within the network can often change. To adapt *DS*s in these scenario several researches have been conducted. These researches can be classified in two major domains: Interaction and Deployment. Context-aware interaction focuses on decision making for *DS*s [15][16][17]. The adaptive deployment domain is in an early stage compared to the first usage of *DS*s. However, this domain decreases the probability for being fingerprinted by adapting to other entities in the network and also increases the intrusion detection probability by optimizing the ratio between *DS*s and production systems within a network. Conducted works are learning mechanisms of new unknown services and protocols [18], context-awareness for *DS*s [19] and automated configuration [20]. An overview of conducted research is given by Zakaria [21][22].

3 Unsupervised Machine Learning

The data acquired from our framework is not labeled. Even the number of clusters is unknown. To determine the optimal *DS*s deployment, we employ unsupervised machine learning methods to identify clusters and derive deployment prototypes. In this chapter we introduce and investigate several methods we identified as promising. These methods are later employed in our framework.

Table 1: Deployment concepts for *DS*s in internal networks

Concept	Description
Sacrificial lamb	Single deployment isolated from any production systems
Deception ports on production systems	Deployment on the production system
Proximity decoys	Deployment near the production systems
Redirection shield	Redirection of certain traffic outside the internal network
Minefield	Deployment of a vast amount of *DS*s near the perimeter
Zoo	Deployment of a vast and versatile amount of *DS*s isolated from any production system

3.1 Methods and Algorithms

We investigated three different clustering algorithms. All three are assigned to a different class of cluster algorithms. First is the centroid based k-medoids method [23]. In difference to the well known k-means algorithm, k-medoids always sets an entity from within a cluster as centroid. This centroid is called medoid. As given in (1), we define the Jaccard-Tanimoto metric [24] as distance measurement:

$$d(x,y) = \frac{\left|x \cup y\right| - \left|x \cap y\right|}{\left|x \cup y\right|} \tag{1}$$

where x and y are either a feature set of an observation or a feature set of an aggregation of observations. We employ this distance measurement as reference for all further investigations in this paper. There are, however, several distance measurements that are also feasible such as the Manhattan, Euclidean, Simpson, Dice and Mahalanobis distance [25]. The definition of the k-medoids method is given in (2):

$$\arg\max_{S} \sum_{i=1}^{k} |S_i| \, Var S_i \tag{2}$$

where k is the number of clusters and $S = S_1, S_2, ..., S_k$ the sets of all observations.

Our evaluation is based on the partition around medoids (PAM) [23] implementation. *PAM* is a heuristic method, employed to circumvent the *NP*-hardness of k-medoids.

Second is the connectivity based single linkage clustering [26]. We also chose the Jaccard-Tanimoto distance as distance measurement to ensure comparability. The single linkage method is an agglomerative hierarchical clustering method. All observations are considered as cluster and then merged into an agglomeration of clusters based on the distance between the clusters. The distance is calculated by a linkage function, which is given in (3) for the single linkage method

$$D(S_i, S_j) = \min_{u \in S_i, v \in S_j} d(u,v) \tag{3}$$

where D is the linkage function, S_i and S_j are subsets of S, u is a observation in cluster S_i and v a observation in cluster S_j. In our experiments we found that more complex linkage functions such as WPGMA, UPGMA and WPGMC do not significantly improve the results of our application. We used the SLINK implementation [27] to decrease the time complexity from $O(n^2 log(n))$ to $O(n^2)$.

Finally, we evaluated the density based spatial clustering of applications with noise (DBSCAN) method [28]. *DBSCAN* defines a distance measurement $d(x,y)$ and a minimal number of observations $minPts$ that need to be in a certain distance ϵ of a given observation x to consider the observation x as part of the cluster. If a observation x is within the distance ϵ of less than $minPts$ observations, it is considered as cluster edge and is part of the cluster. The Jaccard-Tanimoto metric is employed as $d(x,y)$.

All three methods imply different advantages and disadvantages. A comparison is given in table 2.

It can be seen that the optimal algorithm depends on the application. Determining a suitable method requires an understanding of the data set. In our application it is not possible to assume a certain distribution of systems within a network. The diversity of clusters and the occurrence of outliers depend on the network architecture.

3.2 Convergence Criteria

The introduced algorithms require a proper parametrization to ensure reasonable results. Even methods that need no predetermination of k need parameters to calculate k.

We employed three methods to estimate the convergence criteria: The Elbow method, the GAP method and the Silhouette coefficient. An increasing number of clusters decrease the mean squared error (MSE). The *MSE* is defined as follows:

$$\sum_{i=1}^{k} \sum_{u \in S_i} \left\| u - \mu_i \right\|^2 \tag{4}$$

where k is the number of clusters, u an observation in cluster S_i and μ_i the mean value of S_i. The elbow method [29] investigates, if further incrementation of the number of clusters do significantly decrease the *MSE*. If the decrease is not significant, the optimal number of clusters is found. The GAP method [30] is based on the elbow method, but instead of $\frac{\Delta MSE}{\Delta k}$, the maximal difference between the *MSE* of the elbow function and the *MSE* of randomly distributed observations indicates the optimal number of clusters. A widely employed method to determine the number of clusters in machine learning applications is the silhouette coefficient [31]. The definition is given in (5).

Table 2: Comparison of different clustering algorithms

Feature	k-medoids	Single linkage	DBSCAN
Class	Centroid	Connection	Density
Predetermined k	Yes	No	No
Outliers	-	+	+
Efficiency	PAM: $O(k(n-k)2)$	SLINK: $O(n^2)$	$O(nlog(n))$
Divers clusters	-	0	+
Deterministic	No	Yes	No

$$s_j = \begin{cases} 0 & \text{for } dist(S_i,u) = 0 \\ \frac{dist(S_v,u)-dist(S_i,u)}{\max\{dist(S_i,u),dist(S_v,u)\}} & \text{else} \end{cases} \quad (5)$$

The distance measure for the silhouette method based on (1). For the distance between an observation and a cluster, the mean value of the cluster is employed as defined in (6) and (7).

$$dist(S_i,u) = \frac{1}{|S_i|}\sum_{x\in S_i} d(x,u) \quad (6)$$

$$dist(S_j,u) = \min_{S_y\neq S_i} \frac{1}{|S_x|}\sum_{y\in S_y} d(y,u) \quad (7)$$

The distance between S_j and u is the difference as defined in (1) to the nearest cluster $S_y \in S$. For an evaluation we will employ the three introduced convergence criteria.

4 Adaptive Deployment Framework

We developed an adaptive deployment framework consisting of a data acquisition engine (DAE), a clustering engine (CE) and a deployment engine (DE). A specific data format was also developed. In this chapter we describe our framework and the single components. The adaptive deployment consists of four consecutive processes: Context perception, context evaluation, configuration and deployment. In the first step the *DAE* collects context information such as other hosts. The acquired data is then stored in our data format. Based on this data, the *CE* statistically analyzes the stored data and determines k prototypes P. These prototypes P are *DS*s that are $\min d(P,S_i)$. The configuration process depends on the *DE*. In general, however, the required configuration file is generated in this process. Finally, the *DE* deploys the *DS*s based on the configuration file. The overall process of adaptive deployment is restartable at any time. This enables a fast adaption to changing architectures and contexts. The process is shown in Figure 1.

4.1 Data Acquisition Engine

The *DAE* captures the context and stores it in a defined data format. In our implementation we define the other hosts in the same subnetwork as context. To capture as much information as possible about the context, the *DAE* combines passive information gathering by *p0f* [32] and active information gathering by *nmap* [33] and *xprobe* [34]. For each host in the subnetwork the information sources decide by vote for an operating system. The services available from a host are determined by *nmap*.

4.2 Data Format

The data format we developed is based on the Extensible Markup Language (XML). First an unique identifier (ID) is generated for each host. These *ID*s are associated with features. There are three major sections: meta data, services and operating system. The first section contains available meta data such as up time, MAC address, IP address and a time stamp. In the second section open TCP and UDP ports are listed. We map port numbers directly to services. This is efficient and produces sufficiently reliable results. In the third section we store information about the TCP stack based fingerprint. This information is extracted from the *nmap* and *xprobe* scan.

4.3 Clustering Engine

In the *CE* the prototypes for the deployment are generated. These prototypes need to contain all information that is needed for a sufficient deployment. In our implementation we employ the same data format for context information and prototypes. The *CE* determines k clusters containing S_i hosts. The TCP stack and the available services for each P are equal to the medoid in S_i. However, meta information is generated on distributions within S_i. For example the MAC address: The first three octetes are extracted from the most prevalent vendor within S_i and the other three are chosen randomly. For the IP address we developed an algorithm to reduce impact on the distribution in subnetworks. First a random IP within the cluster is chosen then the upwards next unoccupied IP address is assigned to the prototype. By the use of this algorithm the distribution within the cluster remains the same, since a specific probability distribution is preserved if only uniformly distributed observations are added on the existing observations. Please note that IP addresses are only assigned to one host at the same time and therefore the distribution is not perfectly preserved. Uptimes for prototypes are determined based on the mean uptime within a cluster.

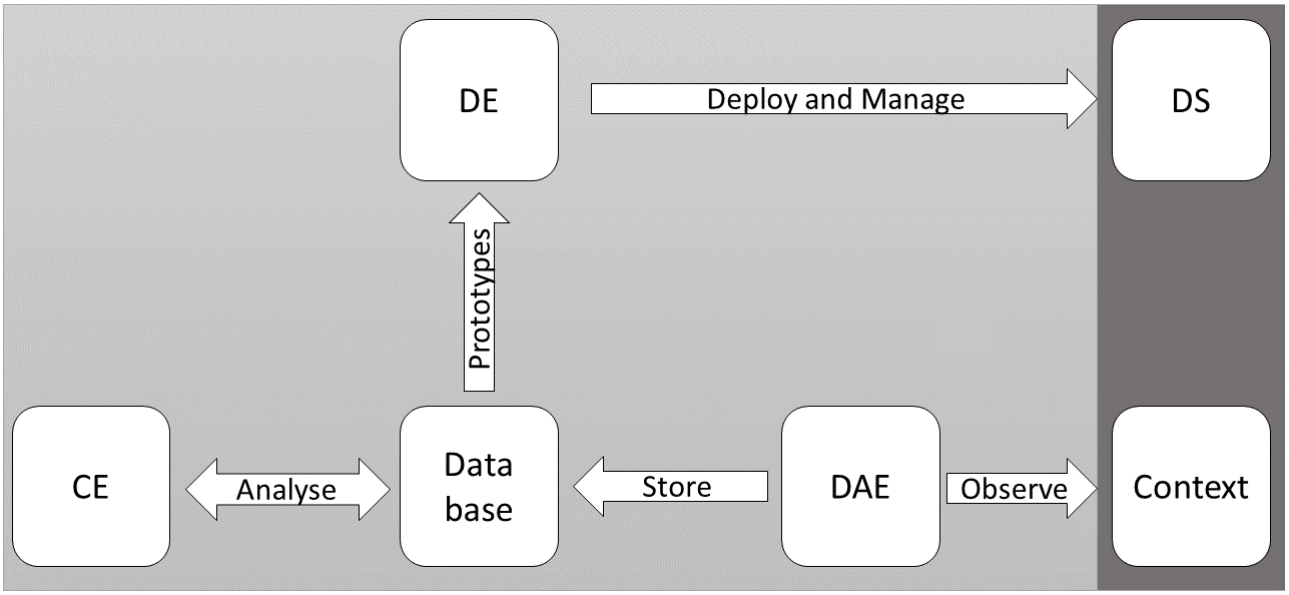

Figure 1: Overall process of the adaptive deployment framework

4.4 Deployment Engine

In a last step the actual deployment is executed. This step is most crucial to all previous steps. The required information for a proper configuration needs to be calculated or assumed. In our implementation we employ *honeyd* [35] as *DE*. *honeyd* is able to emulate a vast amount of hosts with TCP stack and offers the ability to open TCP and UDP ports as well as the execution of scripts to emulate services on the open ports. If it is needed *honeyd* is also able to emulate large network architectures including network elements such as routers, switches and tunnels [36].

5 Evaluation

In the evaluation chapter two different settings are investigated. First, an artificial scenario is evaluated. This scenario consists of several virtual machines (VMs) in an isolated network. The second scenario is an actual production network in which we deploy *DS*s by our framework.

5.1 Artificial Data Sets

As shown in table 3 eight different *VM*s are prepared for the simulation of a production network: Windows 10, Windows 7, Ubuntu 17.04, Ubuntu 12.04, Debian 8.8.0, Fedora 25, openSUSE 42.2 and Android 4.3. Two scenarios are defined in this evaluation. The first scenario mimics a network with equally distributed cluster sizes. In the second scenario the cluster sizes are different. We chose these diverse settings to not favor a specific algorithm. The deployment is realized with Virtualbox.

5.2 Real World Scenario

For scenario 3 we scanned a class C development network. The network consists of: 7 Windows 10 machines, 4 Ubuntu machines, 2 TP Link switches, 2 Cisco switches, 11 Raspberry Pis, 1 Android system and 4 other Unix systems. Unlike in the artificial scenarios the configurations of the systems are different.

5.3 Results

First we evaluated the determination of the number of clusters. In Figure 2 the comparison of combinations of different methods in scenario 1 is shown.

As it can be seen for the elbow method and the silhouette coefficient all three algorithms perform similarly. However, for GAP there are differences. We found that *DBSCAN* is not suitable when using GAP. Please note, that the determined number of clusters is six in this scenario for all algorithms. This is because Ubuntu 12.04 and Ubuntu 17.04 as well as Windows 7 and Windows 10 have closely resembling TCP-Stack implementations and similar open ports in the default configuration, reducing the number of clusters from eight to six. In Figure 3 we compare the same algorithms for scenario 2.

For *DBSCAN* the elbow method does not give a feasible result. The GAP method results only for *SLINK* in suitable results. *PAM* as well as *DBSCAN* result in a number of clusters of four. The silhouette coefficient only results in suitable values for the *PAM*. Figure 4 compares the results for the development network.

DBSCAN is not feasible with any convergence criteria in this scenario. This fits in our overall evaluation. However, it is recommend to estimate ϵ not on the number of cluster, but on the k-distance graph for *DBSCAN*. By doing so the results are probably better. *PAM* and *SLINK* both result in reliable values for the

elbow method and the silhouette coefficient. The overall performance evaluation is given in Table 4.

Comparing the algorithms the best results are achieved for the *SLINK* implementation. For the convergence criteria the elbow method appears to provide the best results. However, the elbow method requires an additional criterion for the detection of the *elbow*. Formally a criterion detecting significant changes for $\frac{\Delta MSE}{\Delta k}$ is required. These criteria tend to be unreliable [37]. For the silhouette coefficient it is also difficult to detect a reliable number of clusters. This is because the local maximum before a monotonic increase determines the optimal number of clusters and this maximum can be ambiguous, as shown in Figure 2.

Besides the optimal number of clusters the clustering results are of importance for the adaptive deployment. In scenario 1 eight clusters are existing, all with the same size. In Table 5 the clustering results are evaluated. As similarity measurement we employ the Jaccard index.

In scenario 1 *PAM* performed best. This is as expected since a particular strength of centroid based clustering algorithms are equally sized clusters. However, in networks an equal distribution of hard- and software cannot be assumed. To evaluate also heterogeneous environments, scenario 2 features an unequal distribution of systems.

It can be seen, that *SLINK* and *DBSCAN* outperform *PAM* clearly. This result was expected since connection and density based algorithms are better suited for unequal sized clusters. The obtained results in our experiment suggest, that *SLINK* in combination with the elbow method or *GAP* produce the best results. However, since we did not compare *SLINK* with other connection based clustering algorithms, it is possible that other algorithms outperform the single linkage algorithm. The proposed method of an adaption of the *DS* to the context by observing and scanning the network and determining prevalent systems to mimic is possible by an employment of the investigated methods.

6 Conclusion and Discussion

In this work the authors proposed an adaptive framework for the deployment of deception systems for cyber defense. The proposed framework is implemented for an evaluation. Different algorithms and convergence criteria are evaluated in different aspects such as computational time, determination of the number of clusters and the cluster accuracy. The focus of the implementation are server-side deception systems. However, the framework can easily be extended to feature also token based deception systems. We found that *SLINK* provides the best results. Even though the lowest error was achieved for the elbow convergence criteria, we recommend to consider *GAP* in this application because of its robustness and the simple determination of the global maximum. The adaptive deployment framework enables deception based security mechanisms for a broad range of users and a significant decrease in configuration, deployment and maintenance effort of such systems. It provides an enhanced security concept in a simple to use solution.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

Epilepsy is a neurological disorder which is most widespread in human beings after stroke. Approximately 70% of epilepsy cases can be cured if diagnosed and medicated properly. Electro-encephalogram (EEG) signals are recording of brain electrical activity that provides insight information and understanding of the mechanisms inside the brain. Since epileptic seizures occur erratically, it is essential to develop a model for automatically detecting seizure from EEG recordings. In this paper a scheme was presented to detect the epileptic seizure implementing discrete wavelet transform (DWT) on EEG signal. DWT decomposes the signal into approximation and detail coefficients, the ApEn values the coefficients were computed using pattern length (m= 2 and 3) as an input feature for the Least square support vector machine (LS-SVM). The classification is done using LS-SVM and the results were compared using RBF and linear kernels. The proposed model has used the EEG data consisting of 5 classes and compared with using the approximate and detailed coefficients combined and individually. The classification accuracy of the LS-SVM using the RBF and Linear kernel with ApEn using different cases is compared and it is found that the best accuracy percentage is 100% with RBF kernel.

1. Introduction

Epilepsy in humans is an intrinsic brain pathology and its major manifestation is epileptic seizures. Epileptic seizures may affect partial part of the brain (partial) or the whole cerebral mass (generalized), seizures are recurrent with interictal period ranging from several minutes to several days. Brain's electrical activity is measured through the electroencephalogram (EEG) signal which is an effective tool for studying functioning of brain and diagnosing epilepsy [1]. EEG signals are a non-invasive testing method that provides valuable details of distinct physiological states of the brain. The data recorded usually are of long duration and inspected by experts to analyze the huge data recorded in the form of EEG signal to detect epilepsy.

The advanced signal processing has enabled to process and store the EEG signal digitally. The processed EEG data is then feed as an input for the automatic detection system to detect the traces of epilepsy. The automatic system reduces the workload of neurologists by reducing the amount of effort and time required to detect the traces of epilepsy in the recorded EEG signal. Automatic prediction and detection of epilepsy from the EEG signal are developed using different signal processing techniques like frequency domain analysis, wavelet analysis, spike detection, and non-linear methods. Gotman [2] has presented an automatic detection system for epilepsy by decomposing the EEG signal into elementary waves. Srinivasan et al., [3] has used time domain and frequency domain analysis to detect epilepsy the author has selected five features out of which two features were from frequency-domain and three features were from time-domain. The author has used the recurrent neural network for detecting epilepsy and the neural net-

https://dx.doi.org/10.25046/aj0203162

work was trained and tested for the epileptic EEG signal with an accuracy of 99.6%, Keshri et al., [4] has used the slope of the lines between each pair of two consecutive data points (x1, y1) and (x2, y2) and feed it into Deterministic Finite Automata and got the accuracy level as high as 95.68%. Geva et al., [5] has used wavelet analysis as both time and frequency domain view can be provided with the use of WT.

Various methods are available to detect and predict the epileptic seizure. Artificial Neural Network (ANN) has been widely used for detecting the epileptic spike [1, 6, 7, 8, 9]. Features extraction is an important aspect in the performance of ANN models as the model is trained in and tested on these extracted features. ApEn was proposed by Pincus [10] as a statistical parameter to measure the regularity of time series data. ApEn is being predominantly used in the electrocardiogram and other related heart rate data analysis [11, 12, 13] as well as in the analysis of endocrine hormone [14]. It is the measure of regularity as smaller value of ApEn depicts a high regularity and higher value of ApEn depicts low regularity in time series data [15]. Diambra et al., [16] has denoted that parameter ApEn gives the valuable temporal localization of a variety of epileptic activity. Elman, PNN and SVM network for detection of epilepsy through ApEn based feature with 100% overall accuracy. Hence, it is an acceptable feature for automated detection of epilepsy.

The Support Vector Machine (SVM) is a classier method that performs classification tasks by constructing hyperplanes in a multidimensional space which try to find a combination of samples to build a plane maximizing the margin between two classes. SVM is widely used in epileptic detection and prediction [17] has used permutation entropy as a parameter, as it drops during the seizure interval. The Burg Burg AR coefficients has been used as an input for SVM that shows accuracy of 99.56% [18].

In this paper an automated detection of the epileptic seizure was discussed using LS-SVM comparing two kernel functions RBF and linear. In this work EEG signal were decomposed into six sub-bands namely D1-D5 and A5 using DWT. The analysis of complexity in the sub-bands are done by ApEn which acts as an input feature for SVM. Experiments are done using different cases having a different combination of EEG data sets.

2. Proposed Method

In this paper there are four main tasks in sections 2.1) Clinical data 2.2) Preprocessing EEG data through DWT to decompose into several sub-bands in section 2.3) Feature extraction (ApEn) in section 2.4) Classification of EEG data using feature (ApEn). Figure 1 shows the proposed approach used in this paper.

2.1. Clinical data

The data set used in this paper is available in public domain and is accessed online from the University of Bonn, Germany which consists of five different data set of EEG data [19]. The data used is artifact free EEG time series data and is widespreadly used by the ongoing research on epilepsy [1, 3, 7, 15, 17, 20]. The complete data set contains five sets marked as (A-E) each set has 100 single channel EEG segment having duration of 23.6-sec. Each segments of data are selected and cut out after visual inspection for artifacts from continuous mechanical EEG recordings with the sampling frequency of 173.61 Hz with the band pass settings of 0.53-40 Hz. The data contains three different classes normal, epileptic background (pre-ictal), and epileptic seizure (ictal). The normal EEG data (A and B) was collected from five healthy volunteers. The pre-ictal EEG data (C and D) was recorded during the period when there were no traces of seizure from five epileptic patients. The ictal EEG data (E) was recorded during the epileptic seizure from the same five patients. EEG signals were recorded from 128- channel amplifier using an average common reference and digitized at 173.61 Hz sampling rate and 12-bit A/D resolution. Figure 2 and Figure 3 shows the specimen of an epileptic and normal signal.

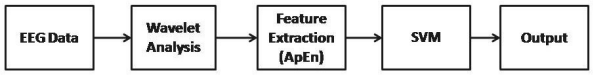

Figure 1. *Proposed Approach*

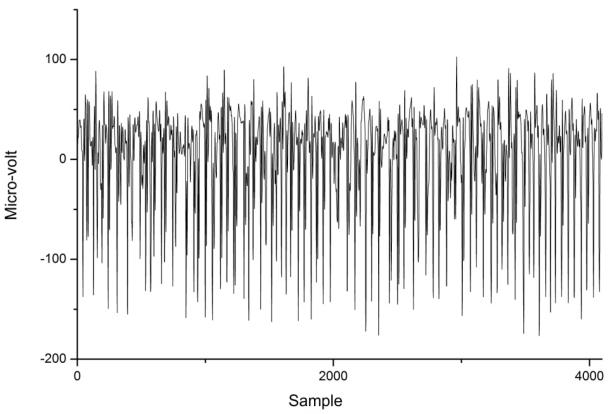

Figure 2. *Epileptic Signal*

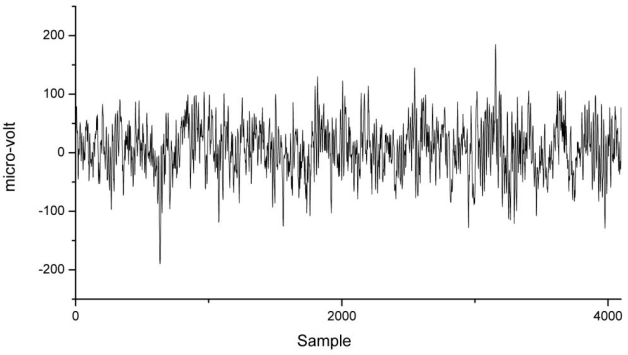

Figure 3. *Normal Signal*

2.2. Discrete Wavelet Transform

Wavelet transform (WT) uses variable window size, has well-known data compression and time-frequency filtering capabilities. It provides a good local representation of the signal in time as well as in the frequency domain which makes it as an effective tool for analyzing the signal and extracting features. The wavelet transform looks for the spatial distribution of singularities whereas fourier transform provides a description of the overall regularity of signals [5]. WT captures transient features and localizes them in time as well as frequency content and is widely used in epileptic seizure detection [21, 22]. WT uses long time windows for obtaining finer low-frequency resolution as well as the short time windows for obtaining high-frequency information. Thus, WT provides specific frequency information at low frequencies and specific time information at high frequencies [23].

Discrete wavelet transform (DWT) x(t), is defined as,

$$DWT(j,k) = \frac{1}{\sqrt{|2^j|}} \int_{-\infty}^{\infty} x(t)\psi\left(\frac{t-2^j k}{2^j}\right) dt \qquad (1)$$

Where ψ, a and b are wavelet function called as scaling and shifting parameters. The quadrature mirror filters are used to realize the scheme by passing the passing the signal through a series of low-pass (LP) and high-pass (HP) filter [24] The out put from the low pass filter is termed as . Approximation (A) and output from the high pass filter id termed as detail (D) coefficients. The figure illustrates the fifth level wavelet decomposition of a signal showing the coefficients A1, D1, A2, D2, A3, D3, A4, D4, A5, and D5 .

In this model fifth-level wavelet decomposition was performed on normal subjects data (A, B, C and D) as well as on epileptic patient data (E) using Daubechies order 4 wavelet (db4). The researchers have found that db4 wavelet is most appropriate for the analysis of epileptic EEG data [25]. The structure for the wavelet decomposition at each level with its approximation and detail coefficients are shown in Figure 4.

2.3. Approximate entropy (ApEn)

Approximate entropy is a statistical feature for quantifying regularity and complexity in a time-series data [10]. ApEn is a non-negative number and has been successfully applied in the field of pattern recognition. ApEn have potential application throughout medicine and prominently in ECG and EEG [14].The following steps determine the value of ApEn [1, 8, 26, 27, 28].

1. The data set contains N data points let it be A=[a(1), a(2), . . . , a(N-m+1)].
2. Let a(i) be a subsequence of A such that a(i) =[a(i), a(i+1), a(i+2), . . . , a(i+m-1)] for $1 \leq i \leq N-m+1$, m is the number of samples used
3. Denote the distance between A(i) and A(j) by d[A(i), A(j)]=

$$\max_{k=0,\ldots,m-1} (|\, a(i+1) - a(j+1)\,|) \qquad (2)$$

4. For a given A(i), number of j is counted as ($j = 1,\ldots,N-m+1, j \neq i$) such that $d[A(i),A(j)] \leq r$ denoted as $M^m(i)$ for $i = N-m+1$

$$C_r^m(i) = \frac{M^m(i)}{(N-m+1)}, \qquad (3)$$

for $i = 1,\ldots,N-m+1$

5. For each $C_r^m(i)$ compute natural logarithm, and average it over i

$$\Phi^m(r) = \frac{1}{N-m+1} \sum_{i=1}^{N-m+1} \ln C_r^m(i) \qquad (4)$$

6. . Repeat step (1) to step (4) by increasing the dimension m to m+1 and find $C_r^{m+1}(i)$ and $\Phi^{m+1}(r)$
7. Finally ApEn is computed as

$$ApEn(m,r,N) = \Phi^m(r) - \Phi^{m+1}(r) \qquad (5)$$

To compute the ApEn value of the signal of length N two parameters length of the compared run m tolerance window r are specified. We have taken the value of m=2 and 3 and r is in between 0.1 to 0.25 times the standard deviation of data. In this model the ApEn values of the approximate (A1-A5) and detailed coefficients (D1-D5) are computed using the length of the compared run (m), tolerance window (r) were set to m= (2,3) and r= (0.2)*standard deviation of the data to compute ApEn.

2.4. Support vector machine (SVM)

Support vector machine (SVM) has been used in several EEG signal classification problems [17, 20] and was first introduced in 1995. SVMs belong to the family of kernel-based classifiers and are extremely powerful classifiers. Linear as well as non-linear classification can be performed in SVM using different kernel functions [29]. The approach of SVMs is to implicitly map the classification data into higher dimension input space where a hyperplane separating the classes may exist. The implicit mapping is achieved through different Kernel functions. In the case of linear SVM to classify linearly separable data, the training data, $\{a_i, b_i\}$ for $i = 1,,m$ and $y_i \in \{-1,1\}$ then the following decision function is determined by [18]:

$$D(x) = w^t g(x) + y \qquad (6)$$

g(x)is a mapping function that maps x into l-dimensional space, y is a scalar and w is the l-dimensional vector. The decision function satisfies the following condition to separate the data linearly:

$$b_i\left(w^t g(a_i) + y\right) \geq 1 \quad for \quad i = 1,,M \qquad (7)$$

There are infinite number of decision functions that satisfy Eq.(8) for a linearly separable feature space. The largest between the two classes are selected between the two classes. The margin given by $D|x|/\|w\|$. Let the margin is ρ then the following condition are required to be satisfied:

$$\frac{b_i D(a_i)}{\|w\|} \geq \rho \quad for \quad i = 1,,M \tag{8}$$

The product of ρ and $\|w\|$is fixed

$$\rho\|w\| = 1 \tag{9}$$

In order to obtain the maximum margin for the optimal separating hyperplane, $\bar{w}$ with the minimum $\|w\|$ that satisfying Eq. (9) should be found from Eq. (10), This provides optimization problem as follows. Minimizing

$$\frac{1}{2}w^t w \tag{10}$$

subject to the constraints: $b_i\left(w^t g(a_i)+y\right) \geq 1 \quad for \quad i = 1,,M$ When training data are not linearly separable a slack variables is introduced $\xi_{\mathbf{i}}$ into Eq. (8)

$$b_i\left(w^t g(a_i)+y\right) \geq 1-\xi_i, \quad \xi_i \geq 0 \quad for \quad i = 1,,M \tag{11}$$

To maximize the margin and minimize the training error the optimal separating hyperplane is determined and is achieved by minimizing,

$$\frac{1}{2}w^t w + \frac{C}{2}\sum_{i=1}^{n}\xi_i^p \tag{12}$$

subject to the constraints:$b_i\left(w^t g(a_i)+b\right) \geq 1 - \xi_i, \quad \xi_i \geq 0 \quad for \quad i = 1,,M$

The tradeoff between the maximum margin and minimum classification error is determined by the parameter C.

2.5. Least squares support vector machines (LS-SVMs)

The LS-SVM are trained by minimizing

$$\frac{1}{2}w^t w + \frac{C}{2}\sum_{i=1}^{n}\xi_i^2 \tag{13}$$

subject to the equality constraints:

$$b_i\left(w^t g(a_i)+y\right) = 1-\xi_i, \quad \xi_i \geq 0 \quad for \quad i = 1,,M \tag{14}$$

The conventional SVM uses inequality constraints where as in the LS-SVM equality constraints are used. The equality constraint has reduced the complexity to obtain the optimal solution by solving a set of linear equations rather than solving a quadratic programming problem. To derive the dual problem of Eqs. (14) and (15) Lagrange multipliers are used

$$Q(w,y,\alpha,\xi) = \frac{1}{2}w^t w + \frac{C}{2}\sum_{i=1}^{n}\xi_i^2 - \sum_{i=1}^{M}\alpha_i\left\{y_i\left(w^t g(a_i)+y\right)-1+\xi_i\right\} \tag{15}$$

where $\alpha = (\alpha_i,...,\alpha_M)^t$ is Lagrange multipliers and by differentiating the above equation with respect to w, ξ_i, b, and α_i and equating the resulting equations to zero the the conditions for optimality are determined [30].

2.5.1. Kernel Function

Classically SVMs were designed to classify the data in linear space, in the nonlinear space SVMs do not preformed well to overcome this limitation on SVMs, kernel approaches were developed. The following kernels are most commonly used [31].

1. Linear Kernels: $k(a,a') = (a^t a')$;
2. Polynomial kernels: $k(a,a') = ((a^t a')+1)^y$ where d is a positive intege r
3. RBF kernels: $k\left(a,a'\right) = \exp\left(-\gamma\left\|a-a'\right\|\right)$

To train a SVM classifier, the user has to determine a suitable kernel function, optimum hyper parameters, and proper regularization parameter. in this paper we have used two kernels 1) Linear Kernel and 2) RBF kernel. The goal to achieve optimum hyper parameter and regularization parameter is accomplished by cross-validation technique. The cross-validation technique can be used to select parameters.

2.6. Cross-Validation

Cross-validation is a validation technique used to determine the quality of the classification model. It partitions a sample data into different subsets such that the analysis is initially implemented on a single subset. The remaining subset(s) are kept for validating the result of initial analysis. The data subset used for initial test is called as training set while the other subsets are called as testing or validation sets [32]. In K-Fold cross validation data is partitioned into k roughly equal size sets and each set is used once as a test set while other remaining sets are used as training sets. For each k=1,2,...N, fit the model parameter for other retained K-1 parts. The cross-validation procedure is repeated for K number of times using each of the K set exactly once as validation data. The average of the K result obtained from the folds produces a single estimation. In this paper, we have used 10-fold scheme to achieve best performance efficiency.

2.7. Performance evaluation parameters

The performance of LS-SVM is estimated by using the parametres, namely, sensitivity (SE), specificity (SP) and overall accuracy (OA) defined as:

$$SE(\%) = \frac{TN_{CP}}{TN_{AP}} * 100 \tag{16}$$

Where TN_{CP} denotes the count of correctly detected positive patterns and TN_{AN} denotes the count of actual positive pattern. The positive pattern represents a detected seizure.

$$SP(\%) = \frac{TN_{CN}}{TN_{AN}} * 100 \tag{17}$$

Where TN_{CN} denotes the count of correctly detected negative pattern and TN_{AN} denotes the actual count of negative pattern. The negative pattern represents a detected non-seizure.

$$OA(\%) = \frac{TN_{CDP}}{TN_{APP}} * 100 \quad (18)$$

Where TN_{CDP} denotes the count of correctly detected pattern and TN_{APP} denotes the count of applied patterns [1].

3. Design of Experiment

The data is processed and the ApEn values of the detailed and approximate coefficients are computed. The design of experiment is done to make different cases of the processed data-set and then compare the results of different cases the cases are as follows

- Case 1: Data set A versus Data set E
- Case 2: Data set B versus Data set E
- Case 3: Data set C versus Data set E
- Case 4: Data set D versus Data set E
- Case 5: Data set A, C and D versus Data set E
- Case 6: Data set A, B, C and D versus Data set E

These cases are then modeled combining all the coefficients A5 and D1-D5 in one set as an input to LS-SVM and using different coefficients individually as an input to LS-SVM. The results were analyzed using all different cases and combinations and compared to find the model providing the best efficiency.

4. Result and Discussion

The EEG data set is decomposed into different sub bands by applying DWT using db4 wavelet having 5 level of decomposition shown in Figure 4. The frequency ranges of these sub-bands are: A1(043.4 Hz), A2 (021.7Hz), A3 (010.85Hz), A4 (05.43 Hz), A5 (02.70Hz), D1 (43.486.8 Hz), D2 (21.743.4 Hz), D3 (10.8521.7Hz), D4(5.4310.85Hz) and D5 (2.705.43 Hz. ApEn values have been computed from the approximation and detail coefficients of each sub-bands of entire 500 EEG epochs of five data sets A-E. Figure 5 and 6 shows the decomposition of EEG signal epoch of data set A and E.

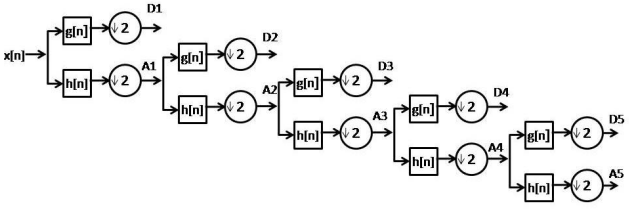

Figure 4. *Decomposition of EEG signal using fifth level decomposition*

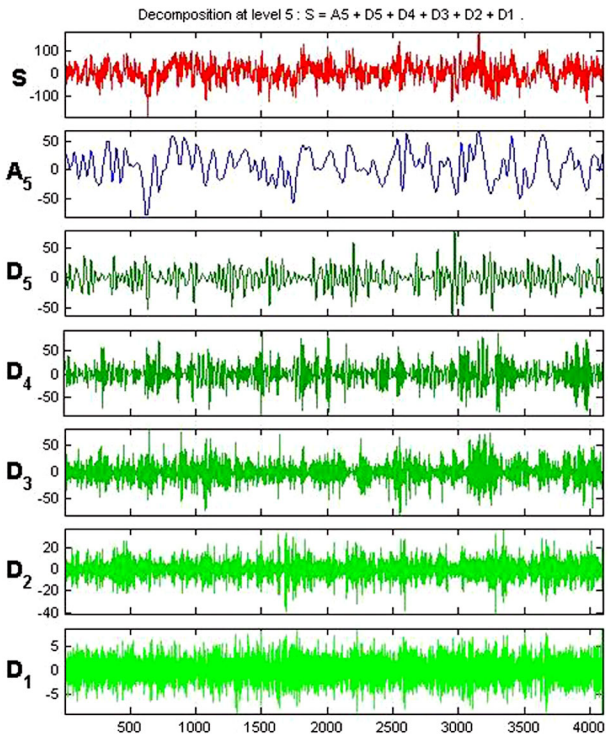

Figure 5. *Wavelet decomposition of Epileptic signal (Data Set E)*

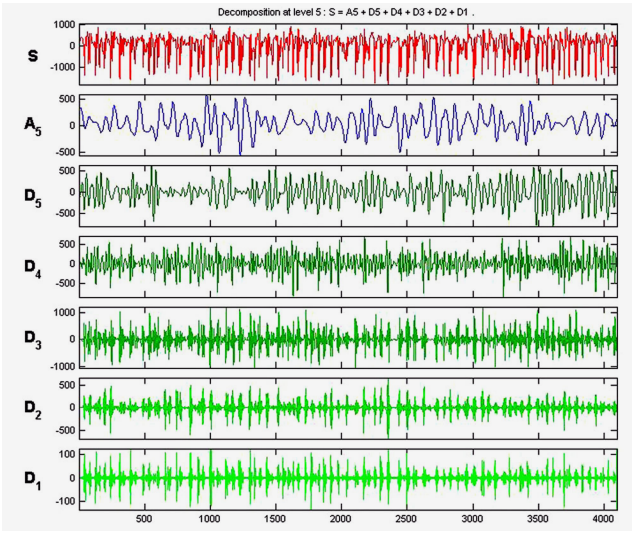

Figure 6. *Wavelet decomposition of Normal Signal (Data Set A)*

The ApEn values of the approximate and detailed coefficients are computed from the entire data set A-E consisting 100 epochs having parameters m=(2,3) and r=0.2*standard deviation of data set. ApEn value of the detailed coefficient D1 from data set A, B which were recorded from the surface of the scalp of the normal subject while they are in a relaxed and an awake state with (Data Set A) eyes open and (Data set B) eyes closed vs E are recorded from the epileptic subjects through intracranial electrodes and having embedded

dimension m=2 is shown in Figure7. The ApEn values for data set A and B are higher than that of data set E which means that the data set E is more ordered and periodic than set A and B. Similarly Figure8 shows the Apen values of detailed coefficient D1 from data set C and D v/s data set E recorded from intracranial electrodes having embedded dimension m=2. The ApEn values of data set C and D are also higher than that of data set E which that data set A,B,C,D are more complex than data set E. Figure 7 and Figure 8 shows that the complexity of the data set A recorded from normal subject and data set C which is recorded from opposite to the epileptogenic zone are almost similar. ApEn values for embedded dimension m=3 are shown in Figure 9 and Figure 10 depicting similar attributes. The calculated value of ApEn got reduced in this case than that of having embedded dimension m=2 the curves and variation of data also got reduced. Data set D and E are overlapping in both the case as the data set is acquired within the epileptogenic zone.

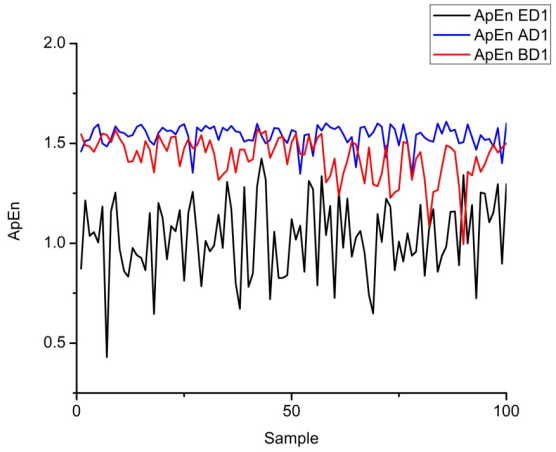

Figure 7. *Epileptic Signal*

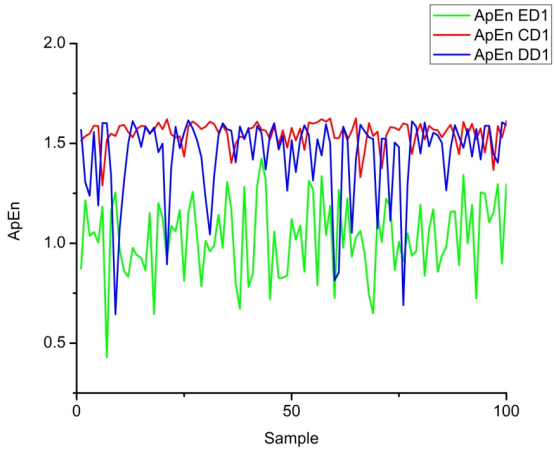

Figure 8. *Normal Signal*

In this paper SVM is implemented by using MATLAB *R2012b* and LS-SVM toolbox [33].The input feature vector ApEn is divided into two parts training data set 60% and testing 40%. The training data set is used to train the SVM while testing data set is used for verifying the accuracy of the trained SVM. For dividing the data set into training and testing part we have used holdout method of cross validation. The SVM is initialized by initlssvm function trained using tunelssvm and trainlssvm function. The performance parameters were tuned by using tunelssvm function for regularization and kernel parameter (gam, sig2) of LS-SVM [34].

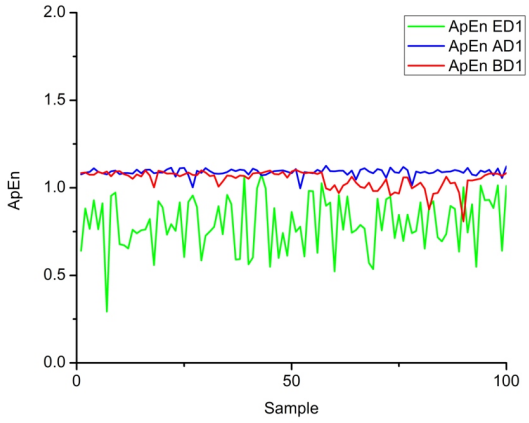

Figure 9. *Normal Signal*

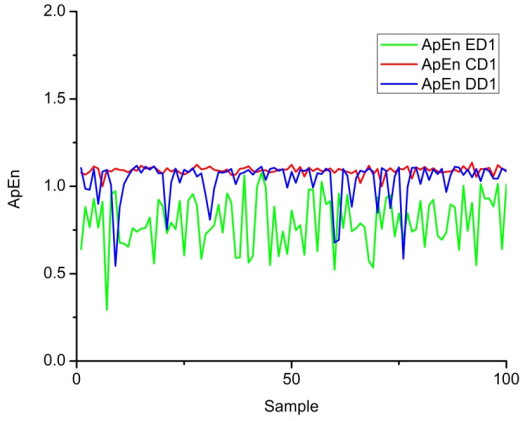

Figure 10. *Normal Signal*

The SVM algorithm is used with linear and Gaussian radial basis kernel functions. Linear kernel function require gamma parameter for training the SVM. SVM with rbf kernel function require gamma as well as sigma parameter which has to be selected based on training data. In this paper we have set gamma $\in [0-1]$ for linear Kernel and gamma $\in [0-10]$ for rbf Kernel. The sigma parameter for rbf kernel is $\in [0.7-9]$ using tunelssvm function. Each row of the input data matrix is one observation and its column is one feature.

The feature vector of each data set has 100 rows (epochs) and 6 columns (D1-D5) and A5. Case $(1-4)$ consist 200 observations, Case 5 consist of 400 observations, Case 6 consists 500 observations. The obser-

vations are normalized by scaling between 0 and 1 and then 60% and training and 40% of testing data is used for training and testing SVM.

- The Case when D1-D5 and A5 is used individually as an Input to LS-SVM

The highest precision accuracy of for embedded dimension $m = 2$ are found in cases 1 and 3 for detailed coefficient D1 are 98.75% using linear kernel and same for rbf kernel ie. in cases 1 and 3 are 98.75%. The lowest accuracy was found to be 55% for case 1 for detailed coefficient D5 in linear kernel and 59% for case 1 for detailed coefficient D5 in rbf kernel. The results suggests that there is marginal differences between the results of rbf and linear kernel but the overall average efficiency remains same for both in this cases as shown in the Table 1 and Table 2. The highest accuracy of for embedded dimension $m = 3$ is found in cases 1, 2 and 3 for detailed coefficient D1 are 96.25% and for RBF kernel it is 98.75% for cases 1 and 3 for detailed coefficient D1. In this modeling RBF kernel shows better results than that of linear kernel the overall result is summarized in Table 3 and Table 4.

- The Case when D1-D5 and A5 is combined as an Input to LS-SVM

The precision of the proposed system for embedded dimension m = 2 with linear kernel is 100% which is maximum and a lowest of 98:12% respectively for cases 1, 3, 4, 5 and case 6. Similarly, the precision of the proposed system for embedded dimension m = 2 with RBF kernel is 100% maximum and lowest of 99.50% respectively for cases 1-5 and case 6. The precision of the proposed system for embedded dimension m = 3 with linear kernel is 100% maximum and a lowest of 97.0% respectively for cases 1, 3, 4 and case 6. Similarly, the precision of the proposed system for embedded dimension m = 3 with RBF kernel is 100% maximum and a lowest of 99.5% respectively for cases 1, 3 – 5 and case 6. It is clearly observed in the results summarized in Table 6 and Table 7 that RBF kernel based automatic epileptic seizure detection system gives better precision than linear kernel based automatic epileptic seizure detection system. Table 5 presents the the comparison of results between the existing and the proposed method using same data set.

5. Conclusion and Future Scope

The least squares version of support vector machine classifiers is discussed in this paper. The quadratic programming problem has been eased to solving a set of linear equations with the use of equality constraint instead of inequality constraint. In this paper we have modeled LS-SVM using EEG data set with different combinations of input features as well as changing the parameters of the ApEn. The results suggest that the combination of detailed and approximate coefficients ie. D1-D5 and A5 as an input to classifier produces better results than using single feature D1 as a classification input. The kernel function also plays significant role in the classifying the EEG data set using LS-SVM and RBF kernel produces better results than the linear kernel in this modelling. The embedded dimension m for calculation the ApEn is also significant ad this model suggests that at m=2 the classification system performs better than that at m=3. The proposed approach can be deployed as a quantitative measure for monitoring EEG signal associated with epilepsy. As an extension of the proposed method, it would be challenging to scrutinize the efficacy of the proposed method for other neurological disorders which uses brain signals for analyzes such as Parkinson diseases etc [35]. Furthermore, it would be interesting to analyze the learning effectiveness of this model on other database. In this study, the

ABSTRACT

In recent years, big data analysis is gaining immense credence in the fields of academics and business. Businesses such as management and marketing have demonstrated a strong inclination and interest in data analytics. However, many businesses are unable to utilize data even if they have access to it. The main reason for that is the lack of familiarity with data analytics procedures. Hence, a system needs to be developed that can perform data analytics and demonstrate its benefits. In this study, we use point of sales data obtained from a supermarket chain to analyze and show the relationship between purchase goods at the same time. A supermarket is one of the ideal places to demonstrate data analysis because retail stores have many purchase records and are always conducting various marketing activities. We propose an easy-to-handle visualization system to show the goods that are inter-related. By using our system, a store manager can obtain information about the item sales easily and interactively.

1 Introduction

In recent years, big data analytics has been receiving increasing attention due to the progress of information and communication technologies in various fields [1,2]. Big data can be defined as data characterized by the 3Vs-Volume, Variety, Velocity, i.e., a large amount of data of rich variety and accumulated at high frequencies [3]. Big data has increased drastically due to the increase in internet penetration with the development of digital devices such as smart phones and the prevalence of social networking services. More and more businesses are trying to utilize big data for business planning and corporate strategies using in-house expertise, so that they do not have to depend on data analysis experts.

Supermarkets and department stores are trying to devise an effective sales strategy to address diverse consumer needs by critically analyzing point-of-sales (POS) data. However, effective big data analysis requires extensive knowledge of data structures and programming, which can be built over a period of time. Hence, businesses and services are still not able to effectively utilize big data analytics on-site.

Retailers such as supermarkets are often required to make quick decisions. Quick decision-making requires quick data analysis to grasp the various needs of the consumer, and consequently, the store, and utilize the insights derived for strategic planning to increases sales, minimize inventory, improve efficiency, etc. Consequently, retail stores need interactive operations and real-time analysis capabilities.

This study is organized as follows: Section 2 presents the purpose of our study. Section 3 describes the study conducted to attain the objectives and the features of the proposed system. Section 4 describes the basic concepts and technology. Section 5 outlines the proposed system, its functions, and the way it can be applied. Section 6 describes the experimental evaluation of the proposed system. Finally, Section 7 concludes the paper and discusses the future topics to follow up on this study. This paper is an extension of work originally presented in *Future Technologies Conference (FTC) 2016* [4].

2 Purpose of our research

In this study, we propose a system that allows users to visualize relationships between goods while manipu-

[*]Takashi Namatame, 1-13-27 Kasuga, Bunkyo-ku, Tokyo, 112-8551 Japan, +81-3-3817-1932& nama@indsys.chuo-u.ac.jp

https://dx.doi.org/10.25046/aj0203163

lating interactively. The proposed system enables:

- Automation of the data analysis process from data extraction to visualization to reduce the burden on users.
- Development of a real-time sales strategy by constructing a platform that can freely operate under various conditions.

The proposed system aims to devise a real-time sales strategy that is not dependent upon the intuition and experience of individuals, instead relying on insights gained from the data collected on-site. Even if the data analyst does not have programming knowledge, the proposed system can help him/her understand the relationship between the goods. From the analysis of relationships between the goods, the analyst can derive the insights. Moreover, the proposed system is available as a web application, allowing users to share the results of the analysis by using a web browser. The proposed system can be utilized for the arrangement of goods on shelves and offer suggestions for their effective promotion, such as the distribution of a free recipe with hot-selling goods.

3 Related studies

In this section, we discuss other studies related to this study and describe the characteristics of the proposed system.

As mentioned above, various data are being accumulated in recent years. Under such situation, SNA(social network analysis) which is based on "graph theory", has been attracting attention as a method of analyzing a large amount of data. SNA is an analytical method that clarifies the structure of a network composed of "Vertex" and "Edge". In recent years, with the advent of social media, there are many studies targeting SNS. In these studies, the users are regarded as vertexes, join relationships defined between users are regarded as edges. For the purpose of these studies, the characteristics of the community, comparison of network structures, creation of formation model of social network are set up[5, 6, 7]. On the other hand, there is also research that systematizes technology of social network analysis[8].

Ito et al. proposed a visualization system using the conditional parts from the results of association rule mining. With this system, the user can figure out the relationship between the conditional parts in association rules by using hierarchical graphs [9].

Matsuo et al. used databases of academic theses and picked out the human relationship within a specific community from information acquired from the web. From the results, the human relationships could be understood appropriately. The information on human relationships can then be used to find people who are in the same academic field for the benefit of students and researchers. To judge the strength of the relationship, they used an index, which is based on a combination of the principles of the Dice coefficient and the Jaccard coefficient. They then performed a comparative verification of the index [10].

These studies showed that it is useful as a system using network analysis. However, such a system is not effective in reducing the burden on analysts and providing an easy-to-use platform. In this study, we propose a system that satisfies the following expectations:

1. *Real-time processing*:
   The system is able to visualize the network even if the user wants real-time data. For example, the system can help the analyst identify how the relationship between the goods will change in an hour's time in case of a limited-time sale and which relationships are strong in a particular time zone, all of this in real time.
2. *Interactive processing*:
   The system allows the analyst to interactively extract data and set the threshold, allowing him/her to customize information based on specific needs.
3. *Ease of operation*
   In a conventional analysis, the analyst needed to run the script, which was written as an R script, to prepare appropriate data for visualization. Moreover, it was necessary to write more scripts for appropriate visualization. Since it takes time to understand these scripts, it is difficult for beginners to process them. Therefore, the proposed system automates these processes to help the analyst who is not good at programming understand the results easily.

4 Basic concept and technical elements

In this section, we explain the basic concepts used in this study including association rule mining, co-occurrence indexes, and network analysis.

4.1 Association rule mining

In recent years, POS data has become easy to obtain. However, one of the significant problems here is the effective use of the enormous accumulated data. Association rule mining [11] is a popular and well-known method for analyzing useful relationships between variables in large databases. It extracts frequent combinations (association rules) of items from transaction data. The main aim of this method is to derive the pertinent rules from the data. The association rule uses Support (1), Confidence (2), and Lift (3) as the indexes that show the relationships between the goods. The rule which states that "When X is bought, Y is also bought" is transcribed concisely as {X}⇒{Y}. The sets of items X and Y are called antecedent (left-hand-side or LHS) and consequent (right-hand-side or RHS) of rule respectively. Moreover, in a few cases, one rule

is formed by more than three goods. For example, {potato, carrot}⇒{onion} means that "When potatoes and carrots are bought, onions are also bought."

$$Support(X,Y) = \frac{|X \cap Y|}{|M|} \tag{1}$$

$$Confidence(X,Y) = \frac{|X \cap Y|}{|X|} = \frac{Support(X,Y)}{Support(X)} \tag{2}$$

$$Lift(X,Y) = \frac{Confidence(X,Y)}{Support(Y)} \tag{3}$$

where X, Y denote the set of items respectively. $|X|$ is the number of transactions that includes X. $|X \cap Y|$ is the number of transactions that include X and Y. $|M|$ indicates all transactions.

4.2 Co-occurrence index

Co-occurrence indexes [12] are used in the field of language processing. These indexes are mainly used for text data analysis. Co-occurrence means the simultaneous appearance of more than one word in one sentence. The sentences are usually taken from platforms such as Twitter or search history. For example, "test" and "pass" are often used at the same time in many cases, which indicates that "test" and "pass" have a strong co-occurrence. In this way, it is possible to guess a relationship between words by extracting the strong co-occurrence from a large number of combinations. In this study, we try to extract the relationship by using the co-occurrence index to measure the strength of the relationship between goods. Then we use indexes such as Jaccard coefficient (4), Simpson coefficient (5), Dice coefficient (6), and Cosine coefficient (7). Features of these indexes are discussed below:

$$Jaccard(X,Y) = \frac{|X \cap Y|}{|X \cup Y|} \tag{4}$$

$$Simpson(X,Y) = \frac{|X \cap Y|}{\min(|X|,|Y|)} \tag{5}$$

$$Dice(X,Y) = \frac{2|X \cap Y|}{|X| + |Y|} \tag{6}$$

$$Cosine(X,Y) = \frac{|X \cap Y|}{\sqrt{|X||Y|}} \tag{7}$$

The values of these indexes range from 0.0 to 1.0. The correlation is presumed to be strong when the value is higher. The features of the indexes are indicated in Table 1.

Table 1: Features of each index

Co-occurrence index	Features
Jaccard	Something with the large number of appearances by the independence whole the value are lower.
Simpson	If the number of appearances by independence is extremely small, the value becomes high even if the relationship is not strong.
Dice	When there is a great difference between two appearances, the lower value remains lower even if the relationship is strong.
Cosine	When both appearances are 0, those are ignored.

It is necessary to use the appropriate index that expresses co-occurrences according to the information needed and based on the situation.

4.3 Basic expressions about the network analysis

In this section, we explain the concepts of centrality [13] and modularity [14], which are used in the network analysis. A network of relationships using goods of Electronic Commerce (EC) site is researched widely in recent years[15].

4.3.1 Centrality

Degree centrality:
The degree is the number of adjacencies for a node. Degree centrality is the most basic method of calculating centrality in which the nodes where the edges converge are deemed as having higher centrality. If we assume a node p_k, the degree of p_k, $Degree(p_k)$:

$$Degree(p_k) = \sum_{i=1}^{n} a(p_i, p_k) \tag{8}$$

where $a(p_i, p_k)$ is 1 if and only if p_i and p_k are connected by a line; otherwise, it is 0.

Closeness centrality:
The closeness is measured by summing the geodesic distances from one node to other nodes. Closeness centrality is a method of calculating centrality in which centrality is higher when the closer the distance (therefore other nodes can be reached with a small step) is between the nodes. If we assume a node p_k, $Closeness(p_k)$:

$$Closeness(p_k) = \left(\sum_{i=1}^{n} d(p_i, p_k) \right)^{-1} \tag{9}$$

where $d(p_i, p_k)$ is the number of edges in the geodesic linking p_i and p_k.

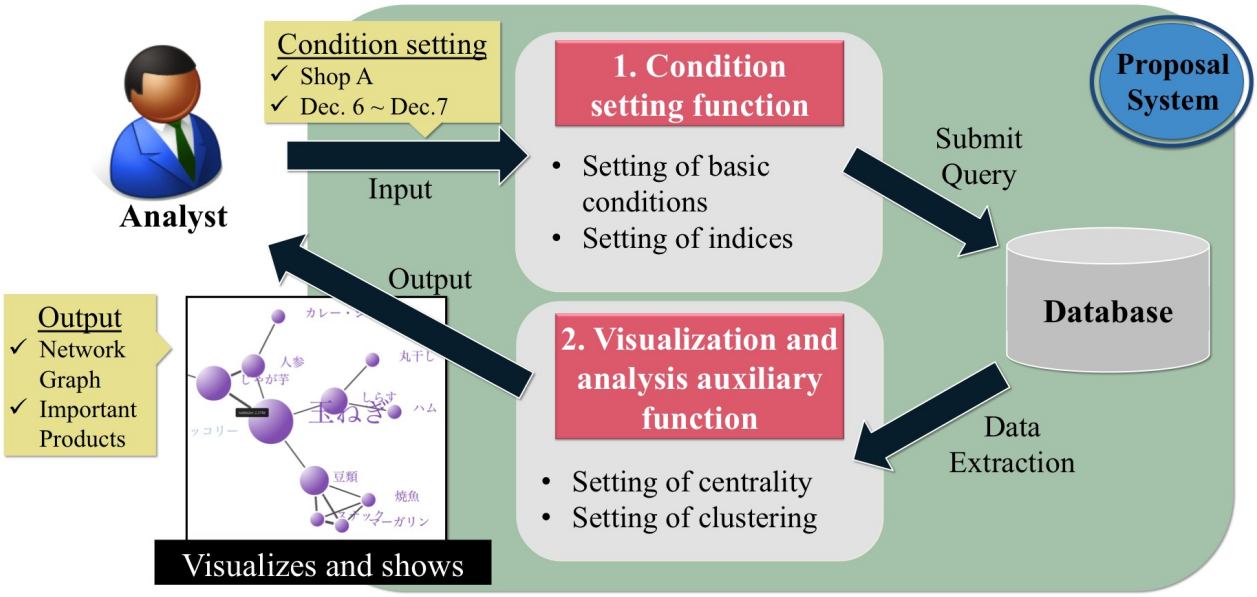

Figure 1: Image of the proposal system

Betweenness centrality:
The betweenness is based upon the frequency with which a node falls between pairs of other nodes on the shortest or geodesic paths connecting them. Betweenness centrality is a method of calculating centrality in which centrality is higher when more channels pass through a certain node. Therefore, this implies the importance of nodes acting as bridges between nodes in the network. If we assume a node p_k, the betweenness of p_k, $Betweenness(p_k)$:

$$Betweenness(p_k) = \sum_{i}^{n} \sum_{j}^{n} \frac{g_{ij}(p_k)}{g_{ij}} \quad (i < j) \qquad (10)$$

where $\frac{g_{ij}(p_k)}{g_{ij}}$ is the probability that node p_k falls on a randomly selected geodesic linking p_i with p_k.

4.3.2 Modularity

The modularity is an effects function that is used for network and graph analysis. It is a numerical index of how appropriate a particular division of communities is from the network. For a division with g groups, we define a $g \times g$ matrix E whose component e_{ij} is the fraction of edges in the original network that connects vertices in group i to those in group j. Then, the modularity Q is defined as follows.

$$Q = \sum_{i} e_{ii} - \sum_{i,j,k} e_{ij} e_{ki} \qquad (11)$$

The modularity ranges from 0 to 1. Local peaks in modularity during the progress of the community structure algorithm indicate particularly good divisions of the network.

5 Proposal and implementation of the visualization system

5.1 Outline of the proposal system

In this study, we develop the web application by using the R Language's package from Shiny [1]. We use R as a computational engine. For visualization, we use D3.js[2], which is a JavaScript library. We accumulate the analysis data, which is fixed in the database of MySQL[3]. In Figure 1, we show the analysis image of the proposed system. It will be possible to get the result through the web browser by mounting the system on a web server. We developed the system in the following environment.

- OS : Mac OS X Yosemite
- CPU : Intel Core i7 2.9GHz
- Memory : 8GB
- Language : R, JavaScript, SQL

In Figure 1, we explain the working of the proposed system. First, an analyst inputs a condition (e.g., shop name, periods) to analyze POS data. Next, a condition setting function defined in subsection 5.2 submits a query to the database based on the input

[1] http://shiny.rstudio.com/
[2] http://d3js.org/
[3] https://www.mysql.com/

conditions. Then, a visualization and analysis auxiliary function described in subsection 5.2 performs processing for visualization. This function calculates the centrality and clustering values of the network. Finally, this function delivers the network graph of the product relationships and important goods to the analysts.

5.2 Two functions of the proposal system

In this section, we are going to explain two functions of the proposed system outlined in Figure 1. The proposed system has the following two functions:

1. Condition setting function
2. Visualization and analysis auxiliary function

The condition setting function is a function to select dates, store numbers, and visualization indexes. With this function, users can interactively manipulate the data and enable free condition setting. The visualization and analysis auxiliary function is a function to set centrality and clustering and decide how to visualize. With this function, users can see the relationship between goods under the conditions set that they can set by themselves.

5.3 Details of the proposal system

For this study, we used POS data with the ID of a supermarket in Japan. POS data is the data of the sales of all goods in a store. POS data with the ID contains the customer information. By utilizing this data it is possible to grasp the customer behavior and improve the sales in a store. The data used in this study is obtained from 18 stores of a supermarket through one fiscal year in 2014. It consists of purchase data and personal attribute data.

- The purchase data
  - Purchased goods, number of goods to be purchased, purchase price, purchase stores, purchase dates, and so on
- The personal attribute data
  - Gender, age, and so on

In this study, we use purchase stores, purchase dates, days of the week, time zone, and receipt numbers for identifying the receipt of the purchased goods and purchased goods. Those are accumulated in a MySQL database.

The proposed system visualizes on the basis of the indexes of the relationship. The user can choose the index. The indexes are association rules that are used in simultaneous analysis, and co-occurrence indexes show the similarity between the sets. By using association rules and co-occurrence indexes, it is possible to obtain the rules from an enormous network. However, if the rules are also enormous, it is difficult to derive the useful rule just by visualizing. Generally, a threshold value of the index is set and the important rule is picked out. However, when the threshold is made too high, important information may not be even picked out. To address this problem, we provide the system with the function that sets the threshold freely. The system allows the analyst to freely set the dates, time zone, index, threshold value, and the number of clusters by using dynamic D3.js. Thereby, the analyst can easily inspect sets as the rule. Here, in Figure 2, we show the whole layout of the system and explain the operation of the system.

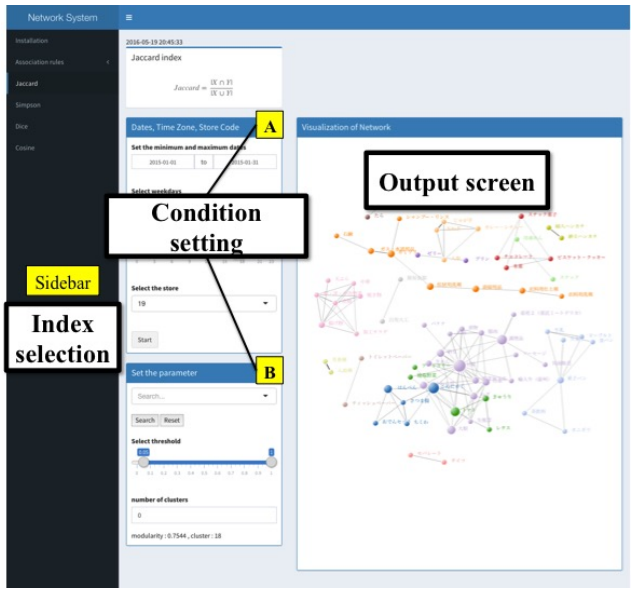

Figure 2: Screenshot of our proposal system

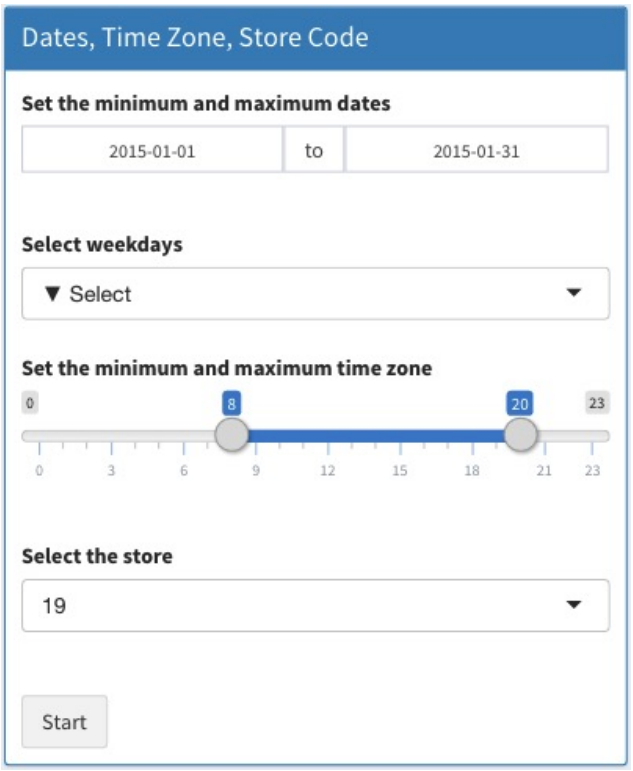

Figure 3: Screenshot of condition setting about dates, time zone, and store code

After the application starts, the user selects the index by clicking on "Sidebar," as shown in Figure 2. The layout of the application is switched to the respective indexes on selection of the index.

In Figure 3, the condition of the analysis period, the time zone and the analysis target shop is set to extract the data from the database. First, it sets the analysis period that the analyst wants through "Set the minimum and maximum dates." As shown in Figure 3, it sets the period from "2015-01-01" to "2015-01-31" as 1 month. In this way, the analyst can set it by a week unit or a month unit as well as a single date and time. Next, the day of the week can be selected when necessary in the period. In Figure 3, day of the week setting is not being used because of "▽Select." Next, it sets the analysis time zone that the analyst wants in the period using "Set the minimum and maximum time zone." In Figure 3, it sets the time zone from 8 to 20, which is the time zone from "8 a.m." to "8 p.m." in the period that is set from "2015-01-01" to "2015-01-31" as 1 month. It sets the target store through "Select the store." In this way, the analyst can set the target store that the analyst wants. Finally, the series of processing steps starting from the extraction of the data to visualization is begun by clicking the button "Start."

Figure 4 depicts the way in which the threshold of the index and the number of clusters can be set. In addition to the condition that was set in Figure 3, it is possible to set condition setting for threshold and the number of clusters. As shown in Figure 4, the visualized goods can be searched using the "Search..." button. If the goods for which the search was conducted existed in the graph, only the relevant goods are indicated. Otherwise, it displays the message "The search goods did not exist in the visualization." It sets the threshold of the selected index in "Set threshold." In this way, it is possible to adjust the enormous network by choosing rules in the case of many goods. In Figure 4, the rules that are greater than 0.05 of Jaccard coefficient value are selected. A visualized network is divided into more than one cluster in "number of clusters." The default number of clusters is 0 and this setting is calculated by using the modularity. In Figure 4, the number of clusters in the network is divided by the default setting, and the color of network is set automatically.

Here, the network is visualized based on the conditions set in Figure 3 and Figure 4. Then, the analyst can perform actions such as clicking, moving, and scaling of the network. In our proposed system, when the analyst clicks the target node, the system shows the relationship between the target node and the others that are related to the target node. When the analyst double-clicks the node, the network returns the original state. Figure 5 shows that all goods are interrelated, which is because goods that have no relationships at all are excluded beforehand. Though we excluded goods that have no inter-relationships from the system, there is a possibility that they are contributing to the sales. Figure 5 shows an example of the network visualization, which is based on the condition of the purchase history from "8:00" to "20:00" of January at a particular store. The index is the Jaccard coefficient and the threshold is 0.05. The color of the network is divided by the modularity. And we focus on two partition parts in Figure5.

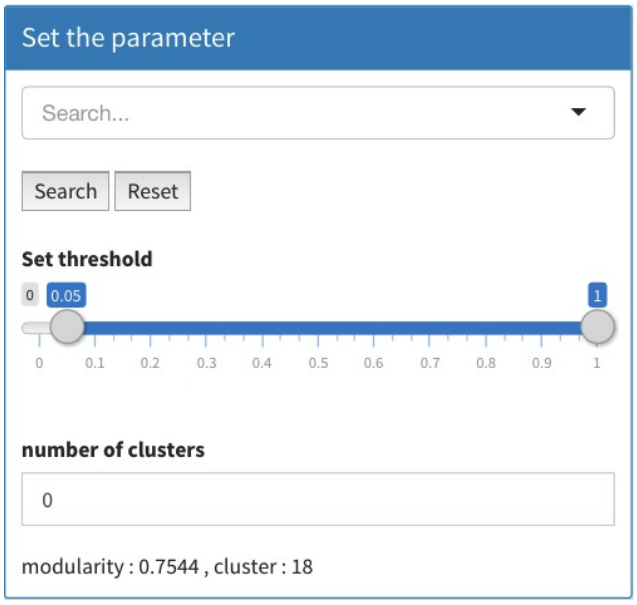

Figure 4: Screenshot of condition setting about threshold of the network index and the number of clusters

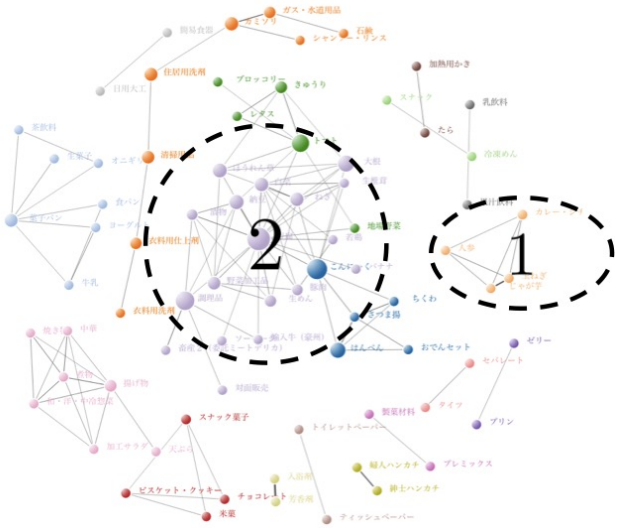

Figure 5: An example of the output screen

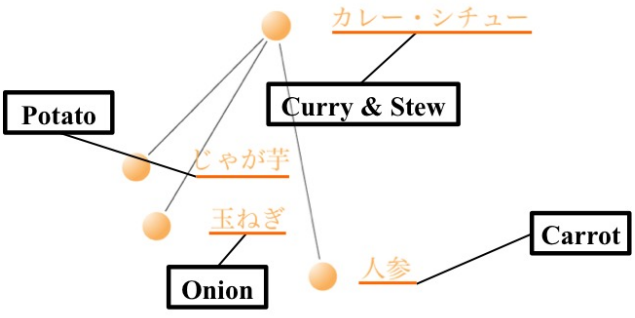

Figure 6: 1st partition part

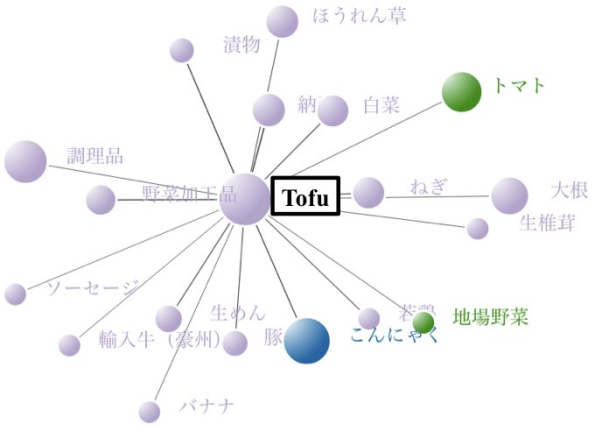

Figure 7: 2nd partition part

Figure 6 shows the first part of the partition in Figure 5. This figure shows that "Curry & Stew" is related to "potato," "onion," and "carrot." This indicates that it was possible to extract the typical ingredients from the network for curry and stew in Japan.

And Figure 7 shows the second part of the partition in Figure 5. This figure shows that "Tofu" is related to many goods and it is also involved in the other community goods. From this, it turns out that "Tofu" is a goods to be a hub that has relationships with various goods in supermarkets. When the particular goods extracted have relationships to many other goods and the threshold is high, they can indicate the core goods in the supermarket. Sales can be promoted by cross-selling with the core goods in the sales strategy.

Visualizing in this manner will help create the sales strategy and the analyst can easily understand the relationships between the normal goods and the core goods in an enormous network.

6 Experimental evaluation

In this section, we describe the evaluation of the system. We conducted an experimental evaluation based on a semi-structured interview. We set evaluation criteria beforehand to get the evaluation of the system. The evaluation criteria are shown below:

1. Quality of visualization (Is the relationship between the goods captured?)
2. Interactive processing (Is condition setting sufficiently interactive?)
3. Real-time processing (Is it used for a decision-making at a site?)

In the evaluation experiment, we identified the target analyst who had experience in management and working at a supermarket. However, she had limited knowledge of data structures and programming. The system was used by the analyst and we received the evaluation for each evaluation criteria, as shown in Table 2. In addition, we received the feedback on possible improvements in the system, as shown in Table 3.

Table 2: Evaluations

No.	Evaluation
1	Relationship between goods that tend to be bought at the same time is classified by colors. Therefore, the visualization is easy to understand and the appearance of the visualization is dynamic and interesting.
2	User can interactively perform various condition settings on the system and it is possible to visualize it using various patterns. Best of all, it can be expected to shorten analysis hours because there is no necessity to process the data by each condition setting.
3	It enables real-time analysis if the system is equipped with a server and the environment is adequately equipped. For this reason, the headquarters can cooperate and do quick strategic planning as well as on-site judgment.

Table 3: Areas of improvement

No.	Improvement points
1	Calculation speed and large scale database
2	Addition of the function for actual use
3	Documents for users are required

Based on the evaluation as per Table 2, we can conclude that the visualization display was found to be easy to understand. This is because of the appropriate grouping of goods, which makes it easier to understand the relationships between goods. The evaluation also showed that analysis hours could be reduced because there is no need to process the data by each condition setting. The proposed system enables real-time analysis if the system is adequately equipped. From the evaluation, it can be inferred that the proposed system is effective in terms of reducing the burden on the analyst for data processing.

We also studied the suggestions for improvement, as described in Table 3. Admittedly, the calculation speed of the system is inferior because of the usage of R script instead of compiler languages such as C and Java. The computational complexity is proportional to the amount of data and as the data becomes big, it takes more time to analyze it. For example, if the relationship between the goods is visualized for a 1-month time period, the operation becomes difficult and slow. Therefore, it is necessary to improve the interactive operations in such cases. The system is definitely just a prototype. Faster calculation time can be achieved by improving the environment and introducing compiler languages.

The lack of sufficient functions pointed out in Table 3 arises from the business experience at a supermarket. In particular, decisions such as elimination of the node (goods) that an analyst deemed unnecessary, multi-selection of stores, and condition setting

of the category of goods, etc. are planned for improving user convenience when the actual system is introduced. Therefore, the problem will be resolved by adding the function to the interface.

The third area of improvement in Table 3 points toward the necessity of a document explaining the analysis methods and usage. Although the proposed system can visualize the relationships between goods using various methods, it is necessary to take into account the kind of scene for each visualization indexes can be used. For example, it is necessary to demonstrate and recommend to the user that degree centrality should be used to extract goods that are purchased at a high frequency, such as bargain items.

7 Conclusion and future studies

In this study we proposed a system that allows users to visualize relationships between goods while manipulating interactively. Data extraction, processing, calculation, and visualization are automated even when an analyst does not have knowledge of programming, and an interface has been developed. We made it possible to freely set the threshold settings such as association rules and co-occurrence indexes. In addition, the system can support the proposal of real-time sales.

In this study, we used association rules and co-occurrence indexes to select the rule from a network. However, we could not demonstrate how the rule is useful by extracting with indexes. Therefore, we need to clarify index selection, which is a key topic for future studies. In the experimental evaluation of this study, some improvement areas were pointed out. In the future, it is necessary to improve and impart various functions in order to make the proposed system easier to use. Moreover, we could not obtain the quantitative evaluation about the system during the experiment, which is another necessary topic that needs to be explored.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

The paper explores an issue of efficient public transportation network design as a part of the urban developing process. Having data about everyday residents travelling inside of an urban area, we can consider this data as people's requirements for the public transport system. We propose a novel method for initial public transportation network design based on clustered geospatial data containing origin/destination point of travel patterns of residents. The core of a method is a set of four algorithms for selecting terminal clusters based on a number of centres (or focuses). The appropriate quality criteria are proposed: degree of transport demand satisfaction, the coefficient of non-straightness, and transport network density. Use cases allow evaluating a performance of proposed method and give sufficent conclusions about its application.

1 Introduction

Urban Computing is a scientific area which provides models and methods for designing convenient urban environments. Also, the set of models allows predicting how the urban area changes and supporting decision making for urban planning and reconstructing [1]. For instance, urban planning includes operations for transportation, communication and distribution networks design toward to improving residents quality of life [2].

The public transportation network (PTN) in general meaning (including buses, underground, taxi, etc) is sufficient part of the city. From the one side, the city is growing around transport infrastructure, from another side, the expansion of city leads to the implementation of infrastructure projects. Residents select their location for living based on many criteria, but the transport is the essential one. Generally, the ideal public transport networks provide a service with minimal travel time, also including time for waiting and changes. As PTN contains the different service provider, the concurrency leads to increasing quality of service. In real life, PTN is not so efficient, moreover for new developing areas. Commonly used methodologies for transport system design and development evaluates technical features, but they do not take into consideration the residents opinions and preferences into consideration. It leads to a fundamental contradiction: if people do not use public transportation network due to its inefficiency, they prefer personal carriers, but increasing the number of cars in a city leads to negative ecological and economical effect, like traffics. Developing new data-driven tools which consider residents' preferences of travel paths is challenging tasks for Urban Computing domain.

Actually, new data collecting technologies allow gathering data about different aspects of people's life. Cell operators can detect the position of a subscriber with acceptable quality level. A post in Twitter contains data about location rectangle event, where a post was made. Geospatial data is are a common part of most information gathered by software applications. In this case, if a person has his/her own common travel paths (the most used origin-destination points) they can be considered as personal requirements for transportation systems. Having this data, we are able to (i) evaluate the efficiency of the current transportation network and (ii) to suggest modifications based on citizen's preferences.

So, in the research, we consider the following question. Given anonymised travel data in the framework of an urban area, what the data-driven technologies which allow designing the optimal public transportation network? To find the answer this question, the following high-level steps need to be performed: (i) collecting geospatial travel data, (ii) reasonable

*Corresponding Author: Alexey Golubev, PhD Student, CAD, Faculty of Electronics and Computer Engineering, Lenin av., 28, Volgograd, Russia & ax.golubev@gmail.com

https://dx.doi.org/10.25046/aj0203164

data reduction for generalisation of key points in routes in a PTN, (iii) designing a set of (sub)optimal routes and (iv) picking up the appropriate PTN according to multicriteria decision analysis based on quality criteria [3]. If we have travel data of every single person in an urban area, we can evaluate the most optimal stops as nodes in public transportation routes. Suppose we get information about 5% of residents of a city with 1 million population. In this case, the correspondence matrix has 50000^2 elements. Reduction of original nodes count allows to detect the centres of clusters and to understand where stops could be located. Attempts to solving the problem of optimal PTN design lead to many subtopics including data processing algorithms over geospatial data [4]. As an example, a task of finding public transportation network with (sub)optimal routes based on defined clusters. This problem includes the well-known tasks like shortest path search problem as well as specific task need to be explored, e.g. how to create initial public transport network based geospatial data analysis. In contrast with shortest path search problem with its many efficient and fast program solutions e.g. OpenStreetMap (OSRM), the initial network design is the unstructured problem containing multi-criteria decision analysis.

The main contribution of the paper is a novel method for initial public transportation network design based on clustered geospatial data containing origin/destination point of residents. The core of a method is a set of four algorithms for selecting terminal clusters based on focuses.

A paper has the following structure. After the introduction, we observe literature referring to a problem of data-driven approaches for transportation network design. Next, we propose a novel method for initial PTN design with various approaches for terminal clusters choice. Use cases section describes how the method was implemented and estimated over data according to performance evaluation criteria. The conclusion contains the main findings and future work ideas.

2 Background

Classical planning and development of the public transport network is a well-studied field of science. Methodologies for planning the transport network of the city according to [5] includes the sequence of actions: (i) public transportation network design; (ii) setting timetables; (iii) scheduling vehicles to trips, (iv) and assignment of drivers and other maintenance work.

You can also observe the emergence of a number of theoretical studies. In work [6] author proposed a hypothesis about the routing of tables with a symmetric shortest trajectory. It describes the symmetric routing of the shortest path table and presented counterexamples for its hypothesis. In their article [7], Daniel Delling et al. investigate the problem of calculating all optimal Pareto travels in a dynamic public transport network and introducing an algorithm for a public transit route (called RAPTOR). Another of their work [8] offers a routing mechanism for calculating traffic directions in large-scale road networks. And in [9], we suggest public transit transportation as the solution of the journey in the future. Turning to other works, one can distinguish [10]. The authors study the problem of finding good alternative routes in road networks. They look for routes that (i) differ significantly from the shortest path, (ii) have a small extension, and (iii) are locally optimal. The authors of the paper [11] proposed the RICK algorithm for constructing popular routes from undetermined trajectories, using information on the sequence of locations and time intervals. In the article [12] Tim Duyer and Lev Nahmanson proposed fast cross-routing for large graphs. They focus on discussing two methods for achieving faster routing using approximate methods of finding shortest paths. In such sources as [1, 13–15] the issues of theoretical research, planning and optimization of the transport network are given very great attention. Special attention is paid to the best practices in [1, 15].

Also we analysed different well-known algorithm to solve short path problem such as $A^\star$, $IDA^\star$, Breadth-First-Search, Best-First-Search, Dijkstra's algorithm, Bi-directional $A^\star$, Jump Point Search, Orthogonal Jump Point Search, Two-stage algorithms (ALT, Reach) and genetic algorithms of random search. Such algorithms like $A^\star$, $IDA^\star$, Best-First-Search, ALT ($A^\star$ labeling and methods are based on the inequality of the triangles used to work without prior preparation data that leads to the intersection large graphs and create significant problems in the time cost. In contrast to these algorithms exist such as HLC [16], HL, TNR [17] and lookup tables, where the costs associated with the pre-processing and data storage, while the speed of the algorithms are very fast.

Besides theoretical results, software implementations for decision support in urban transportation planning have been observed. PTV Visum [18] is software for evaluation existed (defined by a responsible person) public transport network based on transportation matrix. Another software called Emme, proposed by "INRO Software" [19] and SaaS solution by Citilabs is named Cube Cloud [20]. The Transportation Analysis and Simulation System (TRANSIMS) developed by [21] is a set of tools for analysis of regional transportation systems. TRANSIMS is an open source project which is available for public usage under NASA Open Source Agreement Version 1.3. Software like Aimsun is used in urban development traffic modelling that allows to model fusing travel demand and simulate networks of difference complexity [22].

The task is closely related to the task of routing from point A to point B, but it has some differences. First, in the typical task of routing, the objective function is the journey time from the beginning to the end of the route, which must be minimized. In the

case of the construction of a network of public transport routes, the objective function is an integral function that takes into account the average time of the pedestrian travel to the stop, the length of the path, the number of transplants and other characteristics of [5, 23]. Secondly, in the typical task of routing for the movement, any intermediate points that reduce the route are selected, whereas in the problem under consideration the intermediate points are located in the same place as the cluster centers. All of these variables are averaged over the number of residents. Moreover, an important difference between the two algorithms is that the end point in the route can not be arbitrary since each route must contain nodes (stops) which represent the centers of clusters.

The main conclusion of the review can be drawn: in spite on different approaches for network design, the initial network structure design is not studied well. Especially, if these network obtained for data gathered from residents.

3 A geospatial data-driven method

Algorithm 1: The scheme of the method for route network design

Data: n_r, C_t, C_{nt}
Result: RN
for $i = 1 \dots n_r$ **do**
  Build R_i direct route, containing a pair of opposing points of C_t;
  Add R_i to RN;
end
while C_{nt} *is not empty* **do**
  for $i = 1 \dots n_r$ **do**
    Select R_i from the route RN,
    $R_i = [n_1, n_2, \dots n_R]$;
    Split R_i on a pair of nodes
    $PN^{(R_i)} = [[n_1, n_2], [n_2, n_3], \dots, [n_{R-1}, n_R]]$;
    Initialize RC list;
    for *pairs* $[n_x, n_y]$ *in* $PN^{(R_i)}$ **do**
      /* Find the node minimally increases the length of the direct route $[n_x, n_y]$ */
      Find c_j node from C_{nt} with j index, which $j = argmin(|len(n_x, n_y) - (len(n_x, c_j, n_y))|)$;
      Add $[n_x, c_j, n_y]$ to RC;
    end
    Compose $\|RC\|$ options for new routes: one variant of the RC, the rest of the $PN^{(R_i)}$ and compile a list of routes candidates to replace RCC;
    Evaluate the length of routes from the list RCC and choose the route R_i^* with minimal length;
    Replace R_i to R_i^* from RN;
    Remove c_j node entered to R_i^* from C_{nt};
  end
end

3.1 General description

The basic idea of the initial public transport network design is to find the network consistently adding new nodes to existed routes in respect with minimal length increasing of designed network.

Let's consider the task statement. Given n_r number of routes in the designed public transportation network, n_c number of nodes (clusters centers) which should be added into network, C_t a set of terminal nodes, C_{nt} a set of non-terminal nodes, correspondence matrix $\|C_{nt}+C_t\| \times \|C_{nt}+C_t\|$. Note, that $C_t+C_{nt} = n_c$. Output of proposed algorithm is a transportation network RN with routes containing non-overlapping set of nodes,

$r_i = [p_1^{(i)}, \dots, p_k^{(i)}]$, where $i = 1, \dots, n_r$.

We propose the algorithm which contains the following steps represented in the scheme 1.

3.2 Explanation

Consider the operation of the method using a simple example. We choose the number of routes in the network $n_r = 2$ and assume that the algorithm for the choice of terminal clusters has given us A, A', B, B' (C_t) and nonterminal clusters C, D, E, F, G, H (C_{nt}).

In the first step, we combine terminal clusters into pairs and put them in the list $R_i = [AA', BB']$. The image 1a represents this network configuration.

Next, select the first route from the list of R_i and divide it into parts (two clusters each). Because We have two clusters in the route, then we have only one route $PN = [AA']$.

Next, we compose a new set of routes by adding a new cluster to the middle of the existing routes from PN. In our case, we have $ACA', ADA', AEA', AFA', AGA', AHA'$.

In the next step, we need to calculate the length for each new option and choose the one that has the shortest length – ACA'. Add this route to the list RC.

Next, we compose all variants of routes from the lists RC and PN. In our case, we have only one route ACA' and we add it to the list of $R*_i$. The used cluster ACA' is removed from C_{nt}. We perform similar operations for BB' and get a new route BFB'. The image 1b demonstrates this stage of construction.

On the next iteration of the algorithm we have $R_i = [ACA', BFB']$. Using ACA' we get two pairs $PN = [AC, CA']$. By successively adding nonterminal clusters, we get the following set: $ADC, AEC, AGC, AHC, CDA', CEA', CGA', CHA'$. Suppose that GA' is the shortest of all.

We make variants from CGA' and AC, CA' and get $ACGA'$. Add the resulting version to $R*_i$ and remove G from C_{nt}. Similarly, for BFB' we obtain $BFHB'$. The image 1c represents this stage of building a route network.

We continue to execute the algorithm while C_{nt} contains clusters. Finally, we get the network shown in the figure 1d.

(b) Second step

(c) Third step

(d) Fourth step

Figure 1: Illustration of the network design process.

3.3 Algorithms for choice of terminal clusters

In the last paragraph we mentioned some algorithm for selecting terminal clusters. We proposed 4 algorithms with which you can select the origin-destination clusters. Let us now examine them in more detail.

Algorithm 1: opposite clusters (opposite). The essence of the method is the connection of clusters lying on opposite sides of an imaginary circle.

The main goal of this method is to choose clusters that lie on opposite sides of the city. If the city has sleeping and industrial areas located in different parts of the city, then this method will allow transportation of a large number of people to and from work.

The algorithm contains the following steps.

1. Find the geometric center C of the convex hull
2. Find the furthest cluster from the center C on the convex hull and consider it to be the radius R
3. On the imaginary circle formed by R, marks uniformly $2 \cdot n_r$ points
   - the circle is given by the center of the shell C and the radius R
   - n_r – number of routes in PTN
4. Combine the diametric points into groups of two
   - for each point, we search for the nearest clusters in the Δ neighborhood
   - choose the points with the largest value of people

Algorithm 2: from the center to the suburbs (c2out). The essence of the method: pulling all the routes to the center of the congestion of people. The main idea of the method is transportation of people from the suburbs to the center. This method is designed for the type of city for which the center is the main place for the work of a large number of people, and the suburbs – sleeping areas. The ideal form of the city for this method is the circle.

The algorithm

1. Repeat steps 1-2 from method 1
2. On an imaginary circle, points n_r of points F are uniformly marked
3. Find the center G of the city (and accordingly the nearest cluster with the largest number of people)
4. Choose n_r clusters near G (it is permissible to repeat clusters)
5. Pair pairs of clusters from G and F

Algorithm 3: two focuses (2focus). The essence of the method: is similar to the second method, but with two focuses (cluster centers). This method is a logical continuation of method 2, but with the account that in a city there can be not one center, but two. The centers determined by this method need not be located near the geographical center of the city. Another important observation is that routes are also constructed between the focuses. The ideal shape of a city can be an ellipse or a circle.

The algorithm

1. Find F_1 and F_2 for the convex hull of a city
   - clusters with the largest concentration of people
   - and, accordingly, the closest clusters in their neighborhood along $n_r/2$ for each focus
2. On an imaginary circle, points B (K are uniformly $n_r - K$ – the number of routes connecting focal points)
3. The first K routes include two clusters (one from F_1 and the other from F_2)
4. Distribute the remaining points between B, F_1 and F_2 (one point from B, and the other from F_1 or F_2 (depending from distance))

Algorithms 4: N-focuses. The essence of the method: generalization of methods 2 and 3 for an arbitrary number of focuses (cluster centers).

This method is a generalization of the previous two methods: *c2out* and *2focus*. In this case, you can choose an arbitrary number of "focuses" for the best provision of passenger traffic between the focuses and the suburbs of the city. The form of the city for this algorithm can be arbitrary.

The methods implements the following steps

1. Choose N focuses F_N with the largest number of people
2. On the convex hull, $n_r - N \cdot K_N$ points B (K_N – the number of routes connecting N focal points)
3. The first $N \cdot K_N$ routes between the focal points
4. The remaining points are distributed between B and F_N (by analogy with method 3)

As an algorithm for searching for a convex hull, the Graham algorithm used in the methods is used.

4 Use cases

4.1 General information

To explain how the proposed methods are applied in urban development task, we showed the example for new public transportation network design for midsize city located near the large regional centre. For the subset of residents in the city, we obtain a pair of origin and destinations expressed as longitude and latitude. Origin might be where the certain resident lives and the destination where the same resident works. It means each pair shows the most popular path of the certain person in the city. This path contains a part when the public transportation is used, and walking zones. An ideal public network meets requirements according to the several criteria. We use such criteria as: the degree of satisfaction of demand for transport, the coefficient of tension and the density of the transport network.

We apply the straightforward procedure containing the following steps: (i) generation of origin-destination pairs for residents; (ii) clustering all the points into 82 clusters (the number of clusters has been chosen experimentally); (iii) creating the initial transport network using the methods and algorithms described in the article.

4.2 Data

We generated data about travel citizens preferences inside of mid-sized town with approximately 350,000 residents. We received 6,000 pairs of origin-destination points of 12,000 in total. In this case correspondence matrix has a large size 6,000 × 6,000 elements where every element with 0 value means no connection or 1 stands for connection existence.

4.3 Implementation

Proposed algorithms were implemented using Python and Open Source Routing Machine (OSRM) service for urban terrain distance calculation between the nodes. The program code is published online in the Git-like repository. The software used:

- Python v 3.5.2
  - numpy 1.12.1
  - scipy 0.19.0
  - geographiclib 1.48
  - polyline 1.3.2
  - requests 2.9.1
  - json 2.0.9
- OSRM v5.8.0

4.4 Performance evaluation

As an estimation method, an integral formula was used to evaluate the efficiency of the transport network with the following calculation criteria:

- Degree of transport demand satisfaction

$$U = \frac{1}{T}\sum_{i=1}^{N} F_i$$

where T is the total number of passengers in need of transportation, F_i is the number of passengers carried with i transplants, N is the number of traffic.

- Coefficient of non-straightness

$$P = \frac{\sum\limits_{i=1}^{N} D_i}{\sum\limits_{i=1}^{N} L_i}$$

where D_i is the direct distance from the initial to the final point of the route for the i route, L_i is the length of the i route, N os the umber of routes in the transport network.

- Transport network density

$$L = 1 - \frac{1}{4 \cdot S}\sum_{i=1}^{N} L_i$$

where S is the area of the city, L_i is the length of the i route, N is the number of routes in the transport network.

Integral formula for assessing the efficiency of the PTN is based on additive convolution function:

$$O(I, W) = \frac{\sum\limits_{i=1}^{n} I_i w_i}{\sum\limits_{i=1}^{n} I_i} \quad (1)$$

where O – integral assessment of the transport system; I – values of criteria; w – weights for the criteria that determine their importance; n – number of criteria. The decision maker's preferences are defined as weights w.

4.5 Experimental design

To evaluate the efficiency of the algorithm and to study its specifics, we carried out experimental design varying the number of nodes and routes. The most interesting case is big geospatial data processing where a lot of nodes we processed.

To reduce the size of correspondence matrix and to understand the most popular locations, we applied clustering algorithms for original/destination geospatial data. In contrast with typical and well-known cluster techniques such as k-means and MeanShift, our algorithms used OSRM for distance calculation according to urban terrain conditions. As centers of clusters are considered as stops in a transportation network with the most populated neighborhoods, we designed different use cases regarding a number of nodes as it is a variative parameter.

As the input data for the program, the data was used after the clustering stage: 82 clusters, as well as the correspondence matrix. The following parameters were chosen as the variable experimental parameters:

- n_r – the number of routes in the network (the number of routes varied from 10 to 60 in steps of 2)
- method used
  - *opposite* (method 1)
  - *c2out* (method 2)
  - *2focus* (method 3)
  - $*$*focus* (method 4, where the focus value varies from 3 to 9)

The experiment was carried out using a computer running the Linux Mint 18.1 Serena operating system (4.4.0-77-generic x86_64 core), Intel (R) Core (TM) i5-4690 processor.

5 Result and discussion

Based on method implementation, we consider results regarding the following specifics:

(i) analysis of the efficiency of the designed transport networks with respect to different methods for selecting terminal clusters, based on the proposed criteria;

(ii) analysis the relationship between such quality criteria and parameters of methods;

(iii) analysis dependencies of performance (in terms of time complexity) and on a predefined number of routes in the network.

The graph of the network quality versus the number of routes is shown in the figure 2a. The trends of the methods are shown in the figure 2b.

The method ($*$*focus*) based on the idea of £allocation of clusters-focuses, where the largest number of people accumulate, proved to be better than all other implementations.

Depending on the number of focuses, the method behaved differently. For example, with 4 focuses, the quality of the network has the highest value in the current data set, for 8 and 9 focuses, with an increase in the number of marches, the quality of the transport network tends to grow, while for 4 and 6 – the periodical character is observed, and at 3 and 5 in general it starts to decrease (see figure 3b).

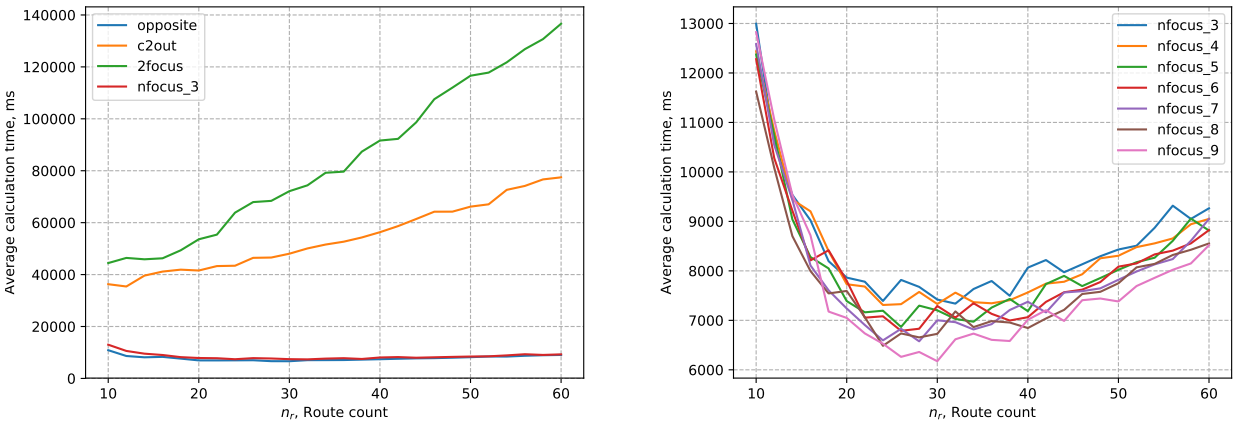
Table 1: Results of calculation time (part of the results in increments of 10)

From the general trends, the result with 7 focus has a slight decrease in the quality of the network, It can be connected with an unbalanced network configuration when number of routes. For other methods of selecting terminal clusters, things are slightly worse. The methods opposite, *c2out* and *2focus* have the greatest value of network quality for small values of the number of routes, and then they only decrease. If for *2focus* the quality of the constructed network can be described by a linear decreasing function, then the opposite and *c2out* have non-periodic oscillations in their basis.

Turning to the analysis of time necessary for the calculation (Fig. 3a and 3b), we can say that the methods *∗focus* and opposite are the fastest, while *c2out* and *2focus* grow with the increase in the number routes. This can be explained by the fact that *c2out* and *2focus* methods use a costly function to search for clusters in a given radius, i.e. With the increase in the number of routes, the number of calls to this function also increases. The calculation time for the *∗focus* method for any n basically has the smallest parsing (Fig. 3b). Calculation of the algorithm running time using different methods for n_r with step 10 is presented in the table 1.

We can say that the method *∗focus* with a different number of foci (from 3 to 9) for the given set of geodata is the most optimal. It combines a good execution speed with the methods *c2out* and *2focus*, and the transport networks obtained with its use have the highest quality value for any n_r.



(a) Calculation time for different algorithms of terminal nodes choice

(b) Calculation time of *∗focus* algorithm depending on a number of route count

Figure 3: Experimental results

The main algorithm used to build a transport network by empirical evaluation of complexity (in terms of calculation time), the complexity of the algorithm 1 could be estimated as $O(n^3)$, where n is a number of nodes.

6 Conclusion

This article presents the method for initial a public transport network design based on the processing of geospatial data. The main idea of the proposed method is the successive addition of clusters in the transport route, taking into account its minimal increase in length. Also performance evaluation criteria is presented.

A method includes four different algorithms for terminal cluster choice: (i) algorithm based on opposite clusters, (ii) algorithm considering travelling experience from the center to the suburbs, (iii) algorithm for cities with two centers or focuses (*2focus*), and, finally, (iv) algorithm processing n focuses.

In accordance with the results obtained, it can be concluded that this algorithm can be used to construct the preliminary PTN. Based on the heuristic evaluation, it has cubic time complexity and the most choke point is in interaction with external services (e.g. OSRM). The proposed method *∗focus* with a different number of focuses (from 3 to 9) for the given set of geospatial data is the most suitable for terminal clusters choice, because of its speed and performance.

The evaluation is based on synthesized data and thus allows only an evaluation of the performance and scalability of the approach, rather than on its effectiveness in supporting planning transport managers decisions. A feedback from mobility expert on a real case study will increase the quality of evaluating the usefulness and effectiveness of the approach. So, these can be considered as future work based on theoretical findings.

ABSTRACT

Electronic Control Units (ECUs) generate diagnostic and telemetric data that is communicated over the internal vehicular network. ECUs are resource constraint devices and have limited resources to devote for data security. In recent times, threats against vehicular networks have emerged that require attention of the research community. In this paper, we demonstrate data security threats in automobile, present a hardware based security framework that provides real time secure communication using lightweight cryptographic primitives and propose hardware based authentication protocol. Implementation details, performance and security analysis of proposed framework are presented.

1. Introduction

Vehicles are no longer composed of just mechanical components with limited control operations of electrical components. Digital transformations in electronics have contributed in the advancement of automotive industry in terms of customer interactions and experience in improving the overall driving experience of a vehicle and critical operations. Some examples of on-board electronic components are air-fuel mixing, temperature-control, thermostats, vents, doors-locking, seat-adjustments, radio, wind-shield wipers, transmission, ignition, engine, steering, brakes, acceleration, air-bags, navigation, in-dash entertainment, cameras, braking system, etc. Electronic systems that are connected with on-board systems are called Electronic Control Units (ECU). ECUs work in cooperation with each other, and need to communicate their state with one another. Instead of using dedicated signal wires for information exchange, that may require a lot of wiring and effort on part of the car manufacturer, the automotive industry has moved towards using data communication networks. Similar to traditional data communication networks, data security of the ECU network is becoming a concern. Following section covers the vulnerabilities, and recent attacks on on-board car networks and the new security requirements. The security vulnerabilities are demonstrated and existing countermeasures and their limitations are discussed. This is an extension to the paper [1] which was presented in IEEE Vehicular Networking Conference 2016. Columbus, OH, U.S.A.

1.1. Recent Documented Attacks

In 2014, a group of researchers were able to remotely control a Jeep Cherokee[2]. The vehicle is equipped with an on-board infotainment system. To gather local information, it uses an internet connection to connect to its server. The researchers could remotely hack into the dashboard system, using software vulnerability. The dashboard system is also connected to the internal network of connected ECUs using a popular network standard known as Controller Area Network (CAN)[3]. This gives access to all the other actuation units such as the brakes, accelerator, steering control etc. A more recent attack is discussed in [4]. The authors extracted master global shared encryption keys from deciphering the software code using a wireless key fob. This gave the researchers access to shared keys used by all the vehicles using the wireless key fob system from the affected brand.

1.2. Current Security Needs

A robust and secure framework is needed to improve the resiliency to malicious attacks. Traditional cryptographic primitives are computation intensive and rely on secrecy of shared

*Corresponding Author: Ali Shuja Siddiqui, Dept. of Electrical and Computer Engineering, University of North Carolina at Charlotte, U.S.A.
Email: asiddiq6@uncc.edu

or session keys, and are applicable on large systems like servers and secure databases. These are unsuitable for embedded devices with fewer resources to allocate dedicated hardware for implementing security protocols with extra storage requirements. Alternatively, if external *Hardware Security Modules* (HSM) are considered to provide security, they are costly and require additional physical area and power.

This paper demonstrates a hardware based light authentication framework integrating strong physical unclonable function for secret key generation and light cryptographic primitives, such as Elliptic Curve Cryptography to improve authentication protocol for small and resource constrained embedded devices at lower levels of composition. We evaluate the security methods for CAN protocol and propose techniques to mitigate those attacks on ECUs. Furthermore, the framework addresses the issue of unauthorized physical access to a vehicle via electronic means, and to the connected digital components within a vehicle.

2. The CAN Bus Protocol

The CAN bus, known as ISO 11898 architecture is a multi-master bus connecting embedded components, I/O interfaces as well as gateways to communicate with the external world. It consists of three signals, CAN High, CAN Low and Ground, and the CAN standard specifies three data rates 125kbps, 500 kbps and 1Mbps. In the more recent standard for CAN Bus, named *CAN Flexible Datarate*, CAN allows transfers of additional frames at non-standard and faster speeds.

Figure 1 describes the standard data frame of CAN bus. The SOF bit denotes the start of frame, 11 bits store destination ID, Data field of 64 bits and CRC field is 15 bits to hold the checksum of the entire packet. The length of the standard CAN frame is 108 bits whereas 131 for an extended CAN frame. On the physical medium CAN uses Non-Return to Zero (NRZ) encoding, that is after five consecutive zeroes on the stream, an extra '1' bit will be added to that position before putting it on the bus.

SOF	Arbitration	Control	Data	CRC Field	ACK	End of Frame
1 bit	12 bits	6 bits	0 – 64 bits	16 bits	2 bits	7 bits

Figure 1 Standard CAN Bus Frame.

3. Threat Models

CAN is susceptible to replay, man in the middle and stealing identifiers attacks. We demonstrate these attacks on CANBus, with the testbed using Raspberry Pi 2, PiCAN Duo CANBus Shield, Arduino UNO and CAN-BUS Shield.

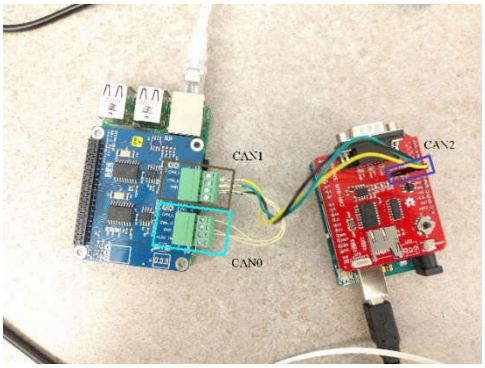

Figure 2 Experimental Setup.

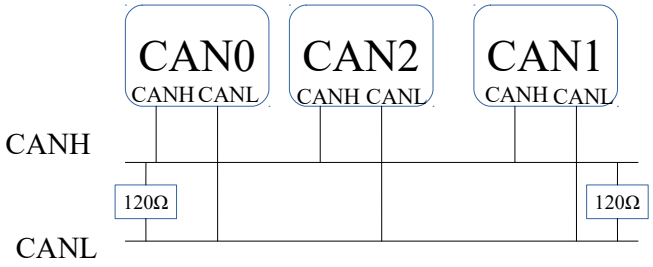

Figure 3 Block diagram of the Experimental Setup.

The PiCAN shield with two CAN nodes is connected with the Raspberry Pi. These nodes are considered to be legitimate nodes on the network. These nodes are referred as CAN0 and CAN1, as shown in Figure 2. The malicious node CAN2 is a CAN shield which is connected to an Arduino UNO. Figure 3 describes the block diagram of the complete setup.

3.1. Eavesdropping

CANBus is an insecure communication medium that transmits data in broadcasting the unencrypted packets to all connected nodes on the network. Malicious node getting physical or remote access to CANBus network has access to all the packet transfers and payload. Figure 4 shows traffic of packets on CANBus. The messages and destination identifiers are broadcasted and sent unencrypted on CAN. CAN0 messages for other nodes can be seen and recorded by CAN1. Similarly, any other device physically connected to the CAN bus can read all the communication over the network.

To mitigate eavesdropping, the information passing on the bus needs to be securely encrypted. In [5], the authors present an external security solution, and [6] proposes 3DES encryption and an external controller for the transfers and traffic monitoring. The added area, power requirements and slower performance of the software based encryption and decryption processes make the solution impractical.

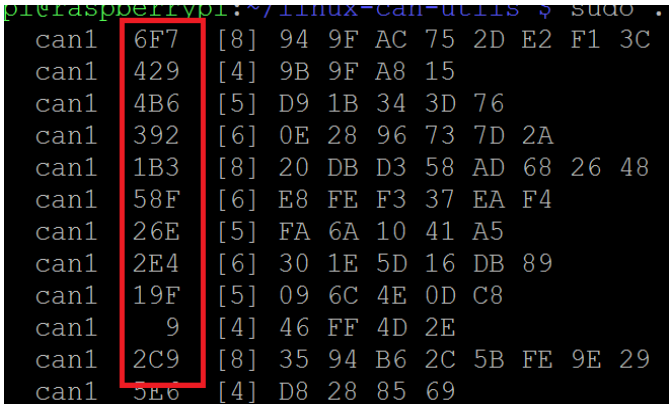

Figure 4 Screenshot of data transfer on the CAN.

3.2. Stealing Identifiers

As shown in the Figure 4, the destination address in the identifier field are visible to the hacker/ attacker on the CAN bus. All devices probe the ID field of each message received and based on the ID, deduce if the message was meant for them or not. Malicious device records these identifiers and can launch attacks against other nodes.

In [7], an authentication and encryption mechanism is described, but it requires about three times more CPU cycles than the cycles required for normal operation of a CAN node.

3.3. Non Repudiation

The frame consists of the destination identifier and not source identifier. The communication network cannot confine the attack or identify the originating node based on the network analysis. This results in incorporating non-repudiation requirements at each device (ECU).

3.4. Denial of Service

Denial of Service attacks makes the resources or services unreachable; the CAN communication channel is made inaccessible by the malicious node CAN2 by broadcasting random messages on the bus without pause as demonstrated in figure 5, while CAN0 and CAN1 are exchanging information. With the vendor provided code, the legitimate nodes stopped operation and notified about receiving a buffer overflow error as shown in Figure 6.

```

Figure 6 Screenshot demonstrating buffer-overflow occurring at CAN0.

In section 4 we propose a hardware based framework to introduce secure communication over CANBus and provide countermeasure against the discussed attacks.

4. Hardware Based Encryption and Digital Signature Solution

The limited processing power available on the hardware and real time constraints bound the traditional software based cryptographic solutions to provide secure communication. In embedded systems with a software solution, an attacker can extract the executable source code of the device using various methods to reverse engineer cryptographic algorithms and keys[8][9][4].

We propose hardware based secure enhancements to each connected electronic control unit (ECU). The secure framework can be embedded into the processor fabric itself as a co-processor. The hardware design is made to minimize software dependency on the resource scarce devices. Additionally, with incorporation of hardware based obfuscation techniques, reverse engineering attacks or attempts for extraction of keys using hardware based attacks can be further mitigated. The proposed framework requires no secret keys to be stored on non-volatile memory within the nodes/ECUs, thus eliminating the probing attacks.

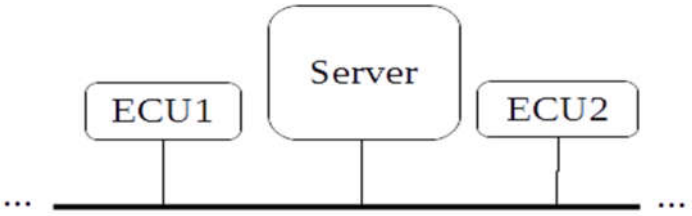

Figure 7 Server locally connected to the nodes.

The security framework is based on client server architecture. A local server node present on the network is responsible for handling all ECU nodes that are joined on the network. Each client must first be registered and authenticated at the server before they can communicate with the other nodes on a network. This process takes place in a secure and trusted environment, referred to as *registration*. Registration can be performed during manufacturing, assembly of vehicle components or at the trusted diagnostic centers. Figure 7 illustrates the local on-board server.

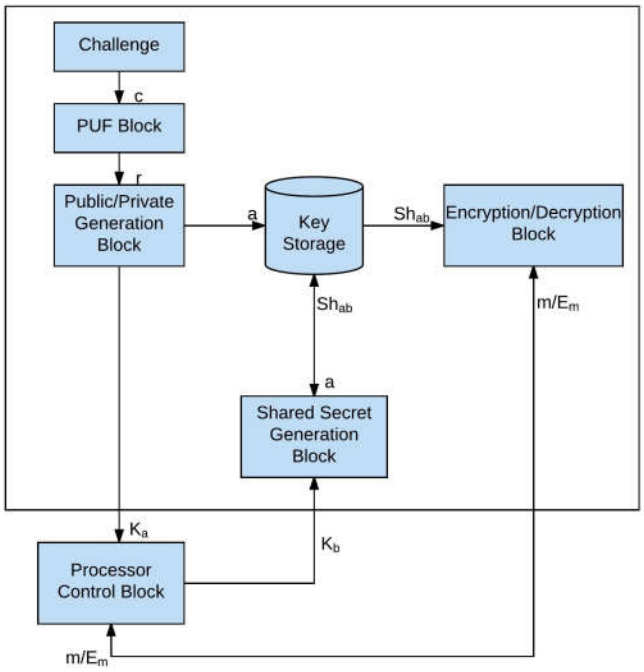

Figure 8 Secure block implemented at each client node.

Figure 8 shows the enhancements and design flow in form of block diagram of each secured ECU. Our framework assumes the server is secure and trusted. Following subsections discuss each of the components and their function in the framework.

4.1. PUF Block

Physical unclonable function (PUF) is an emerging physical layer cryptographic primitive used in hardware security and privacy protocols. These are embedded structures that utilize inherent manufacturing process variations to extract unique but reproducible secrets [10][11]. PUFs are based on a challenge-response pair (CRP) mechanism. The challenge for a PUF is defined as a digital input, usually in the form of a bitstring of '0's and '1's. The output of a PUF is also digital but for most PUFs, this requires an on-chip mechanism to convert the small analog variations leveraged by the PUF to be digitized.

There two different types of PUFs, namely *Weak* and *Strong* PUFs. A major difference between the two is that the weak PUFs have few challenges for which they can uniquely generate a key whereas strong PUFs have a large challenge space and therefore have a unique response for most of the challenges. The bit-

generation for cryptographic applications is a two-step process that is enrollment and registration. During the enrollment process, each PUF is given a set of challenges and the response pairs are recorded. Later when the PUF is in field, these responses are regenerated for use in identification and encryption applications.

During the registration, each ECU produces a unique reproducible response/key that serves as private key. This response is reproduced using the error correction code and is used to generate public private pair. Helper data for reproducing the secrets is stored on the NVM of ECU for the given challenge and public key is communicated to the secure server, where it is stored. PUF based authentication is implemented within vehicle network[11]. All client nodes (or devices) are enrolled at the server before they can be used. The registration process is summarized in Table I.

Table I. Registration of nodes in a trusted environment.

Algorithm: Registration process of client nodes in a trusted environment.
Input: Challenge c, configuration parameters for the ECC curve.
Output: Public key K_a of ECU.
1: At each client node, input a challenge *c* for the PUF Block.
2: PUF block computes a response *r*.
3: Generate a public private key pair (a, K_a) using PUF response r and configuration parameters.
4: K_a for each ECU is stored communicated to server, where it is stored in a public database accessible to every node on the bus.
5: Public key of the server, K_s is stored in non-volatile memory at each client node for later access.

4.2. Private/Public Key Generation Block

We implement Elliptic Curve Cryptography Diffie-Hellman (ECDH) based asymmetric key exchange and encryption engine in hardware. ECC algorithm is suitable for the resource constraint devices, providing same strength of security as RSA. ECC algorithms are implemented in Galois Field(GF) which limit the range of output values and thus reducing the resource requirements. ECC implementations have been presented over two types of Galois Fields, namely Prime Fields (GF(Fp)) and Binary Fields (GF(F2^m)). National Institute of Standards and Technology (NIST) provides a set of recommended elliptic curves (http://csrc.nist.gov/groups/ST/toolkit/documents/dss/NISTReCur.pdf).

This block is used to generate public and private keys for a node. It is used in the one-time registration process (as described in the previous subsection). Based on the reliable PUF response, public and private keys are generated at each ECU during the authentication process that is initiated every time the vehicle starts (turning on of the ignition).

4.3. Authentication and Shared Key Generation Process

During the startup, each connected device requires authentication with the server to enable trusted environment. ECU sends a packet with its own id as target identifier and its public key encrypted with the shared key formed using ECC in the payload. The shared key block is used to generate a shared key between two communicating nodes to have an encrypted communication. At the startup of vehicle each device/ECU, the private key of the current node and the public key of the server, are used in Elliptic curve Diffie-Hellman (ECDH) algorithm for the secret shared key generation. This shared key is used in symmetric key encryption algorithm. All generated keys are stored in the volatile memory for the whole time vehicle is running and requires real time communication.

Server decrypts the payload and compares the public key with the sender ID sent in the arbitration bits. Once the ECU is authenticated, server shares the public keys of the other ECUs the requesting node is allowed to communicate.

Table II. Algorithm for authentication performed at the beginning of each session.

Algorithm: Authentication process.
Input: None.
Output: None.
1: Each ECU generates PUF response r using stored challenge c, and helper data.
2: With *r* as the input to the Public / Private Key Generator Block, generate public and private keys, K_a and *a* respectively.
3: With public key of the server K_s and private key *a*, generate shared symmetric encryption key Sh_{ab} using the Shared Key Generation Block.
4: Encrypt the generated public key K_a with the shared key Sh_{ab}.to form message E_m.
5: Transmit E_m to the server while setting the node ID I_A of the current node as CAN message arbitration ID.
6: At the server, once an encrypted message E_m is received, Server decrypts it using the shared encryption key associated with I_A to get message *m*, which holds the public key of node A, K_a.
7: If K_a received is equal to the K_a stored in the database then consider node A authorized for the rest of the session.
8: Wait for other nodes to register themselves.
9: Server prepares a message for each ECU encrypting with the ECU's shared key containing the public keys of all the registered nodes.
10: Once this message is received at a node, decrypt it using the shared key.
11: Each node communicates with the other nodes and generates session keys using both its private key and other nodes public key.

The authentication process is a timed process. If any node fails to authenticate itself with the server in the time allocated, then it is blacklisted for communication for the entirety of that session. Private keys for all nodes are generated at run time and are not stored to ensure security. No private keys leave the node and are erased at the end of session. Figure 9 illustrates the sequence of communication during authentication of a node.

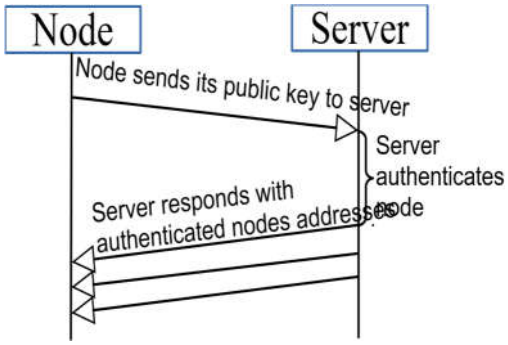

Figure 9 Sequence Diagram for Authentication.

4.4. Key Storage

The key storage block consists of a non-volatile memory (NVM) to store:

- Input challenges to capture unique responses from PUF on each ECU.
- Helper data consists of tuning stages configuration to re-produce PUF response for private key(discussed in the next section).
- Public key K_s of the server for server authentication.
- Parameters to generate public private key pairs.

The framework allows each ECU to generate the private key on fly thus does not require it to be stored in a NVM. Private keys can be stored temporarily in volatile storage along with the shared session keys between ECUs. For each pair of communicating nodes, the following elements are stored in the volatile key storage:

- Sh_{ab}: Generated Shared secret key for encryption for each pair of nodes (a being the source node and b the node being destination node).
- K_b: Public key of the communicating node.

No access is possible to the storage other than to the nodes connected to it.

4.5. Encryption / Decryption Block

Once shared keys are generated for each pair of nodes, these keys can be used for encryption and decryption for the given session. Every message that is sent must first be encrypted before it can be transmitted. Selection of a symmetric key algorithm is dependent on the choice of the system designer, for example an AES-128 engine. The message is sent to the Encryption / Decryption Block that encrypts the message at the sender and decrypts the message at the receiving node using the shared key.

5. Implementation and Performance Analysis

Following section discusses the implementation details of framework and its performance evaluation. Xilinx Kintex KC705 FPGA Evaluation Board is used to implement the design IP with the clock speed of 200 MHz.

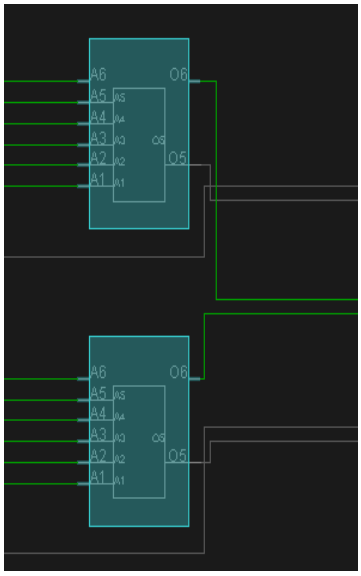

Figure 10 Implementaion of a single PUF stage.

5.1. PUF Implementation

The *Arbiter* PUF is a strong PUF with multiple CRPs that utilizes the process variations in the identical delay lines to generate response bits. The traditional Arbiter PUF implementation is hard to implement on FPGAs because of limited capability on place and route process. This causes systematic bias and the bitstream is not random. An alternative Arbiter PUF implementation is proposed in [12] that utilizes the internal delays of an LUT as a source of entropy for the process variation. The FPGA implementation design details with symmetric delay lines are in further explained in [12].

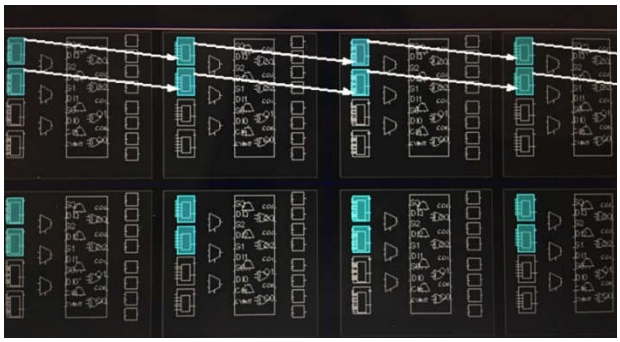

Figure 11 Section of a PUF delay line.

A single stage of the delay line is illustrated in figure 10. The output is a function of A1, where A2 to A6 inputs decides the route of input to output. LUT is configured as an invertor, when the input signal A1 is 0, the output changes to 1 and vice versa. A rising edge is propagated to the first LUT of both upper and lower path that propagated through 64 stages. In our implementation, we have instantiated 16 copies of lower and upper delay lines to produce 16-bit output response for each given challenge. The routing between the stages is shown in Figure 11.

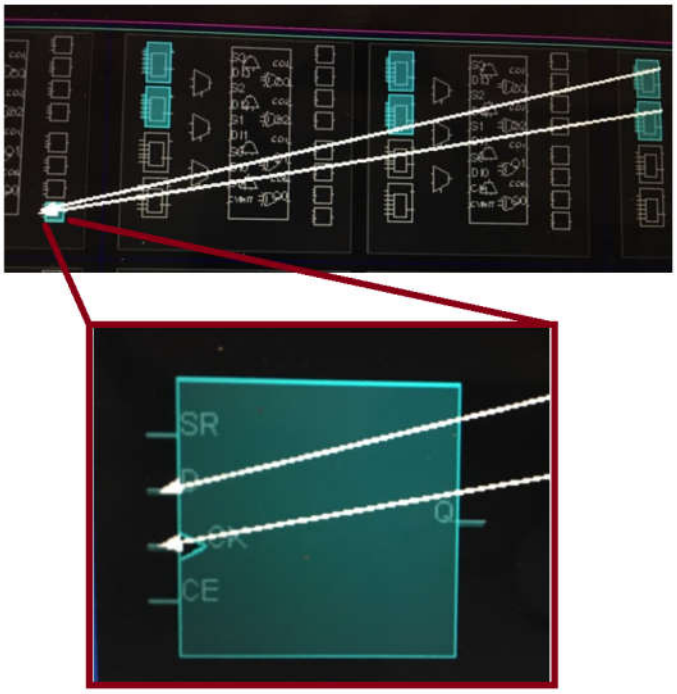

Figure 12 PUF Response stored in DFF.

In order to fine tune the delay difference due to routing, tuning stages are added to the end of the delay lines as described in [12]. Each delay line ends at an arbiter, in our implementation, we are using a D Flip Flop. The difference in the delay caused by the physical variation will result in either capture of a '0' or a '1' based on whether the lower or upper rising edge is reached on the flip-flop clk or D input respectively. The capture stage is illustrated in figure 12. The implementation uses a total of 2416 LUT slices.

5.2. Key Generation Subsystem

ECC engine operating over the binary field GF (2^163)is used [13]. The ECC engine is only used on boot up to generate the public and the shared keys. Figure 13 shows the internal configuration of the ECC core.

The selected implementation of the ECC engine is organized as a pseudo multi-core processor and has a total of three cores for finite field (FF) computation. They are connected using a RISC like instruction controller. For computation of a single point multiplication, the ECC core requires a total of 1428 cycles. Since our target platform is running on 200 MHz, the total time to compute a single multiplication point is 7.14 microseconds. In the process for shared key generation, there is a need for two single point multiplication operations at each node. On our target platform, the ECC core uses a total of 25,454 LUT slices.

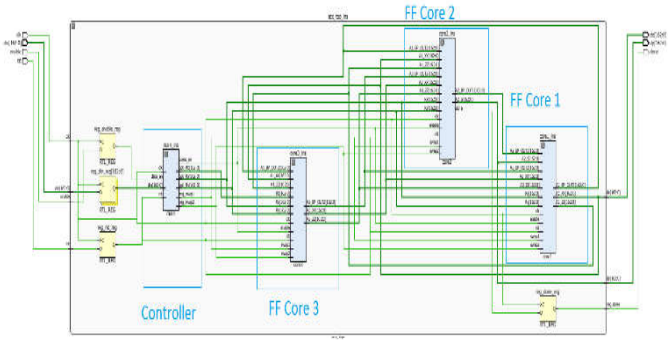

Figure 13 Block Diagram of the ECC Core.

5.3. Encryption/ Decryption

The encryption/decryption module consists of AES-128 for encryption. The AES engine uses the shared key generated by the ECC subsystem to encrypt any traffic leaving the node and decrypt any traffic coming in. AES-128 engine takes a total of 22 clock cycles for encryption and decryption and a total of 110 nanoseconds. The AES engine has a footprint of 2560 LUT slices.

Table III shows a comparison of different block computation speeds at different clock speeds.

Table III. Comparative analysis of block computation speeds at different system clock rates.

	AES-128	FF Multiplication
At 60 MHz	366.66 ns	23.8 µs
At 100 MHz	220 ns	14.28 µs
At 200 MHz	110 ns	7.14 µs

5.4. Storage Elements

For implementing the storage elements of the framework, we are using the FPGA's on-fabric block RAM resources. A block RAM of 128-bit width and 512 elements is instantiated. On our target board, a total of two 36K BRAM elements were used. This memory element has a read and write speed of one cycle.

5.5. Timing Analysis

The framework has system clock speed of 200MHz and CAN speed is 1Mbps. Time for transmitting one bit at the data rate of 1Mbps is 1µs. We are ignoring bit stuffing due to NRZ encoding in our computation. The time required to transmit one data frame is 1 x 108µ = 108 µsecs. Each frame has a total of 64 data bits, to send an AES-128 encrypted 128-bit message, two data frames are required. The total time for transmission for an encrypted message is 108µ x 2 = 216 µsecs.

During Authentication

At the time of boot up, at each node the first the public key is generated using the private key. This process requires one point multiplication operation to be performed in the ECC core. As stated in subsection 5.2, this operation requires a total of 7.14µsecs. Using the stored public key of the server, another point multiplication operation will be required to generate the shared encryption key. Per Table II, this key is encrypted before it is sent to the server. The encryption operation takes 110 ns. Therefore, the total minimum time required from boot-up to sending the server the shared key is:

$$(7.14\mu \times 2) + 110\text{ns} + (2 \times 108\mu) = 230.39\mu\text{s}.$$

For each node that has been authenticated by the server, the server will send a 3-part message (as described in figure 12) to all the connected nodes. The first part contains the node ID of the node authenticated, and the two parts (total of 128 bits) will consist of the encrypted public key of an authenticated node.

Time taken to send these three messages is:

$$108\mu \times 3 = 324\ \mu\text{s}.$$

This process will be repeated for all successfully authenticated nodes.

Since the public key of an authorized node is encrypted in the message, it needs to be decrypted. This process will take another 110 nanoseconds. To generate the shared key for that public key requires another 7.14 µs by the ECC unit.

Receiver ID	ID Packet 1	ID Packet 2

Figure 14 Server's reply to a node after authentication.

During normal operation

During normal operation, CAN message is encrypted, it will take a total of two frames to transmit a message. Table IV gives a message overhead incurred for authentication on CANBus communication operation.

Table IV. Overhead overview at standard can connection speeds.

	125 kbps	500 kbps	1 Mbps
Time for sending one frame	864µs	216µs	108µs
During Authentication			
Node sending encrypted message to server (2 frames)	1.728ms	432µs	216µs
Server's reply (3 frames)	2.592ms	648µs	324µs
Normal Operation			
For a message (2 frames)	1.728ms	432µs	216µs

6. Security Analysis

The proposed framework assumes a secure server, and the legitimate/authorized ECUs are not compromised and does not allow unauthorized code execution. In the proposed framework, the payload of CAN Bus packets are encrypted. There are no private key storage or exchanges in the untrusted field. An ECU node stores only the public key of the server. This makes it difficult for an attacker to retrieve keys through probing or man in the middle attack.

No new device can be added in the field, since the device needs to register with the server in a trusted environment before the server can send the shared key of this node to the other connected ECUs, it must be authenticated. Since the malicious node's public key is not stored in the server, it will not authenticate it and therefore will not communicate its ID with the other nodes. Thus, eliminating backdoors for accessing the network physically. All the nodes have different keys and as such on compromise of a single node, even if an attacker can retrieve a private key from one node, the private key to the other node will still be unknown to the attacker.

In the scenario where an attacker has acquired the public key of a legitimate node on the network or in case of a server database compromise, an adversary can only retrieve the public keys of participating ECUs. Once a communication from the adversary is initiated, the legitimate node will reject it since public key was not initially sent by the server.

7. Conclusion

In this paper, we investigate the threat models of internal vehicular network communication using CANBus. We present a secure framework for authentication and point to point encrypted communication for ECUs. Paper presents the architecture and implementation details and area overhead of FPGA implementation. The hardware based security solution for the resource constraints and time critical applications are viable for the automotive industry.

Rising usage of web applications in every aspect of life has created intense need of enhancement of user experience and formation of intelligent web applications. This research work was conducted with a view to do so. This paper focuses on the reorganization of web application content based on user's specific interests while browsing any web application by providing new algorithms and a new approach.

1. Introduction

This paper is an extension of work originally presented in 19th International Conference on Computer and Information Technology (ICCIT). IEEE, 2016 [1]. The number of users using the internet is rapidly rising with the advancement of the internet as it helps users to find information of their interest with in very short possible time. Compared to the number of internet users in 1995 which was only 1% of world's total population, it has increased up to 40% in recent years. This mass communication media has gained so much popularity that people have been using this on daily basis.

The internet serves its users through web applications and websites. The reasons why web applications have gained so much popularity are given below-

- Zero installation cost
- Reduce business costs
- Reach anybody, anywhere in the world
- 24/7 accessibility
- Access to the latest information

Web applications are being used in medical, banking transactions, online buying selling, online marketing, communication etc. Web application can help doctors to prescribe elder people [2]. With the escalation in number of web applications, the amount of information is increasing. Any kind of web applications have numerous number of contents within it. With large number of contents it is often difficult to satisfy the users. Most of the time users have to go through a large number of information to find out their required information which is leading towards usability problems. To evaluate and improve web applications, usability issue has become an important field of study. Nowadays Facebook, YouTube etc. have become so much popular because of their advanced recommendation systems. In order to solve the usability problem researchers are consistently working on how user experience can be improved. How the user's experience can be improved is described in [3]. This paper focuses on how web application contents can be made more user friendly

through mouse tracking. We propose a generalized approach that will solve any kind of web application's usability problems at the same time improving the user experience.

2. Background

A large number of contents often make it hard for the users to find their items of interest. Solution to this problem is to make user-centered web applications. Developing a user centered web application is not an easy task as it's often very difficult to take user's feedback manually. There have already been many works for knowing user's preferences and expectations automatically without bothering the user [4]. An earlier study [5] shows adaptive navigation mechanisms and illustrates how these can help web applications. The paper [6] focuses on architecture, database design, local concepts, and user interface design for developing content management system. User interest can be predicted by eye tracking [7]. An alternative way for predicting user's engagement can be mouse activity and cursor movement. Mouse activity can be used for web designing to make the user interface more precise for user usage [8]. In our previous work [1] it's described how user-modeling and recommendation by mouse-tracking can be used for the construction of an intelligent e-commerce website. In the previous version of work, we only worked with the registered users of ecommerce websites. We tracked their mouse movement and clicked information for modeling their interest in database. Based on modeled data, we provided them recommendation so that they can easily find their product of interest. In this version of work, we suggested generalized algorithms which will support any kind of web applications. User interest data will be stored in the browser cookie rather than database which will improve the loading time of application and overall performance. More detailed brief of data collection process and content reordering is provided. We have compared some exiting approaches defining their problems and solving those issues with our system. This paper mainly focuses on how web application content can be organized in a manner that responds to user interest. For achieving this goal, this paper will focus on providing algorithms, observe user engagement, find user interest, store data in browser cookie, re-organize the web application contents based on interest data.

3. Overview of Previous Work

Previous approach that was taken earlier was to design a recommendation model based on the interests of users of ecommerce web applications. The overall process was to learn about the interests of users through mouse-tracking, analyze the interest data to create user model and recommend user according to the best match of their interest using. To complete the process, we proposed two algorithms: Modeling Algorithm (MA) & Recommendation Algorithm (RA). Modeling algorithm is used to collect user interests data through some specific button click (like search button, compare button & detail button) and mouse movement over various content. These information are stored in database. Recommendation algorithm uses these data from database and try to find out any matched product from the intersection of clicked data and mouse movement data and provide recommendation based on obtained product/products category/categories. On finding no matched product at first, it checks for maximum clicked data as it reflect more user interest specifically and recommends product according to the category of that/those product/products. If this happens that user have not yet clicked anything, then it checks for maximum mouse movement data and recommends product/products according to this. If both mouse clicked and movement data are null, then it recommends nothing but the default items.

4. Proposed Algorithm

4.1. User Interest Capturing Algorithm (UICA)

UICA or User Interest Capturing Algorithm is used to observe user behavior in a web application to capture user interest and store interest data in browser cookie. A web application has several content section. We mark each of them with id. At first, we find out the type of activity in which user is involved. In our case, there were two possible scenarios. One is button or hyperlink click and the other one is mouse movement over content. Each of the activity is stored in different way (different array for both click information and moue move information) in browser cookie. Whenever this section is clicked or mouse moved over the content for threshold time, we get that id. Figure 1 shows the code snippet how we identified each of the content.

```
<div class="row">
    <div class="col-md-12">
        <div class="content1">
            <div class="main-content" id="1"
                onmouseover="cookied_mousemove_entry(1)"
                onmouseout="cookied_mousemove_exit(1)"
            >
                <p>Some Information</p>
            </div>
            <div class="link content">
                <a href="some_link" id="1"
                    onClick="cookied_click_entry(1)"
                >
                    Some Link
                </a>
            </div>
        </div>
    </div>
</div>
```

Content Type ID for Data Collection

Figure 1 Code snippet of identification of a content

After getting the content id depending on what type of activity user is involved in, we find out whether that item existed in the browser cookie or not. Upon earlier existence we increased the counter of that product. If the item is not already stored in the then we store it in the browser cookie on relevant place (for mouse movement we store the information in cookied_mousemove_data array and for click activity we store the information in cookied_click_data array). Details discussion about the whole process is presented in the implementation section of this paper.

Figure 2 shows the visualization of how mouse data is stored

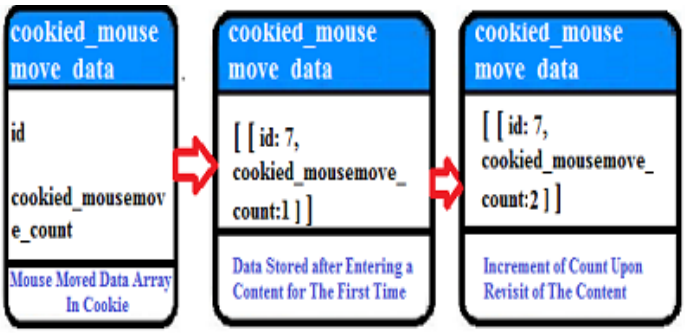

Figure 2 Visualization of how mouse data is stored.

Figure 3 shows User Interest Capturing Algorithm.

```
1.  cookied_data_click_count[ ] ← null;
2.  cookied_mousemove_count [ ] ← null;
3.  value =threshold;
4.  if (btn_or_hyperlink_click ( ) ==true) then
5.     id = get_item_id ( );
6.     existence_confirm = find_item_in_cookie_click_data(id);
7.     if (existence_confirm == false) then
8.        cookied_data_click_count[ count ] = cookied_data_click_count[ count ] +1;
9.     else
10.       cookied_data_click_entry (cookied_data_click_count[ ],    ['id':id,'count':1]);
11. else if (mouse_movement (value) then
12.    id = get_item_id ( );
13.    existence_confirm = find_item_in_cookie_mouse_data(id);
14.    if (existence_confirm == false) then
15.       cookied_mousemove_count [count]=cookied_mousemove_count [ count ] +1;
16.    else
17.       cookied_mousemove_entry (cookied_mousemove_count [ ], ['id':id,'count':1]);
18. else
19.    no_data_enrty ( );
```

Figure 3 User Interest Capturing Algorithm

4.2. Content Reordering Algorithm (CRA)

CRA or Content Reordering Algorithm as the name suggest is used for content reorganization based on browser cookie data which was collected through UICA. The process of reordering is discussed below:

First we get all the mouse moved and content clicked data from browser cookie. We find out the max clicked and max mouse moved item/items id/ids. Assuming that both of the max clicked and mouse moved items are not empty, the system will find out intersection of both information and try to find out related items. Finding upon any related items the content will be reorganized or else default content will be served to the user. If any of the mouse moved and clicked data is empty then the system will find out related items based on the kind of data that was available. When any related item/items is found, then the system will automatically reorganize its content accordingly. If there is no information stored in the cookie both for mouse moved and clicked data than the default content will be displayed. More brief discussion is covered in the Implementation section.

Figure 4 shows Content Reordering Algorithm.

Content Reordering Algorithm (CRA)

```
1.  clicked_data [ ] =  get_cookied_data_click_count();
2.  mouse_movemenet_data [ ] = get_cookied_mousemove_count();
3.  max_clicked_items [ ] = find_max_clicked_items(clicked_data );
4.  max_mouse_moved_items[ ]=find_max_mousemove_items(mouse_movemenet_data);
5.  if(max_clicked_items  !=null && max_mouse_moved_items !=null) then
6.       result = intersection(max_clicked_items ,max_mouse_moved_items );
7.       realated_items_id=get_item_id(result);
8.       if(realated_items_id !=null) then
9.              show_related_items(realated_items_id);
10.      else
11.             no_reordaring();
12.  else
13.      if(max_mouse_moved_items ==null && max_clicked_items != null) then
14.        realated_items_id=get_item_id(max_clicked_items);
15.        if(realated_items_id !=null) then
16 .            show_related_items(realated_items_id);
17.        else
18.             no_reordaring();
19.      else if(max_clicked_items ==null && max_mouse_moved_items != null) then
20.        realated_items_id=get_item_id(max_mouse_moved_items);
21.        if(realated_items_id !=null) then
22 .            show_related_items(realated_items_id);
23.        else
24.             no_reordaring();
25.      else
26.           no_reordaring();
```

Figure 4 Content Reordering Algorithm

5. Proposed Approach for Web Applications

Web applications engage users. Web interfaces that has confusing navigation and huge content bores the user. People often avoid these applications and go elsewhere to perform their tasks. The most challenging task for any web application is how to design so that it can satisfy all of its users. Successful web applications serves appropriate content which stimulate and maintain the users interest, motivation, and attention through relevant and exquisite information related to individual. In short, they ease users enjoyment of their tasks. User engagement (UE) and user experience can help user in judging product quality during interaction [9]. Our approach will solve this problem as discussed in previous section.

For any kind of user-centered application, it is mandatory to know about what each user interested in. User interest is very difficult to find out as it varies with age and culture. Click data can identify user interest [10]. Interest model can be built upon user reading and organizing of documents [11]. Interest of users can be known explicitly or implicitly. Explicit learning includes feedback from users or the rating system. As there is no benefit of giving feedback or rating has no influence on their user experience they may not give any rating [12]. In implicit learning procedure users remain completely unaware of the fact that they are giving information about their liked contents. Mouse scroll movement and time spent any content can be hint of user's interests [13]-[14].

Eye tracking is the best possible way to learn about user interest for this reason human eye has been studied in HCI [15]. The advertising industry, entertainment industry, packaging industry

and web design [16] can be significantly benefited from studying the visual behavior of the user. The automotive, medical and defense industries have also been using eye tracking technology to make us safer. Understanding of how eye moves has become an extremely important consideration in research and design. There are some problems in eye-tracking. They are:

- Eye-tracking equipment's are costly.
- For getting correct data these devices need proper alignment with user's eyes. As user's eye position cannot be fixed to a place as body moves so the task becomes more difficult.
- If one or both eyes do not move smoothly, accurately and quickly across a line or from one object to another it creates problems. This problem includes the inability to fixate (lock one's eyes) onto a single target (like a word on a printed page).
- If a person's word to word eye movement is not tracked precisely then it creates major problems like reading, writing or copying.

The remedy of this problem lies in mouse tracking. As users have to use mouse to interact with any web application, it is the best and most cost effective way to find out user interest from their mouse movement. Earlier studies shows that how mouse movement is related to eye movement [17]-[20]. We would like to mention here that this paper is beyond the debate of the relationship between eye movement and mouse movement. The paper [21] represents an estimation of visual attention on Search Engine Result Pages (SERP) by log-based mouse movement model. This includes snippets, aggregated results and advertisements. The mouse movement and click data can reflect user's behavior while interaction [8], [22], [23]. Previous research shows that user interest can be traced by clicking, reading, hesitating, mouse hovering and scrolling [24]-[27]. Biometric identification can be done by mouse movement [28]. It is essential for any web application to learn whether existing user interface provides support to different kinds of users [29]. The effectiveness, efficiency and usability of the website is improved by the involvement of the users in design and evaluation [30]. In the field of web marketing mouse tracking plays a vital role as it improves user experience in web applications by effective mouse movement and user hesitation levels [31].

Any software usually uses database to store information. Large scale application contains huge number of information offering to its users. In such situation it would not be feasible to use database to store user interest information as it can lead to crash or the application being slow. Other possible way is browser cookies.

User preferences, shopping carts information and anonymous data of third party applications like Google Analytic etc. are retained in cookies. User authentication is made dynamic and validated with the help of browser cookies [32]. Cookies also make user browsing experience better. The paper [33] defines how structured data should be stored in browser.

Continuous growth of web application has led to overload problem both for information and its usage. User often finds it difficult to find their necessary information when it is needed the most [34]-[35]. Recommendation system identifies the problem and comes up with a solution by finding user interest data from large number of contents [35]-[36]. Recommendation systems use details of user's views, opinions, liking, disliking, habits etc. to find out the best match information that is nearly or in some case exactly the same as their interests..

6. Implementation

Implementation steps are followed as below:

6.1. Demo Website

First and the most obvious necessary thing is a website. We developed a e-commerce web application for our testing with an attractive outlook.

6.2. Data Collection

The data were collected from user implicitly. We asked users to visit our system. System will then observed user behavior while interacting with our system and reorganize its contents according to user specific behavior. For knowing user interest we used our User Interest Capturing Algorithm (UICA). The whole process of data collection are described below:.

6.2.1 Click Data Collection: In any kind of interaction with the web application user click is a very important feature. As user is intended to click the things that attracts them most or the things that fulfill their needs, user clicked data were taken into consideration in our content reordering. Our system will check if user have clicked on button or hyperlink or not, if so then it will search for that content in the browser cookie where all clicked data are stored. If any match is found then system will increase the number of click of that item otherwise it will add the content in the clicked data as a new entry. The below figure shows how button click data will be stored in the cookie. Figure 5 how button click data will be stored in the cookie.

6.2.2 Mouse Data Collection: What if user only browses a system without clicking any content? User can only read the summery in this situation. If user mouse enters any specific content over and over again, this indicates that user is interested in that specific content. This also should be taken into consideration while collecting user interest information. Mouse movement data are collected on user's each movement. We defined a threshold time in our case it is 1 sec. If at any time user mouse remains still over a content for the threshold time then we will take that action in our consideration and check if the content is already in the mouse movement data in the cookie. If this happens then we will increase the number of mouse movement data of that item otherwise it will add the content in the mouse movement data as a new entry. Figure 6 shows how user mouse movement data would be stored in the browser cookie.

6.3. Content Reordering

For content reordering our developed system will use Content Reordering Algorithm (CRA). As user mouse may remain still at some content even if user has no interest in that content. This will not provide us with an actual solution. That is why we will mainly focus on user clicked data.

Figure 5 Process of collecting user clicked data.

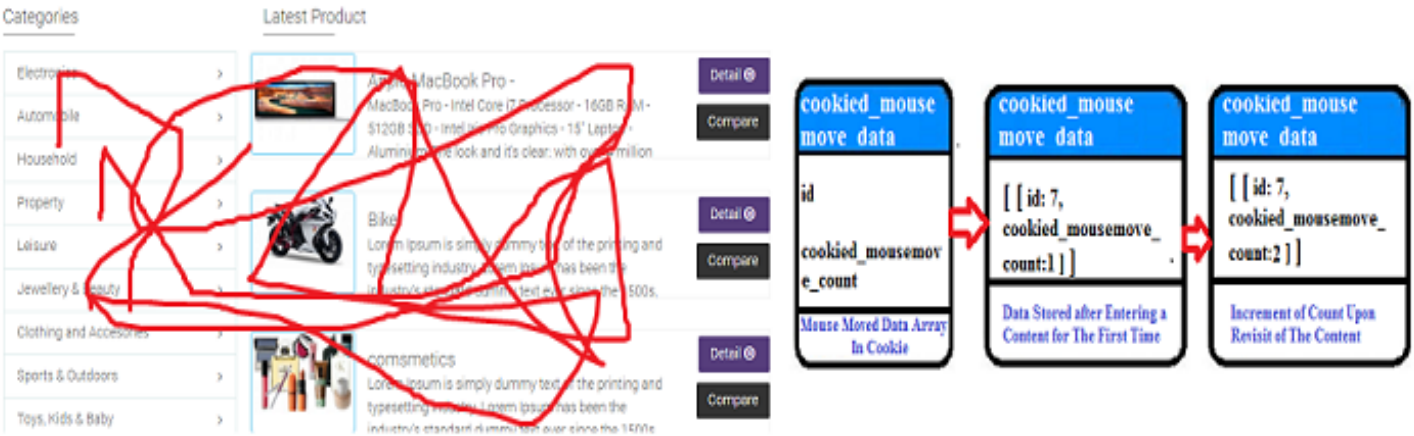

Figure 6 Process of collecting user mouse movement data.

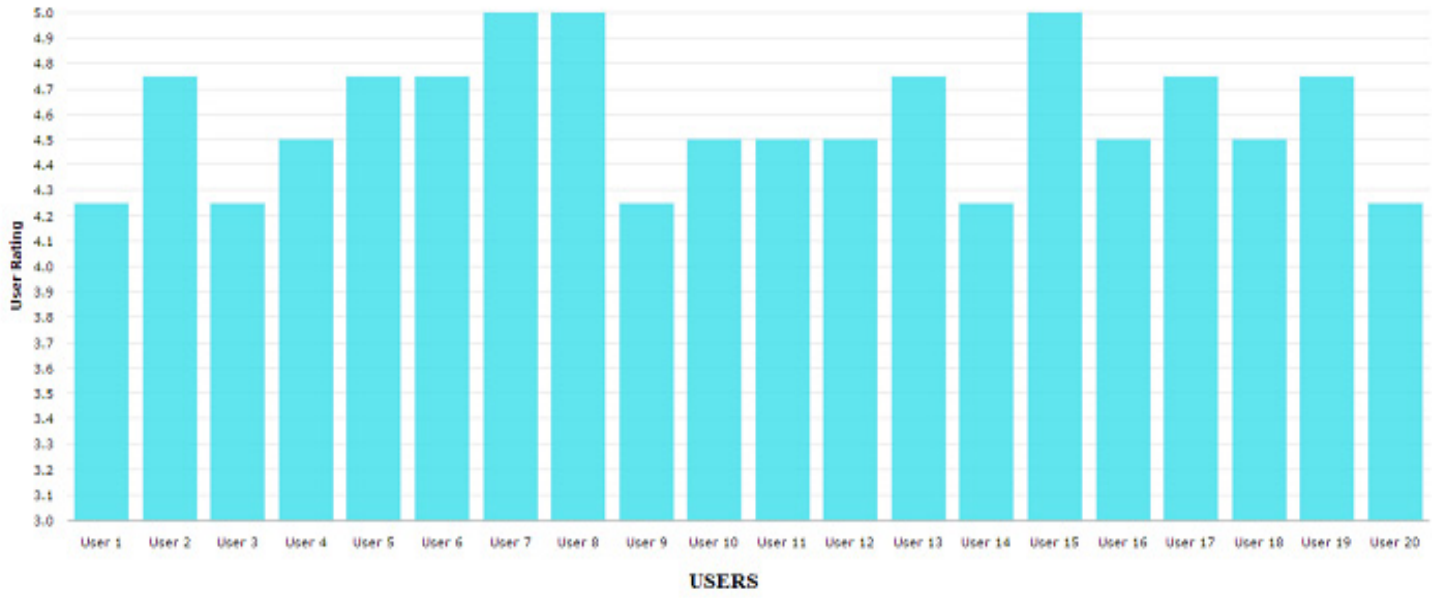
The total process of content reordering is given below in brief:

- First of all the system will get all the clicked and mouse movement data from cookie.
- Finding out the max clicked and max mouse moved items from the cookie is the next step.
- The next step of our procedure is to check whether both of the max clicked and max mouse moved items are empty or not. When this happens the system will then find the intersection of max clicked and max mouse moved items. On finding any item or items then it organizes its contents in manner that responses to the related items to the item or items from the intersection. If it fails to find any item, the system will not change or reorder its contents at all.
- On the failing of above situation system will check out for max clicked items. If it finds one or more item/items then content of the web application will adapt to the situation by reordering its contents.
- Whenever step 3 and step 4 fails then the system will prioritize on the max moused moved items. In the state where the system finds one or more items, then it will reorder its contents related to those item/items. Otherwise, there will be no reordering.
- Lastly if a situation arises that user visits the application for the first time or above step 3, 4, 5 don't provide with the related item/items required then the content will remain the same as it was earlier.

7. Result Analysis

For evaluating our algorithms and data collection process our demo website was put into a web server. That was there for about a month. We asked the visitors to browse our application for 5-10 minutes. By this time using our UICA, we collected user interest data and system adapted to its contents using CRA. We also asked users explicitly about their liking's (contents) in our system for better understanding of the efficiency of our proposed algorithm UICA and CRA.

Over the period of a month data was collected from 120 users of different age and profession. Figure 7 shows rating from anonymous users. Over all findings are quite satisfactory. Rating from user averaged 4.43 out of 5.00.



The system incredibly got accuracy of 91.67% (110 out of 120 users) of serving user according to their interests. Figure 8 shows the accuracy of our evaluation.

For better understanding of our approach we will briefly describe content reorganization for a random specific user among the 120 users. Figure 9 shows the content before user browse our system. The user is a businessman aged around 42 years. He visited our developed e-commerce web application. Figure 10 shows the visualization of his interaction with the system.

While he was interacting with the system, system closely monitor his mouse movement and click on web content. We stored the type id/ids in our case the category of the product both for mouse movement and click in browser. Figure 11 shows how data is stored in user's browser and findings of user interests.

Reorganization of content is done with the help of CRA. Using the algorithm, the system found out that he has mostly visited the electronic goods or clothing type items (type/category id 7 and 15) which was the intersection of mouse moved data and clicked. The system than reorganized its products which were of electronics and clothing (serve products of electronics category first as it has the most count value which was acquired from the sum of click and mouse moved count value). Figure 12 shows the content after reordering based on his interest data stored in the browser cookie.

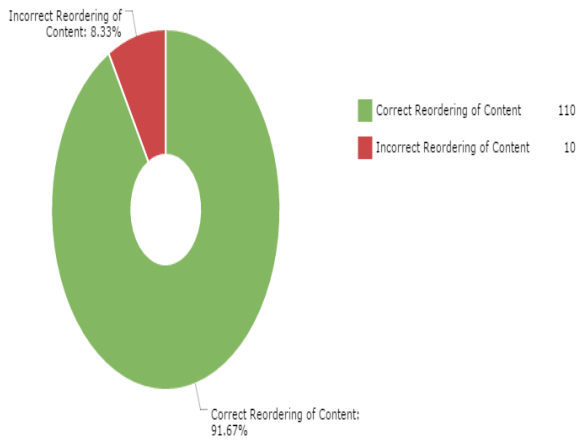


Figure 8 Content reordering accuracy

Figure 9 Content before user browsing

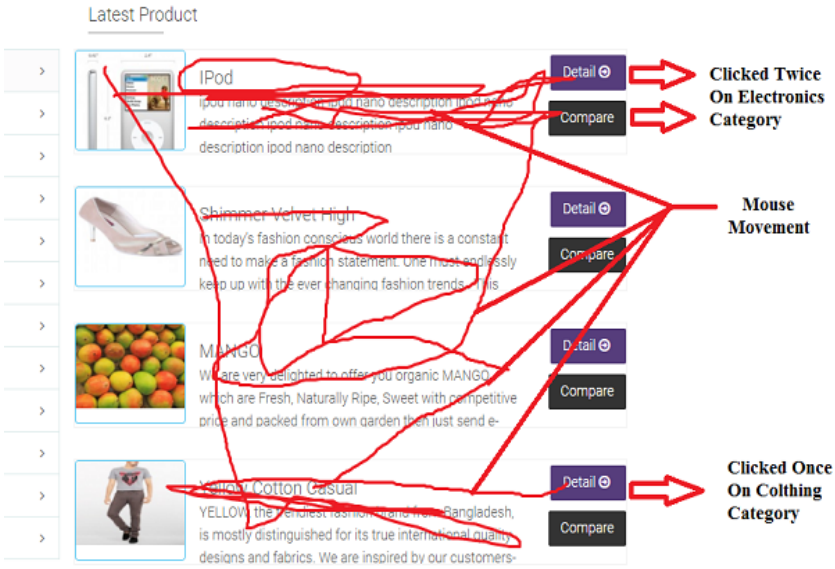

Figure 10 Visulaization of user interaction with the system

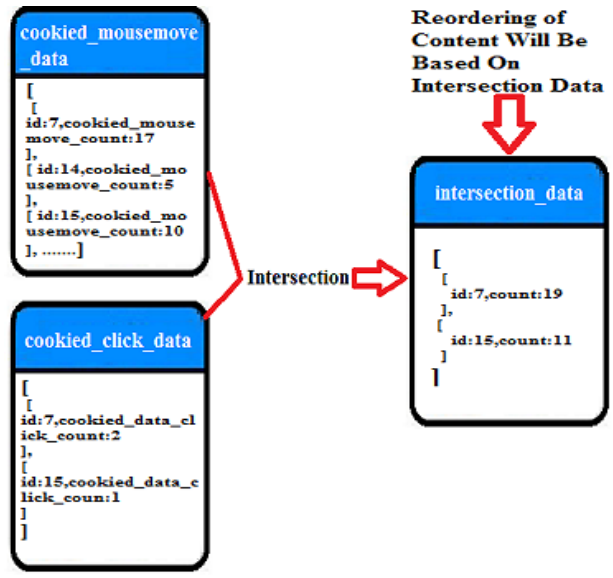

Figure 11 Data storage and user interest finding process

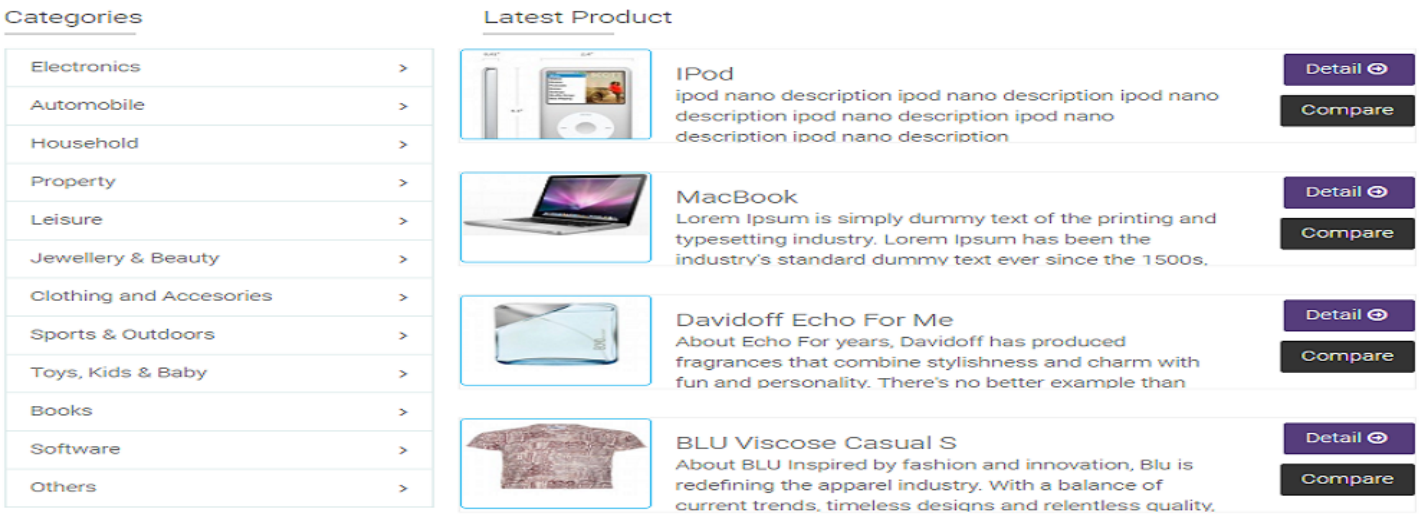

Figure 12 Content after user browsing

At the completion of his browsing we asked him for his experience. He told that he was overwhelmed to see contents being changed almost immediately after his each activity. He gave us rating of 4.75 out of 5.00.

8. Comparative Analysis

The paper [8] introduced mouse movements as an additional layer of information that interprets user interest. In our previous work [1] we implemented the idea. We gave a new approach and algorithms which gives the accuracy of 87.50 %.

Our proposed system [1] solved the problem of e-commerce website by storing registered user interest in database and providing recommendation based on the interest data but can face problem in large scale application if we approach with same approach. With huge number of users the system loading time may increase. This will be quite frustrating for the users. The approach discussed in this paper can solve all the existing problems using our newly given two algorithms UICA, CRA and storing data in browser cookie. This will not affect the performance of the application and there is no need to distinguish between registered or unregistered user anymore. New approach gained accuracy of 91.67% compared to earlier accuracy which was 87.50%. So the accuracy has increased 4.17%. Figure 13 shows the accuracy of different systems.

There was 1.2% improvement in the rating system. Our previous system loading time was 2.8749 sec where new system loads in 2.6531 sec leading to 22.14% improvement of performance. Figure 14 shows the improvement of performance using our new approach.

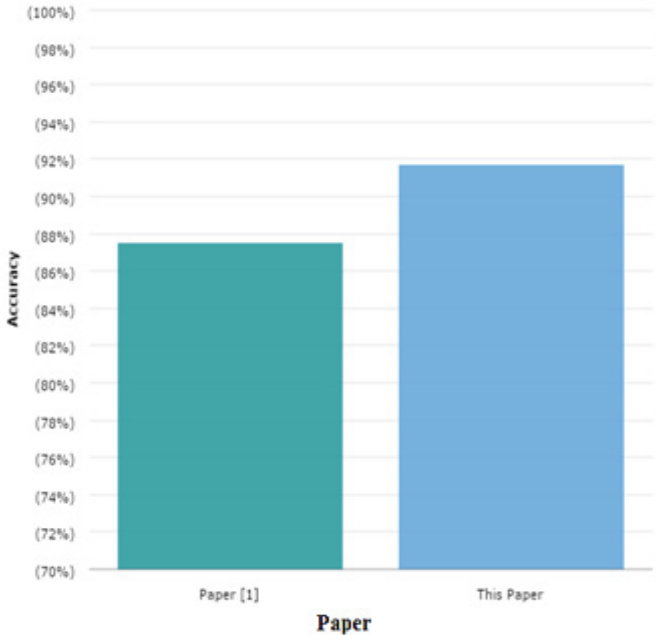

Figure 13 Accuracy comparison graph

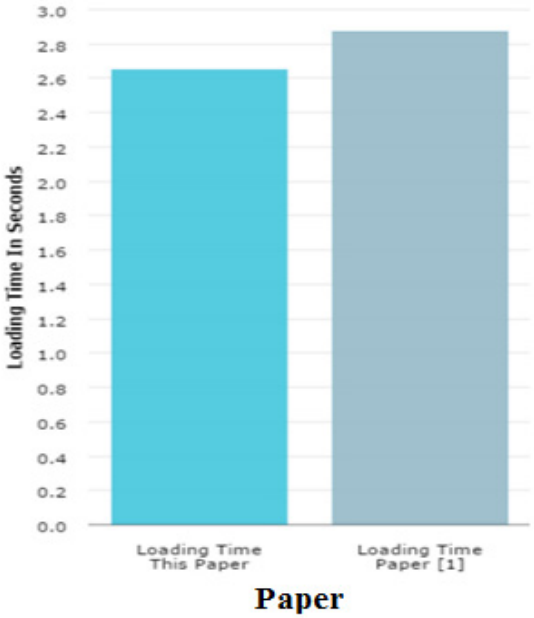

Figure 14 Loading time comparison graph

9. Conclusion

Purpose of this research is to make web applications more user oriented for better interaction and better user experience. Our proposed approach is hassle free as our system will observe user's common actions (mouse movement and click) without bothering them and reorganize its contents according to their needs. This approach can be helpful for both large and small scale web applications. Our system also provided great accuracy in identifying user's interests and reordering its content according to each user interest. We would like to introduce machine learning to raise the accuracy level in future.

Conflict of Interest

The authors declare no conflict of interest.

Bidding strategy

ABSTRACT

Multi-attribute reverse auction is widely used for the procurements of enterprises or governments. To overcome the difficulty of identifying bidding attribute weight and score function of the buyer, the multi-round auction and bidding models with multiple winners are established based on fuzzy data envelopment analysis. The winner determination model of the buyer considers the integrated input-output efficiency of k winners. The bidding strategy of seller is divided into two parts: the first one estimates the weight of the ideal supplier that is thought to be the buyer's preference; the second one is to calculate the weight of the test supplier which reflects the change trend of current weights and the seller's weakness. The final predicted weight is the weighted sum of both. On the basis of known weight, the test supplier can improve his efficiency to increase the winning chance in the next round auction. Our models comprise crisp numbers and fuzzy numbers. Finally, a numerical example verifies the validity of the proposed models.

1. Introduction

This paper is an extension of work originally presented in 2016 31st Youth Academic Annual Conference of Chinese Association of Automation [1].

With the rapid development of network technology and electronic commerce, multi attribute reverse auction has been widely applied to the enterprise or government procurement of goods or services due to saving cost, increasing income and conducting comprehensive assessment of multiple indexes. Especially, online procurement auction plays an important role in E-commerce [2].

In the multi-attribute reverse auction, winner determination problem of the auctioneer and bidding strategies of bidders are two key problems. Many scholars have done a lot of work. At present, there are two main research methods: one is from the perspective of game theory. An optimal auction model was designed with two attributes of price and quality and the best bidding strategy for a bidder was provided where a linear score function was used to evaluate the bids in [3]. This model was extended to an extensive application from different aspects in [4, 5]. A decision support model was used to solve the winner determination problem of the multi-attribute reverse auction in [6]. Another is from the perspective of decision theory. The multi-attribute auction problem based on the technique of order preference was studied in [7]. A fuzzy multi-attribute matching and negotiation mechanism of single round reverse auction with fuzzy numbers was studied in [8]. A PT–BOCR decision method of risk-averse bidders was developed where prospect theory was incorporated into the "benefits, opportunities, costs and risks" framework in [9]. Mathematical programming model was applied for the selection of suppliers in [10]. In [11], the winner determination problem was solved through an evolutionary algorithm of goal programming model.

In all these studies, the score function of supplier evaluation and the weight of bidding attribute need to be predefined ahead of time. But in the real auction process, it is hard to achieve because of complex environment. Furthermore, accurate description of uncertain or vague attributes is another critical issue in practice, especially in a multi-round multi-attribute reverse auction.

Since data envelopment analysis (DEA) was firstly proposed by Charnes in [12], it has been broadly used in various fields. DEA is a nonparametric linear programming method for evaluating the input-output efficiency of decision making unit (DMU) [13]. Thus,

to avoid the difficult of the determination of score function and weight of bidding attribute, DEA is proved to be an advantageous tool in multi-attribute reverse auction. Bogetoft and Nielsen developed a DEA based auction mechanism with asymmetric information and correlated costs [14]. DEA was combined with an integer programming model to elicit preference information of the buyer in [15]. Data envelopment analysis was applied to the selection problem of multi-attribute reverse auction from the perspective of the suppliers in [16]. But all these DEA models are solved under the assumption of the crisp input–output data [17]. However, the input–output data in most auction models are often vague or imprecise in a real world when the auction relates to multiple different attributes. Thus fuzzy DEA provide a powerful tool to solve the vague or imprecise information. Meanwhile, a great of works has already been done in many fields [18–21].

In this paper, by the fuzzy DEA and possibility theory, we develop a winner determination decision model with multiple winners, in which sealed-bid multi-attribute reverse auction can be conducted regularly, that means a multi-attribute multi-round simultaneous auction. From the perspective of unselected supplier, we consider weight information of ideal supplier and winning supplier simultaneously, and predict the possible weight in the next round auction. Under the premise of increasing input-output efficiency, the test supplier will stand a chance to win bids in the next round auction by improving the value of bidding attribute. The developed methods comprise two new characteristics. To begin, Fuzzy numbers are allowed for existence in the multi-attribute reverse auction model. The score function of buyer is not essential to auctioneer and bidders. Moreover, strategies of buyer and sellers are given based on the same principle. The decision of bidding attribute weight is no longer a complicate problem. All the models can be transformed into linear programming problems and it is easy to compute for the practical application.

The rest of this paper is organized as follows: The multi-attribute multi-round reverse auction design is depicted in section 2. In section 3, the winner determination model for the buyer with multiple winners is suggested in view of fuzzy DEA. The bidding model of unselected seller is also presented for the same scene. A numerical example is given to demonstrate the proposed models in section 4. In section 5, the conclusions are presented.

2. Auction Mechanism Design

In this section, the proposed multi-attribute reverse auction mechanism is described and the related application background and conditions are presented.

There exists a buyer and multiple suppliers in the proposed multi-round sealed-bid reverse auction. The single buyer needs to procure the same k indivisible commodities provided by the different k suppliers at regular intervals. All the suppliers want to make a bid to become the winners in each procurement auction. It is similar to a multi-unit multi-round multi-attribute simultaneous auction. When k=1, it is a multi-attribute single–item reverse auction for an indivisible commodity.

In every auction cycle, the buyer first sends the request for quotes which provides the basic demand and requirement for the bidders. For example, the buyer has a minimum or maximum threshold value for bidding attributes. At the same time, the last round winners' quotes information is shared by all the bidders. All the bidders know that the buyer evaluates suppliers mainly through the input-output performance. However, they don't know the true attribute weight. Second, the qualified suppliers, who fulfill the demand and requirement of buyer, submit bids on multiple attributes of procured commodities. And some of attribute value are fuzzy numbers which describe the vague and imprecise information of procured commodity. Here the previous winners' bidding information is a common reference for all the suppliers. Each supplier only has one chance to bid and the submission cannot be revised. Finally, the buyer decides the final k winners according to their integrated input-output efficiencies and declares the corresponding information of the k winning suppliers.

This auction mechanism is common among enterprise and government procurement. Therefore, the decision of strategies of buyer and sellers are significant. In the next section, winner decision making model of buyer and the bidding model of sellers are established respectively.

3. Winner Decision Models of the Buyer

In this section, basic knowledge of fuzzy number and fuzzy DEA is introduced. Then the winner determination model of buyer with multiple winners is proposed based on fuzzy DEA model. At last, the bidding model of sellers is constructed, where the preference weight of buyer and possible weight reflecting the weakness of the seller are reckoned simultaneously.

3.1. Fuzzy Arithmetic and Fuzzy DEA

A fuzzy number is a fuzzy set characterized by a given real number interval, whose value of membership is between 0 and 1. It is often used to describe a vague, imprecise variable or a linguistic variable in a more direct form. The triangular fuzzy number is most commonly used in practice. It is defined by the following membership function $\tilde{\mu}_X(x)$.

$$\tilde{\mu}_X(x)=\begin{cases}(x-x^1)/(x^2-x^1), & x^1<x\le x^2,\\ (x^3-x)/(x^3-x^2), & x^2<x\le x^3,\\ 0, & otherwise,\end{cases} \tag{1}$$

where x, x^1, x^2, x^3 are non-negative and $x^1 \le x^2 \le x^3$ holds. A crisp real number is regarded as a special case of triangular fuzzy number. We usually denote the triangular fuzzy number $\tilde{X}$ as $\tilde{X}=(x^1,x^2,x^3)$.

We denote two triangular fuzzy numbers as $\tilde{X}=(x^1,x^2,x^3)$ and $\tilde{Y}=(y^1,y^2,y^3)$ respectively. Then the fuzzy arithmetic operations on $\tilde{X}$ and $\tilde{Y}$ are defined as follows [19]:

Addition: $\tilde{X}+\tilde{Y}=(x^1+y^1,x^2+y^2,x^3+y^3)$;

Subtraction: $\tilde{X}-\tilde{Y}=(x^1-y^3,x^2-y^2,x^3-y^1)$;

Multiplication: $\tilde{X} \times \tilde{Y} \approx (x^1 y^1, x^2 y^2, x^3 y^3)$;

Division: $\tilde{X} / \tilde{Y} = (\frac{x^1}{y^3}, \frac{x^2}{y^2}, \frac{x^3}{y^1})$.

Fuzzy DEA model has the following primal linear programming statement for the CCR model [18].

$$Max \quad \sum_{r=1}^{s} u_r \tilde{y}_{r0}$$

$$s.t. \quad \sum_{r=1}^{s} u_r \tilde{y}_{rj} - \sum_{i=1}^{m} v_i \tilde{x}_{ij} \le 0, \; j = 1,2,\cdots,n$$

$$\sum_{i=1}^{m} v_i \tilde{x}_{i0} = 1 \tag{2}$$

$$v_i, u_r \ge 0, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

where the subscript 0 is the decision making unit(DMU) under the evaluation. When input and output data of (2) are be characterized by positive triangular fuzzy numbers $\tilde{x}_{ij} = (x_{ij}^1, x_{ij}^2, x_{ij}^3)$ and $\tilde{y}_{ij} = (y_{rj}^1, y_{rj}^2, y_{rj}^3)$ including crisp input and output data as a special case of triangular numbers, we can obtain the following fuzzy DEA model.

$$Max \quad \tilde{E}_0 \approx (e_0^1, e_0^2, e_0^3) = (\frac{\sum_{r=1}^{s} u_r y_{r0}^1}{\sum_{i=1}^{m} v_i x_{i0}^3}, \frac{\sum_{r=1}^{s} u_r y_{r0}^2}{\sum_{i=1}^{m} v_i x_{i0}^2}, \frac{\sum_{r=1}^{s} u_r y_{r0}^3}{\sum_{i=1}^{m} v_i x_{i0}^1})$$

$$s.t. \quad (\frac{\sum_{r=1}^{s} u_r y_{rj}^1}{\sum_{i=1}^{m} v_i x_{ij}^3}, \frac{\sum_{r=1}^{s} u_r y_{rj}^2}{\sum_{i=1}^{m} v_i x_{ij}^2}, \frac{\sum_{r=1}^{s} u_r y_{rj}^3}{\sum_{i=1}^{m} v_i x_{ij}^1}) \le 1 \tag{3}$$

$$v_i, u_r \ge 0, i = 1,2,\cdots,m; r = 1,2,\cdots,s; j = 1,2,\cdots,n$$

where $\tilde{E}_0$ represents the fuzzy efficiency of DMU0 under evaluation and it is also a triangular fuzzy number. In accordance with the existing method, (3) can be transformed into the following three linear programming models [19].

$$Max \quad e_0^1 = \sum_{r=1}^{s} u_r y_{r0}^1$$

$$s.t. \quad \sum_{i=1}^{m} v_i x_{i0}^3 = 1 \tag{4}$$

$$\sum_{r=1}^{s} u_r y_{rj}^3 - \sum_{i=1}^{m} v_i x_{ij}^1 \le 0, j = 1,2,\cdots,n,$$

$$v_i, u_r \ge 0, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

$$Max \quad e_0^2 = \sum_{r=1}^{s} u_r y_{r0}^2$$

$$s.t. \quad \sum_{i=1}^{m} v_i x_{i0}^2 = 1,$$

$$\sum_{r=1}^{s} u_r y_{rj}^3 - \sum_{i=1}^{m} v_i x_{ij}^1 \le 0, j = 1,2,\cdots,n \tag{5}$$

$$v_i, u_r \ge 0, i = 1,2,\cdots,m; r = 1,2,\cdots,s$$

$$Max \quad e_0^3 = \sum_{r=1}^{s} u_r y_{r0}^3$$

$$s.t. \quad \sum_{i=1}^{m} v_i x_{i0}^1 = 1,$$

$$\sum_{r=1}^{s} u_r y_{rj}^3 - \sum_{i=1}^{m} v_i x_{ij}^1 \le 0, j = 1,2,\cdots,n \tag{6}$$

$$v_i, u_r \ge 0, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

The fuzzy efficiency of each DMU is derived from the above models. All the DMUs are ranked according to efficiencies of the above objective value.

A variety of methods are proposed to compare fuzzy number, we use the preference degree approach to rank the fuzzy numbers [19]. Let $\tilde{X} = (x^1, x^2, x^3)$ and $\tilde{Y} = (y^1, y^2, y^3)$ be two triangular fuzzy numbers, then the degree of preference of $\tilde{X} > \tilde{Y}$ is defined as follows.

$$r_{\tilde{X}>\tilde{Y}} = \frac{S_{\tilde{X}>\tilde{Y}}}{S_{\tilde{X}>\tilde{Y}} + S_{\tilde{Y}>\tilde{X}}}$$

$$= \begin{cases} 1, & x^1 \ge y^3 \\ 0, & x^3 \le y^1 \\ \dfrac{(x^3 - y^1)^2}{(x^3 - y^1 + y^2 - x^2)(x^3 - x^1 + y^3 - y^1)}, & if \; x^2 \le y^2, x^3 > y^1 \\ 1 - \dfrac{(y^3 - x^1)^2}{(y^3 - x^1 + x^2 - y^2)(x^3 - x^1 + y^3 - y^1)}, & if \; x^2 > y^2, x^1 < y^3 \end{cases}$$

where $S_{\tilde{X}>\tilde{Y}}$ represents the area of $\tilde{X} > \tilde{Y}$ in the imagine of membership function of $\mu_{\tilde{X}-\tilde{Y}}(x)$ and $S_{\tilde{X}<\tilde{Y}}$ represents the area of $\tilde{X} < \tilde{Y}$ in the imagine of membership function of $\mu_{\tilde{X}-\tilde{Y}}(x)$. From the definition of the degree of preference $r_{\tilde{X}>\tilde{Y}}$, we know that $r_{\tilde{X}>\tilde{Y}} + r_{\tilde{X}<\tilde{Y}} = 1$. In general, if $r_{\tilde{X}>\tilde{Y}} > r_{\tilde{Y}>\tilde{X}}$, we think that $\tilde{X}$ is bigger than $\tilde{Y}$ and if $r_{\tilde{X}>\tilde{Y}} < r_{\tilde{Y}>\tilde{X}}$, we think that $\tilde{X}$ is smaller than $\tilde{Y}$. When $r_{\tilde{X}>\tilde{Y}} = r_{\tilde{Y}>\tilde{X}} = 0.5$, $\tilde{X}$ is indifferent to $\tilde{Y}$.

Based on the degree of preference, we can compare any two fuzzy numbers, and then a complete priority order of fuzzy

efficiencies of suppliers can be obtained in the following multi-attribute reverse auction.

3.2. Auction Models of the buyer with Multiple Winners

In the multi-attribute reverse auction, multiple attributes of procured commodity may be vague or imprecise which cannot be impressed by the crisp real numbers. For example, the design level of a commodity, the reputation of a seller and so forth. It is necessary to consider the evaluation problem of suppliers with fuzzy attribute data. Thus, on the base of the fuzzy DEA theory, we construct a winner determination model of multi-attribute reverse auction with multiple winners from the perspective of buyer.

As we need to determine k winners once in an auction, total input-output efficiency of selected k suppliers is taken for the objective function. After adding some appropriate constraints, (3) can be transformed into the following three linear programming models to determine the final k winners of multi-attribute reverse auction.

$$Max \quad \tilde{E} = (e^1, e^2, e^3) = \left(\frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^1}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^3}, \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^2}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^2}, \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^3}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^1}\right)$$

$$s.t. \quad \left(\frac{\sum_{r=1}^{s} u_r y_{rj}^1}{\sum_{i=1}^{m} v_i x_{ij}^3}, \frac{\sum_{r=1}^{s} u_r y_{rj}^2}{\sum_{i=1}^{m} v_i x_{ij}^2}, \frac{\sum_{r=1}^{s} u_r y_{rj}^3}{\sum_{i=1}^{m} v_i x_{ij}^1}\right) \le 1 \qquad (7)$$

$$\left(\frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^1}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^3}, \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^2}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^2}, \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^3}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^1}\right) \le 1$$

$$U_1 u_p \le u_i \le U_2 u_p, \quad 0 < U_1 < U_2 \in R^+$$

$$V_1 v_q \le v_r \le V_2 v_q, \quad 0 < V_1 < V_2 \in R^+$$

$$v_i, u_r \ge \varepsilon, i = 1,2,\cdots,m; r = 1,2,\cdots,s; j = 1,2,\cdots,n,$$

where $\tilde{E} = (e^1, e^2, e^3)$ is the optimal fuzzy efficiency of the combination $(j_1, j_2, \cdots, j_k)$ of k suppliers, compared with the previous fuzzy DEA model. Here the input and output are the total sum of k suppliers respectively. U_1, U_2, V_1, V_2 are the proportional coefficients of preference of the buyer corresponding to the inputs and outputs. They indicate the relative preference of the buyer for the different attributes, and $\varepsilon > 0$, which ensures nonzero solution of weight in (7).

Similarly, (7) can also be transformed into the following three linear programming models.

$$Max \quad e^1 = \sum_{r=1}^{s} u_r \left(\sum_{t=1}^{k} y_{rj_t}^1\right)$$

$$s.t. \quad \sum_{i=1}^{m} v_i \left(\sum_{t=1}^{k} x_{ij_t}^3\right) = 1,$$

$$\sum_{r=1}^{s} u_r \left(\sum_{t=1}^{k} y_{rj_t}^3\right) - \sum_{i=1}^{m} v_i \left(\sum_{t=1}^{k} x_{ij_t}^1\right) \le 1 \qquad (8)$$

$$\sum_{r=1}^{s} u_r y_{rj}^3 - \sum_{i=1}^{m} v_i x_{ij}^1 \le 0, \quad j = 1,2,\cdots,n$$

$$U_1 u_p \le u_i \le U_2 u_p, \quad 0 < U_1 < U_2 \in R^+$$

$$V_1 v_q \le v_r \le V_2 v_q, \quad 0 < V_1 < V_2 \in R^+$$

$$v_i, u_r \ge \varepsilon, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

$$Max \quad e^2 = \sum_{r=1}^{s} u_r \left(\sum_{t=1}^{k} y_{rj_t}^2\right),$$

$$s.t. \quad \sum_{i=1}^{m} v_i \left(\sum_{t=1}^{k} x_{ij_t}^2\right) = 1$$

$$\sum_{r=1}^{s} u_r \left(\sum_{t=1}^{k} y_{rj_t}^3\right) - \sum_{i=1}^{m} v_i \left(\sum_{t=1}^{k} x_{ij_t}^1\right) \le 1 \qquad (9)$$

$$\sum_{r=1}^{s} u_r y_{rj}^3 - \sum_{i=1}^{m} v_i x_{ij}^1 \le 0, j = 1,2,\cdots,n,$$

$$U_1 u_p \le u_i \le U_2 u_p, \quad 0 < U_1 < U_2 \in R^+$$

$$V_1 v_q \le v_r \le V_2 v_q, \quad 0 < V_1 < V_2 \in R^+$$

$$v_i, u_r \ge \varepsilon, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

$$Max \quad e^3 = \sum_{r=1}^{s} u_r \left(\sum_{t=1}^{k} y_{rj_t}^3\right)$$

$$s.t. \quad \sum_{i=1}^{m} v_i \left(\sum_{t=1}^{k} x_{ij_t}^1\right) = 1,$$

$$\sum_{r=1}^{s} u_r \left(\sum_{t=1}^{k} y_{rj_t}^3\right) - \sum_{i=1}^{m} v_i \left(\sum_{t=1}^{k} x_{ij_t}^1\right) \le 1 \qquad (10)$$

$$\sum_{r=1}^{s} u_r y_{rj}^3 - \sum_{i=1}^{m} v_i x_{ij}^1 \le 0, \quad j = 1,2,\cdots,n$$

$$U_1 u_p \le u_i \le U_2 u_p, \quad 0 < U_1 < U_2 \in R^+$$

$$V_1 v_q \le v_r \le V_2 v_q, \quad 0 < V_1 < V_2 \in R^+$$

$$v_i, u_r \ge \varepsilon, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

Calculate the above three linear programming models, the optimal fuzzy efficiency of multiple winners can be obtained and the corresponding k winners are determined.

3.3. Bidding Models of Sellers

In the proposed multi-attribute procurement auction, the attribute value of winning suppliers is the common knowledge in each period. A seller knows that the input-output efficiency of suppliers is the principal index that the buyer evaluates a supplier. In this specific context, the only available information is the bidding attribute values of k winners and the seller's own quote. The seller thinks the accurate weight value of bidding attributes of procured commodity is affected by the following two aspects: one is the preference of the buyer which can be characterized by the weight of the ideal supplier; the other is the current impact which can be described by the weight of the unselected supplier reflecting his weakness. The predicted weight in the next round auction can be seen as a weighted sum of above two parts after being introduced a weighting factor. In view of the above two points, (11) and (12) are established to compute the preference weight of buyer and the current possible weights respectively.

$$Max \quad \tilde{E}_* = (e_*^1, e_*^2, e_*^3) = \left(\frac{\sum_{r=1}^{s} u_r y_{r*}^1}{\sum_{i=1}^{m} v_i x_{i*}^3}, \frac{\sum_{r=1}^{s} u_r y_{r*}^2}{\sum_{i=1}^{m} v_i x_{i*}^2}, \frac{\sum_{r=1}^{s} u_r y_{r*}^3}{\sum_{i=1}^{m} v_i x_{it*}^1}\right)$$

$$s.t. \quad \left(\frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^1}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^3}, \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^2}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^2}, \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^3}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^1}\right) \le 1 \qquad (11)$$

$$\left(\frac{\sum_{r=1}^{s} u_r y_{r*}^1}{\sum_{i=1}^{m} v_i x_{i*}^3}, \frac{\sum_{r=1}^{s} u_r y_{r*}^2}{\sum_{i=1}^{m} v_i x_{i*}^2}, \frac{\sum_{r=1}^{s} u_r y_{r*}^3}{\sum_{i=1}^{m} v_i x_{it*}^1}\right) \le 1$$

$$\left(\frac{\sum_{r=1}^{s} u_r y_{rd}^1}{\sum_{i=1}^{m} v_i x_{id}^3}, \frac{\sum_{r=1}^{s} u_r y_{rd}^2}{\sum_{i=1}^{m} v_i x_{id}^2}, \frac{\sum_{r=1}^{s} u_r y_{rd}^3}{\sum_{i=1}^{m} v_i x_{id}^1}\right) \le 1$$

$$U_1^d u_p \le u_i \le U_2^d u_p, \quad 0 < U_1^d < U_2^d \in R^+$$

$$V_1^d v_q \le v_r \le V_2^d v_q, \quad 0 < V_1^d < V_2^d \in R^+$$

$$v_i, u_r \ge \varepsilon, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

where supplier * is the ideal supplier, that is the best supplier among all the bidders. It is obtained in the ways listed below. First, let $x_{ij}^* = \min_j \{x_{ij}\}$, then we get the m input data of the ideal supplier; Second, suppose $y_{ij}^* = \max_j \{y_{ij}\}$, the s output data are also decided.

When the bidding attribute values are triangular fuzzy numbers, the degree of preference is used to compare them. The ideal supplier * is an optimal result for the selected suppliers which includes minimum input variables and maximum output variables. Supplier d is the test supplier who is not selected in the auction. Furthermore, $U_1^d, U_2^d, V_1^d, V_2^d$ are the proportional coefficients of preference of the buyer that are predicted by the supplier d, in view of calculation results of previous weights and his own experience.

The first constrain means the integrated efficiency of k winning suppliers is less and equal to1. The second and third constrains make the efficiencies of the ideal supplier and test supplier fall in the interval [0, 1].

$$Min \quad \tilde{E}_d = (e_d^1, e_d^2, e_d^3) = \left(\frac{\sum_{r=1}^{s} u_r y_{rd}^1}{\sum_{i=1}^{m} v_i x_{id}^3}, \frac{\sum_{r=1}^{s} u_r y_{rd}^2}{\sum_{i=1}^{m} v_i x_{id}^2}, \frac{\sum_{r=1}^{s} u_r y_{rd}^3}{\sum_{i=1}^{m} v_i x_{id}^1}\right)$$

$$s.t. \quad \frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^3}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^1} \le 1 \qquad (12)$$

$$\frac{\sum_{t=1}^{k}\sum_{r=1}^{s} u_r y_{rj_t}^1}{\sum_{t=1}^{k}\sum_{i=1}^{m} v_i x_{ij_t}^3} \ge \hat{e}$$

$$\left(\frac{\sum_{r=1}^{s} u_r y_{rd}^1}{\sum_{i=1}^{m} v_i x_{id}^3}, \frac{\sum_{r=1}^{s} u_r y_{rd}^2}{\sum_{i=1}^{m} v_i x_{id}^2}, \frac{\sum_{r=1}^{s} u_r y_{rd}^3}{\sum_{i=1}^{m} v_i x_{id}^1}\right) \le 1$$

$$U_1^d u_p \le u_i \le U_2^d u_p, \quad 0 < U_1^d < U_2^d \in R^+$$

$$V_1^d v_q \le v_r \le V_2^d v_q, \quad 0 < V_1^d < V_2^d \in R^+$$

$$v_i, u_r \ge \varepsilon, i = 1,2,\cdots,m; r = 1,2,\cdots,s.$$

where $\hat{e}$ is given by the test supplier. The first two inequalities ensure the efficiency of k winners falls in the interval [$\hat{e}$, 1], where it is considered to be optimal objective value that makes k suppliers become the final winners. In (11), the final weight solution vector is written as $\vec{S}^* = (u_1^*, u_2^*, \cdots, u_s^*, v_1^*, v_2^*, \cdots, v_m^*)$. Solve the linear programming model (12), we can obtain another weight vector $\vec{S}^d = (u_1^d, u_2^d, \cdots, u_s^d, v_1^d, v_2^d, \cdots, v_m^d)$ which reflects the current change trend of weight and the weakness of the test supplier d.

In the auction process, inexact information and random factors are allowed. When including fuzzy data, (11) and (12) can be transforms into three linear programming models to compute the final fuzzy efficiency, three weight vectors will be obtained corresponding to the $\tilde{E}_* = (e_*^1, e_*^2, e_*^3)$ or $\tilde{E}_d = (e_d^1, e_d^2, e_d^3)$ respectively. Here we take $\vec{S}^*$ corresponding to e_2^* , and $\vec{S}^d$ corresponding to e_2^d since the middle bound value of a fuzzy number means the maximum possibility. Given a weighting factor δ , the predicted weight is written as follows

$$\vec{S} = \delta \vec{S}^* + (1-\delta)\vec{S}^d, \quad \delta \in [0,1] \qquad (13)$$

where a seller can select a appropriate weighting factor δ to describe the change trend of attribute weight in the next round auction.

Once the next period weight of bidding attributes is given, we can calculate the efficiencies of the k winning suppliers in the next auction when they do not change their bidding strategies. Because the efficiency of the supplier is a triangular fuzzy number, our goal is to make the lower bound of fuzzy efficiency of the test supplier is greater than or equal to the middle bound of fuzzy efficiency of one or more winning suppliers through adjusting bidding attribute values properly. Then the test supplier will have the opportunity to become the winner in the next round auction.

4. Numerical Example

In this section, an application of the established models is be demonstrated by the following datasets of bidding attribute value of suppliers. An enterprise need to purchase two new machines for production from two different suppliers regularly. There is a trade-off among price, delivery performance, quality and design in the multiple period auctions. The price of procured machine is expressed in thousand dollars and quality is expressed in percentage of qualified products manufactured by this type of machine. Delivery performance is expressed by days of service and it is a triangular fuzzy number. Design is a linguistic variable and it is expressed by a symmetric triangular fuzzy number. Specific bidding attribute data of five suppliers in the third round auction are shown in Table 1.

Table 1 Bidding attribute value of the suppliers

Supplier (DMUs)	Inputs		Outputs	
	Price ($)	Delivery	Quality (%)	Design
1	48	(32,36,40)	96	(90,95,100)
2	46.5	(36,38,41)	99	(85,90,95)
3	47.5	(34,37,41)	97	(80,85,90)
4	46	(34,36,38)	97	(85,90,95)
5	47	(35,38,41)	98	(90,95,100)

First, the buyer need determine the winners using (8), (9) and (10). Conforming to specification of models, we assumed that the weight of quality is somewhere between two and three times than the weight of design. This constrain condition reflects the inexact preference of the buyer for quality and design. It is easier to describe this kind of imprecise information than to give an exact result in practice. At the same time, the buyer thinks $\varepsilon \geq 0.001$.

Because only two suppliers of five will become the final winners, efficiencies of 10 groups of suppliers need to be compared, and it is shown in Table 2. We use previously introduced degree of preference to rank them, supplier 2 and supplier 5 will be the final winners.

Table 2 Fuzzy efficiencies of suppliers with two winners

Suppliers	Efficiency	Suppliers	Efficiency
{1,2}	(0.9465,0.9657,0.9938)	{2,4}	(0.9649,0.9825,0.9978)
{1,3}	(0.9238,0.9440,0.9835)	{2,5}	**(0.9615,0.9809, 1)**
{1,4}	(0.9465,0.9639, 1)	{3,4}	(0.9414,0.9725,0.9835)
{1,5}	(0.9434,0.9644, 1)	{3,5}	(0.9384,0.9585,0.9818)
{2,3}	(0.9415,0.9607,0.9793)	{4,5}	(0.9616,0.9802, 1)

Then we use (11) and (12) to analysis the data of the test supplier and the winning suppliers for three auction cycles in Table 3 and Table 4. From the perspective of an unselected supplier, we need to determine his bidding strategy in the next phase.

Table 3 Bidding attribute value of the winning supplier 1

Period	Attributes of winner 1			
	Price	Delivery	Quality	Design
1	46	(34,36,37)	98	(85,90,95)
2	47	(33,35,38)	97	(75,80,85)
3	**46.5**	**(36,38,41)**	**99**	**(85,90,95)**

Table 4 Bidding attribute value of the winning supplier 2

Period	Attributes of winner 2			
	Price	Delivery	Quality	Design
1	47	(36,39,41)	98	(85,90,95)
2	46.5	(36,38,41)	99	(85,90,95)
3	**47**	**(35,38,42)**	**98**	**(90,95,100)**

Supplier 4 isn't selected in the third round auction, thus supplier 4 is taken as the test supplier. In Table 1, we know that his bidding attribute value is 46, (34, 36, 38), 97 and (85, 90, 95) in the third round auction. The ideal supplier's bidding attribute value is 46, (34, 36, 37), 99 and (90, 95, 100) respectively (as shown in Table 3). The comparisons of fuzzy numbers are based on the degree of preference when calculating the bidding attribute value of the ideal supplier. Furthermore, in view of supplier 4's experience, the weight of quality is somewhere between two and four times than the weight of design.

Computing the linear programming models (11) and (12), we obtain the efficiency of the ideal supplier is $\tilde{E}_* = (0.9769, 0.9879, 1)$ and the efficiency of test supplier is $\tilde{E}_d = (0.9342, 0.9663, 0.9898)$ which also indicate how ineffective the test supplier 4 is. We take the solution vectors of the middle value of above two triangular fuzzy numbers as the preference weight of the buyer and the current possible weight. They are weight vectors $\vec{S}^* = (0.0080, 0.0020, 0.021, 0.0010)$ and $\vec{S}^d = (0.0081, 0.0020, 0.0125, 0.0118)$. Let $\delta = 0.3$, we obtain the predicted weight is $\vec{S} = (0.0081, 0.0020, 0.0150, 0.0086)$. It is noted that δ is decided by the test supplier which reflects his understanding to the future change trend of weights. The derived weight $\vec{S}$ is regarded as attribute weight for the next round auction. Because the winning suppliers don't change the bidding strategies, upon the new attribute weight, the middle bound value of supplier 2's efficiency is 0.9586 and the middle bound value of supplier 5's efficiency is 0.9535. At present, supplier 4 need improve his bidding attribute value to make the lower bound value of his efficiency is greater or equal to 0.9535 at least. For example, suppose quality and design is hard to revise, we might cut down the bidding value of input attributes. Let price is 45 and the others are unchanged, the lower bound value of efficiency of supplier 4 raises to 0.9590 that is greater than the middle bound value of supplier 5's efficiency. Moreover, let delivery performance is (34, 36, 36), and the lower bound value of supplier 4's efficiency is 0.9561 which also meets the requirement. Here the test supplier

has great flexibility to change bid attribute value to be competitive in the fourth round auction.

5. Conclusions

Multi-attribute reverse auction is widely used in the procurement of enterprise and government. In this paper, a winner determination model of the buyer and a bidding model of the sellers are proposed with multiple winners in the multi-attribute multi-round reverse simultaneous auction. The bidding attribute value can be a real number or a triangular fuzzy number which describes the vague or inaccurate information. Basing on the fuzzy DEA theory, we construct a winner determination model with multiple winners for the buyer to compare the overall efficiency of k winners. The k suppliers with the highest efficiency are the final winners. From the unselected seller's view, the weight of each attribute in the next round of auction is a crucial problem. We first compute the weight of the ideal supplier reflecting the buyer's preference. Second, the weight of the test supplier is calculated to indicate the current change trend and the weakness of the failed supplier. In the end, a weighted value of above two parts is regarded as the next round weight. As the k winning suppliers do not change the original bidding strategies, a test supplier might compute their efficiencies and adjust his own bidding attribute value to make his efficiency greater than the known winners so as to have an opportunity to become the final winner in the next round auction. Overall, the proposed models can handle the vague and imprecise data in view of the actual circumstance of the auction and synthesis the previous information. At last, a numerical illustration verifies the feasibility of the proposed method.

Conflict of Interest

The authors declare no conflict of interest.

Command and Control (C2)

ABSTRACT

Command and control (C2) systems direct operators to make accurate decisions in the stressful atmosphere of the battlefield at the earliest. There are powerful tools that fuse various instant piece of information and brings summary of those in front of operators. Threat evaluation is one of the important fusion method that provides these assistance to military people. However, C2 systems could be deprived of valuable data source due to the absence of capable equipment. This situation has a bad unfavorable influence on the quality of tactical picture in front of C2 operators. In this paper, we study on the threat evaluation model that take into account these deficiencies. Our method extracts threat level of various targets mostly from their kinematics in two dimensional space. In the meantime, classification of entities around battlefield is unavailable. Only, category of targets are determined as a result of sensors process, which is the information of whether entities belong to air or surface environment. Hereby, threat evaluation model is consist of three fundamental steps that runs on entities belongs to different environment separately: the extraction of threat assessment cues, threat selection based on Bayesian Inference and the calculation of threat assessment rating. We have evaluated performance of proposed model by simulating a set of synthetic scenarios.

1. Introduction

This paper is an extension of the study that originally presented in 2016 IEEE Symposium Series on Computational Intelligence (SSCI) [1]. The original work focuses on a threat evaluation model that prioritizes entities without any characteristics at all in tactical picture. It accepts all targets without any differentiation and applies same threat evaluation model even if they have great difference because their dynamics. In this work, we separate targets from each other according to their category and apply appropriate methods to each categories independently.

Military operations take place in a stressful environment with a large amount of changing data. This atmosphere could drag C2 operators to erroneous decisions easily and leave them with their biases alone. Therefore, the aid of computer power is indispensable along OODA (Observe-Orient-Decide-Act) in battlefield [2]. The level of assistance changes according to capabilities of equipment deployed on the naval platform. Decision support systems serve operators the compiled tactical picture the combat field by processing raw sensor detections. Operators try to make their best while evaluating identity and kinematics of entities together before reaching final decisions. However, it is very difficult to establish relation between various data and extract value from instant data at a limited time without any automatic assistance tool [3]. Due to uncertain risks of battlefield, operators need to recognize, identify and prioritize surrounding objects continuously without any interruption [4]. The decision cycle of C2 operators are modeled and simulated in lots of studies in order to build up decision support systems [5, 6]. It shows that these systems are one of the core elements in C2 operations.

Situational awareness phase completes the observation step of the C2 processes by working on sensor data. This phase generates necessary tactical information used by orientation step of the C2 processes [7]. At this point, threat evaluation is defined as the analysis of surrounding objects continuously in order to detect their intents against defended assets and rank these objects according to their threat level. After the reveal of intents of these suspected objects, action sequence is determined to neutralize danger on friendly forces [8]. In the meanwhile, threat evaluation methods gain importance to accelerate decision cycle of C2

operators by decreasing time needed between operator perception and reaction time in the tactical area.

Various methods, such as, rule based techniques, fuzzy logic based techniques, neural networks and graphical models, are used in the threat evaluation algorithms to measure the threat level of assets surrounding defended forces [9]. Threat assessment cues are fundamental input data of these threat evaluation methods. As a result of various long-term studies that benefiting from experiences of qualified military personal, the most effective threat assessment cues are determined. Hereby, the environment of the target has a major influence on threat assessment cues. Kinematics of entities changes depending on where they operates. While air objects are able to make fast and sharp moves, surface objects on sea does not have the rapidity belonging to air objects. Similarly, different characteristics of target arising from environment lead to different threat assessment cues. Therefore, the list of threat assessment cues differs according to target's environmental category. The complete list of cues used for air forces is airlane, altitude, coordinated activity, course heading, closest point of approach (CPA), ESM/Radar Electronic Support, feet wet/dry, IFF mode, maneuvers, origin/location, own support, range/distance, speed, visibility, weapon envelope, wings clean/dirty in the study of Liebhaber and Feher [10]. Same researchers defines the list of threat assessment cues for surface forces as follows: cargo, coordinated activity, destination, ESM, heading, number of vessels, own support, range/distance, recent history, regional intelligence, sea lane, speed, voice communication with track and weapon envelope [11]. While important portion of lists are common, there are some significant difference between lists.

Johansson's study approaches threat assessment cues with a different perspective and categorize them as capability, proximity and intent parameters [9]. Mostly, classification of entities forms the list of capability parameters. Those parameters measures the possible deadliness of suspected object against friendly object. Meanwhile, the concern of proximity parameters is the closeness of objects in regards of position and orientation with respect to each other. Finally, intent parameters are interested with the actual aim of the suspected object on friendly asset [9].

Threat evaluation cues are originated from the characteristic of the target, the kinematic data of the target itself and the kinematic relationship of the target and the defended asset. These cues are classified in this regard. The kinematic relationship of objects find place in proximity and intent parameters itself. Classifying and identifying suspected object feeds capability parameters among cues. Small-scale naval platform has a limited foresight about the classification of target due to the lack of technologies, such as IFF and ESM, providing more modal information about the suspected target. In this paper, we examine the naval system that supply whether the target is an air track or a surface track. Moreover, the system provides kinematics of surrounding objects in two dimensional space. We present a threat evaluation model that initially generating scores for each threat assessment cues from kinematics of objects, then performing threat selection by using scores generated from initial phase and finally calculating threat assessment rating by using again cue scores. Data fusion is progressed at different paths for each environmental category. While air objects are evaluated in air container, surface objects are interpreted in surface container. Each category follows same threat evaluation model with different threat assessment parameters that convenient to use in that category.

The remaining part of this paper is organized as follows: Firstly, section II gives information about challenges while designing such a fusion based system. After that, section III presents the reason of why this threat evaluation model needed and the definition of the threat evaluation problem in literature. Then, section IV introduces whole steps of the threat evaluation model in detail. Section V presents the measurement of the performance of the mentioned model by evaluating couple of synthetic scenarios. Section VI gives the brief information about other researches for the threat evaluation problem. Lastly, section VII states the summary of this paper. Significant comparison is performed with this work and original work in discussions at the section VII. Further potential work after this study to complete research will be discussed in the end.

2. Challenges

Fusion problem is a challenging issue in itself apart from threat evaluation problem. Real world is measured by sensors and turns into signals. Then, these information is translated to discrete values to make mathematical calculations possible. There are many questions rising about the registration of data before beginning of the fusion process. In low-level information fusion processing, sensor's detections are associated and concluded as estimated tracks and target identities. After this step, high-level information fusion processing is initiated in order to detect repetitive behaviors, association of entities, prediction of future behavior and classification of situation [12].

Threat evaluation problem is generally related with high-level fusion processing since the problems tries to define tactical situation more clearly. Therefore, challenges for HLIF processing is addressed difficulties for threat evaluation problem, also. From the Fusion08 Panel discussion, these challenges are listed as proper fusion process models, estimation-based capabilities for HLIF relations, formal models for HLIF and use of other domains to contribute fusion solutions [13].

Threat evaluation problem can be assessed within situation assessment process widely discussed by fusion community. Explanation of the process, graphical displays to reveal internal process and interactive control to correct resulting situation are listed as common challenges in situation assessment [13]. C2 operator could be aware of the internal process and interact with system by the aid of graphical interfaces. However, the information displayed and the way of interaction is not fully described and resolved in the threat evaluation problem. There is a guide and studies for the design of graphical interfaces [3, 10]. However, it would be assertive to evaluate this design as a remedy to all needs.

There are various challenges that the community faced with while studying on situation and threat assessment. In general, following challenges are highlighted as a result of heavy discussions performed in the fusion community: situation and environment modeling, representation of knowledge, system design approaches, decision support process and performance and effectiveness evaluation methods for implemented systems. These challenges describes the problems while designing systems that needs fusion study in it.

3. Motivation

There is no complete definition and solution for threat evaluation problem since C2 operator behaviors and evaluations

could not be guessed easily during ongoing military operation [14]. Since the fusion of large amount of instant information on combat field is still needed excessively, the problem is still debatable topic and new approaches are introduced to handle situation continuously [15]. The problem is getting more compulsive in the situation of naval platforms deprived of obtaining adequate information to process. The lack of important detection systems, such as 3D radar, ESM, IFF, lead to less reliable estimation results in threat evaluation problem. In this study, we study on similar case and propose an approach to meet the need of C2 systems that have limited capability.

Any content word related with threat evaluation process is named parameter, factor, characteristic or specifically cue [14, 16]. Fundamental input of threat evaluation process is threat assessment cues. These parameters are determined in different researches. US Navy uses Origin, IFF Mode, Intelligence Report, Altitude, Proximity to an Airlane and ESM parameters as most effective threat assessment cues in their air defense system. Moreover, U.S Navy officers within a Combat Information Center rank the importance threat assessment cues for the surface warfare in another Liebhaber's study. While platform, weapon envelope, ESM, origin-flag parameters dominates the top of the list, range, heading, CPA/Speed cues follows these capability parameters [11]. As a result, the identity and the classification of the platform has a major influence on determining threat level of surrounding objects according to experienced users. Unfortunately, naval vessels with limited detection systems has no chance to use those parameters directly in their defense systems if there will be no operator intervention to the system. Therefore, these platforms need effective threat evaluation process that benefits from kinematics of objects. In this study, we focus on the use of parameters related with kinematics. Only available information in our case is whether the entity is an air object or surface object. Since dynamics of air and surface entities are different from each other, they are evaluated separately. Method section presents how this evaluation differentiate two distinct environment from each other.

The formal definition of the threat evaluation problem is described as follows: While $\mathbf{T} = \{T_1, \dots, T_n\}$ represents targets and $\mathbf{A} = \{A_1, \dots, A_m\}$ is the symbolic definition of friendly assets that need protection. V_{ij} is the relation function between target and defended asset. Moreover, V_{ij} represents the threat assessment rating of target-defended asset pair (T_i, A_j), where $T_i \in$ T, $A_j \in$ A. The normalization is applied to V_{ij} and it takes values between 0 and 1 in the end. Predictably, while 0 stands for safe force, 1 defines dangerous one. The functions describing the relation between these assets is defined as follows [17]:

$$f: \mathbf{T} \text{ x } \mathbf{A} \rightarrow [0,1] \quad (1)$$

In threat evaluation function, each friendly assets establish relationship with each suspected assets separately. When the identification of surrounding object is not possible, own platform is left as only friendly asset. If the function take into account only the platform itself and ignore all other friendly asset, then (1) changes as follows:

$$f: \mathbf{T} \text{ x } A_1 = \mathbf{V} \rightarrow [0,1] \quad (2)$$

In (2), $\mathbf{V} = \{V_1, \dots, V_n\}$ symbolizes threat assessment rating of each target with respect to A_1 which stands for our own platform. Similarly, the main purpose of this paper is to evaluate threat level of targets as function does. Our method will be introduces in following section of this paper in detail.

4. Method

It is compelling duty to separate friendly assets from hazardous ones when there is no identification information about surrounding asset. Kinematics of objects indicates limited foresight about the intent of objects. By fusing information extracted from objects' movement and orientation, it is possible to strength this foresight. Data fusion operation need attention while evaluating kinematics objects, because entities belongs to different environment has dissimilar features and it is impossible to evaluate air and surface objects with same perspective.

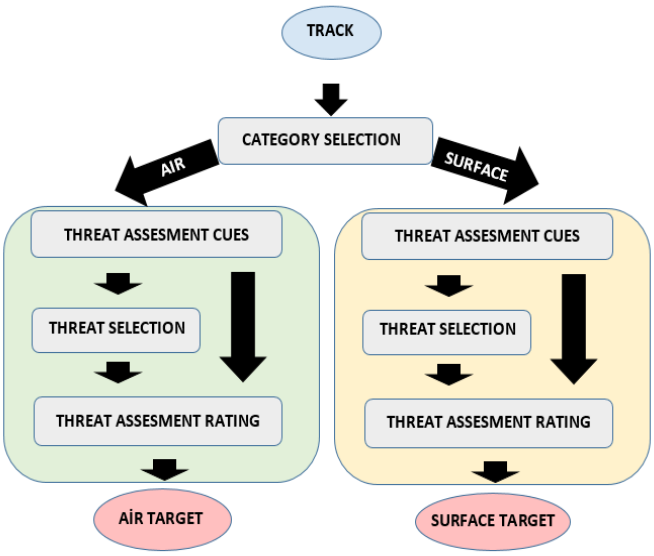

Figure 1 Threat Evaluation Model

The flow of each categories for threat evaluation process differentiate from the beginning of the model. The information about the environment of track is available. If track is a surface, then it is directed to flow handling surface tracks. Similarly air tracks are taken care of by air flow. Inside of each flow, steps are very similar to each other. Mainly, there is a three phase method inside each flow. Firstly, threat assessment cues phase generates various scores by benefiting from kinematics of objects. Then, these scores are transferred to threat selection phase that determined whether the entity show friendly or unfriendly attitude. This step marks the unfriendly objects as threat. Then, scores generated from first phase also transferred to final phase that calculates threat assessment rating of each object. This final phase provides to ranking of surrounding object depending on their threat level.

The Mentality of flows for each category is very similar as mentioned. Difference between each flow is to use convenient threat assessment cue in the right category.

Figure1 summarizes the general situation of threat evaluation model in this paper. Potential objects move to the related container depending on their environmental information. In each container, firstly, flow related threat assessment cues scores are generated from kinematics of objects. Then, threat selection phase determines dangerous objects by benefiting from these scores according to Bayesian Inference based algorithm. Dangerous objects are marked as threat at this phase for the use of the operator.

Finally, threat assessment rating phase calculates the threat rating of each track by using category related cue scores.

In brief, the model accepts potential objects as input and produces two different target list for each category. Surface objects are ranked among themselves. Similarly, air objects are listed on their own list. Objects carries threat rating and target mark with themselves.

4.1. Category Selection

At the beginning of the model, tracks are directed to different models according to their categories. If track is air track, then the remaining model specializes to air object; otherwise, surface dynamics are taking into account in the remaining model. Steps performed after this selection is differentiated from each other. This step is source of main difference with original work. Category selection could be seemed a very simple step. In fact, its effect spread out the remaining model in deep.

4.2. Threat Assessment Cues

It is important to use accurate threat assessment cues that generate convenient relationship between friendly assets and dangerous ones in right place while estimating threat level of an object [18]. In lots of studies, many threat assessment cues have been suggested for the use of threat evaluation models. However, it is impossible to benefit from all parameters since sensors of the naval platform could not provide all necessary information. Therefore, threat evaluation model is restricted to present parameters. Kinematic of objects serves position, speed and course values as input to the model in order to generate threat assessment scores.

Table I: Threat assessment cues with respect to environment

Air Tracks	Surface Tracks
• Speed • Distance • Heading • Maneuver • Closest Point of Approach (CPA) • Time Before Hit (TBH)	• Speed • Deceleration • Distance • Heading • Closest Point of Approach (CPA) • Time Before Hit (TBH)

Table 1 gives the full list of threat assessment cues that is generated from only kinematics objects which is basically position, speed and course of objects. Parameter lists are very similar to each other with a few difference. The way of generating scores does not change in each environment flow. However, weights of these parameters in algorithm changes according to category of asset. While determining parameters itself and weights of them, we benefit from mostly air warfare and surface warfare studies separately [9-11]. After the performance evaluation of the algorithms, weights of the parameters adjusted according to observation made during trials. Details of each parameters, namely speed, deceleration, distance, heading, maneuver, CPA and TBH are given as follows:

1) Speed: Speed parameter has a potential to be used to reveal classification of targets. An ordinary single engine aircraft could not reach the speed of fighter which is much more dangerous. However, a fighter could travel at lower speed. Similarly, for a surface track, fish boat can reach limited speed while boats are able to travel at higher speed. However, assault boat can stop in the middle of ocean and hide its characteristics easily in manner of speed. Therefore, there is no certain judge that classification could be made by only using speed parameter. Moreover, it is not close to the top of threat assessment cues with respect to importance. Still, speed is a good indication of target capability when it exists [10, 11, 14, 16].. Threat evaluation model uses this parameter considering seriously weight of it to final result. Speed parameter contributes the model as follows:

$$s_i = \frac{s_c}{s_{max}} \tag{3}$$

The score generated by speed parameter is found by dividing current speed value of target to maximum value of platforms. Here, maximum value of platforms differentiate according to category of target given in the beginning of model.

2) Deceleration: Change of speed does not imply important indication for air tracks. There is no pattern in speed parameter that indicates danger when observing air platforms. Therefore, the deceleration parameter does not used in air flow part of the threat evaluation model. When it comes to surface platforms, deceleration of naval platforms indicates abnormal intent for friendly assets [11]. If a naval vessel follows its route with steady speed, this vessel is supposed to be safe object for our own ship. Moreover, acceleration at speed of target indicated a danger for our own ship, but it is not much as deceleration case. The formal definition of the deceleration/acceleration score is indicated as follows:

$$r_i = \frac{s_i - s_{i-1}}{s_{max}}\ ,\ \begin{cases} r_i > 0\ , then\ w_a r_i \\ r_i < 0\ , then\ |r_i| \end{cases} \text{ where } w_a < 1 \tag{4}$$

As (4) shows, deceleration of objects has more influence on the score than acceleration does. This influence is adjusted with weight coefficient that decrease the score of acceleration with a specific ratio.

3) Distance: Location information of both own ship and target on earth sphere is available. Therefore, the haversine formula is able to compute the distance from our platform to target object [19]. The calculated distance is found in two dimensional space since there is no altitude data of surrounding air objects. Since the third axis in space is missing on calculation for air objects, the distance does not reflect the real situation for tactical picture of air entities. However, the amount of distance in two dimensional space is still serve valuable opinion about the intent of objects. At least, the objects are not closer than the amount calculated in two dimensional space. As expected, farther target is thought as safer than closer one. Therefore, it has lower score than closer one [10, 11, 14, 16].

$$d_i = 1 - \frac{d_c}{d_{max}} \tag{5}$$

The score of this cue is calculated in similar way for both air and surface objects. However, the contribution of this cue to total score is different with respect to importance level. While range is the most important kinematic cue for surface objects[11], some of other cues pass the importance level of this cue in air threat assessment studies [16]. Therefore, the contribution of the threat assessment cues is not same in air and surface tactical picture. It is adjusted with weight parameters according to their importance in algorithms while calculating total score.

4) Heading: The direction of target's heading is another important cue to understand target intent against defended asset [10, 14, 16]. As expected, if the target's heading is pointed out to defended asset, then it is a signature of danger for the defended one. If target's heading is not related with the positon of defended asset, then it means that target does not show any interest to defended object in manner of heading cue.

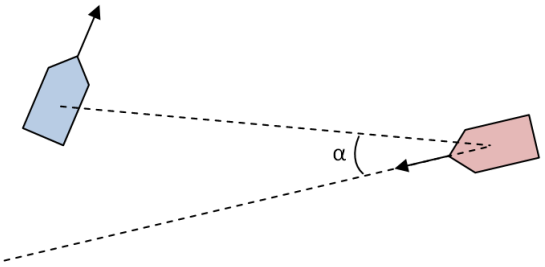

Figure 2 Heading Angle

The measurement of the danger level in this cue is computed by determining the orientation of target with respect to own ship position. In Figure 2, the red object is target and its heading is pointed out to blue object which is the defended entity with a degree of α angle. If α angle is getting bigger, then it means that target is not interested with the position of defended asset. Therefore, this situation decrease the danger on blue object. When α angle is getting smaller, then it means that red object point out its heading to blue object and it will come closer in time to defended asset. As a result, this positioning cause danger for the defended asset in manner of heading cue. As a result, the score generated by heading cue is calculated as follows:

$$h_i = 1 - \frac{\alpha}{\pi} \tag{6}$$

Since air objects has a hidden altitude value in two dimensional space, they would fly over defended asset even if their heading directly point out the defended asset. However, in surface tactical picture, this behavior is the danger of impact in the end. Therefore, the heading of target reveal more danger in surface tactical picture when compared to air tactical picture.

5) Maneuver: Maneuvers around the defended target is another unusual behavior that implies unfriendly act for it. Therefore, it is useful to take into account this kinematic data to threat evaluation process [10, 14, 16]. There are various options to measure the value of maneuver cue. The method could count maneuvers made at a specified time interval. However, this approach needs more frequent in order to determine the specific number of maneuvers. What behavior is thought as a maneuver is another discussion that needs to be solved. Instead of this complexity, a simple method come forward to handle situation. Firstly, the difference between consecutive course values is calculated and this value is divided to angle of maximum maneuver.

$$m_i = \frac{c_i - c_{i-1}}{c_{max}}, \text{ where } c_{max} = \frac{\pi}{2} \tag{7}$$

Air objects are capable of making sharp maneuvers. However, a plane that follows steady path does not requires to make this move frequently. Therefore, if a maneuver is observed from kinematics of air objects, then it make contribution to threat level of them. However, maneuver is not considered as a serious indication of danger for surface objects. Therefore, it is not used in the calculation of threat level for surface objects indeed.

6) Closest Point of Approach (CPA): Another key parameter in threat evaluation models is CPA of the target according to defended asset [20]. In many threat evaluation techniques, threatening tracks are prioritized by measuring the distance of threatening track to its CPA by own platform.

$$p_i = 1 - \frac{p_c}{p_{max}} \tag{8}$$

The score is generated in same manner of other cues. There is an acceptable maximum value for CPA distance, and the method divide the current value to maximum value.

CPA cue is beneficial to understand behaviors of air tracks and surface tracks. Air tracks are able to change their heading rapidly. This affects the CPA of target asset very quickly, also. According to air warfare studies, it has respectable impact on CPA. Actually, it is the one the most effective cue that measuring threat level of surrounding asset [11]. However, CPA for surface tracks does not produce same effect as air track does. Still, it is not an ignorable parameter and has specific effect on threat level of assets.

7) Time Before Hit: CPA is very useful indication to estimate behavior of threating asset. It is possible to strengthen this cue by taking account other kinematic information. In the study of Johnson and Falkman, TBH term is proposed in that manner. At that case, the speed of target and both CPAs are decisive factors. The time that suspected object follow the route to reach defended asset by passing through CPAs is measured. While calculating this time, defended asset is presumed to be stationary. If this time is smaller, then it means that there is undeniable threat against defended asset. Otherwise, defended asset is in safe territory...

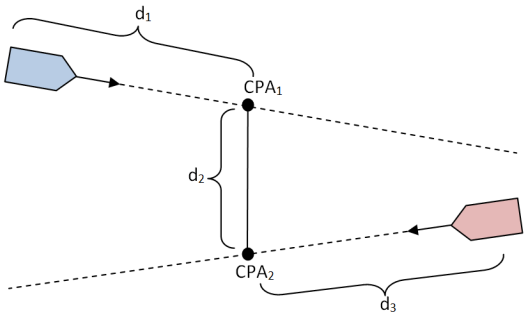

Figure 3 The Route Passing Through CPAs

Figure 3 shows the route of the suspected object needs to follow to get defended asset by passing through CPA points. Explanation of each leg of the route is described as follows:

- d_1: The distance between friendly asset and its CPA to the threating object.
- d_2: The distance between two CPA points.
- d_3: The distance between threating object and its CPA to friendly asset.

The time that takes the catch friendly asset in its current position by passing CPA points determines TBH: The score of this is generated by dividing TBH to a reasonable maximum value expected from TBH.

$$t_i = 1 - \frac{TBH_i}{TBH_{max}}, \text{where } TBH = \frac{d_1 + d_2 + d_3}{s_o} \tag{9}$$

TBH is taken into account for both air and surface tracks with a specific weight. This weight is adjusted by running scenarios consecutively and interpreting output of them.

4.3. Threat Selection Process Based on Bayesian Inference

It is difficult to observer dozens of surrounding objects even if a threat assessment rating is assigned to each of them by a threat evaluation algorithm. Classically, operator begin to examine targets from top of the list. After enough observation and investigation, C2 operator classify unknown target as friend and go on examining next target in the list; or C2 operator classify unknown target as hostile and take the necessary action needed. There is no border in the middle of list, which shows remaining part of the list is not worth to further investigation.

It is very critical to save time for C2 operator while making these observation and spend valuable time on real suspected object. We brings a mechanism based on Bayesian Inference that highlight the targets that need more attention than others. Formally, the method draws the border line on ranked list, which separates targets needs to be seriously assessed.

In Bayesian Inference, a hypothesis is put forward and the reality of this hypothesis is tried to be proved by evaluating evidences related with hypothesis [21]. After the evaluation, the hypothesis is interpreted as true or false. In our case, the hypothesis is whether a track is a target or not with a given scores of threat assessment cues. Here, threat parameters take the role of evidences in Bayesian Inference. The answer of the hypothesis gives the information whether track is target. If the result is positive, then related track is marked in the list. Therefore, C2 operator can concentrate on more these tracks that interpreted as target.

Bayesian Inference is an useful method showing the formula learning unknown status of the situation from available data [21]. Simply, Bayes' rule let us reach the posterior probability (the posterior) of a hypothesis with given prior probability (the prior) and compatibility of the observed evidence with the hypothesis (the likelihood) [22]. Bayes' formula points out the method to change probability statements by the use of evidences [15]. Formally, Bayes' theorem is formulized as follows [21]:

$$P(H \mid E) = \frac{P(E \mid H).P(H)}{P(E)} \tag{10}$$

Definition of each term in Bayes' theorem and the corresponding instances of these expressions inside the threat selection problem can be described as follows:

- H stands for the hypothesis that is tested according to Bayes' rule. The tested hypothesis in this paper is whether track is a target or not.
- E stands for the evidence that is available information to calculate posterior probability from prior probability in Bayes' formula. Threat assessment cues take role of evidences in this paper.
- P(H) stands for the prior probability of the hypothesis before the evidence is observed. In this paper, previous result of threat selection algorithm hold the place of the prior probability.
- $P(H \mid E)$ stands for the posterior probability of a hypothesis (H) after observing the evidence (E). In this paper, initial situation is the previous result of the threat selection algorithm, which is formally P(H). The fusion of the threat assessment cues bring to pass the observation of evidences. Then, posterior probability is obtained after application of this observation on prior probability.
- The remaining term in the formula, $\frac{P(E \mid H)}{P(E)}$, is the impact of evidence on the prior probability. Similarly, the data fusion of threat assessment cues' scores is determinant factor for the threat selection process.

Bayes' formula takes the following form after reinterpretation of terms according to threat selection process:

$$P(T_i \mid \mathbf{C}) = \frac{P(\mathbf{C} \mid T_{i-1}).P(T_{i-1})}{P(\mathbf{C})} \tag{11}$$

Similarly, explanation of each term in (11) as follows:

- T symbolizes the threat selection hypothesis that if a track is target.
- $\mathbf{C}$ denotes threat assessment cues which are evidences of hypothesis T.
- $P(T_{i-1})$ is the prior probability of the hypothesis before evidences are observed, namely, the probability found at the previous iteration of threat selection method.
- $P(T_i \mid \mathbf{C})$ stands for the posterior probability of the threat selection hypothesis (T) after observing threat assessment cues ($\mathbf{C}$).
- The remaining term in (11) is $\frac{P(\mathbf{C} \mid T_{i-1})}{P(\mathbf{C})}$ and it is the impact of the fusion of threat assessment cues on previous result of the threat selection method.

Threat selection method uses threat assessment cues according to their rank of importance is listed in Table 2 below. The importance ranking of the threat assessment cues mostly determined by taking reference of air warfare studies and surface warfare studies [11, 16].

Table II: Threat assessment cues according to the importance in threat selection

Air Tracks	Surface Tracks
