ISSN: 2415-6698

EDITORIAL BOARD
Editor-in-Chief

Prof. Passerini Kazmerski
University of Chicago, USA

Editorial Board Members

Prof. Rehan Ullah Khan
Qassim University, Saudi Arabia

Dr. Nguyen Tung Linh
Electric Power University, Vietnam

Mohamed Mohamed Abdel-Daim
Suez Canal University, Egypt

Prof. María Jesús Espinosa
Universidad Tecnológica Metropolitana, Mexico

Tariq Kamal
University of Nottingham, UK

Sakarya University, Turkey

Dr. Omeje Maxwell
Covenant University, Nigeria

Dr. Hongbo Du
Prairie View A&M University, USA

Dr. Mohmaed Abdel Fattah Ashabrawy
Prince Sattam bin Abdulaziz University, Saudi Arabia

Prof. Majida Ali Abed Meshari
Tikrit University Campus, Iraq

Dr. Heba Afify
MTI university, Cairo, Egypt

Regional Editors

Dr. Hung-Wei Wu
Kun Shan University, Taiwan

Dr. Ahmet Kayabasi
Karamanoglu Mehmetbey University, Turkey

Mr. Aamir Nawaz
Gomal University, Pakistan

Dr. Shagufta Haneef
Aalborg University, Denmark

Aamir Nawaz
Gomal University, Pakistan

Dr. Maryam Asghari
Shahid Ashrafi Esfahani, Iran

Dr. Ebubekir Altuntas
Gaziosmanpasa University, Turkey

Dr. Gomathi Periasamy
Mekelle University, Ethiopia

Dr. Gomathi Periasamy
Mekelle University, Ethiopia

Abdullah El-Bayoumi
Cairo University, Egypt

Dr. Shakir Ali
Aligarh Muslim University, India

Dr. Sabry Ali Abdallah El-Naggar
Tanta University, Egypt

Dr. Walid Wafik Mohamed Badawy
National Organization for Drug Control and Research, Egypt

Dr. Walid Wafik Mohamed Badawy
National Organization for Drug Control and Research, Egypt

Ayham Hassan Abazid
Jordan university of science and technology, Jordan

Dr. Abhishek Shukla
R.D. Engineering College, India

Editorial

Advances in Science, Technology and Engineering Systems Journal (ASTESJ) is an online-only journal dedicated to publishing significant advances covering all aspects of technology relevant to the physical science and engineering communities. The journal regularly publishes articles covering specific topics of interest.

Current Issue features key papers related to multidisciplinary domains involving complex system stemming from numerous disciplines; this is exactly how this journal differs from other interdisciplinary and multidisciplinary engineering journals. This issue contains 220 accepted papers in Computer, Electrical and Electronics domains.

Editor-in-chief
Prof. Passerini Kazmersk

ADVANCES IN SCIENCE, TECHNOLOGY AND ENGINEERING SYSTEMS JOURNAL

Volume 2 Issue 3 **May-June 2017**

CONTENTS

Transmit / Received Beamforming for Frequency Diverse Array with Symmetrical frequency offsets 01
Shaddrack Yaw Nusenu

Detailed Analysis of Amplitude and Slope Diffraction Coefficients for knife-edge structure in S-UTD-CH Model 07
Eray Arik, Mehmet Baris Tabakcioglu

Applications of Case Based Organizational Memory Supported by the PAbMM Architecture 12
Martín, María de los Ángeles, Diván, Mario José

Low Probability of Interception Beampattern Using Frequency Diverse Array Antenna 24
Shaddrack Yaw Nusenu

Zero Trust Cloud Networks using Transport Access Control and High Availability Optical Bypass Switching 30
Casimer DeCusatis, Piradon Liengtiraphan, Anthony Sager

A Derived Metrics as a Measurement to Support Efficient Requirements Analysis and Release Management 36
Indranil Nath

Feedback device of temperature sensation for a myoelectric prosthetic hand 41
Yuki Ueda, Chiharu Ishii

Deep venous thrombus characterization: ultrasonography, elastography and scattering operator 48
Thibaud Berthomier, Ali Mansour, Luc Bressollette, Frédéric Le Roy, Dominique Mottier

Improving customs' border control by creating a reference database of cargo inspection X-ray images 60
Selina Kolokytha, Alexander Flisch, Thomas Lüthi, Mathieu Plamondon, Adrian Schwaninger, Wicher Vasser, Diana Hardmeier, Marius Costin, Caroline Vienne, Frank Sukowski, Ulf Hassler, Irène Dorion, Najib Gadi, Serge Maitrejean, Abraham Marciano, Andrea Canonica, Eric Rochat, Ger Koomen, Micha Slegt

Aviation Navigation with Use of Polarimetric Technologies 67
Arsen Klochan, Ali Al-Ammouri, Viktor Romanenko, Vladimir Tronko

Optimization of Multi-standard Transmitter Architecture Using Single-Double Conversion Technique Used for Rescue Operations 73
Riadh Essaadali, Said Aliouane, Chokri Jebali and Ammar Kouki

Singular Integral Equations in Electromagnetic Waves Reflection Modeling 82
A. S. Ilinskiy, T. N. Galishnikova

Methodology for Management of Information Security in Industrial Control Systems: A Proof of Concept aligned with Enterprise Objectives 88
Fabian Bustamante, Walter Fuertes, Paul Diaz, Theofilos Toulqueridis

Dependence-Based Segmentation Approach for Detecting Morpheme Boundaries 100
Ahmed Khorsi, Abeer Alsheddi

Paper Improving Rule Based Stemmers to Solve Some Special Cases of Arabic Language 111
Soufiane Farrah, Hanane El Manssouri, Ziyati Elhoussaine, Mohamed Ouzzif

Medical imbalanced data classification 116
Sara Belarouci, Mohammed Amine Chikh

ADOxx Modelling Method Conceptualization Environment 125
Nesat Efendioglu, Robert Woitsch, Wilfrid Utz, Damiano Falcioni

GPSR+Predict: An Enhancement for GPSR to Make Smart Routing Decision by Anticipating Movement of Vehicles in VANETs 137
Zineb Squalli Houssaini, Imane Zaimi, Mohammed Oumsis, Saïd El Alaoui Ouatik

Optimal Synthesis of Universal Space Vector Digital Algorithm for Matrix Converters 147
Adrian Popovici, Mircea Băbăiţă, Petru Papazian

Control design for axial flux permanent magnet synchronous motor which operates above the nominal speed 153
Xuan Minh Tran, Nhu Hien Nguyen, Quoc Tuan Duong

A synchronizing second order sliding mode control applied to decentralized time delayed multi-agent robotic systems: Stability Proof 160
Marwa Fathallah, Fatma Abdelhedi, Nabil Derbel

Fault Diagnosis and Tolerant Control Using Observer Banks Applied to Continuous Stirred Tank Reactor 171
Martin F. Pico, Eduardo J. Adam

Development and Validation of a Heat Pump System Model Using Artificial Neural Network 182
Nabil Nassif, Jordan Gooden

Assessment of the usefulness and appeal of stigma-stop by psychology students: a serious game designed to reduce the stigma of mental illness 186
Adolfo J. Cangas, Noelia Navarro, Juan J. Ojeda, Diego Cangas, Jose A. Piedra, José Gallego

Kinect-Based Moving Human Tracking System with Obstacle Avoidance 191
Abdel Mehsen Ahmad, Zouhair Bazzal, Hiba Al Youssef

A security approach based on honeypots: Protecting Online Social network from malicious profiles 198
Fatna Elmendili, Nisrine Maqran, Younes El Bouzekri El Idrissi, Habiba Chaoui

Pulse Generator for Ultrasonic Piezoelectric Transducer Arrays Based on a Programmable System-on-Chip (PSoC) 205
Pedro Acevedo, Martín Fuentes, Joel Durán, Mónica Vázquez, Carlos Díaz

Enabling Toy Vehicles Interaction With Visible Light Communication (VLC) 210
M. A. Ilyas, M. B. Othman, S. M. Shah, Mas Fawzi

Analysis of Fractional-Order 2xn RLC Networks by Transmission Matrices 217
Mahmut Ün, Manolya Ün

Fire extinguishing system in large underground garages 221
Ivan Antonov, Rositsa Velichkova, Svetlin Antonov, Kamen Grozdanov, Milka Uzunova, Ikram El Abbassi

Directional Antenna Modulation Technique using A Two-Element Frequency Diverse Array 227
Shaddrack Yaw Nusenu

Classifying region of interests from mammograms with breast cancer into BIRADS using Artificial Neural Networks 233
Estefanía D. Avalos-Rivera, Alberto de J. Pastrana-Palma

Magnetically Levitated and Guided Systems 241
Florian Puci, Miroslav Husak

Energy-Efficient Mobile Sensing in Distributed Multi-Agent Sensor Networks 245
Minh T. Nguyen

Validity and efficiency of conformal anomaly detection on big distributed data 254
Ilia Nouretdinov

S-Parameters Optimization in both Segmented and Unsegmented Insulated TSV upto 40GHz Frequency 268
Juma Mary Atieno, Xuliang Zhang, HE Song Bai

Synthesis of Important Design Criteria for Future Vehicle Electric System 277
Lisa Braun, Eric Sax

Gestural Interaction for Virtual Reality Environments through Data Gloves 284
G. Rodriguez, N. Jofre, Y. Alvarado, J. Fernández, R. Guerrero

Solving the Capacitated Network Design Problem in Two Steps 291
Meriem Khelifi, Mohand Yazid Saidi, Saadi Boudjit

A Computationally Intelligent Approach to the Detection of Wormhole Attacks in Wireless Sensor Networks 302
Mohammad Nurul Afsar Shaon, Ken Ferens

Real Time Advanced Clustering System 321
Giuseppe Spampinato, Arcangelo Ranieri Bruna, Salvatore Curti, Viviana D'Alto

Indoor Mobile Robot Navigation in Unknown Environment Using Fuzzy Logic Based Behaviors 327
Khalid Al-Mutib, Foudil Abdessemed

Validity of Mind Monitoring System as a Mental Health Indicator using Voice 338
Naoki Hagiwara, Yasuhiro Omiya, Shuji Shinohara, Mitsuteru Nakamura, Masakazu Higuchi, Shunji Mitsuyoshi, Hideo Yasunaga, Shinichi Tokuno

The Model of Adaptive Learning Objects for virtual environments instanced by the competencies 345
Carlos Guevara, Jose Aguilar, Alexandra González-Eras

An Overview of Traceability: Towards a general multi-domain model 356
Kamal Souali, Othmane Rahmaoui, Mohammed Ouzzif

L-Band SiGe HBT Active Differential Equalizers with Variable, Positive or Negative Gain Slopes Using Dual-Resonant RLC Circuits 362
Yasushi Itoh, Hiroaki Takagi

Moving Towards Reliability-Centred Management of Energy, Power and Transportation Assets 369
Kang Seng Seow, Loc K. Nguyen, Kelvin Tan, Kees-Jan Van Oeveren

Secure Path Selection under Random Fading 376
Furqan Jameel, Faisal, M Asif Ali Haider, Amir Aziz Butt

Security in SWIPT with Power Splitting Eavesdropper 384
Furqan Jameel, Faisal, M Asif Ali Haider, Amir Aziz Butt

Performance Analysis of Phased Array and Frequency Diverse Array Radar Ambiguity Functions 389
Shaddrack Yaw Nusenu

Adaptive Discrete-time Fuzzy Sliding Mode Control For a Class of Chaotic Systems 396
Hanene Medhaffar, Moez Feki, Nabil Derbel

Fault Tolerant Inverter Topology for the Sustainable Drive of an Electrical Helicopter 401
Igor Bolvashenkov, Jörg Kammermann, Taha Lahlou, Hans-Georg Herzog

Computational Intelligence Methods for Identifying Voltage Sag in Smart Grid 412
Turgay Yalcin, Muammer Ozdemir

A Highly-Secured Arithmetic Hiding cum Look-Up Table (AHLUT) based S-Box for AES-128 Implementation 420
Ali Akbar Pammu, Kwen-Siong Chong, Bah-Hwee Gwee

Service Productivity and Complexity in Medical Rescue Services 427
Markus Harlacher, Andreas Petz, Philipp Przybysz, Olivia Chaillié, Susanne Mütze-Niewöhner

Principal Component Analysis Application on Flavonoids Characterization 435
Che Hafizah Che Noh, Nor Fadhillah Mohamed Azmin, Azura Amid

A Reconfigurable Metal-Plasma Yagi-Uda Antenna for Microwave Applications 441
Giulia Mansutti, Davide Melazzi, Antonio-Daniele Capobianco

Verifying the Detection Results of Impersonation Attacks in Service Clouds 449
Sarra Alqahtani, Rose Gamble

Image Segmentation Using Fuzzy Inference System on YCbCr Color Model 460
Alvaro Anzueto-Rios, Jose Antonio Moreno-Cadenas, Felipe Gómez-Castañeda, Sergio Garduza-Gonzalez

Segmented and Detailed Visualization of Anatomical Structures based on Augmented Reality for Health Education and Knowledge Discovery 469
Isabel Cristina Siqueira da Silva, Gerson Klein, Denise Munchen Brandão

Intrusion detection in cloud computing based attack patterns and risk assessment 479
Ben Charhi Youssef, Mannane Nada, Bendriss Elmehdi, Regragui Boubker

Optimal Sizing and Control Strategy of renewable hybrid systems PV-Diesel Generator-Battery: application to the case of Djanet city of Algeria 485
Adel Yahiaoui, Khelifa Benmansour, Mohamed Tadjine

RFID Antenna Near-field Characterization Using a New 3D Magnetic Field Probe 492
Kassem Jomaa, Fabien Ndagijimana, Hussam Ayad, Majida Fadlallah, Jalal Jomaah

Design, Fabrication and Testing of a Dual-Range XY Micro-Motion Stage Driven by Voice Coil Actuators 498
Xavier Herpe, Matthew Dunnigan, Xianwen Kong

Self-Organizing Map based Feature Learning in Bio-Signal Processing 505
Marwa Farouk Ibrahim Ibrahim, Adel Ali Al-Jumaily

A delay-dependent distributed SMC for stabilization of a networked robotic system exposed to external disturbances 513
Fatma Abdelhedi, Nabil Derbel

Modelization of cognition, activity and motivation as indicators for Interactive Learning Environment 520
Asmaa Darouich, Faddoul Khoukhi, Khadija Douzi

Homemade array of surface coils implementation for small animal magnetic resonance imaging 532
Fernando Yepes-Calderon, Olivier Beuf

An Encryption Key for Secure Authentication: The Dynamic Solution 540
Zubayr Khalid, Pritam Paul, Khabbab Zakaria, Himadri Nath Saha

Multi-Domain Virtual Network Embedding with Coordinated Link Mapping 545
Shuopeng Li, Mohand Yazid Saidi, Ken Chen

Semantic-less Breach Detection of Polymorphic Malware in Federated Cloud 553
Yahav Biran, George Collins, Borky John M, Joel Dubow

Impact of PSS and SVC on the Power System Transient Stability 562
Mohammed Omar Benaissa, Samir Hadjeri, Sid Ahmed Zidi

The Search for a Convergent Option to Deploy Smart Grids on IoT Scenario 569
Hamilton da Gama Schroder Filho, José Pissolato Filho, Vinicius Luciano Moreli

Optimizing the Decoding Complexity of PEG-Based Methods with an Improved Hybrid Iterative/Gaussian Elimination Decoding Algorithm 578
Reem Alkanhel, Marcel Adrian Ambroze

FAG – a management support tool with BI techniques to assist teachers in the virtual learning environment Moodle 587
Luciana Silva Zapparolli, Itana Stiubiener

A comparative between CRISP-DM and SEMMA through the construction of a MODIS repository for studies of land use and cover change 598
Herman Jair Gómez Palacios, Robinson Andrés Jiménez Toledo, Giovanni Albeiro Hernández Pantoja, Álvaro Alexander Martínez Navarro

Power requirements and battery life measurement for wireless transmission between two nodes in different mediums 605
Radouane Karli, Abdellatif Bouchalkha, Khalid Alhammadi

A Novel Dual-Band Rectenna for Ambient RF Energy Harvesting at GSM 900 MHz and 1800 MHz 612
Dinh Khanh Ho, Van-Duc Ngo, Ines Kharrat, Tan Phu Vuong, Quoc Cuong Nguyen, Minh Thuy Le

Optimisation of Software-Defined Networks Performance Using a Hybrid Intelligent System 617
Ann Sabih, Yousif Al-Dunainawi, H. S. Al-Raweshidy, Maysam F. Abbod

Data Error Detection and Recovery in Embedded Systems: a Literature Review 623
Venu Babu Thati, Jens Vankeirsbilck, Jeroen Boydens, Davy Pissoort

Augmented Reality Prototype HUD for Passenger Infotainment in a Vehicular Environment 634
Shu Wang, Vassilis Charissis, David K. Harisson

Incorporating Spatial Information for Microaneurysm Detection in Retinal Images 642
Mohamed M. Habib, Roshan A. Welikala, Andreas Hoppe, Christopher G. Owen, Alicja R. Rudnicka, Adnan Tufail, Catherine Egan, Sarah A. Barman

Human Robot Interaction for Hybrid Collision Avoidance System for Indoor Mobile Robots 650
Mazen Ghandour, Hui Liu, Norbert Stoll, Kerstin Thurow

Multi Level Integrity Management in LTE/LTE-A Networks 658
Ouafae Kasmi, Amine Baina, Mostafa Bellafkih

Development of an automated vehicle stop system for cardiac emergencies 669
Tung T. Nguyen, Issey Takahashi, Takahiro Tanaka, Eijiro Takeuchi, Shinpei Kato, Tatsuya Suzuki, Hitoshi Kanamori, Yoshiki Ninomiya, Hirofumi Aoki

Computer Aided Classification using Support Vector Machines in Detecting Cysts of Jaws 674
Veena Divya K, Anand Jatti, Revan Joshi P, Sabah Meharaj

Spatiotemporal Traffic State Prediction Based on Discriminatively Pre-trained Deep Neural Networks 678
Mohammed Elhenawy, Hesham Rakha

Low-cost Hybrid Wheelchair Controller for Quadriplegias and Paralysis Patients 687
Mohammed Faeik Ruzaij Al-Okby, Sebastian Neubert, Norbert Stoll, Kerstin Thurow

Preparation of Ni-C Ultrafine Composite from Waste Material 695
Mahmoud A. Rabah, S.M. Abdelbasir

Schizophrenia Prediction Using Integrated Imaging Genomic Networks 702
Su-Ping Deng, Wenxing Hu, Vince D. Calhoun, Yu-Ping Wang

IGS: The Novel Fast IC Power Ground Network Optimization Flow Based on Improved Gauss-Seidel Method 711
Qinghao Ye, Xiaoxiao Wang, Jiansong Gong, Songhao Ru, Donglin Su

GNSS Positioning in Non-line-of-Sight Context—a Survey for Technological Innovation 722
Julia Breßler, Marcus Obst

Collision avoidance between a wheelchair front wheels and a step wall during step climbing using a care robot 732
Hidetoshi Ikeda, Kazuki Hashimoto, Daisuke Murayama, Rikuto Yamazaki, Eiji Nakano

Adapting Model Predictive Control for a PV Station and Evaluating two different MPPT Algorithms P&O and FLC 741
Imad Elzein, Yury Petrenko

Human Sit Down Position Detection Using Data Classification and Dimensionality Reduction 749
Paul Rosero-Montalvo, Daniel Jaramillo, Stefany Flores, Diego Peluffo, Vanessa Alvear, Milton Lopez

Designing a Smart Car Parking System (PoC) Prototype Utilizing CCTV Nodes: A vision of an IoT parking system via UCD process 755
Muftah Fraifer, Mikael Fernström

Multilingual evaluation of voice disability index using pitch rate 765
Shuji Shinohara, Yasuhiro Omiya, Mitsuteru Nakamura, Naoki Hagiwara, Masakazu Higuchi, Shunji Mitsuyoshi, Shinichi Tokuno

Efficacy of multiple anticancer therapies may depend on host immune response 773
Kritika Karri, Dhundy R Bastola

Interdisciplinarity to Integrate Knowledge in Engineering 788
Stella Abreu, Amélia Caldeira, Alexandra R. Costa, Tiago Gomes, Luís A. C. Roque

Treadmill and Vision System for Human Gait Acquisition and Analysis 796
Paulo A. Ferreira, João P. Ferreira, Manuel Crisóstomo, A. Paulo Coimbra

Assessment of the heat sinking effect of a human hand that holds a flexible phototherapy device for use in Kangaroo Mother Care 805
Luis Jimenez, Luis Vilcahuaman, Jorge Galdos

Network Intrusion Detection System using Apache Storm 812
Muhammad Asif Manzoor, Yasser Morgan

Towards Optimality in Online Learning – The OLeCenT Approach 819
Carl Beckford, Ezra K. Mugisa

An efficient model to improve the performance of platelet inventory of the blood banks 839
Annista Wijayanayake, Manisha Dandunna

Performance Evaluation of Associative Classifiers in Perspective of Discretization Methods 845
Zulfiqar Ali, Waseem Shahzad

A novel model for Time-Series Data Clustering Based on piecewise SVD and BIRCH for Stock Data Analysis on Hadoop Platform 855
Ibgtc Bowala, Mgnas Fernando

Analysis of Wireless Traffic Data through Machine Learning 865
Muhammad Ahsan Latif, Muhammad Adnan

Video-frame Quality Improvement before Shot boundary Detection by using Logarithm, Wavelet and Contoulet Transform 872
Songpon Nakharacruangsak

Electromagnetic Field and Lumped Circuit Analysis of Planar Transformer at Medium Frequency for Converter Application 878
Chengjian Lian, Daming Zhang

Indoor monitoring in Public Buildings: workplace wellbeing and energy consumptions. An example of IoT for smart cities application 884
Stefania Nanni, Elisa Benetti, Gianluca Mazzini

EEG Mind Controlled Smart Prosthetic Arm – A Comprehensive Study 891
Taha Beyrouthy, Samer Al Kork, Joe Akl Korbane, Mohamed Abouelela

Features based approach for indexation and representation of unstructured Arabic documents 900
Mohamed Salim El Bazzi, Driss Mammass, Abdelatif Ennaji, Taher Zaki

The Analysis and Comparison of Multiport Converter used for Renewable Energy Sources 906
Sarab Al-Chlaihawi, Ammar Al-Gizi, Aurelian Craciunescu

Structural Optimization of Wavy FinFET for Leakage Reduction and Performance Enhancement 913
Anju Chakkikavil, Nisha Kuruvilla, Ayoob Khan, Shahul Hameed

Program with Ixquic 918
Carmen Ramos, Tania Patiño

A Design of SDN Based IP Mobility Management Considering Inter-Domain Handovers and Its Evaluation 922
Misumi Hata, Mustafa Soylu, Satoru Izumi, Toru Abe, Takuo Suganuma

Computer Tomography from Micro-Electronics to Assembled Products 932
Keith Bryant, Ragnar Vaga

Mathematical Modeling and Digital Control of A Hybrid Switching Buck Converter 937
Muhammad Umar Abbasi

Effect of Ambient Temperature Variations on Particle Dimesions in Ultrasonic Nebulizers during Cold Vaporization 946
Ali Akpek

Graphics on demand: the automatic data visualization on the WEB 951
Ramzi Guetari, Maha Mallek

Spectral Reflectance Estimation and Color Reproduction Based on Sparse Neugebauer Model 958
Kohei Inoue, Kenji Hara, Kiichi Urahama

3D Senor-based Library Navigation System 967
Abdel-Mehsen Ahmad, Zouhair Bazzal, Roba Al Majzoub, Ola Charanek

Deterministic Approach to Detect Heart Sound Irregularities 974
Richard Mengko, Amy Hamidah, Ricky Saputra

Spatial Modulation Technique For Filtered-OFDM Based Wireless Transmission 981
Shaddrack Yaw Nusenu

Template-like Tensor Domain Operations to Enhancing Diffusion Datasets Quality 987
Fernando Yepes-Calderon, Flor M. Medina

Ensemble of Neural Network Conditional Random Fields for Self-Paced Brain Computer Interfaces 996
Hossein Bashashati, Rabab Kreidieh Ward

Optimal Plant Growth in Smart Farm Hydroponics System using the Integration of Wireless Sensor Networks into Internet of Things 1006
Nathaphon Boonnam, Jumras Pitakphongmetha, Siriwan Kajornkasirat, Teerayut Horanont, Deeprom Somkiadcharoen, Jiranuwat Prapakornpilai

Skeletonization in Natural Image using Delaunay Triangulation 1013
Vicky Sintunata, Terumasa Aoki

A High Efficiency 0.13μm CMOS Full Wave Active Rectifier with Comparators for Implanted Medical Devices 1019
João Ricardo de Castilho Louzada, Leonardo Breseghello Zoccal, Robson Luiz Moreno, Tales Cleber Pimenta

Multiclass Myoelectric Identification of Five Fingers Motion using Artificial Neural Network and Support Vector Machine 1026
Jawad Ahmad, Ammar Mohsin Butt, Muhammad Tanveer Riaz, Shoaib Bhutta, Muhammad Zeeshan Khan, Inam-Ul-Haq

Group of UAVs Moving on Smooth Control Law with Fixed Obstacles 1034
Dmytro Pavlovich Kucherov, Andrei Nikolayevich Kozub, Oleg Nikolayevich Kostyna

Predictive Technology Management for the Identification of Future Development Trends and the Maximum Achievable Potential Based on a Quantitative Analysis 1042
Michael Fries, Markus Lienkamp

Improving the Performance of Fair Scheduler in Hadoop 1050
Shou-Chih Lo, Ya-Wen Cheng

Ranking of Two Multi Criteria Decision Making Cases with Evidential Reasoning under Uncertainty 1059
Farzaneh Ahmadzadeh

Applied Horizontal and Vertical Geothermal Heat Exchanger with Heat Pump System to Provide Air Conditioning for an Academic Facility in Mexico 1064
Daniel Alcantar Martínez, Oskar Javier González Pedraza, Crisanto Mendoza Cavarrubias, J. Jesus Pacheco Ibarra, Jorge Alberto Rangel Arista

Space Time – Track Circuits with Trellis Code Modulation 1070
Marius Enulescu

Support Vector Machine based Vehicle Make and Model Recognition System 1080
Muhammad Asif Manzoor, Yasser Morgan

Estimation of voltage unbalance at an AC traction substation with different train operational scenarios 1086
Thanatchai Kulworawanichpong, Nattapong Mingpruk, Tosaphol Ratniyomchai

A Microwave Reflectometer Prototype for Detection of Body Through the Rubble of Collapsed Buildings 1092
Syed Daniyal Ali Shah

Rotary Cutting of Electrical Steel Laminations – A Contrast to Traditional Stamping 1107
Markus Hubert, Simon Kutter, Marco Ziegler, Michael Schneider, Joerg Franke

Design for Smaller, Lighter and Faster ICT Products: Technical Expertise, Infrastructures and Processes 1114
Omer Aydin, Orhan Uçar

A Novel Ultra High Speed and Configurable Discrete Wavelet Packet Transform Architecture 1129
Mouhamad Chehaitly, Mohamed Tabaa, Fabrice Monteiro, Abbas Dandache

Cognitive Artificial Intelligence Method for Interpreting Transformer Condition Based on Maintenance Data 1137
Karel Octavianus Bachri, Bambang Anggoro, Arwin Datumaya Wahyudi Sumari, Adang Suwandi Ahmad

Selective Detrending using Baseline Drift Detection Index for Task-dependant fNIRS Signal 1147
Jinung An, Gihyoun Lee, Seung Hyun Lee, Sang Hyeon Jin

Autonomous Micro-Air-Vehicle Control Based on Visual Sensing for Odor Source Localization 1152
Kenzo Kurotsuchi, Mitsuharu Tai, Hiromasa Takahashi

EMI Shielding Performance For Varies Frequency by Metal Plating on Mold Compound 1159
Min Fee Tai, Swee Leong Kok, Kenichiroh Mukai, Stephan Hotz, Patrick Brooks, Diego Reinoso Cocina

Comparative Study of Adaptive Consensus Control of Euler-Lagrange Systems on Directed Network Graph 1165
Yoshihiko Miyasato

Future Contract Selection by Term Structure Analysis 1172
Vasco Grossmann, Manfred Schimmler

Optimal Rotor Design of Line Start Permanent Magnet Synchronous Motor by Genetic Algorithm 1181
Bui Minh Dinh

Fault-Tolerant in Embedded Systems (MPSoC): Performance Estimation and Dynamic Migration Task 1188
Kamel Smiri, Habib Smei, Nourhen Fourati, Abderrazak Jemai

Incremental Control Techniques for Layout Modification of Integrated Circuits 1196
Patrik Vacula, Vlastimil Kotě, Adam Kubačák, Milan Lžíčař, Radek Zelený, Miroslav Husák, Jiří Jakovenko

Effect of Cold Drawing Pass Schedule on Mechanical Properties and Microstructure of ST 52 during Cold Drawing of Seamless Tubes and its Influence on Springback 1202
Dadabhau Baban Karanjule, Sunil Sukhdeo Bhamare, Thota Hanumant Rao

IoT: Their Conveniences, Security Challenges and Possible Solutions 1211
Davar Pishva

Recognition and Position Estimation for Multiple Labware Transportation Using Kinect V2 and Mobile Robots 1218
Mohammed Myasar Ali, Hui Liu, Norbert Stoll, Kerstin Thurow

Grasping and Placing Operation for Labware Transportation in Life Science Laboratories using Mobile Robots 1227
Mohammed Myasar Ali, Hui Liu, Norbert Stoll, Kerstin Thurow

Face Recognition and Tracking in Videos 1238
Swapnil Vitthal Tathe, Abhilasha Sandipan Narote, Sandipan Pralhad Narote

Efficiency of Photovoltaic Maximum Power Point Tracking Controller Based on a Fuzzy Logic 1245
Ammar Al-Gizi, Sarab Al-Chlaihawi, Aurelian Craciunescu

Model-based Development of Safety-critical Functions and ISO 26262 Work Products using modified EAST-ADL 1252
Bülent Sari, Hans-Christian Reuss

On-Chip Testing Schemes of Through-Silicon-Vias (TSVs) in 3D Stacked ICs 1260
Shadi MS. Harb, William R. Eisenstadt

Stability and nonlinear controller design of Fast-Lock Phase-Locked Loop in 0.18-μm CMOS 1266
Fatima Al-Mutairi, Reem Al-Mutairi

Towards Deployment Strategies for Deception Systems 1272
Daniel Fraunholz, Marc Zimmermann, Hans Dieter Schotten

Classification of patient by analyzing EEG signal using DWT and least square support vector machine 1280
Mohd Zuhair, Sonia Thomas

Proposal for a Visualization System of Purchase Relationship Using ID-POS Data 1290
Ko Hashimoto, Kohei Otake, Takashi Namatame

Public transportation network design: a geospatial data-driven method 1298
Alexey Golubev, Maxim Shcherbakov

A Secure Communication Framework for ECUs 1307
Ali Shuja Siddiqui, Yutian Gui, Jim Plusquellic, Fareena Saqib

Content Reordering Based on Mouse-tracking for Web Applications 1314
Md. Tanjim-Al-Akib, Lutfullahil Kabir Ashik, Krishanu Chowdhury, Md. Zahid Hasan, Hosne Al Walid

Multi-attribute Reverse Auction Design Based on Fuzzy Data Envelopment Analysis Approach 1323
Deyan Chen, Dingwei Wang

A Category Based Threat Evaluation Model Using Platform Kinematics Data 1330
Mustafa Çöçelli, Ethem Arkın

The effect of employing knowledge workers from technologically advanced countries: The knowledge spillover caused by the mobility of knowledge workers in electronic industries in Asia 1342
Ayano Fujiwara

Compact wireless control network protocol with fast path switching 1350
Yasutaka Kawamoto, Makoto Kubomi, Yuichi Kado

A Meta-analysis of Content and Language Integrated Learning in English 1358
Jong-Keol Kim, Jeong-ryeol Kim

Hybrid Ontology-based knowledge with multi-objective optimization model framework for Decision Support System in intercropping 1363
Kornkanok Phoksawat, Massudi Mahmuddin

Evaluating the Effect of Mozart Music and White Noise on Electroencephalography Pattern toward Visual Memory 1372
Syarifah Noor Syakiylla Sayed Daud, Rubita Sudirman

A Way for Measuring the Temperature Transients of Capacitors 1381
Zoltan Sarkany, Marta Rencz

Radiation Hybrid Mapping: A Resampling-based Method for Building High-Resolution Maps 1390
Raed Seetan, Jacob Bible, Michael Karavias, Wael Seitan, Sam Thangiah

Two-axis Gimbal with Passive Revolute Joints for Motion Isolation of a Stabilizing Mechanism 1401
Erick Moya, Keizo Araki, Masaki Okada, Akira Mizuno, Kenjiro Tadakuma, Riichiro Tadakuma

Modeling and Performance Evaluation of a Top Gated Graphene Withdrawn
MOSFETJith Sarker, Abu Shami Md. Zadid Shifat,Rezoan Ahmed Shuvro

CAM-Infrastructure: a novel solution for service advertisement in Cooperative Intelligent Transportation Systems 1422
Badis Hammi, Houda Labiod, Gérard Segarra, Alain Servel, Jean Philippe Monteuuis

Use of machine learning techniques in the prediction of credit recovery 1432
Rogerio Gomes Lopes, Marcelo Ladeira, Rommel Novaes Carvalho

Monocular Height Estimation Method with 3 Degree-Of-Freedom Compensation of Road Unevennesses 1443
Alex Masuo Kaneko, Kenjiro Yamamoto

Scalability Dilemma and Statistic Multiplexed Computing — A Theory and Experiment 1453
Justin Yuan Shi, Yasin Celik

Embedded C Programming Using FRDM to Enhance Engineering Students' Learning Skill 1461
Zulzilawati Jusoh, Mohamad Taib Miskon, Hasnorhafiza Husni, Nur Hafizah Rabi'ah Husin

A Modified Patch Antenna with Square-Open Loop Resonator Slot for Improved Bandwidth Performance in WiFi Applications 1467
Rida Gadhafi, Mihai Sanduleanu

A comparative study for using the LBC format for compressing static medical images 1472
Ildikó-Angelica Szöke, Vasile Stoicu-Tivadar, Diana Lungeanu

Image Navigation Using A Tracking-Based Approach 1478
Stephen Craig Stubberud, Kathleen Ann Kramer, Allen Roger Stubberud

Analytical and Algorithmic Approaches to Determine the Number of Sensor Nodes for Minimum Power Consumption in LWSNs 1487
Nukhet Sazak, Ali Soner Kilinc

System for the Automatic Estimation of the Tilt Angle of a Flat Solar Collector 1491
Jorge Fonseca-Campos, Paola N. Cortez-Herrera, Israel Reyes-Ramírez

Source Code Vulnerabilities in IoT Software Systems 1502
Saleh Mohamed Alnaeli, Melissa Sarnowski, Md Sayedul Aman, Ahmed Abdelgawad, Kumar Yelamarthi

Lookup Tables-based mean level detection of spatially distributed targets in non Gaussian clutter 1508
Nabila Nouar, Atef Farrouki

A Machine Learning based Framework for Parameter based Multi-Objective Optimisation of Video CODECs 1515
Maryam Al-Barwani, Eran A. Edirisinghe

2-D and 3-D Visualization of Many-to-Many Relationships 1527
SeungJin Lim

On the Performance of a Clustering-based Task Scheduling in a Heterogeneous System 1540
Hidehiro Kanemitsu, Masaki Hanada, Emilia Ndilokelwa Weyulu, Moo Wan Kim

Symmetrical frequency offset
Transmit/received beamforming

ABSTRACT

Frequency diverse array (FDA) employs a small frequency increment across its array elements to provide range, angle and time dependent beampattern. In most radar systems, FDA with linear frequency offsets have been employed. But, its transmit beampattern is coupled in range and angle dimensions, which may degrade the output signal-to-interference-plus-noise ratio performance. Note that nonlinear offset is also beneficial in FDA radar. In this paper, symmetrical frequency offsets based FDA is investigated which removes the inherent periodicity of FDA beampattern to achieve a single maxima in the target area. In doing so, the signal information at the receiver is improved significantly. Transmit/received beampatterns, signal-to-interference-plus-noise ratio (SINR) and detection probability of the proposed method are compared with the conventional FDA. Computer simulations are used to verify the effectiveness of the proposed method.

1. Introduction

Frequency diverse array (FDA) utilizing a small frequency increment across each antenna elements was proposed by [1], to steer the beam electronically in angle and range dimensions. The FDA concept has range dependent beamforming capability. It was observed that frequency increment makes the array beampattern changes as a function of the range, angle and time [1]–[3]. In [4], FDA applications for various modes of operations in radar systems has been presented. The periodicity of beam pattern in time, range and angle was investigated in [5]. In [6], a linear FDA was proposed to address the range ambiguous clutters and improves the detection ability in a relatively slow moving targets. The radiation capabilities of FDA was presented in [7] to show its beam scanning features. Also it was proven that the scanning speed was related to frequency offset employed between two neighboring antenna elements. In [8], the range and angle coupled beamforming with frequency diverse chirp signals was presented. In addition, [9] investigated FDA range-angle dependent beamforming to suppress interferences at different ranges and directions.

FDA has a lot of promising application [10] which has sparked many interesting investigations in finding a suitable frequency offset to provide range-angle dependent. It is important to mention that frequency offset across the FDA elements plays essential role in improving the overall performance of an FDA radar, especially in controlling range-angle dependency and spatial distribution of generated beam pattern [11], [12]. Hence, researchers have shown great interest to investigate frequency offset between the adjacent elements of FDA to improve its performance. Since FDA offers a range-angle dependent beampattern, it is of great significance as this provides a potential for range-angle localization of targets, however, the beampattern of the conventional FDA is coupled in range-angle dimension.

In this regard, a nonuniform linear array was proposed in [13] to decouple the FDA transmit beampattern, however, the carrier frequency and/or frequency increments cannot be altered in real-time because it requires relocating the elements mechanically. In [14] and [15], logarithmically increasing frequency offsets and time-dependent frequency offsets, respectively are reported to decouple the range-angle beampattern. However, these methods resulted in poor beamforming performance in the range dimension. Note that the best decoupling way is to form a dot-shaped beampattern rather than S-shaped beampattern.

In this paper, transmit/received beamforming FDA radar with symmetrical frequency offset to decouple range and angle beampattern in order to produce a single maxima is investigated. The idea is to use the symmetrical frequency offset to provide extra

*Shaddrack Yaw Nusenu, UESTC-China and Koforidua Technical University-Ghana, Email: nusenu2012gh@yahoo.com

degree of freedom in terms of producing single maxima for a particular target of interest in a given region. Due to single maxima the received signal at the receiver array will be better than the signal for the conventional FDA. Furthermore, the proposed transmit/received beamforming are evaluated by the signal-to-interference-plus-noise ratio (SINR) and detection probability. Results shows the superiority of the proposed method.

The remaining sections are organized as follows: Section II presents the signal model of the conventional FDA, followed by the proposed symmetrical frequency offset FDA radar. Section III presents proposed method transmit / received beamforming. Section IV derives the SINR and detection probability. Section V presents results and discussions and concluding summaries are drawn in Section VI.

2. Background

2.1. Conventional FDA Range-Angle Dependent Transmit Beampattern

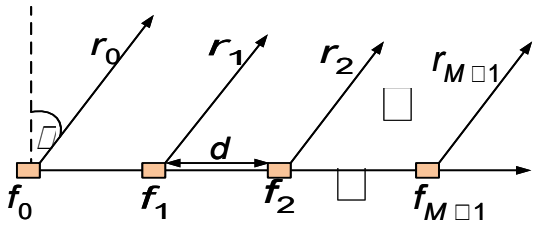

Figure 1: Illustration of linear frequency offset conventional FDA.

Figure 1 shows the conventional FDA antenna array structure. The narrow-band monochromatic signal radiated from each element is identical but with a frequency increment Δf. The radiated frequency of the mth element can be expressed as

$$f_m = f_0 + m\Delta f, \quad m = 0,1,\ldots,M-1 \tag{1}$$

where f_0 is the carrier frequency and M is the number of array elements. Then, the signal transmitted by the mth element can be represented by

$$s_m(t) = \exp\left(-j2\pi f_m t\right) \tag{2}$$

The signal arriving at a far-field point (r,θ) can be expressed as

$$s_m\left(t-\frac{r_m}{c_0}\right) = \exp\left[-j2\pi f_m\left(t-\frac{r_m}{c_0}\right)\right] \tag{3}$$

where c_0 is the speed of light and $r_m \approx r - md\sin\theta$, with d being the element spacing, is the target slant range for the mth element. If uniform weights (all ones) are applied, the array factor can be approximately derived as [16]

$$AF\left(t,r,\theta\right) = \sum_{m=0}^{M-1}\exp\left[-j2\pi f_m\left(t-\frac{r_m}{c_0}\right)\right]$$

$$\approx e^{-j\Phi_0}\frac{\sin\left[M\pi\left(\Delta f t-\frac{\Delta f r}{c_0}+\frac{df_0\sin\theta}{c_0}+\frac{d\Delta f\sin\theta}{c_0}\right)\right]}{\sin\left[\pi\left(\Delta f t-\frac{\Delta f r}{c_0}+\frac{df_0\sin\theta}{c_0}+\frac{d\Delta f\sin\theta}{c_0}\right)\right]} \tag{4}$$

where

$$\Phi_0 = 2\pi f_0\left(t-\frac{r}{c_0}\right)-p\left(M-1\right)\frac{\Delta f r}{c_0}+p\left(M-1\right)\frac{df_0\sin\theta}{c_0}+p\left(M-1\right)\frac{d\Delta f\sin\theta}{c_0}$$

Equation (4) implies that FDA has range, angle and time dependent transmit beampattern. However, the beampattern is coupled in the range and angle dimensions and consequently it will have multiple maximums. To avoid the dependence of range gain on the angle, the FDA parameters should be properly designed.

2.2. Proposed Symmetrical Frequency offset FDA for Transmit / Received Beamforming

In this paper, the symmetrical frequency offsets is proposed to decouple range and angle beampattern in order to localize a target in a given region. In designing symmetrical frequency offset, the central element is chosen as the symmetric point depicted in Figure 2.

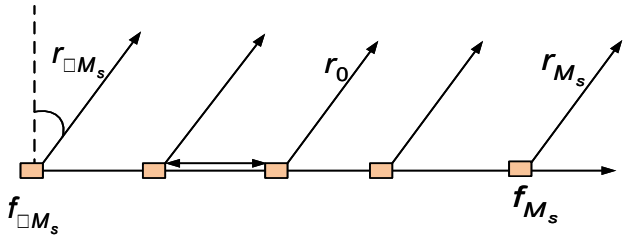

Figure 2: Illustration of proposed symmetrical frequency offset FDA.

In this paper, odd number of elements are assumed, namely, $M = 2Ms - 1$. The frequency offset for the kth element can be expressed as

$$\Delta f_k = |k|\Delta f, \quad k = -M_s+1,\ldots,0,1,\ldots,M_s+1 \tag{5}$$

Note that in order to show distinct representations, a new element index $k \in [-M_s+1,\cdots,0,\cdots,M_s-1]$ instead of m defined in (1) is adopted. Reformulate (4) as

$$AF\left(\theta,r,t\right) = \sum_{k=-M_s}^{M_s}\frac{1}{r_k}\exp\left[-j2\pi\left(f_0+|k|\Delta f\right)\left(t-\frac{r_k}{c_0}\right)\right]$$

$$\approx \sum_{k=-M_s}^{0}\frac{1}{r}\exp\left[-j2\pi\left(f_0-k\Delta f\right)\left(t-\frac{r_k}{c_0}\right)\right]$$

$$+\sum_{k=1}^{M_s}\frac{1}{r}\exp\left[-j2\pi\left(f_0+k\Delta f\right)\left(t-\frac{r_k}{c_0}\right)\right] \tag{6}$$

Similarly, $r_k = r - kd\sin\theta$ is used, where r denotes here as the reference range to the central element. Equation (6) can be rewritten in vector notation:

$$AF(\theta,r,t) \approx \left[\mathbf{w}^H \mathbf{a}(\theta,r,t)\right] \quad (7)$$

Where ^{H} is the conjugate transpose operator, w is the $M \times 1$ weighting vector, and transmit steering vector a (θ,r,t) is

$$\mathbf{a}(\theta,r,t) = \frac{1}{r}\left[\exp(-j\Phi_{-M_s}),...,1,...,\exp(-j\Phi_k),...,\exp(-j\Phi_{M_s})\right]^T \quad (8)$$

with ^{T} being the transpose operator and

$$\Phi_k = 2\pi\left(f_0 + k\Delta f\right)\left(t - \frac{r_k}{c_0}\right) \quad (9)$$

The $\boldsymbol{w}$ can be optimally designed to synthesize the desired transmit beampattern.

3. Transmit / Received Beamforming for Symmetrical frequency offset FDA

In this section transmit and received beamforming for proposed method is presented. The transmit beamforming can be expressed as

$$B_T(\theta,r) = \frac{\left|\mathbf{w}^H a(\theta,r)\right|^2}{\left|\mathbf{w}^H a(\theta_d,r_d)\right|^2} \quad (10)$$

The normalized received beampattern can be written as

$$B_r(\theta,r) = \frac{\left|\mathbf{w}_r{}^H \mathrm{v}(\theta,r)\right|^2}{\left|\mathbf{w}_r{}^H \mathrm{v}(\theta_d,r_d)\right|^2} \quad (11)$$

where $\mathrm{v}(\theta,r) = \left(\mathbf{w}^H a(\theta,r)\right)\mathrm{b}(\theta)$ denotes the virtual steering vector v (θ,r) and b(θ) being the received steering vector due to the propagation delays from a source to the receive elements.

4. Performance Analysis

4.1. SINR

The performance analysis of the proposed method are evaluated by signal-to-interference-plus-noise ratio (SINR) and probability of detection. First of all SINR can be expressed as

$$SINR = \frac{\sigma_d^2\left|\mathbf{w}_r{}^H \mathrm{v}(\theta_d,r_d)\right|^2}{\mathbf{w}_r{}^H Q_{i+n} \mathbf{w}_r} \quad (12)$$

where σ_d^2 is the variance of the target reflection coefficient and Q_{i+n} denotes the interference-plus-noise covariance matrix which is given as

$$Q_{i+n} \approx \sum_{i=1}^{F} \sigma_i^2 \mathrm{v}(\theta_i,r_i)\mathrm{v}^H(\theta_i,r_i) + \sigma_n^2 I \quad (13)$$

where σ_i^2 is the variance of the ith interference reflection coefficient, F is the number of interferences and $\sigma_n^2 I$ is the covariance matrix with I being an identity matrix. Plugging in (13) and $\mathbf{w}_r = \mathrm{v}(\theta_d,r_d)$ into (12) for any radar system, will yields SINR for that radar system.

4.2. Probability of Detection (Pd)

In this section, the probability of detection (Pd) is employed to evaluate the performance of a radar system. For the proposed method, the hypothesis problem can be written as

$$\begin{cases} H_0: \mathrm{x}(t) = n(t) \\ H_1: \mathrm{x}(t) = h(t) + n(t) \end{cases} \quad (14)$$

The noise process is assumed to be Gaussian and independent and identically distributed (i.i.d). The probability density function (PDF) can be expressed as

$$p(\mathrm{x}(t);H_0) = e^{\left(\frac{\|\mathrm{x}(t)\|^2}{\sigma_n^2}\right)} \quad (15)$$

$$p(\mathrm{x}(t);H_1) = e^{\left(\frac{\|\mathrm{x}(t)\|^2}{\sigma_n^2}\right)} \times e^{\left(\frac{\|h(t)+n(t)\|^2}{2\sigma_n^2}\right)} \quad (16)$$

The likelihood ratio test can be given as

$$g = \frac{p(\mathrm{x}(t);H_1)}{p(\mathrm{x}(t);H_0)} \underset{H_0}{\overset{H_1}{\gtrless}} x \quad (17)$$

The probability of detection p_d and probability of false alarm p_{fa}, respectively, is expressed as in [17]

$$p_d = p(g > x|H_1) = 1 - S_{y^2_{(2)}}\left(\frac{\sigma_n^2 S^{-1}_{y^2_{(2)}}(1-p_{fa})}{M^2N + \sigma_n^2}\right) \quad (18)$$

$$p_{fa} = p(g > x|H_0) = 1 - S_{y^2_{(2)}}\left(\frac{2x}{\sigma_n^2}\right) \quad (19)$$

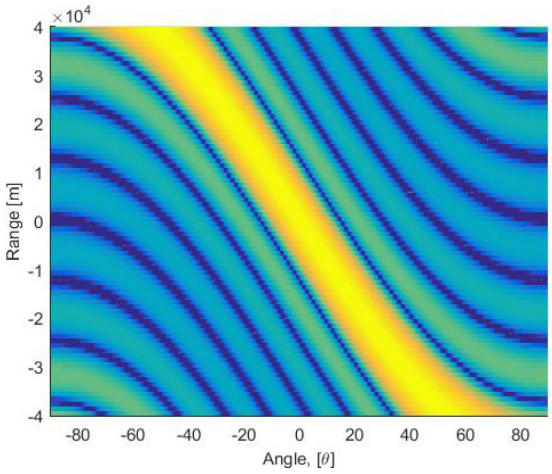
where S $(\cdot)$ denotes the cumulative distributive function, $y^2_{(2)}$ being the chi-square distribution, $P - N + k$ are the number of elements in kth array and R are the number of receiver array elements.

5. Results and Discussions

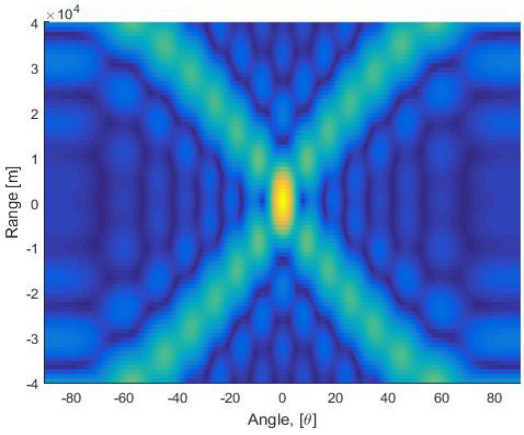
In the simulations, the carrier frequency f_0 = 10 GHz, frequency offset Δf = 3 KHz. Both transmit and receive arrays M and N, respectively, have 8 antenna elements spaced by half wavelength $d = \frac{c_0}{2f_0}$. The target is assumed to be located at (θ_d, r_d) = (50°,50 km). Gaussian noise is utilized as additive noise with zero mean spatially and temporally white random sequence having same variance on each array elements.

A. Transmit Beampattern

First, normalized transmit beampattern for FDA and the proposed symmetrical FDA is presented to show the effectiveness of symmetrical FDA. Note that the two arrays are steered to instantaneous angle θ = 0° and the beam direction ranges are also normalized to zero-range. Figure 3(a) illustrates the conventional FDA beampattern which is coupled in the range-angle dimension.



(a)



(b)

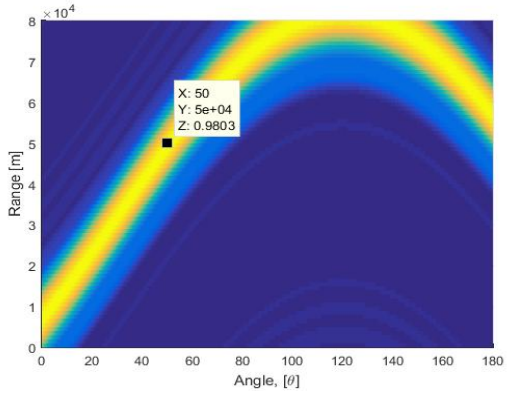
Figure 3: Comparisons of normalised transmit beampattern when Δf = 3 KHz is adopted: (a) Conventional FDA, (b) Proposed symmetrical FDA.

In contrast, Figure 3(b) shows the proposed symmetrical FDA which has decoupled range-angle beampattern. And this is beneficial for targets localization.

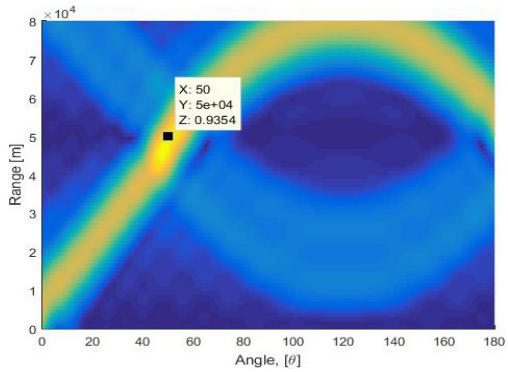
As shown in Figure 4(a), the conventional FDA beampattern shows the problem of periodic maxima. This maxima are undesirable for proper target localization. On the other hand, Figure 4(b) shows the proposed method beampattern which produce exactly one maxima at target location and no other maxima is seen in the entire region of observation.

B. Received Beampattern

In Figure 5(a) and 5(b) both radars produce maxima at the intended range-angle pair, but the conventional FDA has more serious ambiguity problem shown by the arrow in Figure 5(a). It is important to mention that because the conventional FDA has larger total frequency offset, it achieved higher range resolution than the proposed method. In the case of the proposed method, the target is better localized than the conventional FDA. It can be noticed that there is no spread of beampattern in both range and angle dimensions.

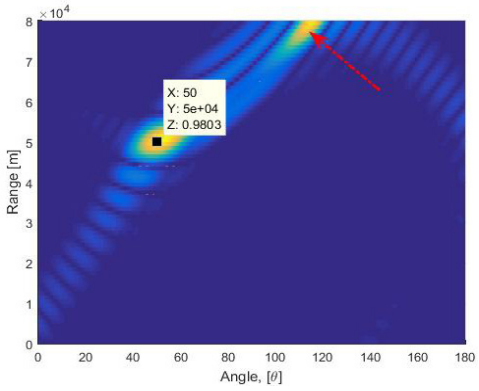


(a)

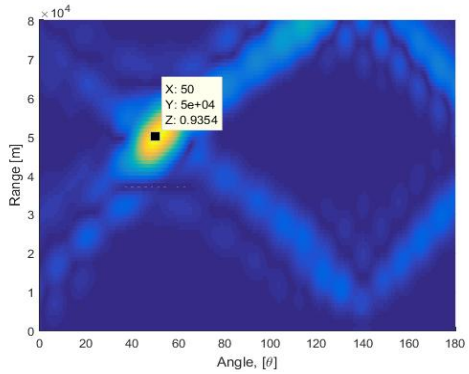


(b)

Figure 4: Comparisons of transmit beampattern when the target is present at (θ_d, r_d) = (50°,50 km): (a) Conventional FDA, (b) Proposed symmetrical FDA.



(a)



(b)

Figure 5: Comparisons of transmit beampattern when the target is present at (θ_d, r_d) = (50°,50 km): (a) Conventional FDA, (b) Proposed symmetrical FDA.

Finally, SINR and probability detection performance of the proposed method and the conventional FDA have been plotted. It can be observed that in Figure 6, the SINR of proposed symmetrical FDA is better than the conventional FDA. Thus proposed method has better robustness against the interferences.

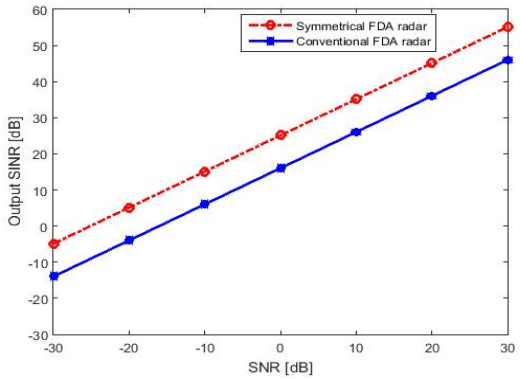


Figure 6: SINR versus SNR performance.

Figure 7 shows the detection probability versus SNR for the proposed method and the conventional FDA radar. Proposed method exhibits better detection performance compared to the conventional FDA radars.

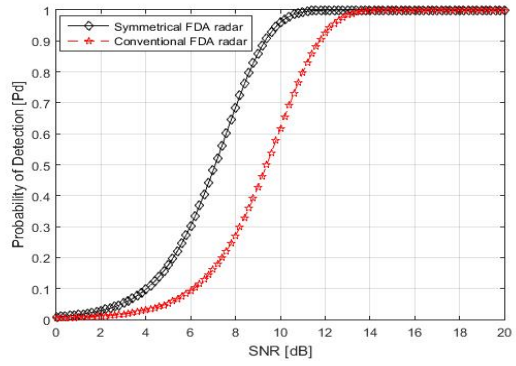

Figure 7: Probability of detection versus SNR performance.

Note that the improvement in performance in terms of SINR and detection probability can be attributed to single maxima due to symmetrical frequency offset employed across the transmit antenna array.

6. Conclusion

A symmetrical frequency offset based FDA has been presented. The proposed method avoids the periodic maxima presented in conventional FDA radar and focus the target with multiple beams to get single maxima for better target localization. Numerical results shows that the proposed method exhibits better robustness against interference as well as better detection performance than the conventional FDA radar due to the employment of symmetrical frequency offset across the transmit antenna array. Overall, the proposed method received beampattern show a reasonable improvement compared to the conventional FDA.

Conflict of Interest

The author declare no conflict of interest.

Diffraction coefficient

S-UTD-CH model

Wave Diffraction

ABSTRACT

In urban, rural and indoor applications, diffraction mechanism is very important to predict the field strength and calculate the coverage accurately. The diffraction mechanism takes place on NLOS (non-line-of-sight) cases like rooftop, vertex, corner, edge and sharp surfaces. S-UTD-CH model computes three type of electromagnetic wave incidence such as direct, reflected and diffracted waves, respectively. As obstacles in diffraction geometry are in the same or closer height, contribution of the diffraction mechanism is dominant. To predict the diffracted fields accurately, amplitude and slope diffraction coefficients and the derivative of these coefficients have to be taken correctly. In this paper, all the derivations about diffraction coefficients are made for knife edge type structures and extensive simulations are performed in order to analyze the amplitude and diffraction coefficients. In plane angle diffraction, contributions of amplitude and slope diffraction coefficient are maxima.

1. Introduction

Diffraction means bending of electromagnetic waves from a sharp edge, wedge, corner and narrow slits. The diffraction takes place in the case of relatively higher wavelength of electromagnetic wave from obstacle or slit aperture. This paper is an extension of work originally presented in Electromagnetic wave theory symposium [1]. In case that wavelength of electromagnetic wave is less than the height of obstacle; high frequency asymptotic techniques are used [2]. Geometrical optics model runs for refraction, reflection, direct propagation and have been used for a long time in wave propagation in lit region. Geometrical optics model cannot explain diffraction concept [3], and thus cannot give accurate field prediction particularly behind an obstacle. In order to solve the diffraction problem in the field prediction, geometrical theory of diffraction (GTD) model is introduced [4]. However, GTD model gives inaccurate outcomes in optical boundaries [5]. GTD gives inaccurate results in the situation that source, diffraction and observation points are in the same line [6]. GTD model is an extension to geometric optic model by adding diffracted fields terms and used in high frequency spectrum [7]. UTD model is introduced in order to overcome singularity problem of GTD model [8]. UTD model gives appropriate and exact outcomes in case of single diffraction [5]. UTD model is also an extension to geometric optic model and reflected waves are also considered in field prediction [6]. UTD model gives inaccurate outcomes in field prediction in the situation of closer building height. In order to predict the field strength more exactly, the second order diffracted field terms are added to total field at the receiver [9]. Slope diffraction model is introduced in [10, 11]. However, there are some singularities in field prediction at shadow boundary points [12]. Higher order diffraction coefficient and diffracted fields are developed to predict the relative path loss at the receiver for wedge and knife edge structures [13-15]. Amplitude and slope diffraction coefficients are developed via providing amplitude, slope and phase continuities in optical boundaries [16]. Slope UTD model applied multi-shaped cascaded obstacles [17] and adapted into time domain and all formulas are

*Corresponding Author: Mehmet Barış Tabakcioglu, Bursa Technical University, Mimar Sinan Campus, Yildirim, Bursa, TURKEY, mehmet.tabakcioglu@btu.edu.tr

www.astesj.com
https://dx.doi.org/10.25046/aj020302

derived in time domain [18]. A new GTD model is introduced for equal heights case [19]. After 10 diffractions slope UTD model loses the accuracy and requires more computation time. S-UTD-CH model is proposed to predict the field strength accurately after 10 diffractions for knife edge and wedge structures [20, 21]. Amplitude and slope diffraction coefficients are used in S-UTD-CH model developed in MATLAB environment. Firstly location and height data of transmitter, obstacle and receiver is entered to program. And then a ray tracing is made and all contribution to total path loss at the receiver is determined. Afterwards, by using amplitude and slope diffraction coefficient path loss is calculated. As an example a simple test scenario is used in order to show that effect of diffraction coefficient is maximum in case of plane angle diffraction. All the simulations are performed in MATLAB.

2. Amplitude Diffraction Coefficient

To calculate the total field behind an obstacle formula [8] is given by

$$E = [E_i D]A(s)e^{-jks} \quad (1)$$

where, E_i is incoming field, D is amplitude diffraction coefficient. $A(s)$ stands for spreading factor. s and k represent travelled distance and wave number, respectively. The amplitude diffraction coefficient for the knife edge type structure is given [12] by

$$D(\alpha) = -\frac{e^{-j\pi/4}}{2\sqrt{2\pi k\cos(\alpha/2)}}F[x] \quad (2)$$

where, α is diffraction angle ($\alpha \equiv \varphi - \varphi'$) and illustrated in Fig. 1. k is wave number and $F[x]$ refers to transition function.

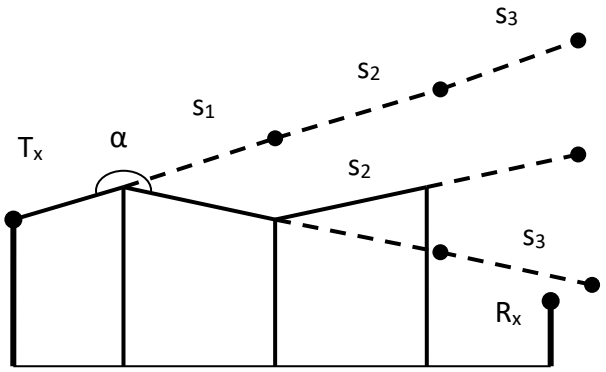

Fig.1. Multiple Knife edge Diffraction Scenario

Amplitude diffraction coefficient used in calculation of the diffracted fields behind the obstacle. The amplitude diffraction coefficient changes with respect to diffraction angle. The diffraction angle is measured between incoming and diffracted fields as depicted in Fig. 1. Changing of the amplitude diffraction coefficient with regard to diffraction angle is shown in Fig. 2.

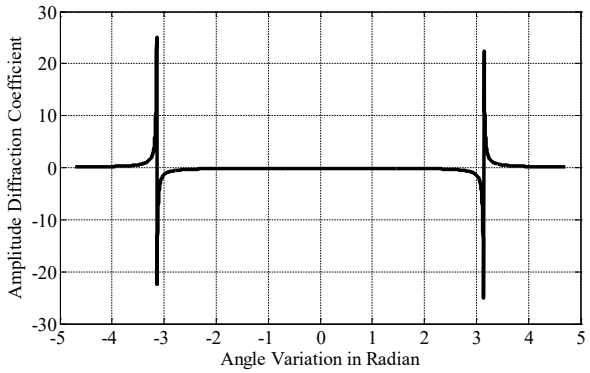

Fig. 2. Amplitude diffraction coefficient vs diffraction angle

As it is seen in Fig. 2, the diffraction angle variation is indicated on horizontal axis. Variation of the amplitude diffraction coefficient is indicated on vertical axis. Also it can be seen in Fig. 2, the magnitude of amplitude diffraction coefficient has the maximum value at π and - π radian (180° and -180°). Plane angle diffraction takes place in the case that source, diffracting and observation points are in the same line.

3. Slope Diffraction Coefficient

In order to calculate the diffracted field behind multiple obstacles, slope diffraction coefficient have to be used to predict the field strength accurately. The slope diffraction coefficient can be calculated by the formula [12] expressed by

$$d_s(\alpha) = \frac{1}{jk}\frac{\partial D(\alpha)}{\partial \alpha} \quad (3)$$

where, k is wave number, $D(\alpha)$ is amplitude diffraction coefficient and j is complex number. The slope diffraction coefficient obtained by partial derivation of amplitude diffraction coefficient with respect to diffraction angle [12] is given by,

$$d_s(\alpha) = -\frac{e^{-j\pi/4}}{\sqrt{2\pi k}}L_s \sin(\alpha/2)\big(1 - F(x)\big) \quad (4)$$

where, k is wave number, L_s is distance parameter for slope diffraction coefficient and $F[x]$ refers to transition function.

Slope diffraction coefficient used in calculation of the diffracted fields behind multiple obstacles. The slope diffraction coefficient changes according to the diffraction angle. Again the diffraction angle is measured between incoming and diffracted fields as depicted in Fig. 1. UTD model fails in predicting of the diffracted field in case of equal or closer obstacle height. In order to remove the discontinuities in the predicted field, derivatives of the amplitude diffracted fields have to be added on the receiver. Changing of the slope diffraction coefficient with respect to diffraction angle is shown in Fig. 3.

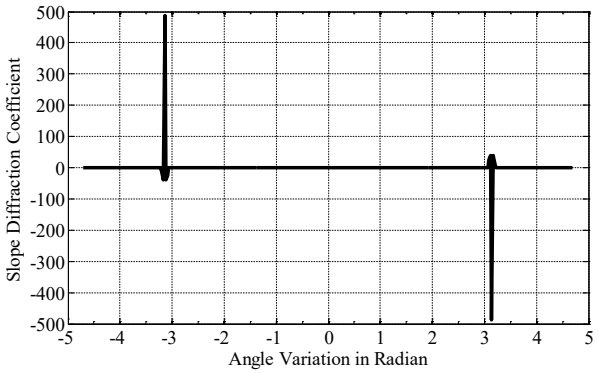

Fig. 3. Slope diffraction coefficient vs diffraction angle

As it is seen in Fig. 3, the diffraction angle variation is indicated on x-axis. Variation of the amplitude diffraction coefficient is indicated on y-axis. Also it can be seen in Fig. 3, the magnitude of the slope diffraction coefficient has the maximum value at π and - π radian (180° and -180°). By adding the slope diffracted fields, the deficiency of UTD model in equal height case is removed [22-23].

If there are 3 or more obstacles in the propagation scenario, normal derivative of the slope diffraction coefficient have to be used in prediction [12] is given by,

$$\frac{\partial d_s(\alpha)}{\partial n} = -\frac{1}{2s}\frac{e^{-j\pi/4}}{\sqrt{2\pi k}}\left\{L_s\cos(\alpha/2)[1-F(x)] + 4L_s^2 k sin^2(\alpha/2)\cos(\alpha/2)\,F'(x)\right\} \quad (5)$$

where, k is wave number, s is travelling distances, is L_s is distance parameter for slope diffraction coefficient and *F[x]* refers to transition function. Also F'[x] is derivative of transition function.

Derivative of the slope diffraction coefficient used in calculation of the diffracted fields behind multiple obstacles, when the obstacle number is greater than 2. The derivative of the slope diffraction coefficient changes with the diffraction angle. Again the diffraction angle is measured between incoming and diffracted fields as depicted in Fig. 1. Changing of the derivative of the slope diffraction coefficient with respect to diffraction angle is shown in Fig. 4.

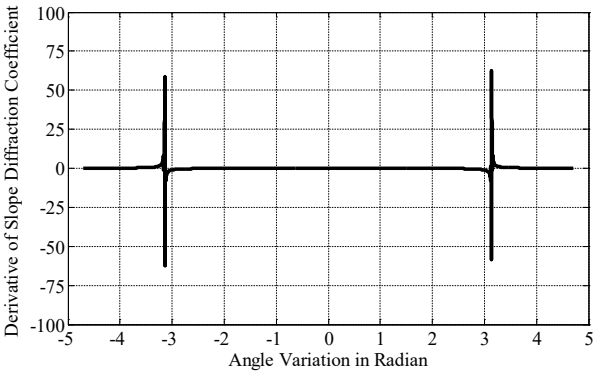

Fig. 4. Derivative of slope diffraction coefficient vs diffraction angle

As it is seen in Fig. 4, the diffraction angle variation is indicated on abscissa. Variation of the amplitude diffraction coefficient is indicated on ordinate. Also it can be seen in Fig. 4, the magnitude of the slope diffraction coefficient has the maximum value at π and - π radian (180° and -180°).

4. Results and Discussion

In order to verify the contribution of diffraction is maxima in the plane angle diffraction, test scenario in Fig. 5 is used.

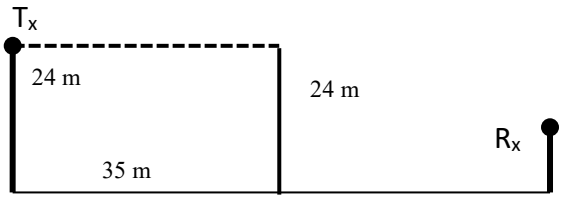

Fig. 5. Plane angle test scenario

As it is depicted in Fig. 5, the transmitter antenna height is 24 m, obstacle is 35 m apart from the transmitter and whose height is 24 m. Operating frequency is 300 MHz. Path loss variation for direct and diffracted fields with respect to the receiver height just behind the obstacle (36 m) is illustrated in Fig. 6

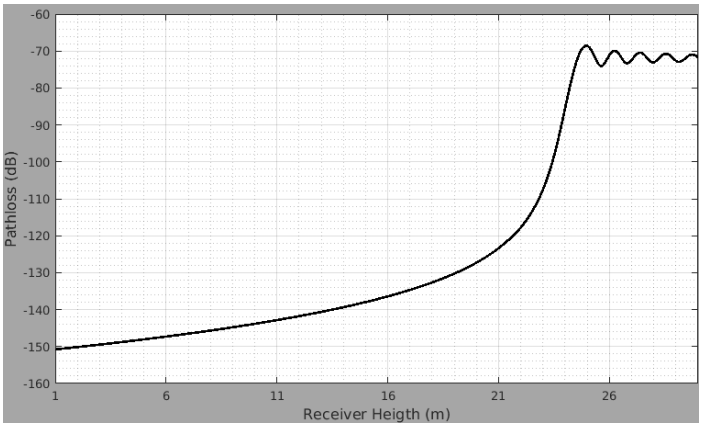

Fig. 6. Path loss of direct and diffracted fields together

As can be seen in Fig. 6, diffraction effect is maxima in the plane angle diffraction case. As the receiver height is 24 m, the angle between transmitter and receiver becomes 180°. After this height of receiver, direct field is dominated.

Path loss variation for only diffracted fields with respect to the receiver height just behind the obstacle (36 m) is illustrated in Fig. 7.

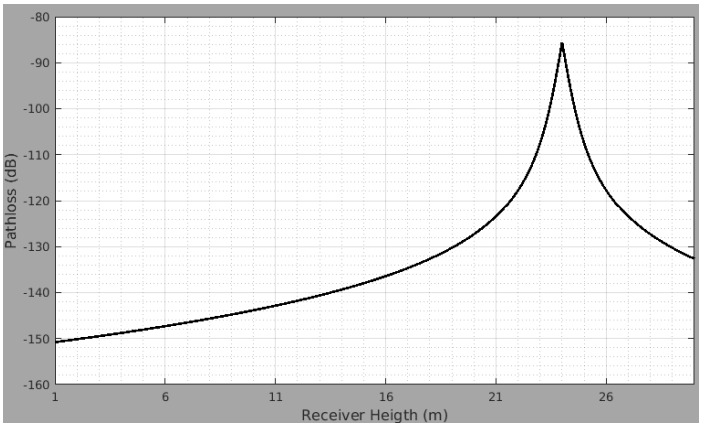

Fig. 7. Path loss of diffracted fields

As can be seen in Fig. 7, the diffraction effect is maxima in the plane angle diffraction case. As the receiver height is 24 m, the angle between transmitter and receiver becomes 180̊.

Path loss variation for reflected and diffracted fields with respect to the receiver height just behind the obstacle (36 m) is illustrated in Fig. 8.

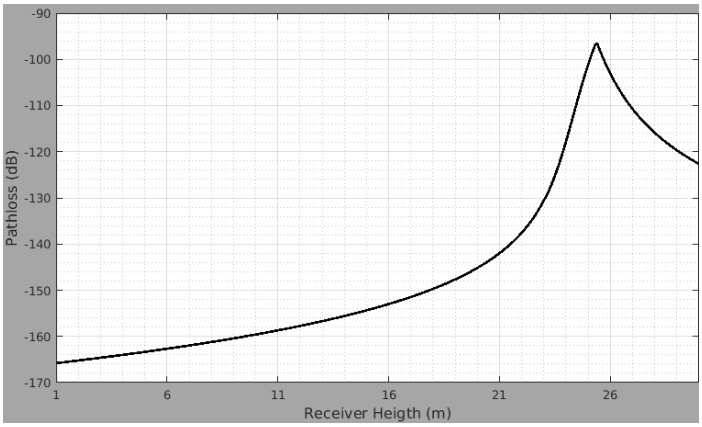

Fig. 8. Path loss of reflected and diffracted fields together

As can be seen in Fig. 8, diffraction effect is very much on the receiver position. In that position ground reflected fields make some contribution to total field. If the receiver height is increased the diffracted field contribution is decreased.

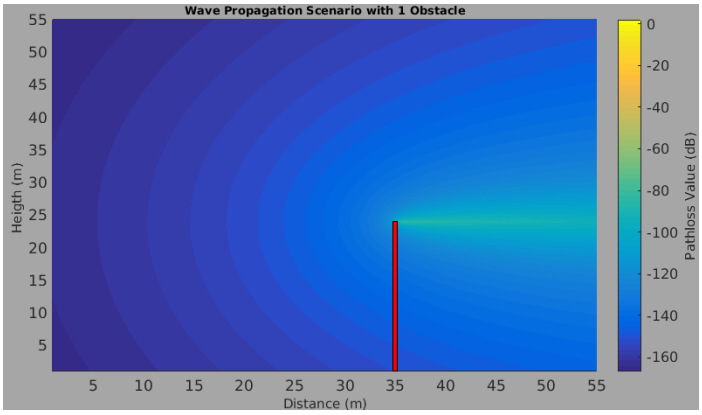

Fig. 9. Coverage Map

Furthermore, a coverage map is generated by using the simple test scenario in Fig. 5. By using only diffracted field, a coverage map is indicated in Fig. 9.

As it is seen in Fig. 9, the diffraction contribution is maxima in the case of plane angle diffraction. Plane angle diffraction takes place in the case that the receiver height is 24 m.

5. Conclusions

The diffraction mechanism is significant to predict the field strength and it is used for coverage prediction in urban, rural and indoor environment behind an obstacle like rooftop, edge, corner, and vertex. This field generated by direct, reflected and diffracted waves. The diffracted fields take place in the case of that wavelength of the electromagnetic wave is close or greater than the slit. In order to solve the diffraction problem in shadow region, a lot of electromagnetic wave propagation models are presented, such as GTD, UTD, S-UTD and S-UTD-CH. Amplitude and slope diffraction coefficient directly affect the total electromagnetic fields at the receiver. As the diffraction angle is close to plane angle, the contribution of slope diffracted field is so high. In the case of diffraction angle π radian; in other words observation, diffraction and field points are in the same line, contribution of amplitude and slope diffraction coefficient is maximum. In future, amplitude and slope diffraction coefficient will be developed for rectangular type structure.

ABSTRACT

In the aim to manage and retrieve the organizational knowledge, in the last years numerous proposals of models and tools for knowledge management and knowledge representation have arisen. However, most of them store knowledge in a non-structured or semi-structured way, hindering the semantic and automatic processing of this knowledge. In this paper we present a more detailed case-based organizational memory ontology, which aims at contributing to the design of an organizational memory based on cases, so that it can be used to learn, reasoning, solve problems, and as support to better decision making as well. The objective of this Organizational Memory is to serve as base for the organizational knowledge exchange in a processing architecture specialized in the measurement and evaluation. In this way, our processing architecture is based on the C-INCAMI framework (Context-Information Need, Concept model, Attribute, Metric and Indicator) for defining the measurement projects. Additionally, the proposal architecture uses a big data repository to make available the data for consumption and to manage the Organizational Memory, which allows a feedback mechanism in relation with online processing. In order to illustrate its utility, two practical cases are explained: A pasture predictor system, using the data of the weather radar (WR) of the Experimental Agricultural Station (EAS) INTA Anguil (La Pampa State, Argentina) and an outpatient monitoring scenario. Future trends and concluding remarks are extended.

1. Introduction

The organizational knowledge management represents a key asset to support decision-making processes by different organizational stakeholders. The main aim of knowledge management systems is to manage, store and retrieve the organizational knowledge, so that it can be used later to learn, share knowledge, solve problems, and ultimately to support better decision-making processes. To ensure an efficient management of organizational knowledge, it is necessary to have technological platforms that support it. In the previous work, we proposed architecture based on data flow processing, for this purpose. Specifically, the Processing Architecture based on Measurement Metadata (PAbMM) [1, 2, 3].

Nowadays, there are processing architectures which allows the real-time data processing through configurable topologies such as Apache Storm [4, 5] and Spark [6]. In this type of architectures, you can dynamically define the processing topology over the data streams and adjust it to different computation necessities, being possible delegating the data structural definition and its meaning inside of the application. In this context, we summarize Processing Architecture based on Measurement Metadata [1, 2], which supported by the framework for measuring and evaluating called C-INCAMI (Context-Information Need, Concept model, Attribute, Metric and Indicator) [7], incorporates metadata to the measurement process, promoting repeatability, comparability and consistency. From the point of view of the semantic and formal support for measurement and evaluation (M&E), the conceptual framework C-INCAMI establishes an ontology that includes the needed concepts and relationships for specifying the data and metadata for any M&E project. Moreover, unlike other strategies for the processing of data streams [8, 9], with the addition of metadata, PAbMM is reliable for guiding the processing of the Measures from heterogeneous data sources, analysing each one in context of origin, as well as its significance within the proposed M&E in which defined.

[1] María de los Ángeles Martín, Street 9 and 110, martinma@ing.unlpam.edu.ar
[2] Mario Diván, Coronel Gil 353, 1st floor, mjdivan@[eco|ing].unlpam.edu.ar

The data streams are structured under C-INCAMI/MIS (Measurement Interchange Schema) [10], which allows gather data and metadata jointly inside the same stream. In this metadata, we can describe the measurement context additionally to the entity under measurement, which permits avoid analysing the measure in isolation way.

The PAbMM evolves the original strategy [1] incorporating support to the big data repositories in contexts of distributed computation. This implies the necessity of gather Big Data and Data Stream Processing technologies; which ensures powerful large data volumes processing, allowing efficient management of knowledge in the Organizational Memory.

The Organizational Memory that integrates the Processing Architecture based on Measurement Metadata serve as base for the organizational knowledge exchange and to be used in recommender systems in decision making processes.

Therefore, by having a well-developed organizational memory that supports the structuring, reusing and processing of organizational knowledge is a primary decision (and likely a success factor) to achieve such an effective management.

Nonaka and Takeuchi have said that an organization cannot create knowledge itself. Conversely, the knowledge creation basis for an organization is the individual's tacit knowledge; and tacit knowledge is shared through interpersonal interactions [11].

Therefore, in order to reach and maintain the organizational effectiveness and competitiveness, an organization needs to learn from past and present experiences and lessons learnt and to formalize organizational memories for enabling to make explicit the individual's tacit knowledge -and why not community's tacit knowledge as well.

One of the main goals of an organizational knowledge management strategy is to make explicit the individuals' implicit knowledge, to try to formalize the informal knowledge in order to allow machine-processable semantic inferences. A way of alleviating this problem from the knowledge representation standpoint is to store the knowledge in a more structured and formal way. We have followed this approach by using the case-based organizational memory strategy. It combines organizational knowledge storage technology with case-based reasoning (CBR) to represent each item of informal knowledge. In general, the organizational memories are intended to store the partial formal and informal knowledge present in an organization with automatic processing capabilities. In particular, by structuring an organizational memory in cases can also facilitate the automatic capture, recovery, transfer and reuse of knowledge for problem solving.

The main goal of this research is the integration of the Organizational Memory and case-based reasoning into the Processing Architecture based on Measurement Metadata as conceptual foundation for any organizational knowledge management. Also, the discussion about the added value of organizational memories; Thus, data, information, and knowledge from heterogeneous and distributed sources can be automatically and semantically processable by web-based applications, for instance, an 'intelligent' recommendation system to support a more effective decision-making process.

This article is organized in six sections. The Section 2 summarizes the conceptual framework C-INCAMI. The section 3 outlines the Processing Architecture based on Measurement Metadata. The Section 4 outlines the case based organizational memory. The Section 5 illustrates the application of the organizational memory to a practical case: a pasture predictor system using the data of the weather radar of INTA EEA Anguil. The Section 6 shows the application of the PAbMM Architecture and organizational memory to an outpatient monitoring and diagnosis case. The Section 7 discusses related work and finally section 8 summarizes the conclusions.

2. C-INCAMI Overview

C-INCAMI is a conceptual framework [12], which defines the concepts and their related components for the M&E area in software organizations. It is an approach in which the requirements specification, M&E, and analysis of results are performed for satisfying a specific information need in a given context. C-INCAMI is structured in the following main components: i) M&E project management, ii) Non-functional Requirements specification, iii) Context specification, iv) Design and implementation of measurement and v) Design and implementation of evaluation. Most components are supported by the ontological terms defined in [13].

The M&E project definition component defines and relates a set of project terms needed for dealing with M&E activities, methods, roles and artefacts.

The Non-functional requirements component allows specifying the Information need of any M&E project. The information need identifies the purpose and the user viewpoint; in turn, it focuses on a Calculable Concept and specifies the Entity Category to evaluate. A calculable concept can be defined as an abstract relationship between attributes of an entity and a given information need. This can be represented by a Concept Model where the leaves of an instantiated model are Attributes. Attributes can be measured by metrics.

Regarding measurement design, a Metric provides a Measurement specification of how quantifying a particular attribute of an entity, using a particular Method (i.e. procedure), and how to represent its values, using a particular Scale. The properties of the measured values in the scale with regard to the allowed mathematical and statistical operations and analysis are given by the scale Type. Two types of metrics are distinguished. Direct Metric is that for which values are obtained directly from measuring the corresponding entity's attribute, by using a Measurement Method. On the other hand, the Indirect Metric value is calculated from other direct metrics' values following a formula specification and a particular Calculation Method.

For measurement implementation, a Measurement specifies the task by using a particular metric description in order to produce a Measure value. Other associated metadata is the data collector name and the timestamp in which the measurement was performed. The Evaluation component includes the concepts and relationships intended to specify the evaluation design and implementation. It is worthy to mention that the selected metrics are useful for a measurement tasks as long as the selected

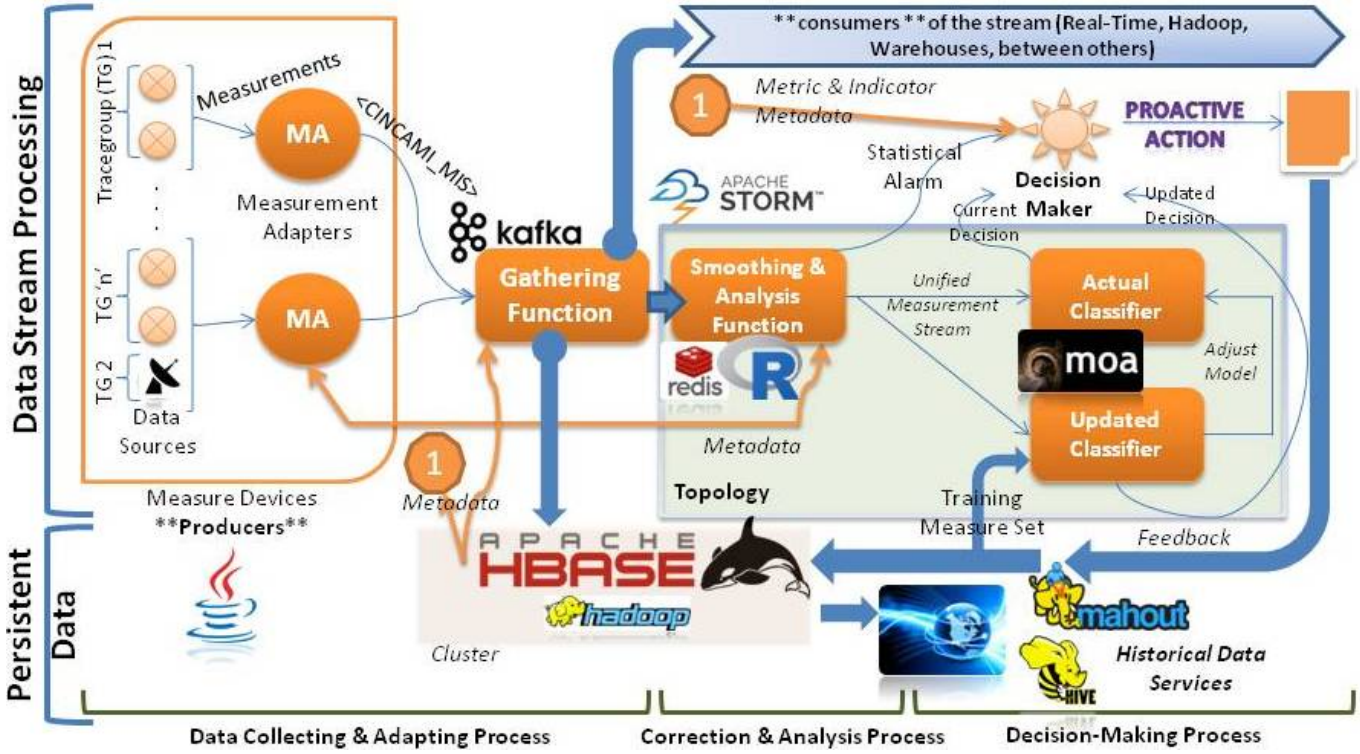

Figure 1. Extensions for the measurement component of C-INCAMI.

indicators are useful for an evaluation tasks in order to interpret the stated information need.

With the formalization of the project M&E based on C-INCAMI, the fact labelling process flow allows structuring the contents of a consistent and aligned with the project objective way. This structuring of the measurements within the PAbMM, maintains the concept that each measure is associated; for example, if a measure of contextual attribute or property.

Inside the stream and jointly with each measure associated with an attribute, the measures associated with the contextual properties are labeled. Thus, it enriches the statistical analysis because it is possible verify the formal and syntactic consistency of each measure against their formal definition, prior to moving forward with more complex statistical techniques.

3. The Processing Architecture Based on Measurement Metadata

The PAbMM is a manager of semi-structured measurements streams, enriched with metadata supported by C-INCAMI, specialized in M&E projects, which incorporates detective and predictive behaviour at online with the ability to manage and provide large volumes of data on demand.

As shown in Figure 1, the conceptual model in terms of stream processing it is as follows. The measurements are generated in the heterogeneous data sources (for example, The INTA weather radar [14]), which supply a module called Measurements Adapter (MA in Figure 1) generally embedded in measurement devices.

MA incorporates together with the measured values, the metadata of the M&E project and reports it to a central gathering function (Gathering Function -GF). GF incorporates the measurements streams in parallel in: a) The big data repository in persistent way, b) The C-INCAMI/MIS stream for the subscribers wishing to process information at the time when it is generated (for example, for INTA weather radar data, a consumer could be the National Meteorological Service), and c) Inside a buffer organized by monitoring groups -dynamic way of grouping data sources defined by the M&E project manager- in order to allow consistent statistical analysis at level of monitoring group or by geographic region where the data sources are located, without incurring in additional processing overhead. Additionally, GF incorporates load shedding techniques, which allows manage the queue services associated with the measurements, mitigating the risks of overflow regardless how they are grouped.

Thus, the C-INCAMI/MIS stream, is incorporated into the big data repository with measurements and metadata, and remains available to meet requests for services associated with data on historical measurement (Big Data Repository and The Historical Data Services in Figure 1). In addition to the measurement stream is sent to the subscribed consumers, a copy of this continues within the data stream processor and applies descriptive, correlation and principal components analysis (Analysis & Smoothing Function -ASF - in Figure 1) guided by their own

metadata, in order to detect inconsistent situations with respect to its formal definition, trends, correlations and / or identify system components that contribute most in terms of variability.

If a situation is detected in ASF, a statistical alert is triggered to the decision maker (DM) for evaluating whether or not to trigger external warning (via email, SMS, etc.) for reporting to the monitoring staff responsible of the situation (for example, in the case of the INTA WR, it could signal a possible device error or WR calibration). In parallel, the new measurements streams are reported to current classifier (Current Classifier -CC-), who must classify the new measurements whether or not correspond to a risk and report its decision to the DM. Simultaneously, the CC is reconstructed online, incorporating new measurements to the training set and producing a new model with them (Updated Classifier -UC).

The UC classifies the new measurements and produce a current decision which will also be communicated to the DM. The DM determines whether the decisions referred by classifiers (CC and UC) correspond to a risk and in which case, what probability of occurrence, act accordingly as defined in the minimum threshold of probability of occurrence defined by the project manager. Finally, regardless of the decisions taken, the UC turns into replacing the previous CC, just if an improvement in their ability for classifying is obtained according to the adjustment model based on ROC curves (Receiver Operating Characteristic) [15].

From a technological point of view, PAbMM evolves the solution proposed in the SDSPbMM, because now it is possible the management of the big data repositories in the distributed computation context, the data provision to thirds by subscription, and maintaining the real-time measurement processing in parallel (See Figure 1). Thus, we prioritize the use of the open source technology with the aim of promoting the extensibility, dynamism and broadcast of the architecture.

In this way and how you can see in the Figure 1, the data sources continue implementing the original interface of SDSPbMM called "*DataSource*", which establishes the responsibilities that a data source must satisfy to provide data in the architecture. Additionally, each MA in PAbMM (See Figure 1) becomes in a producer in terms of Apache Kafka [16, 17]. Thus, the data sent from the producers (for example, the INTA WR) will be processed by a subscription service inside of the processing cluster, under the concept called "Gathering Function" (GF). In this function, the data are collected from the data source, and the measures coming from the same entity under analysis are gathered and organized in a common buffer.

From the common buffer, we use Apache Kafka [17] to generate the unified measurement streams addressed to the consumers (See Figure 1), understanding by this to: a) The real-time subscribers (for example, Argentinian Air Force), b) The real-time processing topology which runs on Apache Storm [4], and c) The big data repository which store the streams in Apache HBase [18, 19] to support the historical data services.

Now, because the PAbMM runs on the Apache Storm and uses Apache Kafka, it is possible to consume and to process the measurement streams from the GF in a continuous way. The latter incorporates flexibility, scalability and dynamism in relation to the configuration of the processing topology, because both the Analysis and Smoothing Function (ASF) and the classifiers are *Bolts* [4], which may be reorganized in agile way and on demand. Moreover, inside the Storm topology, the PAbCMM continues using R [20] for the statistical computing (analysis and smoothing) and Redis [21] as NoSQL database for: *i) Cache Management, ii) Use of intermediate results from R, iii) Storing of snapshot with the last known state of each entity under monitoring.* Finally, the classifiers use the Hoeffding Tree from Massive Online Analysis (MOA) [22] to get a learning incremental strategy which allows to process big streams with limited computation resources.

At persistent level and by a side, PAbMM uses Apache Hadoop and HDFS (Hadoop Distributed File System) [23, 24] to promote the distributed computing, and Apache HBase [19] as columnar database which allows the monolithic scalability and random access to the measurements stored as C-INCAMI/MIS. From this repository, we use Apache Hive [25, 26] to support ad-hoc query on distributed contexts. Moreover, we use Apache Mahout [27, 28] to run classification and clustering analysis according to the needs, which allows one way of feedback the organizational memory.

The organizational memory is case-based and run over the Apache HBase. As the case-based reasoning engine uses MapReduce [24] programs in its recommendation subsystem, each case <fact,solution> is structured in the form of <key,value> to get the advantage from the distributed computing and the parallelism.

Finally and on the one hand, PAbMM is oriented to the distributed computing, scalability and extensibility over mature and open source technologies for supporting big data repositories; and on the other hand, it is possible broadcast the information by Apache Kafka while the stream engine runs over Apache Storm. Thus, PAbMM can be viewed as a simple topology, which allows us to manage the changes, make the adjustments/fixes that being necessaries, and make easier its interoperability.

In the case study that will be presented in section 5, where the architecture is applied for the processing of the data streams from a weather radar, our focus is in: a) Collect the measurements in structured and interoperable way by C-INCAMI/MIS, b) Store all the measures under a single repository, c) Use the stored measures to answer queries or to support a cluster/classification analysis, d) Provide data in real-time and historical on demand, e) Get and maintain an organization memory with the previous experience of the geographical region, and f) Prevent, or at least detect, the potential problematical situations from the documented experience.

4. Case Based Organizational Memory

Once the data (with the associated metadata), are incorporated from the data sources to persistent Big Data repository, it is desirable to structure them in an Organizational Memory, so that can later be exploited and used for recommendation during decision-making processes.

With the aim to manage and retrieve the organizational knowledge, in the last years numerous proposals of models and tools for knowledge management and knowledge representation have arisen. However, most of them store knowledge in a non-structured or semi-structured way, hindering the semantic and

automatic processing of this knowledge. In this section we specify a case-based organizational memory, so that it can be used to learn, reasoning, solve problems, and as support to better decision making as well.

A way of alleviating this problem from the knowledge representation standpoint is to store the knowledge in a more structured and formal way. We have followed this approach by using the case-based organizational memory strategy. It combines organizational knowledge storage technology with case-based reasoning (CBR) to represent each item of informal knowledge. In particular, by structuring an organizational memory in cases can also facilitate the automatic capture, recovery, transfer and reuse of knowledge for problem solving.

4.1. Case Based Organizational Memory Ontology Overview

Although the benefits of applying the knowledge management systems are well known, and the idea of applying case-based reasoning methods to lessons learned and best practices are not new in the knowledge representation area, there is almost no consensus yet on many of the concepts and terminology used in both knowledge management and case-based reasoning areas. In order to reach this aim we have constructed a common conceptualization for case-based organizational memory where concepts, attributes and their relationships should be explicitly specified; such an explicit specification of a conceptualization is one of the core steps for building ontology.

In the following sections, we will describe case-based organizational memory ontology and his application (using the architecture) to the construction of a pasture predictor system using the data of the wheather radar of INTA EEA Anguil.

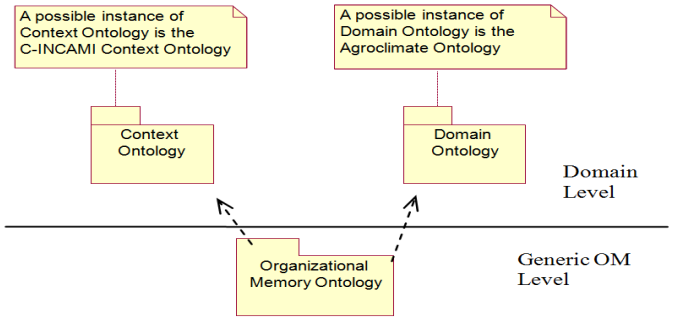

Figure 1. The relationship between ontologies at the specific domain level and at the generic organizational memory level components

The organizational memory ontology aims to be at a generic level from which other representations for specific domain applications can be formulated (see Figure 2). On the one hand, the case-based organizational memory ontology is defined at a generic organizational memory level, and on the other hand, for characterizing the cases according to the specific knowledge domain and its context [29], a domain and context ontologies should also be provided.

The objective of our ontology is to serve as a foundation for the organizational knowledge exchange with semantic power, which in turn facilitates the reuse, the interoperability and the automatic processing by agents [30].

The main concepts of the ontology, which are illustrated in the UML diagram of the Figure 3, are described in the following text, highlighted in italic.

An *organizational memory* is the way in which an organization stores and keeps track of what it knows, i.e., about the past, present and future knowledge. An organizational memory can have one or more *knowledge bases* which are intended to achieve different information needs of an organization –recalling that data, information and knowledge are useful assets for decision making. In addition, an organizational memory may be seen as a repository that stores and retrieves the whole specified, explicit, formal and informal knowledge present in an organization. Thus, a knowledge base is an organized body of related knowledge; taking into account that knowledge is a body of understanding and/or lessons learnt from skills and experiences that is constructed by people.

A type of knowledge base is a *case knowledge base* which stores the acquired knowledge in past experiences, good practices, learned lessons, heuristics, etc. to different domains; that is, it stores cases. A *case* is a contextualized *knowledge item* (i.e., an atomic piece of knowledge) representing an experience by means of a problem and its solution.

The representation of the knowledge through cases facilitates the reuse of the knowledge acquired in past problems to be applied to a new problem in similar situations [31].

A case can be seen as an ordered pair < P, S >, where P is the *problem* space, and S is the *solution* space.

There exists a general description of problems as $P(x_1, x_2, \ldots, x_n)$, where each individual problem is an instance $P(a_1, a_2, \ldots, a_n)$; also a general description of solutions as $S(y_1, y_2, \ldots, y_n)$, and every individual solution $S(b_1, b_2, \ldots, b_n)$ is an instance of that general description. The x_i are variables that characterize the problem (*problem feature*), and the y_i are variables that characterize the solution (*solution feature*), where both are features. A *feature* or attribute is a measurable physical or abstract property of an entity category. Since the stored cases refer to a specific knowledge domain, the features that characterize the problems and solutions are defined by a *domain concept* term; for example, the concepts coming from the meteorology domain ontology (i.e. *Precipitation Accumulation*, *Hail*, *Hail Damage, Environmental Temperature, Environmental Pressure* and so on, as we will illustrate in Section 5.2).

The case-based reasoning process consists in assigning values to problem variables and finding the adequate instances for solution variables. To find the appropriate values for the instances of a solution, the similarity assessment of cases should be performed, so that for each case knowledge base a *similarity assessment model* should be specified.

Greater detail of the functionality of the Organizational Memory can be found in [32], where processes have been formalized by the SPEM metamodel to promote its communicability and extensibility.

4.2. Similarity Assessment Model Representation

Most of the case-based reasoning applications have been focused on problems of specific domains. However, in order to be useful to an organization, a case-based reasoning system should be fitted in with the main knowledge sources that can stem from

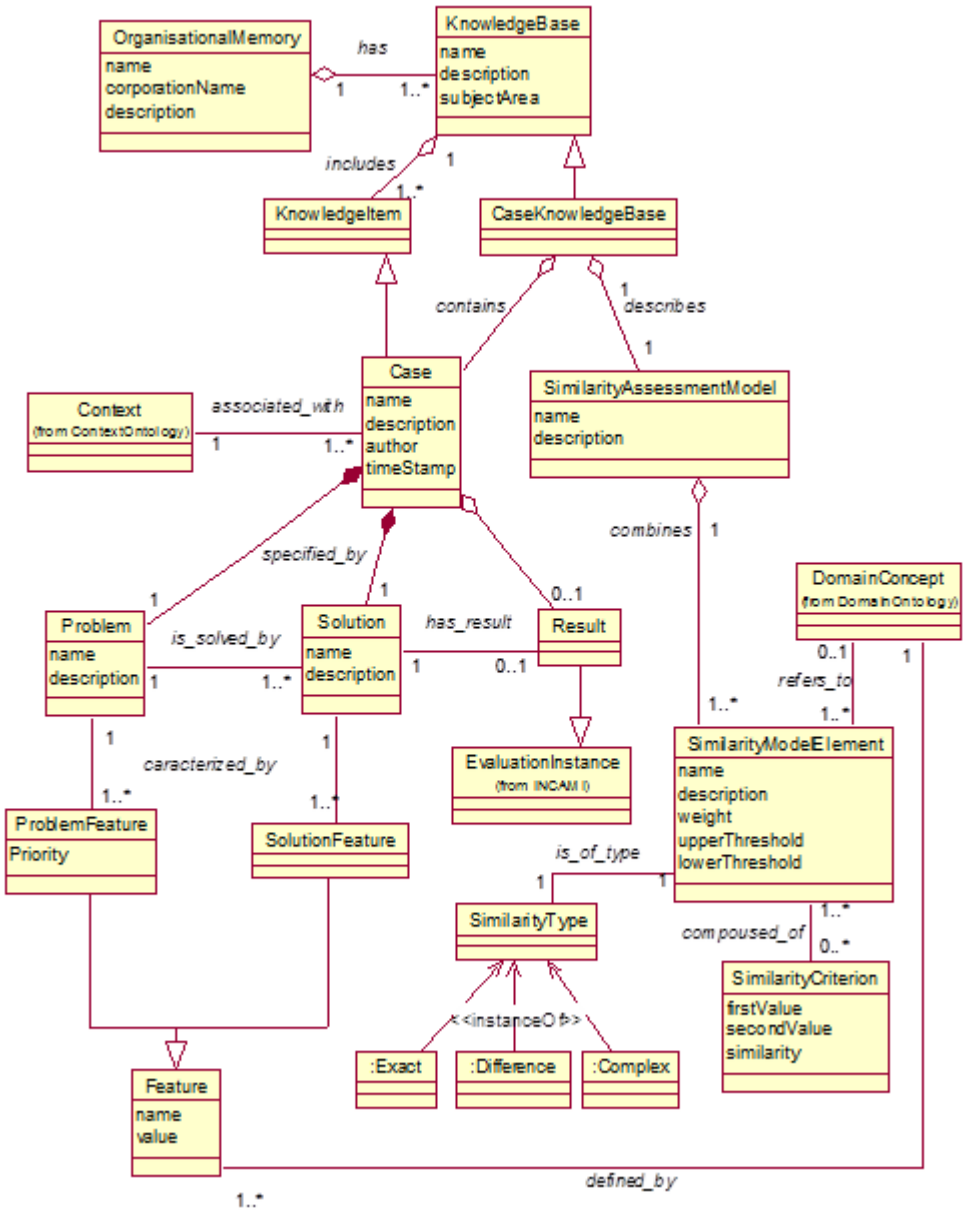

Figure 3. UML diagram that specifies the main terms, attributes and relationships to the Case-based Organizational Memory Ontology.

diverse domains, and so the similarity functions appropriate to each case knowledge base.

Usually, the similarity between a recovered case R and a new case C is defined as the sum of the similarities among its constituent feature values multiplied by their weights, i.e. the so-called Nearest Neighbor formula:

$$Similarity(R, C) = \sum_{f \in F} w_f * sim_f(f_R, f_C) \quad (1)$$

Where w_f is the weight of the feature f, and sim_f is the similarity measurements function to the feature. Therefore, in order to provide an appropriate representation of the similarity model, it is necessary to represent the weights that model the relative relevance, and the similarity function type for each specific feature. The weights are represented as an attribute inside each similarity element (see Figure 3), and the similarity type is restricted to be one out of three general types, namely: Exact, Difference and Complex.

The inclusion of these three types of functions is based on the analysis of numerous investigation works in the case-based

reasoning area, as well as taking into account they cover the similarity representation needs of most cases in the Software and Web Engineering area. Particularly:

- The Exact similarity function returns 1 if two feature values are the same and 0 otherwise.
- The Difference similarity function is inversely proportional to the difference between a feature values. It can only be applied when it is possible to define the value difference; for instance, between numerical values the difference similarity function returns 1 if both features are equals, and return $1/|f_c - f_n|$ in other case.
- The Complex similarity function solves the similarity for all those situations where the two previous functions are not applicable; for example, the semantic difference between two synonymous terms that is neither completely the same nor completely different. If the number of a feature values is finite, it is feasible to have beforehand the similarity measure values for all possible values' pairs. In our model, these parameters are represented in the Similarity Criterion class, which is defined as the assessment pattern used to determine the semantic similarities between two feature values.

Ultimately, an exhaustive glossary of terms, attributes and relationships are shown in [29], where the terminology for the case-based organizational memory ontology is explicitly described.

5. Practical Case 1: A Pasture Predictor

In order to illustrate the above main concepts, attributes and relationships, we will elaborate on an example of case-based knowledge base and its similarity assessment model for a specific domain: a pasture predictor system, using the data of the weather radar of INTA EEA Anguil. This case base stores a body of related knowledge about the growth of pasture based on a range of data, including current weather conditions and forecasts, rainfall events and past climate records, processed by the PAbMM architecture and taking the radar as a data source.

5.1. The Weather Radar of INTA EEA Anguil

Weather radars are active sensors of remote sensing that emit pulses of electromagnetic energy into the atmosphere in the range of microwave frequencies. These sensors are tools to monitor environmental variables, and specifically, the identification, analysis, monitoring, forecasting and evaluation of hydro meteorological phenomena, as well as physical processes that these involve, given the risk that can cause severe events. Its main applications are: a) Weather description, forecasting and nowcasting, b) Forecasting and monitoring of environmental contingencies (hail, torrential rain, severe storms, etc.), c) Security in navigation and air traffic control, d) Studies of atmospheric physics, e) studies of agro climatic risk, f) Provision of basic data for scientific and technological research, and g) Provision of input data for hydrological models (i.e. floods) [14]. The information recorded by the WR is collected through volumetric scans and today, the data are stored in separate files called volumes. The data contains the different variables: reflectivity factor (Z), differential reflectivity (ZDR), polarimetric correlation coefficient (RhoHV), differential phase (PhiDP), specific differential phase (KDP), radial velocity (V) and spectrum width (W).

Two types of data are distinguished: a) raw data and b) some level of data processing or "products". In both cases, the sampling units are 1 km^2 and 1º and each variable are stored in separate files.

Under normal operation, in a full day (00:00h to 23:50h), 8640 files are generated only for the range of 240 km just for one WR. In this sense and for each day, just the WR of the EAS Anguil produces daily a volume of 17GB of data, which represents about 6.2 Tb annually and just for one WR.

From raw data using the proprietary software Rainbow 5, different processing can be obtained, for example, some hydrological products estimating precipitation characteristics as SRI (Surface Rain Intensity), which generates values intensity or PAC (Precipitation Accumulation), which calculates a cumulative rain in a predefined time interval. These products can be formatted in XML or raster image. Also, INTA developed software that can generate more products from raw radar data, for example applications of models to estimate occurrence of hail and hail damage to crops [14].

The users of radar data and radar products, with free and open access are: i) National System of Weather Radar (SiNaRaMe), ii) SMN, iii) Sub secretary of Nation Water Resources (SSRH), iv) National Water Institute (INA), v) Civil Defence vi) Argentinean Air Force, vii) Commercial and General Aviation, viii) Directorate of Agriculture and Climate Contingencies (DACC, Mendoza) ix) Agro climatic Risk Office (ORA), xi) Universities, xii) Research Groups and related product development, xiii) Insurance Companies, xiv) Media, xv) INTA.

In this case, PAbMM define a M&E project which is useful between others things, for detecting decalibration in the WR in each data stream processed. So, and in terms of PAbMM, each WR is a heterogeneous data source that uses a MA. The architecture store the C-INCAMI streams from each WR, provides by subscription the data and allows the monitoring of the stream to make decisions in real time. In this way and from the processed data, you can build knowledge management systems for supporting the decision making in the agricultural production domain, based in the experience stored through the Organizational Memory.

5.2. Knowledge Base for Pasture Production

This case base stores a body of related knowledge about pasture growth in relation to current, past and future weather conditions, so that it serves as the basis to a recommendation system that support the new cycle of pasture production regarding similar past ones.

This knowledge base, collect heterogeneous data from different sources (One source of data is the Weather radar of INTA EEA), as well as manual measurements made by agricultural producers, for example the estimated Daily production of pasture.

The aims of the knowledge base are to support productivity, efficiency and continuing growth in this important industry.

It saves past knowledge about weather conditions (as problems) and their pasture production (as solutions).

By providing 60-day forecasts for the growth of pasture, the aim to help farmers make better decisions in managing their herds, production and costs.

To illustrate the knowledge base and for easier understanding, a simplified model of the Case structure is shown. This case knowledge base characterizes the problem situation through various characteristics including current weather conditions 7-day forecasts, rainfall and hail events, and past climate records. Also the context data of location and time is taken into account. In this example, the case is characterized through four features, namely: Precipitation Accumulation, Hail, Hail Damage, and Rain Forecast that are defined in the meteorology domain ontology.

Table I Example of similarity assessment model for a case base

Feature	Description	Type	Wht
Precipitation Accumulation	Accumulative rain in Last 10 days	Difference	0.40
Hail	Indicates the occurrence of hail in Last 10 days (Possible values are *yes* or *no*)	Exact	0.15
HailDamage	Indicates the occurrence of hail damage in Last 10 days (Possible values are *yes* or *no*)	Exact	0.25
RainForecast	Indicates the next 7 days rain forecast	Difference	0.20

Analogously, the solution will be characterized by the PastureProduction feature; which indicates the daily kg of dry matter produced in one hectare.

For each feature that characterizes a case, we should establish its weight and its similarity function type (see Table 1). These design decisions could be made by an expert taking into account which features are considered more relevant from the similarity point of view to evaluate in the end the global similarity of two cases.

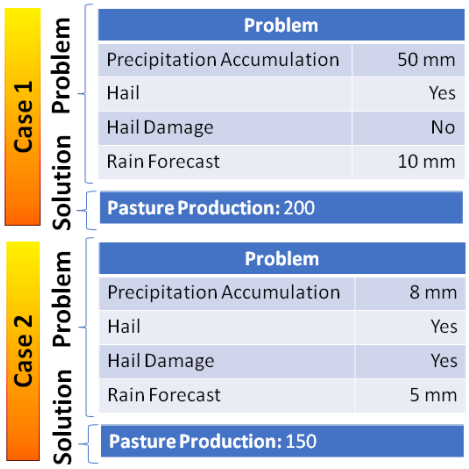

Figure 2. Example of representation of two stored past cases

Once defined the case structure and its similarity assessment model, each case is stored with all the feature values that characterize it and its solution accordingly. Two case examples are shown in Figure 4.

A new decision in herds managing can benefit from the case-based organizational memory by recovering the pasture prediction information of the most similar environmental conditions. Let us suppose that we want to buy animals to fatten and need to know if we have enough grass, and that the case base stores the two cases shown in Figure 4, among others.

In order to minimize risks, we can take advantage of the recorded knowledge by retrieving and reusing the most similar past experience. Therefore, table 2 shows the similarity calculation of each feature of the new case compared to the previous past ones, i.e., "Case 1" and "Case 2". Hence the global similarity calculations give as outcomes:

$$Similarity(Case\ 1, New) = 0.4 * 0.03 + 0.15 * 1 + 0.25 * 1 + 0.2 * 0.2 = \mathbf{0.453}$$

$$Similarity(Case\ 2, New) = 0.4 * 0.083 + 0.15 * 1 + 0.25 * 0 + 0.2 * 0.1 = \mathbf{0.203}$$

Table II. Example of Similarity Assessment between the previous two past cases and the new one

Feature	Case 1	Case 2	New Case	Similarity Case1/New	Similarity Case2/New
Precipitation Accumulation	50	8	20	$\frac{1}{\lvert 50-20\rvert} = 0.03$	$\frac{1}{\lvert 8-20\rvert} = 0.083$
Hail	Yes	Yes	Yes	1.00	1.00
HailDamage	No	Yes	No	1.00	0.00
RainForecast	10	5	15	$\frac{1}{\lvert 10-15\rvert} = 0.2$	$\frac{1}{\lvert 5-15\rvert} = 0.1$

Resulting "Case 1" as the most similar to the new case, and therefore the pasture prediction is 200 daily kg of dry matter produced.

6. Practical Case 2: Outpatient Monitoring and Diagnosis

In this section we show another use of PAbMM and Case Based Organizational Memory oriented to an outpatients monitoring scenario.

Considering a healthcare centre, the doctors need monitor the outpatients for avoiding adverse reactions or major damage in general. In this sense, PAbMM bring to doctors of a mechanism by which they can be informed about unexpected variations and/or inconsistencies in health indicators defined by them (as experts). So, the core idea is: there exists some proactive mechanism based on health metrics and indicators that produces an alarm for each risk situation associated to the outpatient under monitoring.

Considering C-INCAMI, the information need is "to monitor the principal vital signs of an outpatient when he/she is given the

medical discharge from the healthcare centre". The entity under analysis is the outpatient.

According to medical experts, the corporal temperature, the systolic arterial pressure (maximum), the diastolic arterial pressure (minimum) and the cardiac frequency represent the relevant attributes of the outpatient vital signs to monitor. They also consider as necessary monitoring the environmental temperature, environmental pressure, humidity, and patient position (i.e. latitude and longitude) contextual properties.

Indicator Code	ETEMP	
Indicator Name	Level of corporal temperature	
Domain		
(hyperpyrexia, very high fever, fever, normal, hypothermia risk, hypothermia)		
Scale		
Type of Scale	Categorical	
The Value Domain	Ordinal	
Unit	-	
Calculation Method (Elementary Model)		
Name	Temperature Analysis	
Specification	Axillary Temperature (Direct Metric)	Indicator Value
	>= 41.50	Hyperpyrexia
	[38.30 , 41.50)	Very high fever
	[37.50 , 38.30)	Fever
	[36.50 , 37.50)	Normal
	[35.00 , 36.50)	Hypothermia risk
	< 35.00	Hypothermia (While the temperature is descending there is risk of plain encephalogram).

Decision Criteria		
Indicator Value	Level of Acceptability	
Hyperpyrexia	Not Acceptable	
Very high fever	Not Acceptable	
Fever	Poorly Acceptable	
Normal	Acceptable	
Hypothermia risk	Poorly Acceptable	
Hypothermia	Not Acceptable	

Figure 3. Details of the Level of Corporal Temperature elementary indicator specification

The definition of the information need, the entity, its associated attributes and the context are part of the "*Non-functional requirements specification*" and "*Context specification*" components as discussed in section 2. For monitoring purposes, the metrics that quantify the cited attributes, were selected from the C-INCAMI DB repository (Implemented by Apache HBase in figure 1); likewise, the metrics that quantify the cited contextual properties.

After the set of metrics and contextual properties for outpatient monitoring has been selected, the corresponding elementary indicators for interpretation purposes have also to be selected by experts.

In this way, they have included the following elementary indicators: the level of corporal temperature, the level of pressure, the level of cardiac frequency and the level of difference between the corporal and the environmental temperature. The concepts related to indicators are part of the Evaluation Design and Implementation component. Figure 5 shows the specification of the level of corporal temperature elementary indicator; for example, the different acceptability levels with their interpretations are shown, among other metadata.

Besides, considering that ranges of the acceptability levels (shown in Figure 5) are in an ordinal scale type, then the target variable for the stream mining function (classification) is feasible. So, both classifiers, CC and UC, act relying on the values of the given indicators and their acceptability levels.

6.1. Implementation Issues

Once all the above project information was established, it is necessary for implementation issues to choose a concrete architecture to deploy it. Fig. 6 depicts an abridged deployment view for the outpatient monitoring system considering the PAbMM approach.

Let's suppose we install and set up the MA in a mobile device –the outpatient device-, which will work in conjunction with sensors as shown in Fig. 6. Therefore, while the data collecting and adapting processes are implemented in a mobile device by the MA, the gathering function and other processes can reside in the medical centre computer. The MA component informs the measures (streams) to the gathering function (GF) in an asynchronous and continuous way. MA takes the measures from sensors (in fact, the data sources) and incorporates the associated metric metadata for attributes and contextual properties accordingly. For instance, it incorporates the contextual property ID for the environmental temperature joint to the value to transmit; and so, for every attribute and contextual property. Note that data (values) and metadata are transmitted through the C-INCAMI/MIS schema to the gathering function (GF inside of PAbMM in figure 6), as discussed in section 3.

Although all the values of metrics and contextual properties from monitored outpatients are simultaneously received and analyzed, let's consider for a while, for illustration purpose, that the system only receives data for the axillary temperature attribute and the environmental temperature contextual property from one outpatient, and that also the system visualizes them.

The measures and, ultimately, the acceptability level achieved by the level of corporal temperature elementary indicator, indicate a normal situation for the patient.

Nevertheless, the online decision-making process (Inside of PAbMM, See Section 3), apart from analyzing the level of acceptability met for attributes; also it analyzes the interaction with contextual properties and their values.

At first glance, what seemed to be normal and evident, it was probably not because the processing model can detect in a proactive form a correlation between axillary temperature and environmental temperature. This could cause the triggering of a preventive alarm from the medical centre to doctors, because the increment on the environmental temperature can drag in turn the increment in the corporal temperature, and therefore this situation can be associated to a gradual raise in the risk likelihood for the outpatient.

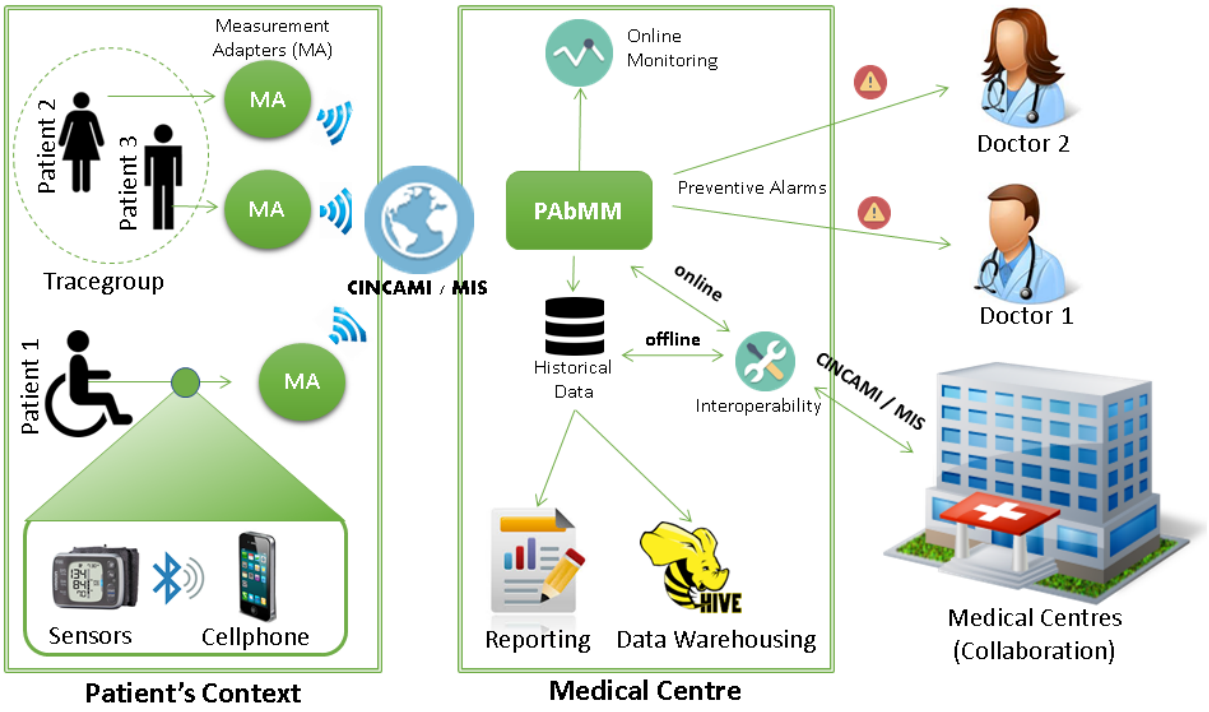

Figure 6. A deployment view for the Outpatient Monitoring System.

6.2. Diagnosis System

Despite of outpatient monitoring task, using the knowledge base of the organizational memory, and the outpatient monitoring data streams, is possible recommend disease diagnosis for a better decision-making. In a similar way to pasture prediction presented in section 5.2, for designing the diagnostic system based on the MOBC, the Organizational Memory must be customized, defining the domain ontology according to the type of knowledge to be stored (See Figure 2).

Case 1

Problem

Problem	
Corporal temperature	38.9°
Systolic arterial pressure	120 mmHg
Diastolic arterial pressure	80 mmHg
Cardiac frequency	95 bpm

Solution

Diagnosis: Influenza **Treatment:**	
Drug	Amoxicillin
Concentration	500 mg
Dose	1 capsule
Daily Frequency	4

Figure 7. Example of a diagnostic case stored in the MOBC.

A problem (possible illness) can be characterized by its symptoms. In order to simplify our example, and for this study, the complete ontology was not developed. We will consider that corporal temperature, the systolic arterial pressure (maximum), the diastolic arterial pressure (minimum) and the cardiac frequency represent the relevant attributes that characterize the problem in the patient, but this list must be completed and adapted to each health institution, according to your needs. Each symptomatic table may have a diagnosis associated with it, and each diagnosis may have different treatments.

Figure 7 shows an example of a case that represents the diagnosis "Influenza", and its respective solution (or corrective action) based on the conceptual model of Figure 2.

For illustrating how the PAbMM classifier can be trained in the arrival of new measures from the monitoring, an example is shown in which the MO stores among its data, two cases: the Influenza case (See Figure 7) and the hypertension case, (See Figure 8). In the case of new data, the classifier will generate a new case (data + metadata using C-INCAMI / MIS) and try to establish an alarm (if applicable) interacting with the MO through the recommendation function.

Measures reported from PAbMM to MO suggest a temperature of 36.9°, a diastolic arterial pressure of 110 mmHg, a systolic arterial pressure of 200 mmHg and a heart rate of 98 bpm. The PAbMM indicates an alarm because it has detected a progressive increase in the pressure, but he does not know how to proceed in terms of medical treatment, and it resorts to organizational memory. The CBR engine of the MO will look for a more similar case. For our example we apply the similarity function Difference, which values the similarity equal to 1 if both characteristics are equal and $1/|f_c - f_n|$ in other case.

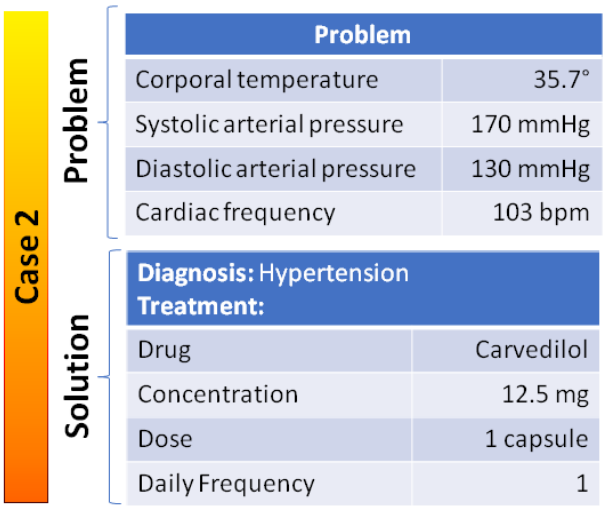

Figure 8. Example 2 of a diagnostic case stored in the MOBC.

Table 3. Medical Recommendation. Example of Similarity Assessment between the previous two past cases and the new one

Feature	Case 1	Case 2	New Case	Similarity Case1/New	Similarity Case2/New
Corporal temperature	38.9	35.7	36.9	0.5	0.83
Systolic corporal pressure	120	170	200	0.0125	0.03
Diastolic arterial pressure	80	130	110	0.033	0.05
Cardiac frequency	95	103	98	0.33	0.20

We also apply equal weight (0.25) to each of the four characteristics. In order to calculate the overall similarity of each pre-existing case with respect to the new case (NC), the formula (1) in section 4.2 is applied, replacing the weights and similarity values for each characteristic (See Figures 7 and 8). As set out below:

$$Similarity(Case\ 1, New) = 0.25 * 0.50 + 0.25 * 0.0125 + 0.25 * 0.033 + 0.25 * 0.33 = \mathbf{0.219}$$

$$Similarity(Case\ 2, New) = 0.25 * 0.83 + 0.25 * 0.033 + 0.25 * 0.05 + 0.25 * 0.2 = \mathbf{0.279}$$

In this way, the most similar case to the new one is the hypertension, which will allow triggering together with the alarm, the recommended treatment (Carvedilol concentration 12.5, 1 capsule per day) for the detected situation.

7. Related Work

In our specific work we have illustrated the use of the case-based reasoning approach to develop a case-based organizational memory; using the advantage of having the PAbMM architecture, which manage large volumes of structured data together with their metadata. The main goal is to exploit the knowledge that con be extracted from organizational memory under a key-value structure (i.e. case-solution structure) stored in the Big Data repository, allowing to incorporate more experience for recommending the courses of actions to the decision-making process.

Firstly, from the organizational memory point of view, there are numerous proposals in the knowledge management area, for example the ones documented in [33, 34]. Most of them capture and store the knowledge in repositories of documents like manuals, memos, and text files systems, etc. where structured or semi-structured storage strategies are seldom used. These approaches usually do not employ powerful mechanisms of semantic and automatic knowledge processing based on ontologies therefore causing very often loss of time and high investment in human resources.

Secondly, from the stream processing architecture point of view, there are recent works which make focus on the data stream processing from a syntactic point of view [8, 9]. In this context, the data model of the stream is based in a key-value structure and incorporates techniques for the adaptive management of high-rate streams [35]. Our architecture incorporates metadata based on a M&E framework, which allows to guide the organization of measures (for example, through snapshots in memory and the last known state of the entities under analysis), facilitating consistent and comparable analysis from the statistical point of view, being able to fire alarms based in the interpretation of the decision criteria of the indicators whose value was got from the data.

8. Conclusions

The organizational knowledge management represents a key asset to support a more effective decision-making process by different stakeholders. In this direction, by having an IT-based organizational memory that supports the structuring, reusing and processing of organizational knowledge is a primary decision to achieve that effective management.

In the previous work [3], we had specified a case-based organizational memory for the stream processing architecture based on measurement metadata. In this paper we deepen the former research and considerably expand the development of the proposed technologies. As a result, we obtained a robust and mature platform for the processing of heterogeneous sources data streams and the management of organizational knowledge.

The knowledge representation through cases facilitates the reuse of knowledge acquired in past problems to be applied to a new problem in similar situations, in addition facilitates the automatic knowledge processing as well.

In this way, the proposed case-based organizational memory can benefit from processing power of the PAbMM architecture, which is supported by distributed Big Data technologies. Also, the PAbMM and the importance about how the measures can be informed jointly with the metadata by C-INCAMI/MIS has been shown. The metadata help guide the processing strategy through the definition of the M&E project and it's possible thanks to the

C-INCAMI framework, which establishes the concepts and relations necessaries to support any M&E project.

Finally, we have illustrated these models and approach with two practical cases. On the one hand a pasture predictor system, using the data of the weather radar of INTA EEA Anguil. This case base stores a body of related knowledge about the growth of pasture based on a range of data, including current weather conditions and forecasts, rainfall events and past climate records, processed by the PAbMM architecture and taking the radar as a data source. On the other side the outpatient monitoring and diagnosis case, shows the processing power of the proposed PAbMM Architecture.

Conflict of Interest

The authors declare no conflict of interest.

Transmit beamforming

ABSTRACT

Frequency diverse array (FDA) antenna employs a small frequency increment, as compared with the carrier frequency, across antenna array elements. The use of a frequency increment generates an array factor that is dependent on angle, time, and the range and this yields a range and angle dependent beampattern. In this paper, a transmit array beamforming FDA employing costa sequence frequency increments is proposed that offers low probability of interception (LPI) for radar systems. Because active radars are highly visible to intercept receivers, FDA beam with uniform linear array and non-linearly increasing frequency offsets to reduce the system visibility is replaced by the conventional high gain phased-array antenna beam. The proposed method produce random-like peak distribution without obvious peaks making it difficult to be detected by unfriendly detector or intercept receivers without known of the specified coding sequence for the frequency increments. Numerical simulation results verify the proposed method.

1 Introduction

Phased-array antenna has been extensively employed in many applications such as radar, electronic warfare, radio astronomy and airport safety etc. This is because it can steer the high-gain beam electronically with high effectiveness towards any desired direction [1, 2, 3]. The directional gain obtainable by employing phased-array antenna is beneficial for detecting, tracking weak targets and suppressing sidelobe interferences from other directions [4]. Conversely, the high gain beam is visible to intercept receivers which will degrade the capability of the surveillance system [5]. Furthermore, active surveillance radars are highly susceptible to detection and interception by opposing forces. The electronic support measures (ESM) can be used to intercept the radar transmission and possibly facilitate harmful electronic counter-measures (ECM) techniques [6]. Therefore it is essential to develop low probability of intercept (LPI) radar systems.

LPI radar system employs a distinct emitted waveform intended to prevent a non-cooperative intercept receiver from intercepting and detecting its emission. On the other hand, low probability of identification (LPID) radar system uses a special radiated waveform intended to prevent a non-cooperative intercept receiver from intercepting and detecting its emission but if intercepted, identification of the radiated waveform modulation and its parameters becomes difficult. It is worth mentioning that LPID radar is an LPI radar [7].

Several techniques have been introduced to reduce radar visibility and improve its LPI ability [8]. Mostly, three main areas are considered in order to reduce radar visibility [6]: (i) spreading the energy in time with high duty cycle waveforms (ii) spreading the energy in frequency with wide bandwidth waveforms (iii) spreading the energy in space through broad transmitter antenna beams. In [9], frequency hopping, orthogonal frequency division multiplexing (OFDM), and random waveforms have been put forward for LPI radars. In [10], switched antenna technique called antenna hopping method which uses irregular scan patterns to reduce the susceptibility to receivers was introduced to enhance the LPI performance. Although with specific beamforming technique, the probability of being detected in sidelobe region can be reduced. In [6], LPI transmit array beamforming method was proposed which employed phased array antenna. Even though phased-array antenna has been widely employed for numerous applications, it produce fixed steering beam at an angle for all the ranges [11].

A new flexible antenna array called frequency diverse array (FDA) has been introduced in [12, 13]. The authors reported that the range-angle-time dependent far-field ar-

https://dx.doi.org/10.25046/aj020304

ray pattern formation are the core attributes of the concept. FDA was defined in [15] as an antenna aperture where the frequency of each antenna element is controlled independently to steer the main beam, depending on the time domain of each frequency component in the far-field. The most significant feature of FDA, as opposed to phased-array, is that the former employs a small frequency increment across its antenna array elements. This frequency increment makes the array beampattern to change as a function of the range, angle and time [11, 12, 13]. In [14], FDA radar using costas sequence modulated frequency increments was proposed to decoupled the range and angle beampattern, in which only FDA applications are considered.

In this paper, LPI FDA transmit beamforming with costa sequence frequency increments is proposed. The proposed method transmitted beampattern will have a random-like peak distribution without obvious peaks. This implies that it will be difficult for the intercept receiver from intercepting and detecting without known of the specified coding sequence for the frequency increments.

The rest of the paper is organized as follows: Section 2 proposes the LPI beamforming using costas sequence FDA antenna, which is verified in Section 3 with numerical results. Finally Section 4 concludes the paper.

2 LPI FDA BEAMFORMING

Consider an FDA with M elements which can be excited by either the same waveform or different waveforms. In this paper, we assume costas sequence frequency increments used for the mth element is Δf_m as shown in Figure 1. In the costas coding technique frequencies for the subpulses are chosen in a random pattern, according to some predetermined rule. Consider the frequency-time matrix shown in Figure 2(a), (b) and (c). In this case, the rows are indexed from $i = 1, 2, ..., M$ and the columns are indexed from $j = 0, 1, 2, ..., (M-1)$. The rows and columns are used to denote subpulses and distinct frequencies, respectively. As shown in Figure 2(a), (b) and (c) a dot indicates the distinct frequency value assigned to the associated subpulse. In this fashion, the frequency assignments are chosen randomly. The element of the difference matrix in row i and column j is given as

$$D_{i,j} = a_{i+j} - a_j,\ i + j \leq M \tag{1}$$

where a_i is the ith element of the coding sequence. The remaining locations (where $i + j > M$) are left blank. Using (1) the first row is formed by taking differences between adjacent elements in the coding sequence, then second row by taking differences between next-adjacent elements, and so forth. We employ this technique for FDA antenna, thus, only one carrier frequency is transmitted by any one of the M FDA elements and each carrier frequency is permitted only once. In [16], the details for the construction algorithms for costas signals can be found.

The radiated frequency fed to the mth of the LPI FDA using costas frequency increments can be given as

$$f_m = f_0 + \Delta f_m,\ m = 0, 1, 2, \ldots, M-1 \tag{2}$$

where f_0 and Δf_m are the carrier frequency and frequency increment, respectively, and M is the number of array elements. Specifically, standard FDA is achieved when $\Delta f_m = \mathrm{m}\Delta f$. Suppose a far-field position with range and angle (r, θ), the phase of the transmitted signal of mth element is represented by

$$\alpha_m(r, \theta) = (f_0 + \Delta f_m)\, r_m \beta \tag{3}$$

$$r_m = r + md\sin\theta,\ m = 0, 1, 2, \ldots, M-1 \tag{4}$$

where d is the element spacing. Hence, the phase difference between the signals transmitted by the mth and first elements can be approximately given as

$$\psi_m(r, \theta) = -\beta f_0 md\sin\theta + \Delta f_m r\beta - \beta m\Delta f_m d\sin\theta \tag{5}$$

Next, we apply a set of costas frequency coding, Δf_m and phases, $\delta_m(r)$ to each element to achieve a "spoiled' low-gain beamforming. Hence the transmit array factor (AF), which can be seen as the fundamental basis pattern [17, 18] is expressed as

$$AF_0(r, \theta) = \sum_{m=0}^{M-1} e^{-j\beta f_0 md\sin\theta} . e^{j\Delta f_m \beta r} . e^{-j\beta\Delta f_m md\sin\theta} . e^{-j\delta_m(r)} \tag{6}$$

where Δf_m is designed using Welch-constructed costas coding sequence and $\delta_m(r)$ can be designed using optimization algorithms. By applying a linear phase progression to (6) in increments of $\kappa = \frac{2\pi}{N}$ for first pattern, 2κ for the second pattern and so forth, additional patterns can be created. In such a fashion, $(N-1)$ patterns can be generated. Therefore (6) can be formulated as (7) [18] at the top of the next page, where $n = 1, 2, ..., N$.

It is worth mentioning that, these N steered versions of the fundamental guarantee linear independence. Moreover, they all exhibit low gain and broad beamwidth. Therefore their peak power can be significantly reduced in any directions to ensure LPI property.

Furthermore, to retain the array radar performance and simultaneously achieving LPI property, we synthesize the high gain patterns along the desired direction by linear combinations of the basis patterns. Suppose the nth basis pattern is weighted by the complex coefficient $w_{0,n}$, then N transmit beampatterns can be expressed in matrix formulation as given in (8), [6, 18].

This implies that using (8), high gain beampatterns can be formed by linearly combinations of the N basis patterns.

3 NUMERICAL RESULTS

In the simulations, we assume the LPI FDA operating at a carrier frequency of $f_0 = 10\ GHz$. An 32 elements uniform linear array is used for the standard FDA and phased-array beamforming (see Figure 4). The transmit array element spacing is designed to be $d = \frac{c_0}{2f_0}$. We consider the Welch constructed costas coding sequence for $M = 10$, with the chosen positions as 1,2,4,8,5,10,9,7,3,6. Similarly, for $M = 12$, we have 1,2,4,8,3,6,12,11,9,5,10,7 and $M = 15$, as 2,8,9,12,4,14,10,15,13,7,6,3,11,1,5. These costas sequence coding with $M = 10$, $M = 12$, $M = 15$, respectively, was used for LPI FDA transmit beamforming for the arrays and

their frequency-time matrix representation is shown in Figure 2.

Next, we show the LPI FDA transmit beamforming employing costas sequence with M = 10, M = 12, M = 15, respectively, in Figure 3. It can be seen that for the respective costas sequence coding employed, the LPI FDA transmit beamforming has random-like peak distributions without noticeable peaks. This characteristics implies that it is very difficult to be intercepted and detected by intercept receivers or unfriendly detectors without the knowledge of the specified costas coding sequence used for the frequency increments.

Suppose $\Delta f = 5\ kHz$, Figure 4(a) shows the standard FDA when specifically $\Delta f_m = \mathrm{m}\Delta f$. It can be observed that it produces range and angle dependent and range-angle coupling transmit beamforming. This feature can be exploited for range and angle localization of radar targets. Differently, the phased-array produce angle-dependent only transmit beamforming, as shown in Figure 4(b). However, the phased-array provides no range information because of its range-independent beamforming.

Finally, the ambiguity function of LPI FDA costas coding sequence is shown in Figure 5 for distinct M. It can be seen that the ambiguity functions accumulates into a spike, thus clearly resembles thumb-tack response.

4 CONCLUSION

This paper proposed a transmit beamforming technique using FDA which offers LPI for surveillance systems. The high-gain phased-array antenna beam is replaced with the low gain FDA beams with nonlinear frequency increments to reduce the system visibility. The proposed technique achieves the same performance as the traditional high-gain beam. The obvious advantage of the proposed technique presented here is the random-like peak energy distributions without noticeable peaks. The results show that the proposed technique has the advantages of both FDA radar and guarantee LPI property. The frequency increments are chosen from Welch constructed costas coding sequence across the array element to ensure the LPI property for radar systems. Overall, the proposed technique can possibly be combined with other LPI waveform design techniques to further reduce the susceptibility and visibility of LPI radar systems.

Conflict of Interest The author declare no conflict of interest.

Acknowledgment The author would like to thank Respected Professor Wen-Qin Wang (Senior Member - IEEE) of UESTC for his great contributions, support and encouragement.

ABSTRACT

Cyberinfrastructure is undergoing a radical transformation as traditional enterprise and cloud computing environments hosting dynamic, mobile workloads replace telecommunication data centers. Traditional data center security best practices involving network segmentation are not well suited to these new environments. We discuss a novel network architecture, which enables an explicit zero trust approach, based on a steganographic overlay, which embeds authentication tokens in the TCP packet request, and first-packet authentication. Experimental demonstration of this approach is provided in both an enterprise-class server and cloud computing data center environment.

1. Introduction

Network-based cybersecurity attacks against cloud data centers have been increasing in both frequency and severity, far outstripping traditional defense methods. In an effort to combat this problem, this paper is an extension of work originally presented at the recent IEEE International Conference on Smart Cloud [1] which introduced the use of first packet authentication in a zero-trust cloud network. We further develop the use of transport access control (TCP) for authentication in cloud environments, such as Amazon Web Services (AWS). We then introduce a high-speed optical bypass switch into the system architecture, and characterize its performance under realistic load conditions.

Security remains a significant concern for cloud computing environments. According to recent industry survey data [2], 27% of connected third-party cloud applications introduced into enterprise environments in 2016 posed a high security risk. Authentication is a particular problem in cloud environments, since the traditional security perimeter is effectively virtualized. Many cloud applications cannot be effectively segregated from the corporate infrastructure, and communicate freely with software-as-a-service (SaaS) platforms [2]. Cloud data centers are under constant attack from a variety of bad actors; a moderately-sized commercial data center network can experience over 100,000 security events per day [2,3]. These attackers range from individual hacktivists and cyber-gangs motivated by creating social disruption to large, well organized groups with political or financial motivations who are backed by nation-states. Increasingly, these attacks have multiple goals, including compromising critical network resources such as the network controller.

In response to the growing number and sophistication of cybersecurity threats, a United States Presidential Executive Order tasked the National Institute of Standards and Technology (NIST) with creating a set of voluntary policies and guidelines to help develop the U.S. cybersecurity framework. This eventually led to the so-called "zero trust model" for information security [4]. Traditional security models are based on a perimeter security model (also known as an implicit trust model or "trust but verify" approach), in which all communication is trusted between devices within a specified security group. This relatively static approach is based on segmenting the network and creating a demilitarized zone (DMZ) between trusted and untrusted portions of the network. Perimeter security breaks down in modern cloud computing environments, leading to a new approach that explicitly verifies all network connections. These zero trust networks assume that all traffic is a threat until it is authenticated and inspected. Zero trust is intended to provide a scalable security infrastructure that redefines the approach to resource

*Corresponding Author C. DeCusatis, Marist College, Poughkeepsie, NY, Casimer.decusatis@marist.edu

segmentation, a fundamental principle in which resources to be protected are grouped together and securely isolated or partitioned to limit unauthorized access.

While a full zero trust network has not yet been commercially realized, significant progress has been made towards the development of enabling technologies. It is generally recognized that long-standing segmentation techniques such as VLANs no longer provide sufficient cloud network security [2-6]. Many organizations attempt to segment their networks in a coarse granularity fashion to reduce risk, subject to limitations imposed by legacy hardware, complex virtualization software, and a lack of programmable resources [6]. By contrast, a zero trust network security architecture incorporates an explicit trust model and dynamic, automated security policy that extends across conventional security boundaries but still provides fine granularity segmentation and isolation of critical resources. All traffic needs to be validated, even between virtual machines (VMs) sharing a common physical host. Explicit security is part of a layered, defense-in-depth approach, which avoids kill chains and thus prevents single points of failure from compromising the entire security defense system. Fine grain segmentation improves management visibility and makes it feasible to disrupt network attacks as early as possible in the attack process, preferably to prevent data reconnaissance techniques from even identifying the resources which are being protected, much less being able to fingerprint these resources in preparation for an attack.

Micro-segmentation of a zero-trust network should preferably include authentication of not just users or applications, but also extend to the level of authenticating individual packets. Conventional networks assert the identity of a user or application based on a series of attributes such as network addresses, which may be forged [5]. Such networks may decide to trust a user or application based on some criteria, but the concept of trust does not apply to conventional network packets, which are the fundamental building blocks of any network. Our research implements a form of authentication with packet level granularity, which offers several advantages. First, a finely grained approach (at the packet level) improves visibility, particularly when combined with analysis of management plane data logs. Other potential benefits of our approach include simpler, vendor agnostic architectures, better scalability, and improved application portability.

Our approach helps avoid unauthorized awareness (a request for access to the network should not only be denied, it should avoid providing the requestor with any information about the nature of resources that are connected to the network). For example, modern data center networks are subjected to a constant stream of access requests, since even a denied TCP connection request will return some information about the nature of the network, thereby assisting attackers in fingerprinting the target system [5, 6]. This means that potential attackers can gather useful information about a potential target by repeatedly trying to complete a connection request, even if the request attempt itself does not succeed. The information collected in this manner may be used to plan future attacks or identify weaknesses in the perimeter defenses. The approach demonstrated in this paper prevents error message reconnaissance information from reaching a potential attacker, without compromising performance of the remaining system.

While the theoretical approach to zero trust data center architectures encompasses a wide range of components, for the remainder of this paper we will concentrate on disruptive network technologies. For example, zero trust networks benefit from the centralized management plane and dynamic configurability offered by software-defined networks (SDN). While the definition and basic operating principles of SDN networks are well known [7], we will briefly mention several of their useful features. Programmable SDN controllers are able to implement dynamic network segmentation based on data collected from sources outside the network itself, such as honeypots, security analytic engines, and other sources. The application of security analytics to monitoring or management data sets enables the creation of actionable threat intelligence, allowing an SDN network to proactively discourage security threats and respond in near real time when new threats become apparent. This approach is particularly effective when combined with virtualized network functions (VNFs) such as virtual routers, firewalls, or other appliances [8, 9].

In this paper, we describe an approach that enables zero trust networks by providing first-packet based authentication, combined with transport layer access control, and experimentally demonstrate the use of this approach in defending an SDN controller from cyberattacks. We describe a steganographic overlay that embeds network authentication tokens in a TCP connection request, and blocks unauthorized traffic from completing a request. Resources protected in this manner are effectively concealed from reconnaissance attempts by attackers. We also demonstrate an approach to transport layer identity management and authentication. We show that this approach prevents fingerprinting of key network resources (such as the SDN controller) by blocking any response to unauthorized packets at the transport layer and below. We experimentally demonstrate this approach in both large, enterprise-class servers and a cloud computing test bed.

This paper is organized as follows. After the introduction, we describe the operation of a transport layer identity management scheme in section 2. We then present experimental results for the enterprise server and cloud test bed use cases in section 3. Finally, section 4 presents our conclusions and recommendations for future work.

2. Transport Access Control Architecture

Our approach independently authenticates each network session at the transport layer, prior to granting any access to the network. This is implemented through a combination of two technologies, namely transport access control (TAC) and first packet authentication. To our knowledge, these approaches have not previously been combined in this manner. Unauthorized session requests are completely rejected, and there is no feedback to a potential attacker attempting to fingerprint the network. Explicit trust is established by generating a network identity token during session setup. The network token is a 32 bit, cryptographically secure, single use object which expires after four seconds. Tokens are associated with identities from existing Identity Access Management (IAM) systems and credentials, such as Microsoft Active Directory or the IAM system used by Amazon Web Services [10]. Explicit trust is established by authenticating these identity tokens as early as possible, namely on the first packet of a TCP connection request (see Figure 1).

Tokens are generated for each unique entity (user or device) requesting access to network resources. An in-line virtual appliance (the TAC gateway) is installed between the equipment

being protected (the protected resource) and the rest of the network; a second gateway is installed between the authorized or trusted user and the rest of the network. When the trusted user attempts to access the protected resource, the first gateway inserts an identity token into the first packet of the TCP connection request. When the second gateway receives a connection request, it extracts and authenticates the inserted identity token and then applies a security policy (such as forward, redirect, or discard) to the connection request based on the received identity. This gateway acts as a policy enforcement point transparent to the rest of the system architecture and backwards compatible with existing network technologies. If the network access token for a TCP request fails to resolve to an identity or resolves to an identity that lacks the authority to access the requested resource, then the connection request is rejected without providing any further response to the requestor, effectively cloaking the presence of the protected resource. Failed access attempts are logged in an external Syslog server, which allocates enough memory to avoid wrapping and over-writing log entries. Existing tools such as SIAM can be used to analyze the logs or generate alerts of suspicious activity. We note that continuous logging of all access attempts is consistent with the approach of a zero-trust network (i.e. not allowing any access attempts to go unmonitored). Both the identity insertion gateway and identity authentication gateway appliances can be hosted as VNFs hosted on a virtual server, router, or other compatible piece of networking equipment.

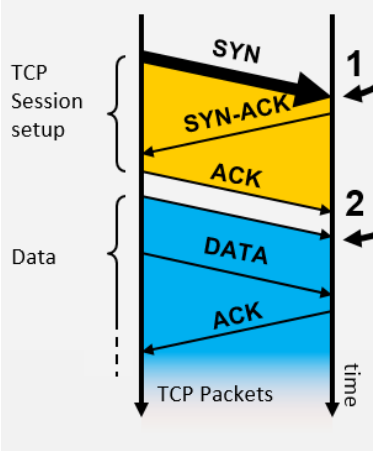

Figure 1: Transport Layer Authentication handshake; first packet authentication is performed at position 1 (as early as possible); traditional session authentication is performed at position 2 (after the session is already established).

This approach offers several advantages, including separation of security policy from the network design (addresses and topologies). This approach works for any network topology or addressing scheme, including IPv4, IPv6, and networks that use the Network Address Translation (NAT) protocol, and is compatible with dynamic addressing often used with mobile devices. This approach extracts, authenticates, and applies policy to the connection requests, not only protecting against unauthorized external reconnaissance of the network devices but also stopping any malware within the protected devices from calling home (exfiltration). Security policies can be easily applied at the earliest possible time to conceal network-attached devices from unauthorized awareness. By preventing unauthorized awareness and access, transport access control blocks both known and unknown attack vectors. This approach is low latency and high bandwidth since packet content is not inspected. Since the network tokens are embedded in the TCP session request, they do not consume otherwise useful data bandwidth. The combination of transport access control and a segmented, multi-tenant network implements a layered defense against cybersecurity threats, and contributes to non-repudiation of archival data. These techniques are also well suited to protecting public and hybrid cloud resources, or valuable, high performance cloud resources such as enterprise-class mainframe computers. Further, this approach can be applied to protecting the centralized SDN network controller from unauthorized access, and enable only authorized SDN controllers to manage and configure the underlying network. TAC uses an innovative identity token cache to provide high scalability and low, deterministic latency. The token cache is tolerant of packet loss and enables TAC deployments in low bandwidth and high packet loss environments.

3. Cloud test bed experimental results

The experimental cybersecurity cloud test bed is illustrated in Figure 2. A protected resource (in this case, the SDN controller) is intended to be accessible only from either of two trusted clients. A BlackRidge hardware appliance gateway, which implements TAC with first packet authentication [11], is placed in-line with the trusted clients, where it inserts tokens in the transport frame headers. Tokenized packets flow through the untrusted network, which eventually routes them to the SDN controller. A virtual gateway appliance is placed between the network and the SDN controller, which will authenticate the tokenized packets and only allow authenticated and authorized packets to pass through to the SDN controller. Any packets without Tokens or identified traffic without the authority to access the SDN controller will be dropped. Our test configuration uses a hardware appliance to insert Tokens and a Virtual Appliance running on VMWare ESXi to authenticate Tokens. The hardware and software appliances are only addressable through their management ports and use the management ports to access the required network time protocol (NTP) Servers. A list of trusted devices to be allowed access is provisioned in the TAC gateways, and the list of trusted devices can be edited using the gateway management ports.

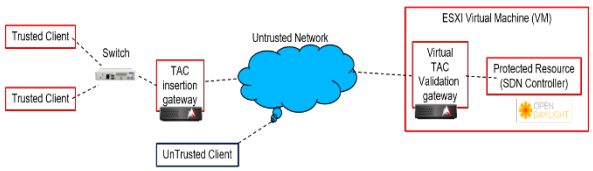

Figure 2 – Experimental cybersecurity cloud test bed

The specifications for the gateway used in this testbed are given in Table 1. This gateway has three modes of operation, known as Bridge, Enforce, and Monitor. In Bridge mode the gateway does not perform authentication or insert tokens into the data packets; rather, it simply functions as a two port, Layer 2 bridge device. Enforce mode will perform authentication and insert tokens into the 32 bit sequence and acknowledgement number fields of a TCP frame, according to the established address list policy. Monitor mode has the same functionality as Enforce mode, with the exception that it does not enforce the security policy. Monitor mode is useful to validate configurations during installation and setup for a new gateway. By toggling a configured gateway between Bridge and Enforce modes, it is possible to observe the effects of turning token-based authentication off and on. The gateway architecture is a “bump

in the wire" approach, and the gateway device is only addressable through its own dedicated device management access port.

Table 1 – TAC gateway capabilities

Performance	Branch Gateway	1G VM, z/VM, and AWS Gateway[1]	1G 1RU Gateway	10G VM Gateway[1]	10G 1RU Gateway	z Systems LPAR Gateway[1]
Throughput	1 Gb/sec	1 Gb/sec	1 Gb/sec	10 Gb/sec	10Gb/sec	1Gb/sec
Latency	<200 µsec	<100 µsec	<80 µsec	<100 µsec	<12 µsec	TBD
Max Capacity	**Branch Gateway**	**1G VM/KVM Gateway**	**1G 1RU Gateway**	**10G VM Gateway**	**10G 1RU Gateway**	**z Systems LPAR Gateway**
Identities[2]	1K	10K	10K	30K	40K	10K
Concurrent Sessions	100K	1M	1M	4M	4M	1M

1. Virtual appliance performance is server platform dependent. Required resources:
   - 1GbE VM, z/VM, AWS: 4 core CPU, 4-GB memory, 8GB storage
   - Branch Gateway 2 cores 8gb memory, 256GB SSD storage
   - 10GbE VM: 8 core CPU, 16 gb memory, 8GB storage
   - z Systems LPAR Gateway: 1 IFL, 16 GB memory, 32GB storage
2. Total Identities is limited by the Enterprise IDMS

We configured the test bed and toggled the gateway between Bridge and Enforce modes. This allowed us to verify that Enforce mode would only permit tokenized packets from one of the trusted clients to reach the SDN controller. We then attempted a reconnaissance scan of the SDN controller from an untrusted client. These scans were conducted using several industry standard tools, including Metasploit, HTTPrint, Firewalk, and PuTTY [5, 6]. When the TAC gateways were in Bridge mode, we were able to successfully fingerprint the SDN controller, and determine that it was an instance of Open DayLight (Helium release) running OpenFlow 3.2 in this example. We then repeated the scans with the gateway in Enforce mode, and as expected we were unable to identify even the presence of an SDN controller since The TAC authentication gateway blocks all potential responses at and below the transport layer. We cannot even determine if there is a TAC gateway present, as TAC was also used to protect the management port of the gateway. This implements both packet level authentication and unauthorized awareness, both desirable properties in a zero trust architecture.

To evaluate the effectiveness of the TAC gateway in defending against denial of service (DoS) attacks, we launched a DoS attack at the network protocol layer from the untrusted client in Figure 2. Common DoS simulation tools require knowledge of the target IP address, but as previously demonstrated the TAC gateway effectively cloaks the IP address for our SDN controller. For test purposes, we assume that an attacker has somehow obtained the SDN controller IP address through outside channels (perhaps a spear phishing attack on the network administrator) and we proceed to launch a DoS attack against the controller. Using a standard tool such as Low Orbit Ion Cannon (LOIC), we launched an attack against the IP address of the gateway data port, management port, and SDN controller. All packets were blocked by the TAC gateway without providing any additional intelligence to the attacker.

The gateway can also be used in a Layer 3 operating mode, which performs NAT for selected ports on the gateway. This is useful in cloud computing environments, allowing the gateway to present a public IP address on its client facing, untrusted port and a private IP address on its trusted port. In this case, the insertion and authentication of tokens is performed before NAT. We have demonstrated this approach in a public cloud deployment, similar to figure 2 except that the protected resource was located within an Amazon Web Services cloud. The cloud service provider infrastructure is located on the right-hand side of figure 2 (replacing the ESXi network), with the public Internet acting as the untrusted network and the cloud users on the left side of figure 2. Public IP addresses are used on ingress ports facing the untrusted network and the cloud service provider's protected resource connect to a trusted egress port.

The virtual TAC gateways were also tested in a enterprise-class environment using the IBM zCloud (a cloud based on a highly virtualized IBM Z Systems mainframe). These servers are commonly used in public, private, and hybrid cloud environments for Fortune 500 applications (particularly in the financial markets) as well as within cloud service providers such as SoftLayer. As shown in figure 3, an IBM model z13 enterprise server was provisioned into four logical partitions, with two partitions running the z/OS operating system, and two partitions running zLinux. For each operating system, one partition served as the protected resource while the other served as the trusted host. All four partitions share common physical network interfaces, provided by an Open System Adapter (OSA) card running 1 Gbit/s Ethernet. The virtual appliances were hosted in two additional logical partitions (LPARs), interconnected with the protected resources, trusted hosts, and OSAs as shown in figure 3. Additional OSA cards were provisioned to serve as interfaces for the network management ports on the virtual appliances.

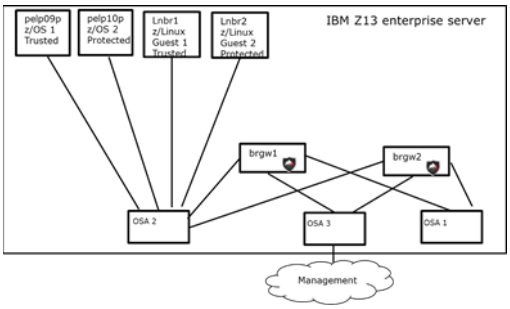

Figure 3 – Enterprise server use case test configuration

Three use cases were tested using this configuration. First, the gateways were configured to allow connectivity only between Linux partitions 1 and 2. We confirmed normal operation of resource connectivity including SSH, SCP, iperf, sftp, and wget functions, and verified that untrusted hosts such as zOS-1 could not access the Linux partitions. Second, the gateways were configured to allow connectivity between Linux-1 and zOS-2 partitions (note that the gateway authentication is independent of the operating system running in either the supplicant or the trusted resource). As before, we verified basic functionality (including multiple sftp file transfers between the trusted host and protected resource) and confirmed that other partitions, such as zOS-1, could not access the protected \resource in this configuration. Third, the gateway was configured to allow connectivity between the two zOS partitions. As in the previous use cases, we verified basic functionality (including multiple sftp file transfers between the protected resource and trusted hosts) and confirmed that the Linux-1 partition was unable to access protected resources in this configuration. These three test cases established that the gateways could be configured to enable or disable applications running between any two partitions on the same physical server, even if the gateway itself is hosted in a partition on the same physical server. This approach directly supports the zero-trust architecture we intended to implement.

The gateway functionality was further demonstrated in a pre-production test environment at Marist College, part of the New York State Cloud Computing and Analytics Center (CCAC).

In this case, the network spans multiple buildings on the campus MAN (about 1 km apart) as shown in figure 4. In the first building, ten sysadmin terminals were interconnected to a Layer 2 switch, and one switch port was connected to the insertion gateway. In this configuration, all terminals connected to the trusted switch port receive authentication tokens and will be allowed to access the protected resource. In a second building, the second gateway was configured in Layer 3 mode, which was then attached to the protected resource (a sysadmin application (Syswiki) running in a SUSE Linux guest VM on an IBM z144 enterprise server (mainframe).

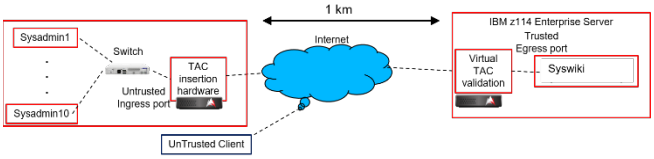

Figure 4 – syswiki BlackRidge

Using this configuration, we verified that the gateway allowed the Sysadmin trusted host terminals to perform operations including SSH, scp, and http post/get functions to the protected resource. We also verified that other terminals (untrusted hosts) on the same network were unable to access the protected resource when the gateways were set to Enforce mode, but could access the protected resource when the gateway was put into Bridge mode. The Sysadmins showed no measurable degradation in response time or performance of the protected resource application with and without the gateway operating in enforce mode.

Further, there was no measurable performance impact when accessing other resources on the campus network or accessing Internet resources when the gateway was in Enforce or Bridge mode. We also conducted a port scan of the gateway using Nmap/Zenmap tools from an untrusted terminal, and were unable to identify any open ports or fingerprint the Syswiki when the gateways were in Enforce mode.

4. Optical Bypass Switch Testing

For the next phase of testing, we incorporate a high-speed optical bypass switch into the system architecture, so that in the event of a hardware or software failure in the gateway, the TAC appliance will not obstruct network traffic. One advantage of an optical bypass switch is that it continues to pass traffic even if a power failure or firmware problem disables the functionality of the TAC gateway. Similar approaches have been suggested in high performance computing applications, where network traffic bypasses firewalls and other security features in order to maintain throughput for the application [12]. For these experiments, we used a 10 Gbit/s traffic stream while evaluating the impact of protection switching on the gateway.

In our environment, the TAC gateway incorporated a 10 Gbit/s multimode Silicom brand optical switch (model PE210G2BP) with optical bypass switch driver ixgbe ver 4.3.15. The optical bypass testbed is shown in figure 5. We configure two ESXi server instances, each driving 10 Gbit/s of traffic (loadgen 1 and loadgen 2, respectively). These servers run the Iperf benchmark test, enabling us to test switch times and throughput in both directions. As shown, the virtual switch on server loadgen1 connects to an untrusted port on the TAC gateway, while the virtual switch on loadgen2 connects to the corresponding trusted port.

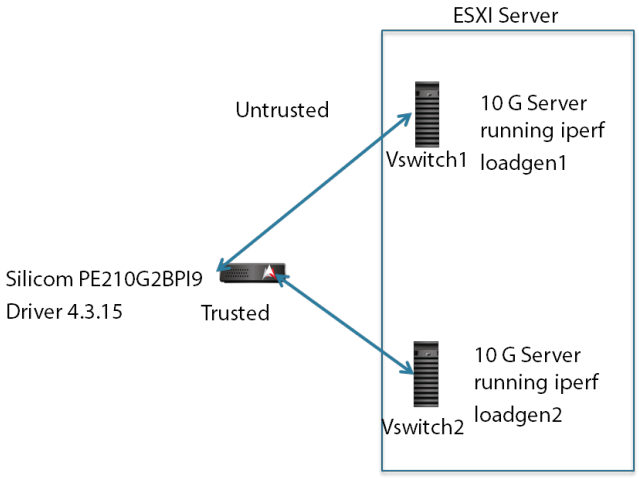

Figure 5 – Optical Bypass Switch testbed

Each test was repeated five times to obtain a meaningful average result, as shown in table 2. We can see that the optical bypass can sustain a data rate of about 8.3 Gbit/s while running Iperf, and about 8.9 Gbit/s in bypass mode (as expected, the bandwidth in bypass mode is somewhat higher).

Table 2 – optical bypass switch sustainable bandwidth measurements

Bypass mode, Gigabits per second	Iperf, Gigabits per second
8.88	8.39
8.95	8.24
8.92	8.33
8.91	8.05
8.85	8.31

In order to determine how long it would take for the optical bypass to tansfer traffic under different conditions, another server was inserted as a tap on the untrusted link, as shown in figure 6. By running WireShark on a 10 Gbit/s interface, this server is able to measure the effective switching times. A representative WireShark trace, shown in figure 7, confirms that the gateway bypass switch exhibits 110 ms recovery time upon a power failure to the gateway. We found that recovery time was faster when simulating a firmware outage (53 ms) and slightly longer when the TAC cloaking function was suspended due to a firmware problem (257 ms).

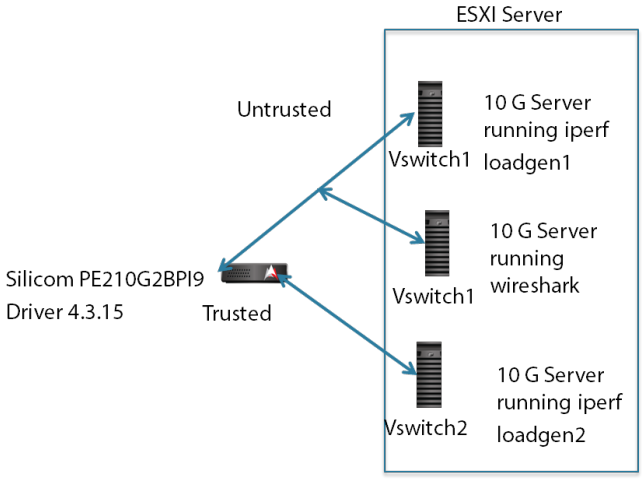

Figure 6 – Optical Bypass swithing time test bed

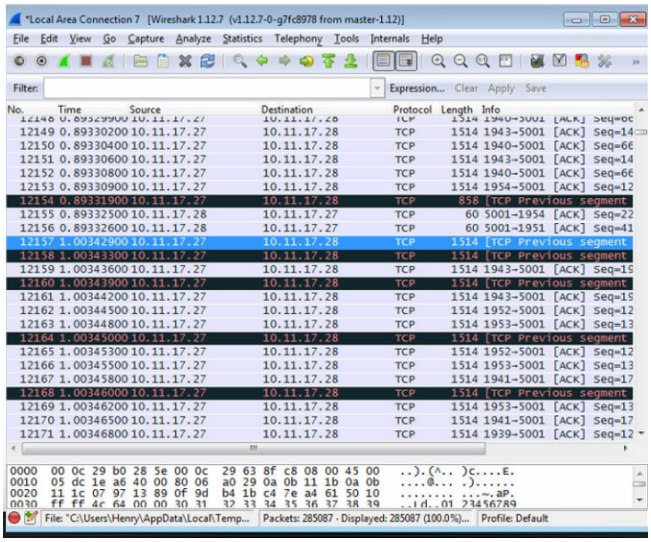

Figure 7 – Representitive WireShark trace from Optical Bypass switching time test bed

Finally, we reconfigured the gateway to conduct syslog benchmark testing, as shown in figure 8. The WireShark server is now monitoring traffic through the TAC gateway with optical bypass. We can run an nmap port scan simultaneously on servers loadgen1 and loadgen 2 using this configuration. For this testing, we configured the gateway to automatically blacklist any IP address which makes more than 100 access attempts in 60 seconds (an effective defense against some types of brute force dictionary attacks). We can keep an address blacklisted for different periods, ranging from 30 seconds to hours or even 24 hours. A blacklisted address generates a specific message type in the syslog, so we can easily determine the number of blacklist events in a given period.

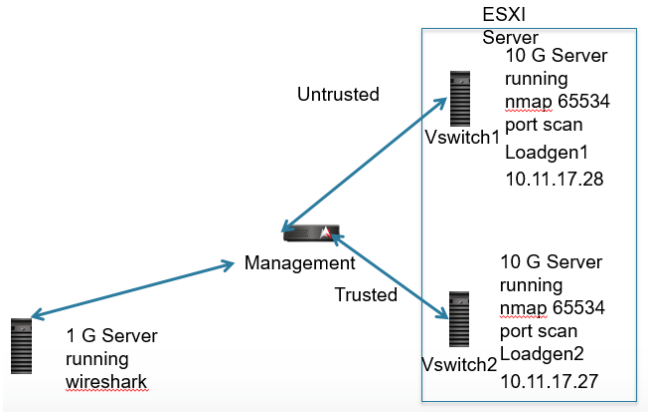

Figure 8 – Optical Bypass syslog test bed

For our tests, the initial default setting was a rate limit of 10 messages within 5 seconds, or a peak rate of 5 Mbit/second. Based on existing data about typical syslog messaging patterns [2, 3, 12], we expect the performance of our system to be well within normal commercial operating parametes. The peak data throughput measured during this experiment was 14 Mbit/second.

5. Conclusions

The growing cybersecurity treat requires an architectural redesign of the data center network, based on the principles of an explicit zero trust network. We have demonstrated several principles of zero trust using a transport access control system, based on a steganographic overlay, which embeds authentication tokens in the TCP packet request and first-packet authentication. The system was tested on both x86 and Z Systems platforms in private cloud environments, and using AWS in a public cloud environment. This system can provide enhanced security in both enterprise computing and cloud environments as part of a defense-in-depth strategy and prevents unwanted fingerprinting of protected resources. An optical bypass switch was also characterized as part of a high availability architecture.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors gratefully acknowledge the support of the National Science Foundation (NSF) grant 1541384, Campus Cyberinfrastructure – Data, Networking and Innovation Program (CC-DNI), per NSF solicitation 15-534, for the project entitled CC-DNI (Integration (Area 4): Application Aware Software-Defined Networks for Secure Cloud Services (SecureCloud). The authors also gratefully acknowledge the support of Marist College and the New York State Cloud Computing and Analytic Center (CCAC).

ABSTRACT

This paper presents a Release Management model to support requirements management. Requirements development and management can be integrated with a release-planning approach to achieve lesser Requirements spillover problems which is an innovative way to capture, control and evolve the user requirements based on integer linear programming.

1. Introduction

The Capability Maturity Model (CMM) and its successor Capability Maturity Model Integration (CMMI) have been widely accepted as a process model to steer software process improvement (SPI) activities [1]. In some parts of the software industry, like the defense industry, software suppliers are obliged to have their software processes at least at CMM [2] level 4 or 5 in order to get any contracts. In many organizations, software has become such a critical part of the product portfolio, that senior management at the strategic level has defined objectives and allocated budgets for improvements. Despite these successes to realize sustainable improvements, the percentage of failures is however probably still higher. It is true of any system that there are several Critical Success Factors [3]. They include both performance requirements (such as serviceability, reliability, portability, and usability) and limited resource requirements (such as people, time and money) In my experience, they either failed because of poor estimation or poor change management or even poor requirements including release plan.

Although modeling activities [4] like Data Flow Diagram, Entity Relationship Diagram, State Charts, Object Oriented Method and Unified Modeling Language helped to better understand the Requirements and to represent them in clear and comprehensive manner, it still failed to adapt to an evolutionary approach for incremental software release and an opportunity for prioritizing requirements. This paper presents a Release Management model to support requirements management. Requirements development and management can be integrated with a release-planning approach to achieve lesser Requirements spillover problems that are an innovative way to capture, control and evolve the user requirements. A metric coupled with the incremental software release that offers organizations an opportunity for prioritizing requirements, an optimization technique, based on integer linear programming, to support software vendors in determining the next release of a software product developed and demonstrated in Section 3. The technique is based on the assumption that a release's best set of requirements

*Corresponding Author: Indranil Nath, Chartered Fellow, BCS, The Chartered Institute for IT, United Kingdom

is the set that results in maximum projected revenue against available resources in a given time period.

2. General Process Metrics

Today measuring processes and products, objective, quantified information can be gathered to support decision-making at all levels. The objective measurements provided allow management and software product engineers to:

1. Identify inefficient processes that need improvement.
2. Reengineer ineffective processes that do not add quality to products.
3. Evaluate process changes to measure process improvement.
4. Utilize historic measurements of productivity, complexity, size, effort, and cost during project planning.
5. Monitor a current project plan's risk by measuring the schedule, cost, size, and effort of the products under development and comparing them to the assumptions and estimates used as the basis for the plan.
6. Monitor product development by measuring current cost, effort, and schedule data to determine if corrective action, such as re-planning, is needed.

A typical Process Flow of the Software Process is shown in Fig1 that is based on Humphrey [4] with only minor changes. In the first phase Analysis the Requirements are studied, where after estimates are made for the size of the resulting program, the productivity, the effort distribution over the subsequent phases, and other product and process metrics. These estimates are recorded on the Project Plan Summary.

During the subsequent phases, the actual defect and time data are logged on the Defect Log Form and the Time Log Form. The Design Review Checklist and the Code Review Checklist are used to structure the review process during the Design Review phase and the Code Review phase. When the program has been tested and is ready to be released as a Finished Product, all recorded data is summarized in the Project Plan Summary, enabling the software engineer to make an analysis in the Post Mortem phase prior to the program release.

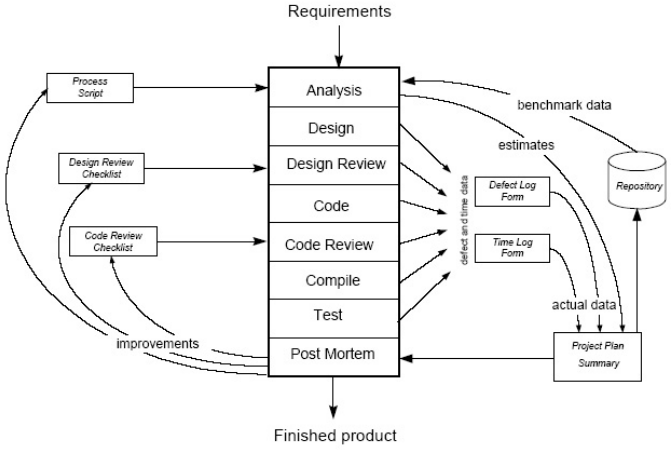

Fig 1: Process flow of the Software Process (based on [HUM 1997]).

The purpose of this analysis is to investigate how the process used can be further improved. The result may be that the Process Script, the Design Review Checklist and/or the Code Review Checklist are adjusted. Further, the data from the Project Plan Summary can be used to calculate accumulated values for productivity, time or effort distribution, and so on. This information can be stored in a Repository to support the estimation process for future programming assignments.

By following the Process Flow of the Software Process [5] Humphrey proved that valuable product and process data could be obtained and the analysis of the data would enable a software engineer to calculate for instance the following metrics for better decision making in software engineering:

2.1. Estimation Accuracy

Estimates are collected for the size of the program to be developed and the process to be followed (time distribution, productivity, etcetera). These estimates are compared with the actual figures when the program has been implemented and tested. The result is the estimation inaccuracy, which can be calculated with the following

Equation:

$$\text{Estimation Inaccuracy} = \frac{\text{Actual Value} - \text{Estiamted Value}}{\text{Estimated Value}} \times 100$$

2.2. Relating Size and Effort: Productivity

By measuring the size and effort of programs, the productivity can be calculated in retrospect. When the productivity has been measured, however, it can be used to proactively calculate the expected effort or time needed to develop a program when the size of the program has been estimated, the equation being:

$$\text{Calculated Effort} = \frac{\text{Estimated Size}}{\text{Measured Productivity}}$$

2.3. Yield

When developing a program subsequent development phases are passed through. In each development phase defects will be injected and removed. Removed defects might have been injected in the current development phase; however, they might also have been injected in previous development phases. The yield of a development phase can be defined as a number, expressing the number of defects removed in a particular phase divided by the sum of the number of defects inherited from previous phases and the defects injected in the phase itself:

$$\text{Yield (X)} \frac{\#\text{removed in } P_X}{\left(\sum_{P_0}^{P_{X-1}} \#\text{inherited in } P_X\right) + (\#\text{injected in } P_X)} \times 100$$

Where #= Number of Defects and P_x is ”Phase x” The yield of a phase can vary from 0% to 100% (if the denominator equals 0, the yield of the phase is equal to 100%). When the yield of a phase equals 0 it means that in that particular phase no defects have been removed. They are all carried forward to the next phase. When the yield of a phase equals 100%, it means that in that particular phase

all existing defects are removed. These are both the defects inherited from previous phases and the defects injected in that particular phase itself. In the ideal case, the yield of each development phase is equal to 100%. This means that in each phase all injected defects are also removed and that the final product is free of defects.

But in practice, not all defects will always be removed. Defects will be carried forward to the subsequent phases. If they are not found in, they will be shipped being part of the final product. Note that the yield of the different development phases can only be calculated when all defects have been found. Only then it is known how many defects were injected and removed in the different phases.

If an injected defect is carried forward to subsequent phases, it is very important to detect and remove the defect as early as possible. The rework effort is proportional to the difference between the injection phase and the detection and removal phase. If an early injected defect is found in one the latest phases of development, the rework effort will extend over more phases. Very expensive defects are the ones that are injected during the Analysis and Design phase and detected during the Test phase. It is assumed here, that there are no defects in the requirements. Another approach is now to calculate the Yield of the phases Analysis and Design (A&D) combined:

$$Yield_{AD} = \frac{\#\text{ removed in A\&D Phase}}{\#\text{ injected in A\&D Phase}} * 100$$

This metric denotes the quality of the early phases before handing over of the product for further implementation and testing.

2.4. Appraisal/Failure Ratio (A/FR)

Striving for a high combined Yield means investing effort in appraisal to detect defects as early as possible. An example of an appraisal action is, for instance, a peer review. The objective of appraisal actions is to pass forward a reliable product to the next phase. Advantages are twofold. In the first place, this will probably lead to a more reliable final product. It is a utopia to think that all transported defects will be found at a later stage. In the second place, the total failure cost in subsequent phases due to fixing detected defects will probably decrease as the number of expensive defects decreases. A new metric is introduced, called the Appraisal/Failure Ratio or A/FR. This is the ratio between the appraisal cost in the early development phases and the failure cost in subsequent development phases, its equation:

$$\text{Appraisal / FAilure Ratio} = \frac{\text{appraisal effort in A\&D Phase}}{\text{failure effort in subsequent phase}}$$

The A/FR can vary from 0 to infinite (if the denominator equals 0, the A/FR is equal to 0 if defects are found but not removed and the A/FR is undefined if no defects are found). An A/FR equal to 0 means that no appraisal effort is spent in detecting and removing defects in the early phases of development. The failure cost to be made in subsequent phases later will presumably be very high, assuming that the reliability of the final product is important.

2.5. Defect Injection and Defect Removal Rate

Collecting defect data enables one to calculate the defect injection and defect removal rate in each development phase. It can, for instance, be related to the effort spent in that particular phase:

$$\text{Injection Rate (X)} = \frac{\#\text{ injected in } P_X}{\text{effort in } P_X}$$

$$\text{Removal Rate (X)} = \frac{\#\text{ removed in } P_X}{\text{effort in } P_X}$$

2.6. Defect Density

The defect density can be calculated by relating the total number of defects found during development to the resulting program size:

$$\text{Defect Density} = \frac{\#\text{ found}}{\text{program size in KLOC}}$$

A defect density equal to 0 means that no defects are introduced during development; in other words, the Yield of each development phase equals 100%. These metrics are powerful to analyze the software process and adjust the process in order to implement improvements. Most metrics are self-explaining with regard to their best values. The best values for Estimation Inaccuracy and Defect Density are for instance 0%, for Yield the best value would be 100%. This is however not evident for a metric like A/FR. But there is more. The best value does not necessarily mean that it is the optimal value. There might be practical limitations to obtain a Yield of 100% for instance. Human work is not perfect, causing the injection of defects, and a project budget is normally limited, meaning that time for appraisal and failure expenditures is limited. It is worth considering the question whether there are optimal combinations of a set of metrics, that there is no metric that allows helping management to decide on prioritizing requirements in the 3-Degree-Of-Freedom [6] of Software Engineering (Software Development Process, System Components and View onto the Systems).

3. The Derived Metrics

This section will have all the derived metric from above and how the derived metrics can be used to support the re-engineering. The set of derived metrics will offer the possibility to analyze and re-engineer processes and their respective work products. Finally, this re-engineering will allow for efficient Requirement Analysis and bi-directional requirement traceability [7-9].

One of the most common life-cycle approaches adopted by most software development organizations is the evolutionary approach. This approach, coupled with incremental software release offers the opportunity for prioritizing requirements [10]. Customers receive part of the full working system early on as a beta release and it is easier to schedule and estimate for each delivery. This approach also enables user feedback early on (during development stage) and changes and additions to requirements are easily handled. Release management is mathematically modeled as follows.

Let us consider a set of requirements $\Re$

$$\Re = \{r_1, r_2, ..., r_n\}$$

Assign $\Re$ into an evolutionary life cycle release categories C as:

I. Next Release (R_{n+1})
II. Next but one release (R_{n+2})
III. Not yet assigned (R_{n+m})

Requirement Dependencies D and requirement precedence within the domain $\Re$ are specified as:

- Requirement Coupling (RC): r_i must be in the same release as r_k
- Requirement precedence (RP): r_i must be implemented before r_k

Effort constraints Ω are formulated as:

- The total effort for implementing $\Re$ is Ω
- For $r_i \in \Re$, an estimated effort is assigned ω_i
- $\sum_{I=1}^{n} \omega_i \leq \Omega$

Stakeholders Prioritization S is formulated as:

- Set of stakeholder: $S = \{s_1, s_2, ..., s_m\}$
- Weight of each stakeholder $s_k \in S : w(s_k)$
- Each stakeholder s assigns a priority to the situation that r_i is assigned to the option $k : P(s, r_i, k)$

Thus, in the evolutionary life-cycle, a software release is defined as:

$$\text{Release } (\Re) = \int (\Re, C, D, \Omega, S)$$

4. Discussion

Release Re-engineering using Requirement Analysis [11]. For software vendors, the process to determine the requirements [12] for the next release of a software product is often difficult. The mathematical formalization of release composition with a corresponding optimization tool that aims to support product managers and development project managers during release planning is discussed as above. The tool is based on integer linear programming and assumes that an optimal set of requirements is the set with maximum projected revenue against available resources in a given time period. The input for the optimization is twofold. Input data like the list of candidate requirements estimated revenue and required team resources per requirement, whether or not a requirement is mandatory, comprise the first type of input. Secondly, several managerial steering mechanisms provide flexibility in the optimization environment.

Companies developing software products face complex challenges when determining requirements for upcoming releases. Often the wish list of requirements extends the capacity of available resources, requirements may not be unambiguous, they may be difficult to prioritize, etc. As a matter of fact, many aspects influence the definition of an optimal set of requirements for a next release. Several scholars have presented lists of such aspects including importance or business value, personal preference of certain customers and other stakeholders, the penalty if not developed, the cost of development in man days, development lead-time, requirement volatility, requirement dependencies, the ability to reuse, and requirements quality.

In order to deal with this multi-aspect optimization problem, different techniques and procedures have been applied. The analytical hierarchy process [13] assesses requirements according to certain criteria by taking all possible requirement pairs, relatively valuing each pair, and subsequently using matrix calculations to determine a weighted list of requirements. Jung extended the work of Karlsson and Ryan by reducing the complexity of applying the analytical hierarchy process to large amounts of requirements using linear programming techniques [14]. Through cumulative voting (Leffingwell and Widrig (2000)) different stakeholders are asked to distribute a fixed amount of units (e.g. euros) between all requirements, from where an average weighted requirement list is constructed. With discrete event simulation, the effect of the development of requirements is modeled, allowing what-if analysis.

The set of derived metrics shown in Section 3 offers the possibility to analyze projects, Software Requirement, and their respective work products in detail [15]. The following can be concluded:

- **Predictability:** There is a considerable budget overrun (+50%) and schedule overrun (+19%), but the realized product size is less than predicted (-24%). The realized overall productivity is nearly half the predicted value (-49%). These data need to be further analyzed in order to find out the reasons for these deviations.
- **Effectiveness:** The cumulative Yield at the Detailed Design phase and the Implementation phase is very low, 10% and 19% respectively. This implies that many defects are transported to subsequent phases and that the failure cost in these phases will probably be high. This is confirmed by the fact that the total amount of rework equals 38% of the overall lifecycle effort.
- **Efficiency:** The efficiency is very low because many defects have been found in the later phases. As a consequence, the overall failure cost is high (38% of overall life cycle effort). This is confirmed by the fact that the cumulative A/FR before the Detailed Design phase and Implementation phase is very low (0.02 and 0.03 respectively).

This analysis gives an organization the possibility to select improvements for future projects, assuming that this project has

not been very exceptional but comparable with similar projects. Improvements might be:

A) Improve the predictability by using a lower productivity figure when estimating projects. In this way, more realistic estimates will be obtained.
B) Increase the quality of the resulting product by increasing the Yield in the earlier development phases. This can be done by increasing the review effort (A/FR higher) or by adjusting the review method.
C) Improve the efficiency by increasing the A/FR in the various development phases before the Integration Test phase. Special interest might be given to the Implementation phase and Unit Test phase as in these phases the Detection Rate and Removal Rate are very high.

In all cases, the available data can be used to make predictions about the expected effects in terms of return on investment. This is not always easy, as the various parameters might be correlated (for instance, a higher A/FR will probably contribute to a higher Yield).

However, by building a record of experiences, the capabilities in this area can be stepwise improved. In this example, the following approach might be applied in an iterative way:

1) Increase the cumulative A/FR by increasing the appraisal cost in the earlier development phases.
2) Estimate what the effect will be on the cumulative Yield at the Detailed Design phase: what will be the reduction of defects injected in the Requirements phase and Architecture phase?
3) Take measures to improve the inspection and review process during the Implementation phase and Unit Test phase and estimate the effect on the Defect Detection Rate and the Defect Removal Rate in these phases.
4) Use the cumulative Yield at the Detailed Design phase to predict the number of defects that will be passed forward to subsequent phases and use the Defect Detection Rate and Defect Removal Rate to calculate the failure cost.
5) Calculate the effect on effort, time, and expected corrective maintenance cost.
6) Repeat the steps 1 till 5 until satisfactory (and realistic) values have been obtained.

5. Conclusion

The derived metrics can be considered to be useful for organizations still having to build a measurement foundation for their software projects and products as well as for organizations looking for further improvements of their software processes. The mature organizations will analyze their available data, select the most promising improvements and re-engineer and re-measure their performance over time. The less mature organizations will not be able to implement re-engineering from day one but need to define a strategy how to implement the model in subsequent steps. The order of the steps can be derived from the most urgent problems the organization is faced with:

I. Predictability. In this case, the first step might be to collect estimates and actual for size, effort and time.
II. Effectiveness. In this case, the focus is on the output of the project, being the quality of the product. Important measurements to be considered first are defects (Yield values per phase and cumulative).
III. Efficiency. In this case, attention must be paid to appraisal cost related to failure cost (A/FR) and defect rates (Defect Detection Rate and Defect Removal Rate).

In all cases, supporting methods and tools might be selected to facilitate the measurements, as long as it is understood that "a fool with a tool still remains a fool". A method or tool will not solve the problem; they can only support a defined process.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In this study, a control system of a feedback device of temperature sensation for myoelectric prosthetic hand users was improved. The device is mounted on a user's upper arm in contact with the skin, and transfers the temperature sensation in the upper arm corresponding to the temperature detected by the temperature sensor at the fingertip to the user. However, since the feedback device developed in the previous study was controlled in an open loop system, it was difficult to maintain the temperature for a long period. To solve this problem, a closed loop control system was constructed for the feedback device by using a PID controller. In addition, in order to verify the performance of the feedback device controlled in the closed loop control system, performance evaluation experiments were performed. As a result, the sufficient capability of the feedback device controlled in the closed loop control system was indicated. Finally, temperature identification experiments were performed based on psychophysical method to verify an effectiveness of the feedback device. As a result, the difference threshold of the feedback device of temperature sensation, 0.62℃ was obtained.

1. Introduction

A myoelectric prosthetic hand is an electrically driven artificial hand in which the intended motion is identified and the movement is controlled based on biosignals generated when muscles are moved. However, myoelectric prosthetic hand users are unable to feel sensations when they touch an object using a prosthetic hand. Therefore, investigation of the functions that provide sensation feedback to the user is required. It is shown that sensory feedback is important for improvement in proficiency level of a myoelectric prosthetic hand [1].

Recent researches focused on developing a feedback device of sensations for myoelectric prosthetic hand users. These included our previous study [2] in which a feedback device of force sensation was developed. In this mechanism, when the myoelectric prosthetic hand held an object, the belt of the device was wound by a motor and tightened the operator's upper arm. This enabled the user to obtain a force sensation. Additionally, the user could feel a difference in the object hardness by changing the winding speed of the belt.

A study [3] also reported a feedback device using vibrations. The device changed the vibration intensity based on the size of the detected force. Another study [4] reported a device that perceives the temperature when touched by a myoelectric prosthetic hand using a hot and cold pad. This device obtains the temperature difference between an object and the user's skin temperature by the changes in the temperature of the hot and cold pads. A study [5] examined transfer of temperature sensation using the Peltier element.

In our previous study [6], a feedback device of temperature sensation was developed by using a Peltier element to perceive the object temperature when the user touches objects by a prosthetic hand. The object temperature is measured by a temperature sensor attached at fingertip of the prosthetic hand. However, the temperature measurement required several tens of seconds. Therefore, a temperature prediction algorithm was proposed to shorten the measurement time. The study [4] examined a device that transmits a temperature difference between skin temperature of cut section and object temperature. However, the temperature sensation differs at each body site. Therefore, the feedback device developed in our study transfers temperature sensation in the upper arm corresponding to the temperature detected at the fingertip of the prosthetic hand. To this end, an experiment to examine the difference in the temperature sensation felt by the fingertip and that felt by the upper arm was performed, and the feedback device reproduces the temperature sensation felt by the fingertip to the

*Corresponding Author: Chiharu Ishii, Email: c-ishii@hosei.ac.jp

upper arm based on the result of the experiment. Furthermore, an identification experiment for temperature was performed to verify the effectiveness of the feedback device. However, the feedback device developed in previous study was controlled in an open loop system. Therefore, it was difficult to maintain the temperature using this control system.

This paper is an extension of work originally presented in 2016 International Conference on Advanced Mechatronic Systems [6]. The key changes from the conference paper are summarized as follows.

In this paper, a closed loop control system was constructed to enhance the performance of the feedback device. In addition, to improve the operability of the myoelectric prosthetic hand, a new myoelectric prosthetic hand was built. Then, performance evaluation experiments were performed to verify the performance of the feedback device controlled in the closed loop control system using the new myoelectric prosthetic hand. Furthermore, psychophysics tests were conducted to measure the difference threshold of the feedback device in terms of the temperature difference.

2. Feedback Device of Temperature Sensation

2.1. Peltier Effect and Seebeck Effect

Exothermic and endothermic reactions occur when an applied current flows through a junction between two conductors. This phenomenon is called the Peltier effect. The Peltier element is an electronic device that changes surface temperature on the basis of the Peltier effect. It enables both cooling and heating by applying a voltage, and temperature can be adjusted by regulating the voltage. The feedback device has a Peltier element, and transfers the temperature sensation to the user. The Peltier element used in this study is "TEC1-12708" Peltier element made by HB Electronic Components.

In contrast to the Peltier effect, the Seebeck effect is a phenomenon that generates a voltage by providing a temperature difference to a conductor. When the temperature difference is provided to the conductor, voltage that is proportional to the temperature difference is generated due to the Seebeck effect. This principle is used to measure temperature. A thermocouple is a temperature sensor that uses the Seebeck effect. In this study, a K type "AD-1214" thermocouple manufactured by T & D Corporation was used as the temperature sensor.

2.2. Outline of Feedback Device

Figure 1 shows the feedback device of temperature sensation (Hereafter, FB device) developed in our study.

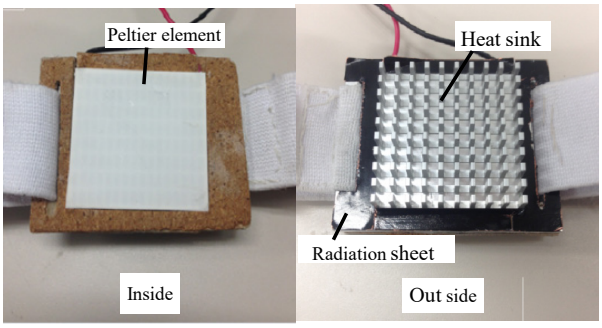

Figure 1: Feedback device of temperature sensation (FB device)

When the FB device is used for a long period, there is a possibility of high-temperature due to the accumulated heat. Hence, the continuous operating time of the FB device controlled in an open loop control system was limited to 5 s. Figure 2 shows relationship between the applied voltage and the temperature produced by the FB device.

The FB device enables refrigeration of surface temperature to a minimum of 15°C for 5 s. In addition, when the FB device increases the temperature, it enables heating exceeding 50°C. However, the temperature of the FB device was limited to 40°C for safety considerations.

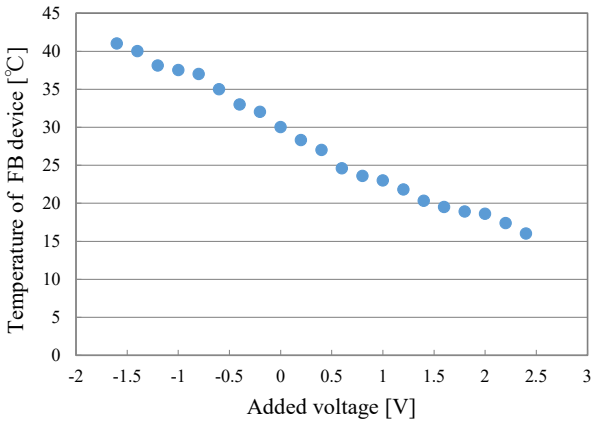

Figure 2: Added voltage and temperature of the FB device

3. Temperature Prediction and Temperature Sensation Investigation

After contact with the object, it takes several tens of seconds until the measured value settles. Thus, the temperature sensor needs a long time for measuring the temperature. Consequently, a temperature prediction was performed to shorten the measurement time.

3.1. Temperature Prediction Algorithm

Let $y(t)$ denote a sensor output and $u(t)$ denote an amount of temperature variation, and let relationship between $y(t)$ and $u(t)$ be given by the following equation in transfer function expression:

$$Y(s) = G(s)U(s) \tag{1}$$

In order to determine the transfer function $G(s)$, the parameters identification was performed by using the gradient method. As a result, $G(s)$ was given by the following equation:

$$G(s) = \frac{0.89s^3+0.66s^2+0.49s+0.06}{s^4+2.54s^3+1.7s^2+0.8s+0.06} \tag{2}$$

Furthermore, let ΔT denote the predicted temperature variation and $\hat{y}(t)$ denote the estimated output, then the estimated output is calculated as follows using the identified transfer function.

$$\hat{y}(t) = \frac{0.89s^3+0.66s^2+0.49s+0.06}{s^4+2.54s^3+1.7s^2+0.8s+0.06}\Delta T \tag{3}$$

Let $\varepsilon(t)$ denote the error between the estimated output $\hat{y}(t)$ and sensor output $y(t)$, which is represented by the following equation.

$$\varepsilon(t) = \hat{y}(t) - y(t) \quad (4)$$

The predicted temperature variation ΔT is updated by using $\varepsilon(t)$ as follows in each sampling period.

$$\Delta T_{new} = \Delta T_{old} + K \cdot \varepsilon(t) \quad (5)$$

where ΔT_{old} is the predicted temperature variation one step before and ΔT_{new} denotes an updated predicted temperature variation. In addition, K is an arbitrary constant, which was chosen as K=70 in this study, since noise was comparatively low and the reaction time was fast when the temperature prediction was performed.

Let T denote the predicted temperature and T_0 denote the room temperature, then the predicted temperature is given by the following equation.

$$T = \Delta T_{new} + T_0 \quad (6)$$

The predicted temperature is updated to reduce the error when the sensor detected a change of the temperature, thus the temperature when reached to the equilibrium state is given by Equation (6). As a result, the sensor can detect the temperature of the object in a short time.

3.2. Verification of Temperature Prediction Algorithm

In order to verify the effectiveness of the proposed temperature prediction algorithm, an experiment to investigate the behavior of the temperature prediction when the touched object was changed to an object with a different temperature during the temperature prediction was performed. When the sensor touched an object with a temperature of 20°C after touching an object with a temperature of 30°C under the room temperature of 25°C, the temperature was predicted by using the temperature prediction method. Figure 3 shows the result of the temperature prediction.

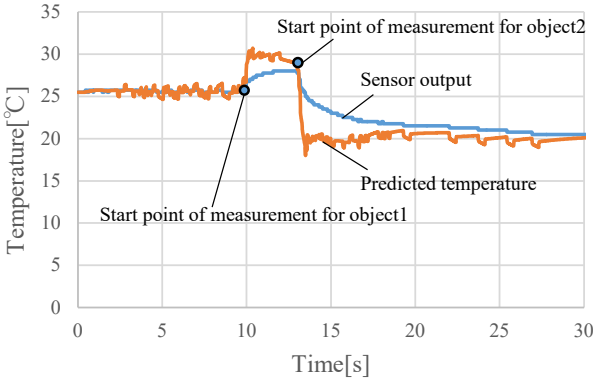

Figure 3: Temperature prediction for objects with different temperature

The results showed that it is possible to perform the temperature prediction even when an object with a different temperature was touched during the temperature prediction.

3.3. Purpose of Temperature Sensation Investigation

It is difficult for the FB device to reproduce the low temperature. As shown in Figure 2, the FB device cannot reproduce a temperature of lower than 15°C. However, the temperature sensations of an individual differ at each body site. For example, there is difference between the temperature sensations when an object with the same temperature is touched with a finger or with the upper arm. Therefore, an investigation of temperature sensation was performed, and a temperature that corresponds to the temperature at which an object was touched with a finger was determined as feedback temperature to the upper arm.

3.4. Method and Result

In order to investigate the difference in the temperature sensation between the fingertip and the upper arm, an experiment was performed in the following procedure using water from temperatures ranging from 5°C to 40°C for each 5°C. The details of the procedure of this experiment are addressed in the literature [6].

Table 1 shows the result of the temperature sensation investigation performed for 7 healthy subjects in their 20s.

Table 1: Result of temperature sensation investigation

Temperature (upper arm) [℃] Subject	Temperature (Fingertip) [℃]							
	5	10	15	20	25	30	35	40
A	15	18	22	27	29	30	34	37.5
B	15	18	22	28	29	30	33	37.5
C	15	18	22	28	29	30	33	37.5
D	15	18	22	27	29	30	33	37.5
E	15	18	22	27	29	30	34	37.5
F	15	18	22	27	29	30	33	37.5
G	15	18	22	27	29	30	33	37.5
Ave.	15	18	22	27.3	29	30	33.3	37.5

Based on these results, the FB device is controlled to reproduce the temperature experienced by the upper arm which is equivalent to the temperature experienced by the fingertip. Thus, the temperature sensation which should be reproduced to the FB device is determined by the temperature prediction at the fingertip. However, the temperature of FB device is not changed when the prosthetic hand touched an object at 30°C. This is because the temperature of FB device is approximately 30°C at normal temperature.

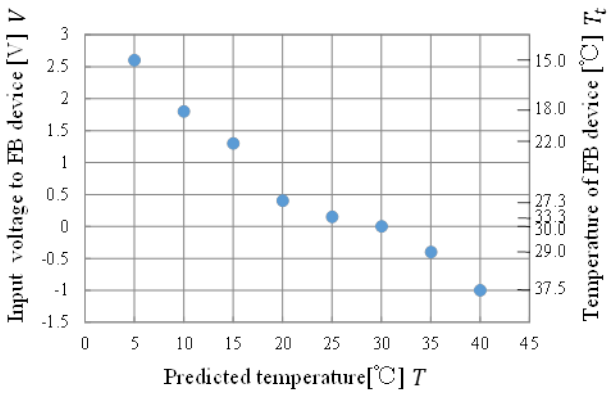

Figure 4: Predicted temperature and input voltage to the FB device

The temperature which should be presented at the upper arm and the voltage which should be applied to the FB device were determined as follows. The relationship between the temperatures experienced by the fingertip and by the upper arm was interpolated as shown in Figure 4. Then, the relationship between the predicted

temperature at the fingertip T and the target temperature in the upper arm T_t, and the relationship between the predicted temperature at the fingertip T and the input voltage to the FB device V are approximated as shown in Equations (7) and (8) respectively, by using the least-squares method.

$$T_t = 0.00008T^4 - 0.006T^3 + 0.1841T^2 - 1.1439T + 16.902 \quad (7)$$

$$V = 1.578 \times 10^{-7}T^6 - 2.135 \times 10^{-5}T^5 + 1.122 \times 10^{-3}T^4 - 2.894 \times 10^{-2}T^3 + 0.3819 \times T^2 - 2.543T + 8.743 \quad (8)$$

4. Temperature Identification Experiment

4.1. Purpose and Equipment

The FB device transmits the temperature sensation corresponding to the predicted temperature of the object which was touched by the fingertip of the myoelectric prosthetic hand to the user's upper arm. In order to verify the effectiveness of the developed FB device, the temperature identification experiment was performed using a myoelectric prosthetic hand developed in the literature [7].

The myoelectric prosthetic hand needs three types of operations in the experiment, namely bending the finger to touch the object, maintaining the posture, and releasing the finger. To distinguish these operations, electrodes were stuck on the flexor digitorum superficialis muscle and the extensor digiti minimi muscle to measure surface electromyogram (SEMG). The flexor digitorum superficialis muscle is used to flex the fingers, and the extensor digiti minimi muscle is used to extend the fingers. Figure 4 shows the positions where the electrodes were stuck on.

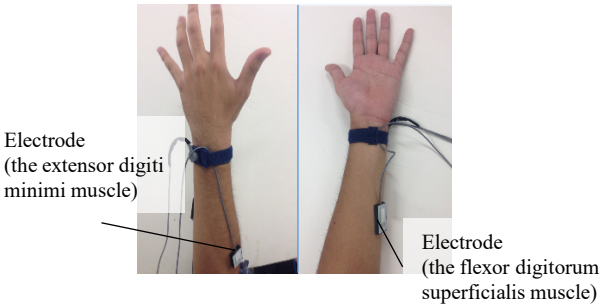

Figure 4: Positions of electrodes

4.2. Method of Experiment

The subjects executed the identification of the temperature transmitted by the FB device. In the experiment, another Peltier element which is different from that of the FB device was used as the object touched by the fingertip of the prosthetic hand. The following five variations in temperature were employed: hot (approximately 40°C), lukewarm (approximately 35°C), not much (25°C–30°C), a little cold (approximately 20°C), and cold (approximately 15°C).

The temperature identification experiment was performed in the following way. The temperature of the object (Peltier element) is randomly selected from the five variations, and the temperature of the object is adjusted to become the selected temperature. The subject operates the myoelectric prosthetic hand to touch the object. Then, the temperature prediction is performed and the voltage calculated from Equation (8) on the basis of the predicted temperature is applied to the FB device. Based on the corresponding temperature sensation reproduced by the FB device, the subject identifies the temperature of the object from the five variations. The experiment was executed for 10 subjects. The experimental environment is shown in Figure 5.

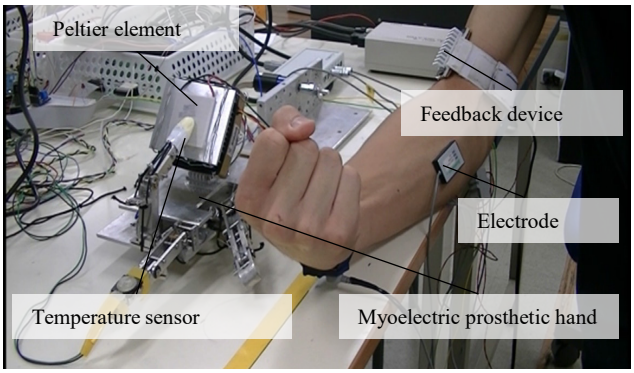

Figure 5: Experimental environment

Table 2 shows the success rates of temperature identification for each subject, and Table 3 shows the success rate of temperature identification for each presented temperature.

Table 2: Result of the temperature identification

Subject	Success rate of identification [%]
A	90
B	80
C	100
D	90
E	70
F	100
G	80
H	100
I	90
J	80
Average	88

Table 3: Success rates for each temperature

Presented temperature [°C]	Success	Failure	Success rate of identification [%]
40	17	0	100
35	23	5	85.2
25–30	9	1	90
20	22	4	84.6
15	17	2	89.5

The results show that the average success rate for 10 subjects is 88%. In addition, the success rate of each presented temperature exceeded 84%. The above results revealed that the difference in temperature can be recognized with high accuracy. The causes for the failure identification include the failure of the temperature prediction and the individual differences of the sensation of each subject.

5. Closed Loop Control System

5.1. Construction of the Control System

The FB device developed in the previous study is controlled in an open loop system, in which the constant voltage through Equation (8) computed from the predicted temperature is applied to the FB device. Hence, it is difficult to maintain the temperature using this control system, because if the voltage is continuously provided to the FB device the temperature keeps increasing or decreasing. Therefore, the continuous operating time of the FB device was limited to 5 s.

To solve this problem, a closed loop control system was constructed. To this end, a temperature sensor which is the same type as one attached at the fingertip of the prosthetic hand was additionally attached on the surface of the Peltier element of the FB device. The target temperature in the upper arm T_t corresponding to the predicted temperature at the fingertip of the myoelectric prosthetic hand T is determined by Equation (7). Then, the input voltage to the FB device is determined by a PID controller. The PID gains were determined by trial and error, and chosen as $K_P = 1$, $K_I = 0.05$ and $K_D = 0.01$.

In order to verify the validity of the closed loop control system with PID controller, sudden change in temperature when the target temperature is decreased from 40°C to 15°C was examined. The transition of the temperature of the FB device and the input voltage to the FB device are shown in Figure 6.

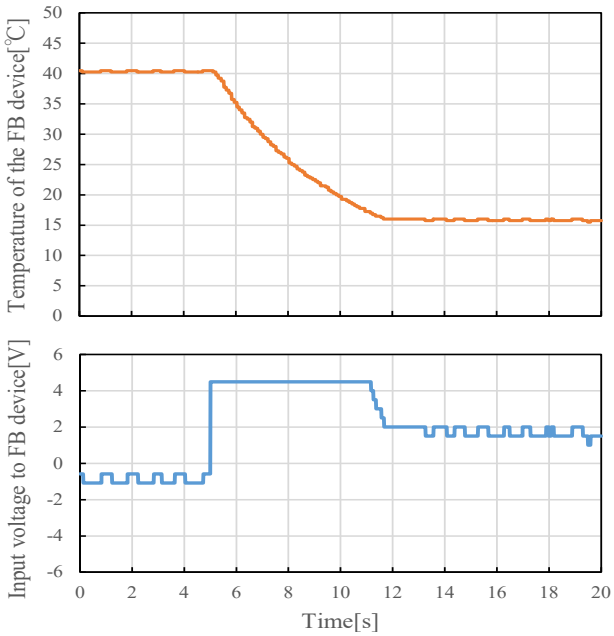

Figure 6: Temperature transition and input voltage to the FB device

As shown in Figure 6, the constructed closed loop system enabled the adjustment of the presenting temperature of the FB device according to the temperature change and also enabled a long time continuous operation of the FB device.

6. Performance Evaluation Experiments

6.1. Purpose and Equipment

In order to verify the performance of the FB device controlled in the closed loop control system, an evaluation experiment was performed.

To improve the operability of the myoelectric prosthetic hand, a new myoelectric prosthetic hand was designed and built by imitating the commercial prosthetic hand, which is shown in Figure 7. The temperature sensor was attached to the silicone finger installed on the fingertip of the index finger of the myoelectric prosthetic hand, and the pressure sensor was attached to the fingertip of the thumb of the prosthetic hand. Thus, when the prosthetic hand holds an object, temperature value of the object and grasping force of the finger are obtained. The new myoelectric prosthetic hand was used in this experiment.

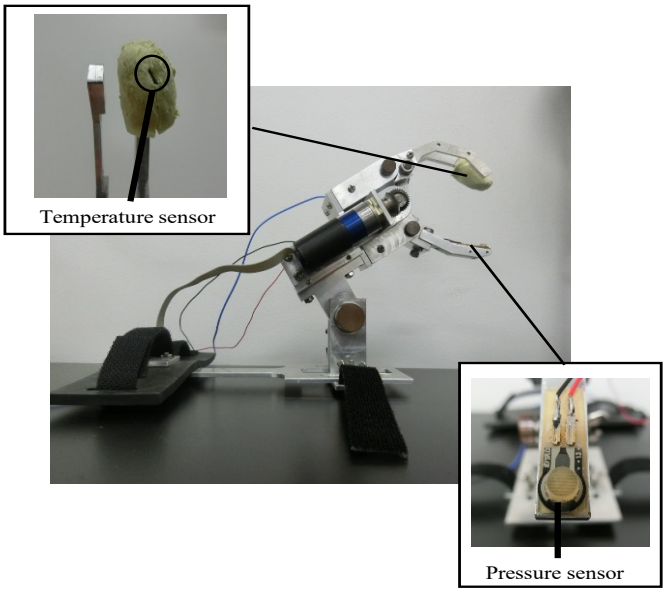

Figure 7: New myoelectric prosthetic hand

6.2. Method of Experiment

The experiment was performed in the following procedure. In this experiment, the following four variations in temperature were employed: approximately 40°C, approximately 35°C, approximately 15°C, and approximately 5°C.

1. The temperature of the object (Peltier element) is adjusted to become the selected temperature.

2. The temperature of the object T_{real} is recorded and the real value of the target temperature in the upper arm T_{t_real} is calculated through Equation (7) from T_{real}.

3. The object is touched by the fingertip of the myoelectric prosthetic hand.

4. The temperature prediction is performed and the target temperature corresponding to the predicted temperature T_t is calculated through Equation (7).

5. The temperature of the FB device is controlled by using the closed loop control system.

6. The temperature of the FB device T_{FB} and the target temperature corresponding to the predicted temperature T_t are recoded.

7. The error between the target temperature T_t and the real value T_{t_real} (prediction error $T_{t_real} - T_t$), and the error between the target temperature T_t and the temperature of the FB device T_{FB} (control error of the FB device $T_t - T_{FB}$) are recorded for 10s.

The above procedure was repeated 5 times for each temperature.

6.3. Result

Table 4 shows the result of the performance evaluation experiment.

From the experimental result, a maximum error of 3.43°C was observed between the target temperature T_t and the real value T_{t_real}, and a maximum error of 2.86°C was observed between the target temperature T_t and the temperature of the FB device T_{FB}. In addition, the overall average of the prediction error and control error of the FB device for 10s were 1.09°C and 0.61°C, respectively. From this result, it is considered that the FB device controlled in the closed loop control system showed sufficient capability to present the temperature sensation.

6.4. Purpose of Difference Threshold Measurement Experiment

The usefulness of the FB device controlled by the closed loop system is objectively verified with a psychophysics experiment method. Namely, a temperature difference threshold of the FB Device is measured by this experiment. The difference threshold is the minimum difference between two stimulations that can be distinguished by the user. Therefore, in this study, the difference threshold means a change in the temperature that the user can recognize using the FB device.

6.5. Method of Experiment

In this experiment, the myoelectric prosthetic hand is not used, but each temperature is input directly to a computer, and then the difference threshold measurement of a single body of the FB device is conducted.

The temperature of 30°C is used as standard stimulation, and five kinds of temperature, 28°C, 29°C, 30°C, 31°C and 32°C, are used as comparative stimulation. The following describes the experimental procedure:

Table 4 Result of performance evaluation experiment

Temperature of the object T_{real} [°C]	Prediction error $T_{t_real} - T_t$ [°C]		Control error of the FB device $T_t - T_{FB}$ [°C]	
	Ave.	Max	Ave.	Max
5.4	0.58	0.98	0.31	0.95
4.7	1.03	1.51	0.49	1.26
5.2	1.03	1.51	0.55	1.26
5.4	1.19	1.78	0.44	1.22
5.4	1.37	1.87	0.55	1.12
14.6	1.27	2.26	0.46	1.62
15	0.27	0.86	0.31	1.13
14.5	1.00	1.70	0.41	1.65
15	1.49	2.28	0.36	1.59
15.4	1.19	1.98	0.36	1.59
35	1.31	2.42	0.40	1.58
35	0.82	1.74	0.47	1.42
35.2	0.97	1.66	0.45	0.85
35.4	1.17	1.70	0.58	1.10
35.4	0.89	1.57	0.40	1.05
41.3	2.23	3.43	1.60	2.49
40.3	0.50	0.93	0.69	1.39
41.5	1.65	2.28	1.75	2.86
40.3	0.93	1.20	1.32	2.14
40.3	0.92	2.00	0.36	0.93

1. The FB Device is attached on the upper arm of the subject.

2. An experimenter inputs the standard stimulation (30°C) to the computer and standard stimulation is presented to the subject by the FB device.

3. An experimenter inputs the comparative stimulation that is randomly selected from the five kinds of temperatures to the computer and comparative stimulation is presented to the subject by the FB device.

4. The subject then answers which temperature is higher or whether the two are the same.

5. 25 sets of the work 2 ~ 4 are performed.

6. The works 2 and 3 was replaced and 25 sets of the work 2 ~ 4 are performed.

In the operations, all the comparative stimulations were used ten times in random orders. The experiment was executed for 5 healthy subjects in their 20s.

6.6. Result

Table 5 shows the result of difference threshold measurement experiment.

Table 5: Results of difference threshold measurement experiment

Temperature of comparison stimulus [°C]	Rate of the subject's answer[%]		
	Hot	Equal	Cold
28	0	14	86
29	4	36	60
30	6	82	12
31	60	34	6
32	86	10	4

When the method of three categories (large, almost equal, small) is used and when the stimulation value at which the occurrence ratio of "large" and the occurrence ratio of the others are both 50% is written as S_U, the stimulation value at which the occurrence ratio of "small" is 50% is written as S_L, the difference threshold ΔS can be obtained by the following equation:

$$\Delta S = \frac{S_U - S_L}{2} \quad (9)$$

The stimulation value S_U and the stimulation value S_L were calculated through a linear interpolation method. Table 6 shows the results.

Table 6: Calculation of difference threshold

S_U	30.81
S_L	29.58
Difference threshold ΔS	0.62

From the above calculation procedures, the difference threshold of the FB device was found to be ΔS = 0.62°C. Therefore, the experimental results suggest that the temperature change can be distinguished if the temperature is changed 0.62°C or more under the standard stimulation, namely temperature of 30°C.

7. Conclusion

In this paper, a control system of the FB device of the temperature sensation developed for myoelectric prosthetic hand users was improved. In the previous FB device controlled in the open loop control system, it was difficult to operate the FB device continuously. Also, the FB device could not adjust the temperature for the temperature change. To solve these problems, a closed loop control system was constructed for the FB device and was tested for sudden change of the temperature.

In addition, a new myoelectric prosthetic hand was built to improve the operability of the myoelectric prosthetic hand. Then, a performance evaluation experiment was carried out using the new myoelectric prosthetic hand to verify the performance of the FB device controlled in the closed loop control system. The overall average of the prediction error and control error of the FB device were 1.09°C and 0.61°C, respectively. Thus, the sufficient capability of the FB device controlled in the closed loop control system was shown.

Furthermore, psychophysics tests were conducted to measure the difference threshold of the feedback device. As a result, the difference threshold of the feedback device of temperature sensation, 0.62°C was obtained.

Conflict of Interest

The authors declare that there is no conflict of interests regarding the publication of this paper.

ABSTRACT

A thrombus or a blood clot is the result of blood coagulation which is a natural process to prevent bleeding. An inappropriate formation of a thrombus in a deep vein is known as Deep Venous Thrombosis (DVT). The main complication of a DVT is a Pulmonary Embolism (PE) which occurs when a thrombus breaks loose and travels to the lungs. DVT, PE, or both are also known as Venous thromboembolism (VTE). It affects an estimated 300,000–600,000 Individuals just in the United States per year and can cause considerable morbidity and mortality. This multifactorial disease related to advanced age, immobility, surgery or obesity is an important public health issue. Our project is looking to link the VTE epidemiology (risk factors, patient history, PE) to the thrombus structure. To reach our goals, we are collecting ultrasonography (echogenicity) and elastography (stiffness) of human thrombus. This manuscript describes our approach to create and preprocess a database using Toshiba Aplio 500. Our approaches to characterize the thrombus structure with ultrasound images are also described. The feature extraction is made with the scattering operator. Obtained features are then reduced using Principal Component Analysis and are analyzed to evaluate our approach.

1. Introduction

This manuscript is an extension of two conference papers presented at 2016 2nd International Conference on Frontiers of Signal Processing [1, 2]. Deep Venous Thrombosis (DVT) is an outcome of an incongruous blood clot in a deep venous network. Due to the clot, the blood flow is slowed or stopped in the affected vessel. Therefore, the remaining blood finds its way back to the heart through the superficial network. This situation can oftenly occur in leg vessels and it may lead to warm, swelling, pain or edema of the affected leg. DVT is a serious disease and has to be treated as soon as possible to avoid the blood clot extent and irreparable damage to the veins. Moreover, it may also have deadly consequences when a clot fragment breaks off, travels to the lung and causes a Pulmonary Embolism (PE). Without an urgent care, a DVT has about a 50% risk of leading to a PE [3]. DVT has multifactorial causes: immobilization, surgery, age, cancers, genetic variations; and it is mostly diagnosed via ultrasound. More precisions on blood clot formation and risk factors are provided in section 2.

Our project is aiming to relate the blood clot structure to its age, its formation cause and PE risk. Ultimately that can lead us to the detection of a cancer in an early stage. Section 2 presents the imaging techniques – ultrasonography and elastography – and our acquisition system. Section 3 describes our databases get with Toshiba Aplio 500 and the preprocessing steps. Section 4 proposes a wavelet-based feature extraction algorithm, the scattering operator [4]. Finally, major energetic relevant features have been selected using Principal Component Analysis.

2. Background and Key issues

Here in after, our project on Deep Venous Thrombosis is described. Subsection 2.1 describes a blood clot and its major risk factors. Subsection 2.2 summarizes the state of art and describes

*Corresponding Author: Thibaud Berthomier, LABSTICC (UMR 6285), ENSTA Bretagne, 2 rue François Verny, 29806 Brest Cedex, France
Email: thibaud.berthomier@ensta-bretagne.org

the main imaging techniques. Subsection 2.3 outlines technical issues related to our acquisition process.

2.1. Medical Background

2.1.1. Blood circulation and coagulation

Blood flows one-way through the body [5]: the arteries (in red on Figure 1) distribute oxygenated blood from the heart to various organs and muscles. Veins (in blue on Figure 1) have thinner and elastic walls and take over from arteries to return back oxygen impoverished blood to the heart. The blood cycle is performed using: (a) Heartbeat to maintain a continuous flow, (b) Diaphragmatic or deep breathing, (c) Muscle pump system (calf muscular contraction) and (d) Venous pump of the foot which is a major factor in blood return activated by walking. Moreover, veins include a valve system to avoid blood reflux. Prolonged immobilization due to plaster cast, bed rest or long distance flights slow down blood circulation and raise the risk of a venous thrombosis.

The physiological process to keep blood within veins and stop bleeding in case of injuries is called hemostasis [6]. Hemostasis involves vascular spasm (reduction of the damaged vessel diameter) and coagulation which change the liquid blood to a gel. The mechanism of coagulation includes: activation, adhesion, and aggregation of platelets along with deposition and maturation of fibrin. When a broken vessel is cared, a process named fibrinolysis starts dissolving the clot and prevents it from growing and causing thrombosis. Hemostasis or fibrinolysis disorder is indeed one of the risk factors for venous thrombosis.

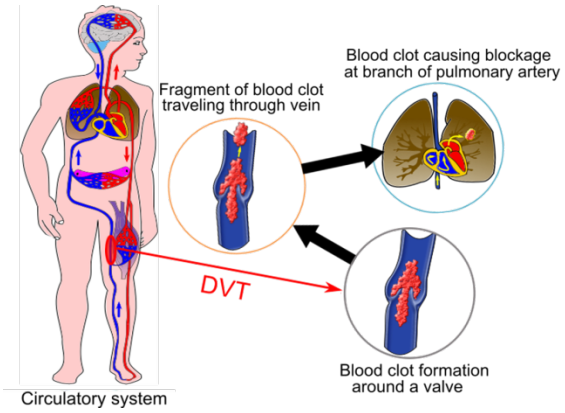

Figure 1: Deep Venous Thrombosis and its major complication, Pulmonary Embolism.

2.1.2. Thrombosis, symptoms and treatment

Thrombosis occurs when an abnormal blood clot is formed and/or when the fibrinolysis process becomes deficient. Thrombosis symptoms are an inflammation of a stamped or obstructed vessel [5], most commonly in the lower extremities. Superficial thromboses occur in the veins near the skin and usually don't cause fever, infection or swelling. On the contrary, DVT are very dangerous because a piece of the clot can break off, be carried by the blood to the lung and cause a PE, as seen in Figure 1.

The clot formation often begins in the calf veins, where the blood flow may slow down (valves, collateral veins) and extends to the knee or thigh veins [6]. The risk of a PE increases when the clot gets closer to the heart. When a deep vein is obstructed by a clot, the blood cannot flow anymore back to the heart through this vein; this creates a hypertension upstream part of the clot, therefore the blood finds another way through the superficial venous network.

Many cases are asymptomatic and resolve spontaneously. Otherwise, DVT can be revealed by three main signs: swelling of the calf or the ankle, leg warm to the touch and leg pain or tenderness. The patient could also have numbing, cramps, a sensation of heavy legs, pain on palpation and/or bluish skin discoloration. At a confirmed stage, DVT may go along with fever, edema, ulcer, tachycardia or even a complete functional impotence [6]. Asymptomatic DVT is about 5 to 20 times more common than symptomatic events [3]. Moreover, relapse is frequent and the patient can have post-thrombotic symptoms, *i.e.* long-term complications.

DVT treatment aims to prevent the clot from getting any bigger or breaking loose and causing a pulmonary embolism. In general, the anticoagulant drugs decrease the blood's ability to form a clot but they don't break up existing blood clots (to avoid a PE). The blood clot will be naturally destroyed by the body (fibrinolysis). Later on, physicians should treat the patient to reduce the risk of new thrombosis.

2.1.3. Epidemiology

Normally in our blood circulation system, there is a trade-off between coagulant and anticoagulant molecules. Many physiopathological mechanisms can unbalance the fragile trade-off and create a venous thrombosis. Virchow's triad [7] for thrombus formation is:

(a) Venous stasis,

(b) Endothelial injury,

(c) Hypercoagulable state.

Venous stasis gathers all factors responsible for the blood slow down: extended immobilization (bed rest, labor, and plaster cast), heart failure, varicose vein and venous constriction (prolonged sitting, long distance flight, cancer). For instance, statistics on venous thrombosis showed an incidence of two to four per ten thousand passengers of a flight over five hours [8]. Smoking also increases the risk as it stimulates the production of fibrinogen in the blood (and hence platelet aggregation and coagulation) and generates more viscous blood.

Endothelial injury brings factors degrading the venous walls. Therefore, an inflammation caused by an infection (related to surgery, catheter, traumatism and age) can produce a thrombosis. According to [8], statistics show that the risks, without preventive thrombosis in medicine, increase in the range of ten to twenty percent in the four to five weeks following a hospital discharge. In the same way, risks become twice larger every ten years after the age of 40.

Hypercoagulability incorporates all mechanisms reinforcing coagulation or disturbing anticoagulation. It can be acquired factors (such as pregnancy, hormone therapy, and cancer), inflammatory disorders or inherited factors (Factor V Leiden mutation, protein C or S deficiency, antithrombin deficiency). Pregnant women or people with hormonal treatment have two to five times more likely to develop a DVT [8].

2.1.4. Diagnosis and imaging techniques

An untreated DVT in the calf has about a 25% risk of extending and reaching the proximal veins (popliteal, femoral, or iliac) [3]. As well, half of untreated proximal DVT will lead to a PE. To reduce the risk of a long term complication (*e.g.* damage of venous valves and wall) and PE, it is vital to diagnose as soon as possible the DVT. However, this task seems to be difficult because the signs and symptoms associated with the DTV are not specific to this disease [6]. A blood test can exclude thromboembolic disease where the DVT probability is low. This test is based on the concentration of D-Dimers (*i.e.* fibrin degradation products) which are present in the blood when the coagulation system is activated. Nevertheless, a positive test does not always indicate thrombosis.

Imaging studies of the venous blood network are needed for diagnosis. Duplex ultrasonography is the standard imaging process. Physicians view the blood network and flow, and check on the veins' compressibility. A vein with a blood clot is relatively incompressible and is more echogenic than a free vein. Contrast venography is a gold standard but it is rarely used because its invasiveness [9]. Magnetic Resonance Angiography (MRA) and Computed Tomography Angiography (CTA) are rarely used: they are costlier and less than ultrasonography which is mostly sufficient to diagnose a DVT. In the event of a PE suspicion, CTA is the standard procedure.

2.2. Medical issues

2.2.1. Venous thrombus characterization

DVT is a multifactorial disease which can cause serious and irremediable health problems. Its early detection would limit the risk. Since this disease is often asymptomatic, prevention measures and surveillance might be used before and after any procedure or event that can increase the risk of a DVT. In case of doubt, the detection using ultrasound is relatively simple. Yet it is a lot more difficult to identify the thrombosis origins, age and to estimate the risk of PE. Thus, the objective of our project is to analyze the blood clot structure with the help of ultrasonography and elastography techniques in order to estimate the age, the origins and the risk of a PE. Elastography is an imaging technique, based on ultrasound, used with success to analyze human tissue stiffness (e.g. liver fibrosis detection).

In the literature, there are studies linking thrombosis maturity to the clot elasticity ([10, 11]), determining the impact of genetic variations on the onset of a DVT ([12, 13]) or estimating treatment efficiency ([14, 15]). But, currently, there is a little or no convincing evidence that there is a correlation between the blood clot structure and its triggering factors, hence making our research even more challenging. To characterize thrombi, *in vivo* data are collected thanks to Brest University Hospital. The following two subsections will respectively describe ultrasonography and elastography. In biomedical Engineering, these two techniques are widely studied in various research projects. In particular, the authors of [16] publish an instructive survey titled "Automated breast cancer detection and classification using ultrasound images". The recent and promising imaging technique, elastography, is mainly considered for detection and characterization of several tissues, such as liver [17], breast [18, 19] and thyroid [20, 21]. The tissue shiftiness is indeed a valuable source of information to diagnose diseases.

2.2.2. Ultrasonography

Ultrasonography (or Brightness-mode with 2-dimension imaging – B-mode 2D) is the default and the most intuitive mode: it is a 2-dimensional cross sectional view of the portions of the organs or the tissues that are intersected by the scanning plane. The shape of the field (sector, rectangular or trapezoid) depends on the used probes. The chosen probe to perform venous examination is a 5-10 MHz linear probe. On a gray scale, high reflectivity (as tissue) is colored white and for no reflection (as blood) is colored black. Two ultrasound imaging findings can point out the presence of a blood clot in a vein: the relative incompressibility of the vein and an echogenic intraluminal material [22].

In most case, the blood clot is echogenic (see Figure 2). At the beginning of a DVT episode (in the first hours or days), the clot is hypoechoic, homogeneous, elastic and it dilates the vein. On the contrary, an older clot (several weeks) becomes slowly more heterogeneous, harder and smaller. The clot echogenicity actually depends on its blood cell composition, distribution and on its fibrin mesh [23]. The incompressibility of the vein during the ultrasound test is considered as the main detection criterion of a DVT. Conversely, using the adjacent artery as a reference point, the full compression of the vein with a minimal deformation of the artery indicates an absence of thrombosis. Moreover, the vascular paresis (fixity of the venous valves) can indicate the presence of a blood clot as well.

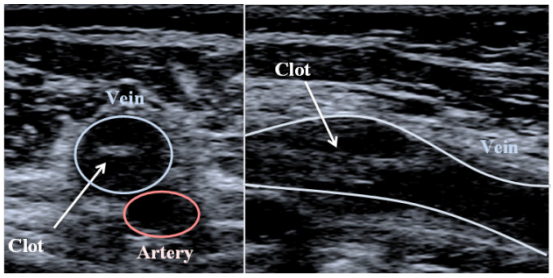

Figure 2: Transverse (left) and longitudinal (right) ultrasonographies of a blood clot in the femoral vein (Images obtained with Toshiba Aplio 500).

2.2.3. A new approach: elastography

Elastography consists in mapping the hardness, or the elasticity, of human tissues, e.g. their resistance when a mechanical force is applied on it: the harder a tissue is, the more elastic it is. A static external stress σ (in pascal Pa), applied to the surface of a solid, is linearly proportional to its fractional extension ε (non-dimensional) by the modulus of elasticity E (in Pa). This principle is named Hooke's law [24]:

$$\sigma = \varepsilon E \quad (1)$$

Human soft tissues can distort under the influence of two types of mechanical waves: compressional and shear waves. Compressional waves are also called longitudinal waves because the particle displacement is parallel to the direction of wave propagation. As well, shear waves are named transverse waves because, this time, the particle displacement is perpendicular to the direction of the wave propagation.

The velocity of these waves is directly connected to the elastic modulus E (or Young's modulus). In soft biological tissues [24], the compressional velocity is much higher (≈ 1500 m/s) than the

shear wave velocity (≈ 10 m/s), so the Young's modulus can be approximated using the following equation:

$$E \approx 3\rho c_s^2 \quad (2)$$

where ρ is the volume density (kg/m^3) and c_s the shear wave velocity (m/s). The volume density is assumed to be constant (1000 kg/m^3 which is the water density) even if it is actually different from one tissue to another (fat ≈ 950 kg/m^3, blood ≈ 1025 kg/m^3, liver ≈ 1060 kg/m^3, muscle ≈ 1070 kg/m^3 and bone between 1380 kg/m^3 and 1810 kg/m^3 [25]).

Elastography systems do not measure directly the hardness of the human tissue but estimate the velocity of the shear waves. These systems send either a mechanical or an acoustic impulse to generate the shear waves and follow their propagation using ultrasound, *i.e.* compressional waves. Ultrasonic echoes are analyzed in order to determine the velocity of the shear waves, and hence the elasticity, using equation (2).

2.2.4. Elastography and venous blood clot

In the medical context, the main application is the diagnosis of hepatic fibrosis because the liver gets harder when the fibrosis gets more severe. In old days, palpation was used to estimate the hardness. Recently, several systems can precisely measure and create a map of the organ hardness (elastography). In theory, the blood clot hardness (and hence elasticity) should increase with age thank to the loaded fibrin. The exact age of the thrombus can help determining the right treatment (anticoagulant, surgery). Several studies ([11, 26]) create an animal model to estimate the exact age of the venous thrombus *in vivo* using ultrasound elastography. On human patients, the treatment efficiency makes the experiment more difficult. However, for some patients still presenting a DVT after three months, the results show a correlation between the shear wave velocity measures and the age of the thrombus [27]. Furthermore, our project aims to characterize the thrombus structure by analyze his stiffness using elastography.

2.3. Technical issues

2.3.1. Acquisition system: Toshiba Aplio 500

Our research project is currently focused on ultrasonography and elastography to characterize the blood clot structures and emphasize the existing links to the patients' physiopathologies. Elastography is a recent imaging technique (about 10 to 20 years) but it becomes inescapable for biomedical manufacturers as it has been introduced in several systems: Toshiba (Aplio 500), Echosens (FIbroscan), Siemens (Acuson S3000), Supersonic Imagine (Aixplorer), Philips (Epiq), Hitachi Aloka (Arietta), General Electric (Ultrasonix, Logic SonixTouch), Esaote (MyLabEight).

At Brest Hospital, Toshiba Aplio 500 machines are used to diagnose DVT with ultrasonography and to practice elastography. This section describes our acquisition systems, the used procedure and relative data. Toshiba Aplio 500 delivers high resolution clinical images to help a physician making quick and reliable diagnostic [28]. As said before, the system provides both modes ultrasonography and elastography.

Three types of 2D-ultrasonography are available:

- Classic Brightness-mode (*cf.* paragraph 2.2.2 or fundamental ultrasound imaging: the probe transmits an impulsion at a certain frequency and measures echoes reflected by the different interaction with the medium. The system then interprets the echoes at the selected frequency to build the image.
- Tissue Harmonic Imaging (THI): the image is produced using higher harmonics. These harmonics are generated by the nonlinear propagation of the ultrasound beam through tissues. THI has a better lateral resolution and a better signal-to-noise ratio.
- Differential Tissue Harmonic Imaging (DTHI): Toshiba develops a new nonlinear sonographic imaging technique where a dual-frequency f_1 and f_2 is transmitted, then the system analyzes the echoes of the difference $f_2 - f_1$ and the second harmonic of f_1. DTHI can combine the advantages of fundamental and THI modes.

In the Shear Wave Elastography (SWE) mode, three display modes are available on Toshiba's system (see Figure 3):

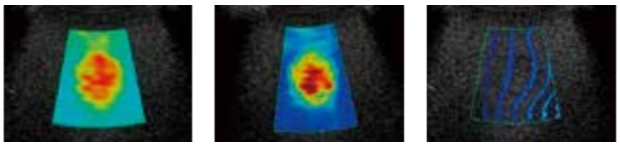
(a) Shear velocity named speed mode (m/s),

(b) Modulus of elasticity named elasticity mode (kPa),

(c) Propagation mode.

The relationship between shear velocity c_s (m/s) and modulus of elasticity E is given by equation (2).

Figure 4. If the shear waves, lines, are parallel, the reliability in this area becomes high. In contrast, distorted and non-paralleled shear waves correspond to a low reliability.



(a) Speed mode (m/s) (b) Elasticity mode (kPa) (c) Propagation mode

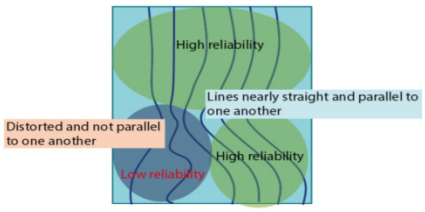


Figure 4: Reliability of the propagation display [29].

Previously, the used probe is primarily intended to observe the organs and their structures within the abdomen. That probe allowed us to use elastography which greatly helps to diagnose a liver or a pancreas fibrosis. Our ultrasound echo signals are acquired using a convex array ultrasound transducer (Toshiba PVT-375BT). With a variable carrier frequency in 1.5 to 6 MHz, the venous network can be observed in a depth of 0 up to 10 cm.

Since June 2016, the Toshiba Aplio 500 has been updated by a new probe: PWT-1005BT. This Linear Array Probe has a frequency range [5, 14] MHz and is intended, in particular, to

small-part imaging. The update and the new probe have improved the imaging quality of our acquisition. However, we ended up by having two distinct databases for feature extraction and classification. Next two subsections describe the acquisition procedure and the data

2.3.2. Data acquisition process with Toshiba Aplio500

In case of DVT suspicion, the medical expert locates the blood clot head using compression ultrasonography. During the diagnosis, the patient lies on his back. Then, the physician switches to the SWE mode and selects a Region Of Interest (ROI). A part of the tissue is deformed by the shear wave. For an existing obstacle (such as a tumor in the tissue or a clot in a vein), the shear wave velocity in that area should be different from the velocity of surrounded areas. A softer obstacle slows down the shear waves as opposed to a stiffer obstacle which makes them faster.

The system displays the elastography on the left side of the screen and the ultrasonography on the right side, see Figure 5. Later on, physicians select a shape (an ellipse or another shape) around the blood clot on the ultrasound image. Then, the system returns the shear wave velocities in this area and displays the mean and the standard deviation values at the bottom of the screen, see Figure 5. After checking the data reliability, several screenshots are made and added to our database.

Previously, and in order to reduce human error (*e.g.* probe pressure on the skin, localization), two experts make 10 measures, each patient. For each patient, a second check-up should be made three months later. In most cases, the treatment dissolves the blood clot but new measurements are performed again. The new system limits operator errors and makes elastographies more stable. Moreover, previously, the blood clot was only analyzed in a transverse view. However, a longitudinal observation is also considered, as shown in Figure 2 or Figure 5.

2.3.3. Data description

The data are exported from Aplio 500 in a format named Digital Imaging and COmmunication in Medicine (DICOM). This is a standard for handling, storing, and transmitting medical imaging information and related data. A DICOM file contains a certain number of attributes (metadata such as name, age, etc.) and also one special attribute containing the image pixel data (ultrasonography, X-rays, MRA, CTA, etc.).

In our case, the image data is a color screenshot as shown in Figure 5 which contains different information: the acquisition parameters (system, probes, and date), the patient's name (erased here for medical secrecy), the ultrasound image, the elastography, the elliptical ROI selected by an expert and the shear wave velocity in this area. Raw images can't be provided with Toshiba's system. For this reason, the ultrasonography and the elastography have to be extracted from the screenshot and then preprocessed.

The metadata provides us information about the patient (name, age, and gender), some acquisition parameters (e.g. probes, emitted frequency) and the images (size, depth). It is worth mentioning that in our data, the DICOM files do not contain any information about the shear wave velocity. Indeed, this information should be recovered from the image data. Thus, a Human Computer Interaction (HCI) is created and described in the next section.

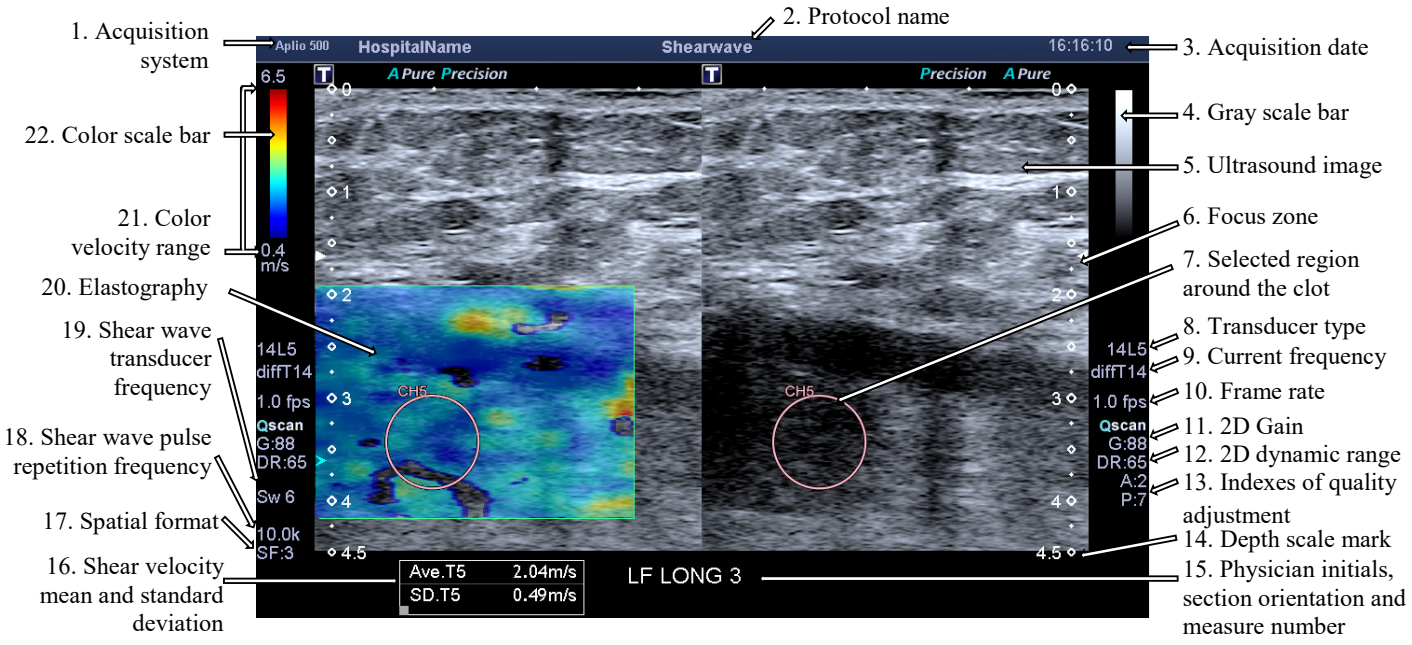

Figure 5: Image exported from Toshiba Aplio 500 and composed of the elastography and ultrasound images; the measurement parameters, the mean and the standard deviation of the shear wave velocity are displayed on the border of the image.

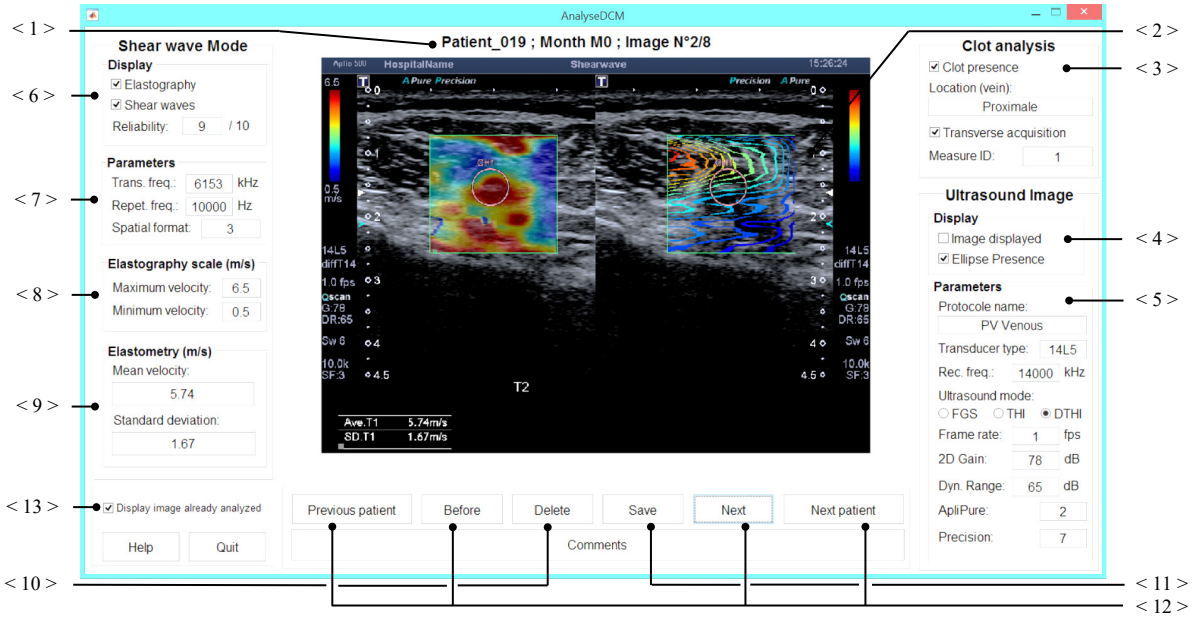

Figure 6: HCI of our application to manually extract information from the DICOM files exported from Toshiba Aplio 500.

3. Database and preprocessing

Previous sections explain the major goal of our project in the characterization of the blood clot structure in order to identify the DVT main triggering factor. To do this, two databases (before and after the updating of the system update) composed of ultrasonography and elastography in DICOM format are built. This current section describes the used process to prepare our data for further image processing (feature extraction and classification).

3.1. Data analysis using a Human Computer Interaction

The first step of the process is to read the DICOM file which is composed of metadata and an image. This image contains mostly two parts (mainly ultrasonography and elastography), the acquisition parameters and the elastometry values. Moreover, the patient physiopathologies and the presence of PE are collected in a spreadsheet enclosed with the database. To gather all those data in a single file, to identify the type of each part of the image and to recover the information unavailable in the metadata, a HCI is built. Our application browses through all DICOM files and is illustrated in Figure 6.

The DICOM image is displayed on the middle of the HCI (the < 2 > pointer of Figure 6). The patient's number, the month (approximation of clot age) and the image number are indicated just above the image (the < 1 > pointer of Figure 6). The right fields of the HCI are related to the global acquisition information and the ultrasonography. The user notices the acquisition orientation (transverse or longitudinal) and the thrombus presence in the two checkboxes (the < 3 > pointer of Figure 6). Since there can be several screenshots for one acquisition (with or without ellipse, shear wave propagation), the acquisition ID (or measure ID) should be specified too. The location of the clot is extracted from the spreadsheet. The two checkboxes indicated by the < 4 > pointer of Figure 6 have to be checked if the image contains an ultrasonography part and an ellipse around the clot. The different fields, indicated by the < 5 > pointer of Figure 6, correspond to the ultrasonography parameters (8. to 13. pointers of Figure 5) and they will be useful to evaluate the impacts of these parameters on our future simulations.

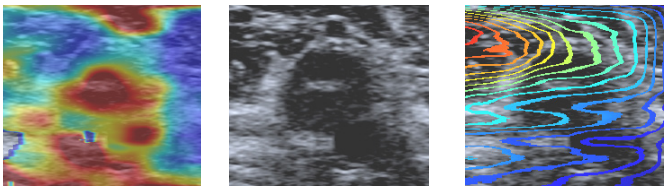
The left part of the HCI is dedicated to the shear wave elastography mode. In the box indicated by the < 6 > pointer of Figure 6, the user can indicate if the image displays the elastography or the shear wave propagation (see Figure 3). He can also estimate the reliability of the acquisition. The shear wave parameters (18. to 20. pointers of Figure 5) are entered fields indicated by the < 7 >pointer of Figure 6. The four next fields (< 8 > and < 9 > pointers of Figure 6) allow the user to enter the color range (the 19. pointer of Figure 5), the means and the standard deviation of the shear wave velocity (the 16. pointer of Figure 5).

Furthermore, the user can delete or save changes using the dedicated buttons (the < 10 > or < 11 > pointer of Figure 6). The image is then converted in the bitmap format ('.bmp'). The recovered information and the metadata are stored in a file. The navigation between the patient's DICOM files is made using the buttons 'Previous patient', 'Next patient', 'Before' and 'Next' (the < 12 > pointer of Figure 6). The already exported files can be skipped by checking the checkbox indicated by the <13> pointer of Figure 6.

3.2. Image extraction and sorting by type

DICOM image contains two parts among elastography, ultrasonography and shear waves propagation. This paragraph explains how these two parts are isolated and how the depth resolution is estimated. The boundaries of each part can be estimated using the metadata. The depth resolution is not contained in the metadata so the depth scale marks are segmented to estimate it (see tag 14. in Figure 5). These marks have a special pixel color whose value is used for the segmentation. Some marks are not filled. After filling them, an erosion removes the isolated pixels (pixel of the ultrasound image with the same color as the marks). Then, the middle mark indexes are calculated, the number of marks is counted and the depth resolution is estimated. The both extracted

images are finally cropped so that neither scale mark nor a black border is present on these images.



(a) Elastography (b) Ultrasonography (c) Propagation mode

Figure 7: Images extracted from a transverse acquisition: a DICOM file of this acquisition is display in Figure 6 (images get with Toshiba Aplio 500).

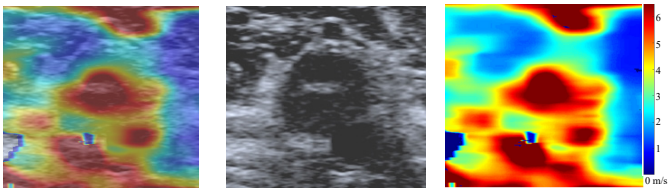
Moreover, for a single acquisition, there could be several DICOM files so our program gathers all files with the same measure ID. Each extracted image is store in the main file and its fieldname is defined by the image type and the ellipse presence. Until all file with the same ID are browsed, the images, if wanted by the user, are cropped to the elastography size. An example is shown in Figure 7.

3.3. Image preprocessing

3.3.1. Elastography

As you can see in Figure 8 (a), the elastography is a RGB map superimposed on the ultrasonography. For further analyses, the ultrasonography has to be removed and RGB colors have to be converted into velocities using the color scale displayed on main image (see Figure 6). Depending on the acquisition parameters, the transparency coefficient γ is either 0 or 0.5. The RGB map I_{RGB} can be computed from the elastography I_{Elasto} and the ultrasonography I_{Echo} with the following equation:

$$I_{RGB} = \frac{I_{Elasto} - \gamma\, I_{Echo}}{1-\gamma} \quad (3)$$



(a) I_{Elasto} (b) I_{Echo} (c) Velocity map

Figure 8: Estimation of the velocity map from the ultrasonography and the elastography (images get with Toshiba Aplio 500).

Then, each pixel of the RGB map is compared with color scale to obtain its velocity value. The final velocity map (see Figure 8 (c)) is stored in the main file.

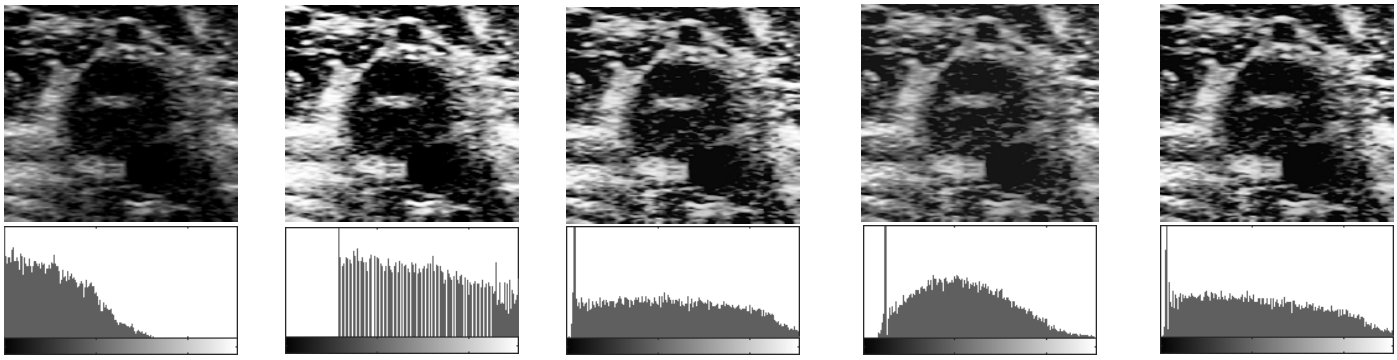
3.3.2. Ultrasonography

During the medical examination, the physician often needs to adjust some parameters to observe the blood clot. Before the system update, most ultrasonographies were acquired with the THI mode at the frequency 5MHz (setup A). After the system update, the Differential THI is preferred and there are two main setups: one with a 10MHz frequency (setup B) and another with 14MHz (setup C). Whatever the setup, the most changing parameter is still the gain which essentially affects the contrast and the brightness. To standardize our acquisition for each setup, this manuscript proposes the equalization of obtained histograms with the two following methods: ordinary Histogram Equalization (HE) and Contrast-Limited Adaptive Histogram Equalization (CLAHE) [30].

HE improves the contrast globally by adjusting intensity values. This process uses the same transformation derived from the image histogram to transform all pixels. The transformation function is proportional to the cumulative distribution function of pixel values. This works well when the distribution of intensity values is similar throughout the image. However, when the image contains regions that are significantly lighter or darker than most of the image, the contrast in those regions will not be sufficiently enhanced. In our images, the blood clot is mostly darker than the surrounding tissues so the contrast inside the blood clot may not be improved.

For improving the local contrast and enhancing the definitions of edges in each region of an image, HE can be applied over each region of the image with a transformation function derived from their neighbor pixels. This method is called Adaptive Histogram Equalization (AHE) and a major drawback concerning the overamplifying small amounts of noise in largely homogeneous regions of the image. This noise problem can be reduced by limiting contrast enhancement specifically in homogenous areas characterized by a high peak in the associated histogram because many pixels will be inside the same gray range.

With CLAHE, the slope associated with the gray level assignment function is limited by a threshold. The main disadvantage of CLAHE is that the ratio between the gray values of the original images and those of the resulted image is not



(a) Ultrasonography (b) HE (c) CLAHE - Uniform (d) CLAHE - Rayleigh (e) CLAHE - Exponential

Figure 9: Ultrasonography contrast enhancement of an image (get with Toshiba Aplio 500) (a) using respectively ordinary Histogram Equalization (HE (b) and Contrast Limited Adaptive HE (CLAHE with uniform- (c), Rayleigh- (d) and Exponential- (e) distribution functions.

constant, so CLAHE images are not suited for quantitative measurements. Figure 13 compares HE and CLAHE for a blood clot image. In this example, CLAHE methods give better results but it is hard to choose the best distribution function (uniform, Rayleigh or exponential) for CLAHE.

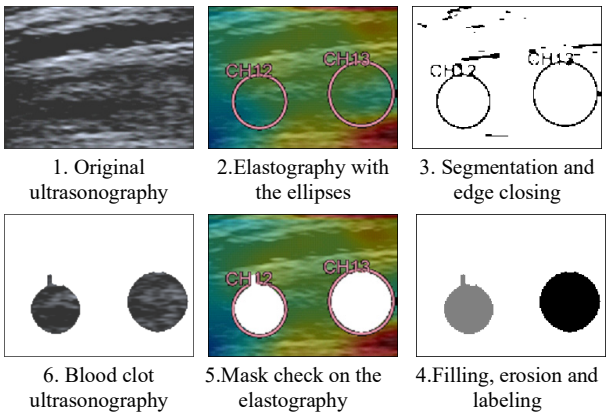
3.4. Blood clot for image extraction

To characterize the blood clot structure and identify the thrombosis triggering factors, hereinafter the scattering operator[1] is applied on the ultrasonographies containing a blood clot. To simplify and reduce the computing effort of the scattering operator, these extracted images should be squares and have a size of 2. The next paragraphs explain our strategy to create our database composed of blood clot resized square images

3.4.1. Blood clot localization

During the acquisition, the physician draws an ellipse to emphasize a blood clot. In the longitudinal observation, several ellipses can be drawn on different areas of the blood clot (see Figure 10 2.). For the structure characterization, the inside of the ellipse is analyzed using image processing. An image mask is created by exploiting the special color of the ellipses. Segmentation at this specific pixel color is made either on the ultrasonography (if available) or on the elastography. Therefore, the segmentation followed by a filing operation give the ellipse mask.

Sometimes, the ellipses are truncated (because of the previous cropping) or their edges are not closed. Thus, a validation step, either manual (display of the result and dialogbox) or automatic (based on the ellipse area), checks if the ellipses are well-segmented. Otherwise, their edges are closed and filled. This procedure can be repeated if necessary. Then, with an image processing toolbox, the ellipses are labelled (see Figure 10) and their properties estimated: area, centroid O, orientation α, major a and minor b axes (see Figure 12). Finally, this information is stored in the main acquisition file.



1. Original ultrasonography | 2.Elastography with the ellipses | 3. Segmentation and edge closing

6. Blood clot ultrasonography | 5.Mask check on the elastography | 4.Filling, erosion and labeling

Figure 10: Segmentation of the ellipses, creation of their mask and extraction of their position (Ultrasonography and elastography get with Toshiba Aplio 500).

3.4.2. Image extraction

At first, the blood clot image was identified as the biggest square inside an ellipse, as shown in Figure 11. This approach includes a rotation if the ellipse and the image have not the same orientation.

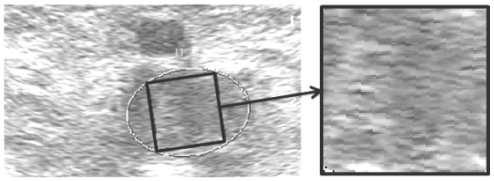


Figure 11: Extraction of the largest square inside an ellipse on an ultrasound image: the rotation distorts the image.

To avoid the artefacts generated by this rotation, this manuscript suggests to not rotate the global image and to find the biggest square in the image orthonormal system. Figure 12 and Figure 13 illustrate this idea, the different variables and the results without artefacts. The width c is computed using the following system:

$$\frac{X^2}{a^2} + \frac{Y^2}{b^2} = 1 \tag{4}$$

where $X = c(cos\alpha - sin\alpha)$ and $Y = c(cos\alpha + sin\alpha)$.

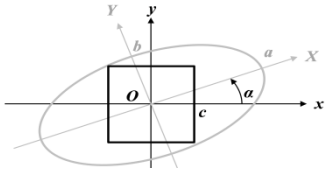

Figure 12: Extraction of the largest square inside an oriented ellipse.

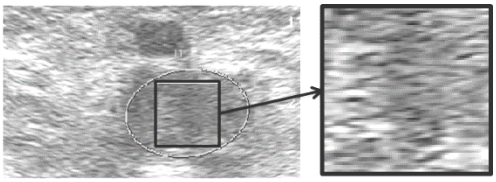

Figure 13: The extracted image is smaller with this second method but there is no artefact.

3.4.3. Image resizing

The size of the square differs according to the patient (its anatomy), the clot age, its size and its localization (vein). To compare their scattering transform, the images need to have the same size. The simulations were made with two different sizes (64x64 and 128x128 pixels) and four resizing methods: nearest neighbor interpolation [31], bicubic interpolation [31] and zero padding in the Fourier or in the cosine representation. If the goal size is relatively close of the original size, these four methods give very similar results. In the next section, the scattering operator is applied on 64x64 images resized with zero padding in cosine transform.

4. Feature extraction and classification

Previous sections describe the background of our project and the collection mechanisms of our data. This section presents our way to characterize thrombi structures with ultrasound images. The exposed simulations are made with our first database (about 200 images for 12 patients). The blood clot will be characterized

[1] The scattering operator is an algorithm based on wavelet transforms implemented in a deep convolution network [4].

with features extracted by applying an algorithm named scattering operator [4]. This technique is based on wavelet transforms and detailed in the subsection 4.1.

This project intends to correlate the images features and the Venous ThromboEmbolism (VTE) epidemiology (Risk factors, history of DVT, and presence of EP). Principal Component Analysis (PCA) is used to reduce the important size of the scattering features. Simulation results are presented in the subsection 4.2.

4.1. Feature extraction using the Scattering Operator

The challenge of automatically classify images resides in the high variability within a same class. This variability is often uninformative in the sense that it does not characterize a class change. The scattering operator aims at reducing this variability by creating a "translation invariant image representation, which is stable to deformations and preserves high frequency information for classification" [4].

4.1.1. Scattering wavelets

The scattering operator combines three three types of operations:

(a) A local average ϕ_J to recovered the low frequencies:

$$\phi_J(u) = 2^{-2J}\phi(2^{-J}u) \tag{5}$$

where 2^J is the maximum scale and u stands for the spatial position vector and ϕ is a scaling function named father wavelet.

(b) Localized band pass filters ψ_λ defined, for each scale $0 < j < J$ and an orientation θ, by the following equation:

$$\psi_\lambda(u) = 2^{-2j}\psi(2^{-j}r_\theta^{-1}u) \tag{6}$$

where, to simplify notation, $\lambda = 2^{-j}r_\theta$ and r_θ is the rotation matrix: $r_\theta = \begin{bmatrix}\cos(\theta) & -\sin(\theta)\\ \sin(\theta) & \cos(\theta)\end{bmatrix}$. The wavelet transform is stable to small deformation and invertible if the rotated and scaled wavelet filters cover the whole frequency plane (see Figure 15) so this operation recovers the information lost by the local average. In the simulation, the Morlet wavelet family is used.

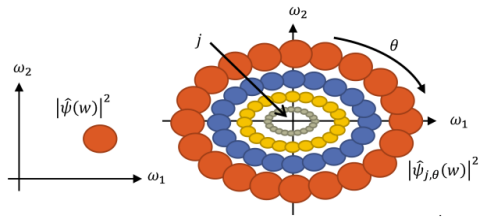

Figure 14: Frequency support of the mother wavelet on the left side and of the child wavelets on the right side: $\hat{\psi}_\lambda$ is the Fourier transform of ψ_λ.

(c) A non-linear operator to contract the space and move the energy to the low frequencies which is the modulus (see Figure 15).

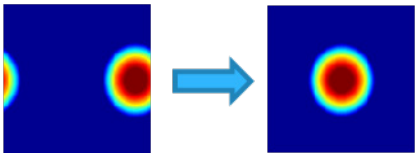

Figure 15: Frequency support (threshold at -3dB) of a localize pass band filter before (left) end after (right) the application of the modulus.

4.1.2. Scattering transform

The first step to compute the scattering transform S of an image x consists in applying the average filter ϕ_J on the image x:

$$S[\emptyset]x = x * \phi_J \tag{7}$$

To recover the high-frequency information lost by this operation, localized band pass filters ψ_λ are applied. Then, that information is extracted with a modulus and a low pass filter again:

$$S[\lambda_1]x = |x * \psi_{\lambda_1}| * \phi_J \tag{8}$$

$S[\lambda_1]x$ defines the first layer of the scattering transform S. To recover the high frequency information lost during the average operations is applied localized band pass filters $\psi_\lambda$to construct the second layer of S:

$$S[\lambda_1, \lambda_2]x = \big||x * \psi_{\lambda_1}| * \psi_{\lambda_2}\big| * \phi_J \tag{9}$$

If $p = (\lambda_1, \lambda_2, \ldots, \lambda_m)$ is a path of length m, then $S[p]x$ is an image called scattering coefficient of order m computed at the layer m of the scattering network (see Figure 16). For a large invariant representation, several layers are necessary to avoid losing crucial information. The number of rotations, scales and layers are key parameters of the scattering transform and need to be optimized.

Finally, each ultrasound image will be represented by the $L_1(\mathbb{R}^2)$ norm of each image $S[p]x$ of the scattering transform. The $L_1(\mathbb{R}^2)$ norm forms a crude signal representation which measures the scarcity of the wavelet coefficients and is defined by:

$$\|Sx\|_1 = \int_{\mathbb{R}} |Sx(u)| du \tag{10}$$

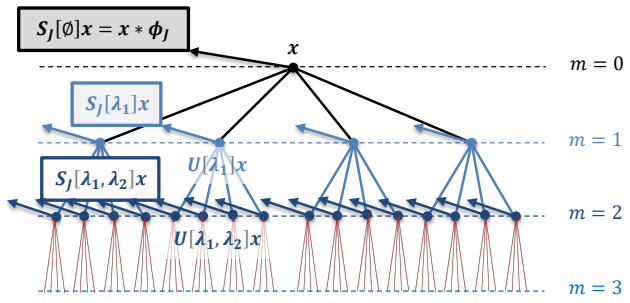

Figure 16: The scattering operator computed the first layer of wavelet coefficients modulus and its local average $S_J[\emptyset]x$ (black arrows). Then, the process is applied again on each wavelet coefficients modulus to forms the second layer of coefficients $S[\lambda_1]x$ (blue arrows). This process is repeated until the desired layer m is reached.

4.1.3. Feature reduction using Principal Component Analysis

Let P be the number of the scattering feature. Firstly, the data are centered around the origin by subtracting the mean of each variable $E(Sx_k)$ from the dataset. PCA algorithm approximates the difference $Sx_k - E(Sx_k)$ by projecting them in a linear space of lower dimension $d \ll P$. Let V_k stands for the linear space generated by the d PCA eigenvectors of Sx_k covariance matrix having the largest eigenvalues. Among all linear spaces of dimension d, V_k is the approximation space $Sx_k - E(Sx_k)$ with the smallest expected quadratic error.

Finally, PCA is equivalent to approximating Sx_k by its projection on an affine approximation space:

$$A_k = E(Sx_k) + V_k \quad (9)$$

This affine space selection is effective if $Sx_k - E(Sx_k)$ is well approximated by a projection in a low-dimensional space. The scattering parameters (number of scales, orientations and layers) and the dimension d must be adjusted so that Sx_k has a better approximation in the affine space A_k.

4.2. Simulations

4.2.1. Experimental process

Our databases are formed by three different categories: the old acquisition system, the new one with 10 MHz and 14 MHz. In this paper, the exposed simulations are made with the biggest possible database including ultrasound images get with exactly the same parameters. Indeed, the use of different presets can affect the scattering coefficients and biased our conclusions. Consequently, the test database contains about 200 images acquired with the older version of the system. Our main goal is to identify the main causes of the DVT and to evaluate the risk of a PE. Thus, the expected classes would include:

- Cancer
- Idiopathic: DVT with unknown pathogenesis of apparently spontaneous origin
- Idiopathic and PE
- Immobilization
- Pregnancy
- Surgery and PE

The scattering operator parameters (number of scales, orientations, layers and the size of the images) should be optimized. The optimization step is necessary; even though, there is no guarantee that it will lead to a satisfactory classification. We are not totally sure that the cause of the thrombosis and the presence of a PE are linked to the clot structure. In our simulations, our images are resized to 64 x 64 pixels because a power-of-2 square image reduces the calculation factor of the scattering operator. All coefficients are computed with the following parameters:

- Number of scales J: 2, 3, 4, 5, 6 and 7
- Number of orientations L: 1, 2, 4, 6 and 8.

The scattering energy has an exponential decay with respect to the order m [4]. Moreover, its energy converges to 0 as m increases and is below 1% when $m \geq 3$. Therefore, all obtained coefficients (for all J and L) are neglected when $m \geq 3$. To analyze the scattering feature for each order, each image will be represented by one vector per order (*i.e.* four vectors: orders m = 0, 1, 2 or m = 3). After that, the dimension of these four vectors is reduced using PCA. The affine approximation space will be projected in two dimensions: the two 2 best discriminant dimension among the three first principal components.

4.2.2. Results

Figure 17 shows the projection of the scattering features in two-dimension spaces. Figure 17 (a) considers coefficients at the order 0: the abscissa axis represents the first Principal Component (PC) and the ordinate axis the third PC (it is more discriminant than the second PC). The point cloud can be separate into four clusters:

- Cluster 1: some images of patient No .2 (immobilization.)
- Cluster 2: some images of patient No. 4 (idiopathic), patient No. 8 (idiopathic) and patient No. 19 (pregnancy);
- Cluster 3: patient No. 9 (surgery & EP)
- Cluster 4 (rest of the point cloud): No. 1, No. 10, No. 13, No. 15, No. 16, No. 17 and No. 18.7

However, it is difficult to link this observation with the main cause of the DVT. There is a pregnant woman in two clusters (No. 17 and No. 19). Idiopathic thromboses are also presented in the two clusters (cluster 1 and 4).

The points of patient No.2 show the impact of the acquisition conditions. Indeed, two levels can be easily distinguished. In fact, these images were taken by two different medical experts. To reduce the effect of the human factor, an articulated arm was used. We can notice as well that there are two levels for patient 19: the beginning of the DVT and three months later. The age of the blood clot seems to impact the scattering coefficients. Naturally, an old blood clot is stiffer, and thus more echogenic than a recent blood clot.

Moreover, the order 0 corresponds to low frequency information which greatly depends on the overall energy of the image. In order to characterize the clot structure, the higher scattering orders appear to be more appropriate. Nevertheless, looking at Figure 17 (b) to (d), the clusters observed at order 0 are less explicit. The scattering coefficients seem to give less information at the deeper order: order 2 (c) and order 3 (d) point clouds are very similar, so it is sufficient to explore until m=2. Finally, if orders 1 and 2 are represented on the same figure, then Figure 17 (e) and (f) show that order 2 do not add a lot of information comparing the order 1: Figure 17 (e) shows that the first PC of these orders are mostly correlated. As well, Figure 17 (c) and (f) are quite similar to Figure 17 (b).

These simulations did not reveal much about a correlation among the blood clot structure, the scattering coefficients and the VTE epidemiology. In our experimentations, we tried other metrics (*e.g.* Minkowski at different exponents), increased the size of the images (128x128 pixels) and applied the described contrast enhancement methods (HE and CLAHE). But, unfortunately, the new parameters do not improve our results.

5. Conclusion

Venous thromboembolism occurs with inappropriate blood clots, causing considerable morbidity and mortality in the world. It affects an estimated 300,000–600,000 individuals just in the

United States per year [32]. The term venous thromboembolism includes both deep vein thrombosis, clots in the deep veins and

Idiopathic	Idiopathic & PE	Cancer	Immobilization	Pregnancy	Surgery & PE
Patient No.1 Patient No.4 Patient No.8	Patient No.10 Patient No.16	Patient No.13 Patient No.15	Patient No.2 Patient No.18	Patient No.17 Patient No.19	Patient No.09

Figure 17: Projection of the scattering features in two-dimension spaces: (a) to (d) display the two best discriminants Principal Component (PC) at each order; (e) displays the first PC of the orders 1 and 2; (f) displays the first PC of the order 1 and the second PC of the order 2.

pulmonary embolism. Multiple factors can cause a venous thromboembolism: stasis, endothelial injury or/and hypercoagulability. Deep vein thrombosis is a common, serious and multifactorial disease. Our project aims at characterizing the blood clot structure in order to date it, explain its formation and estimate the risk of pulmonary embolism. Several techniques exist to analyze their structure: phlebography, magnetic resonance angiography, computed tomography angiography and ultrasonography. Ultrasonography and elastography have the advantage to be easy, repeatable, cheaper and non-invasive. This paper presents our approaches to generate databases using Toshiba Aplio 500. The outputs of Toshiba's system are preprocessed images exported in the DICOM format. Therefore, a human computer interaction is created to read the output files, store the acquisition parameters and extract both the ultrasonography and the elastography.

After some preprocessing steps, the scattering operator is applied to the ultrasonography in order to characterize the blood clot structure. Our simulations show that the scattering operator seems to be not suitable for the clot characterization. In recent work, we compared the obtained results with respect to different image sizes, resizing methods and with histogram equalization (ordinary HE or CLAHE). Even doing the later procedures, similar results are obtained. Currently, we are working on spectral clustering because it gave positive results in prostate and brain MRI images [27, 28]. Moreover, we are looking to increase the size of our database and to standardize the acquisition procedure. In future work, we want to compare the results obtained with the scattering operator, spectral clustering and deep learning. The later approach is recently widely used and shows promising results in breast tumor elastography classification [19].

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This research project is supported by the Brittany region (Région Bretagne, France) and French Clinical Research Infrastructure Network on Venous Thrombo-Embolism (F-CRIN INNOVTE). We would like to acknowledge Brest University Hospital, ENSTA Bretagne and Toshiba for the material support. Finally, our thanks go out to all the people involved in our project and, particularly, to L.Fréchier and B.Hermenault.

ABSTRACT

Countries' effective and efficient border security is becoming increasingly important in today's global world of economy and trade. To ensure these, customs organisations are responsible for the prevention of illicit goods' transportation across borders, particularly upon entry. The predicament of the customs administrations will soon be aggravated by both the increase of global trade and the trend towards 100% screening. It is therefore a goal to advance inspection methods to enable successful cargo handling, a scope towards which this research was aimed at. This work was carried out as part of the project ACXIS "Automated Comparison of X-ray Images for cargo Scanning" a European research project within the seventh framework programme answering the call SEC-2012.3.4-1: « Research on Automated Comparison of X-ray Images for cargo Scanning », to improve the process with the largest impact to trade flow: the procedures of freight X-ray scanning. As such, this project was focused on to implementing a manufacturer independent reference database for X-ray images of illicit and non-illicit cargo, developing procedures and algorithms in order to uniform X-ray images of different cargo scanners, and developing a training simulator for inspection officers and a toolbox enclosing several assisted and automated identification techniques for potentially illicit cargo.

1. Introduction

Within the grand scheme of security, border control, and specifically the screening of border traffic cargo, has seen increasing focus in recent years. Given today's world of trade and the threats that exist to our societies, effective and efficient border controls are increasingly essential. The fiscal integrity and security of the movements of goods across these borders are the responsibility of customs administrations. Accordingly, they are also expected to have a positive impact on the economic competitiveness of their respective nation.

Indeed, customs administrations aim at identifying cargo that is inconsistent with its declaration, contain illicit goods, or that pose threats to society. Smuggling of counterfeited and pirated goods cause harm to a nation's wellbeing due to missed taxes that could otherwise be put to service for society. The Organization for Economic Co-operation and Development (OECD) estimates that the global international trade in counterfeits and pirated goods in 2007 may amount to USD 250 billion, which would equate to 1.95% of global trade [1]. Cigarettes lead the chart in the European Union with around 35% among all smuggled goods [2]. The increasing number of cargo transported through borders requires innovative inspection procedures. In this direction, automatic detection in cargo screening constitutes an important role.

Within the project ACXIS, cargo screening developments are made in supporting the inspection officers' work of illicit cargo detection. More specifically, ACXIS develops automated target recognition (ATR) functions to analyse X-ray images of cargo screened at border crossing points (land, air or sea). These functions can continuously self-improve through a central reference data base. This database contains X-ray images of illicit and non-illicit cargo, and it is designed to be manufacturer independent. All these database images, particularly the ones containing threats, constitute a significant tool for the training of screening officers and also for machine learning methods in automated detection algorithms [3,4].

2. Hardware Set-Up and Optimisation

In order to image illicit cargo mock-ups, laboratory X-ray scanners were used at Empa - the Swiss Federal Laboratories for Materials Science and Technology, at CEA - the French Alternative Energies and Atomic Energy Commission, and at EZRT - the German Development Center for X-ray Technology [5]. The Dutch and Swiss customs administrations used their own commercial cargo scanners, such as Smiths Heimann, Rapiscan and Nuctech systems.

The X-ray source used for the data acquisition at Empa was a portable dual energy 4 and 6 MeV linear accelerator; with a focal spot size of 2 mm (Fig. 1). Certain modifications were made on the existing high energy CT at Empa, in order to optimise the system for this project [6-8]. First, rails were placed on the linear accelerator and the detector towers to allow changing the source-to-detector distance up to 5.4 m. Then, the CT detector were replaced by a newly designed line detector consisting of 20 modules with 32 channels each, made of 30 mm deep CdWO4 scintillators with a pitch of 4.6 mm (X-Scan LCS 4.6, from Detection Technology). A 3D CAD of the new detector is shown in Fig. 2. Careful design and work was carried out in the detector assembly in reducing X-ray scattering. Additionally, new lead and tungsten source collimators were installed to shape the beam according to the detector geometry. An X-ray filter, specially designed, was fitted between the primary and secondary source collimators to flatten the intensity of the X-ray beam over the full detector width (approximately 3 m).

The laboratory scanner built at CEA consists of a linear accelerator, a line detector and a translation table (Fig. 3). The scanning geometry was chosen to match the commercial scanners, namely a horizontal translation of the object, using a vertical detector line. The linear accelerator is a Varian Linatron M9A model, delivering 5, 6 and 9 MeV with a maximal dose rate up to 30 Gy/min. The focal spot size is specified to less than 2 mm in diameter. The detector is made of 10 X-Scan LCS 4.6 modules, assembled on a straight line. A lead collimator is used in front of the active area and the backside is shielded by 5 mm of lead.

Figure 1 ACXIS laboratory set up of cargo container imaged by linear accelerator (left) and new detector (right; hidden behind container).

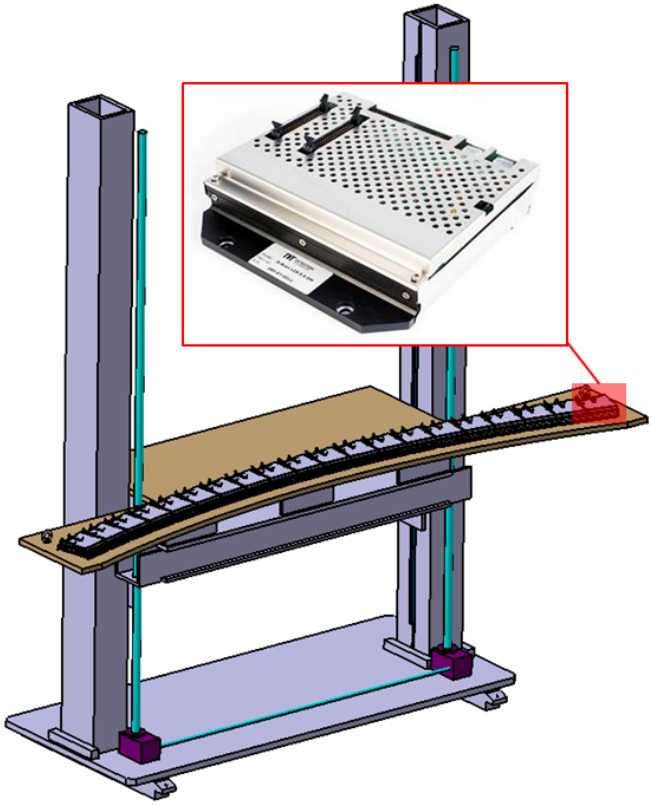

Figure 2 3D CAD of the new detector, shown without the casing, to allow visualisation of the individual detector modules, one of whose close up photo is shown. The CAD shows the detector fitted on adjustable towers.

Figure 3 Laboratory setup at CEA.

The translation table has a second plate that can be tilt with ±15°, as shown in Fig. 4. This option was used for mock-up objects for which different incident views were needed. Tilting the objects is equivalent to placing them at different heights in a full container, hence several combinations of various positions were operated more easily.

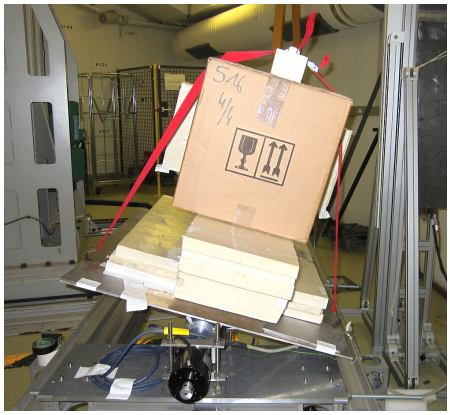

Figure 4 Translation table with tilt in the setup of CEA.

3. Reference Database: An Integration

One of ACXIS key goal is the creation of a reference database of realistic X-ray images of both non-illicit and illicit cargo. Such a database is essential for the development of training systems for customs officers and for providing assisted detection techniques of threats with the use of dedicated algorithms. To construct this database, we rely on historic images provided by customs. However, the number of threat images acquired through real detections remains limited and needs to be increased by additional threat images obtained through simulation. A very important aspect for this project is that all the pre-mentioned images must have a standard format so that images originating from different systems can be incorporated.

3.1. Creating Artificial Images of Illicit Cargo

To efficiently generate X-ray images for the database we can rely on two strategies. The first one consists in using simulation tools to generate artificial X-ray projections of illicit cargo. CEA develops the software CIVA, which integrates a module for modelling X-ray generation, interaction and detection, thus allowing the creation of realistic radiographic projections of any object that is put in the simulation scene. In this case, the shape of the object has to be described by a 3D CAD model and its material has to be specified. For multi-material objects however, each material component has to be segmented, which will result in highly complex objects in the case of a complete cargo. In practice, due to the complexity of container loadings, this approach has not been implemented. The second strategy consists in using real images of legal freights, which are widely available, and to combine these with one or several threat images. For this purpose a so-called "merging tool" has been developed and threat images have been either acquired or created by simulation.

Both approaches have advantages and disadvantages: for instance, cigarettes packs have a very specific texture that is difficult to model in the simulation software and real images have to be used in this case. On the other hand, some realistic 3D models of weapons have been collected and were used to easily generate multiple threat images with various orientations.

3.2. Threat Images

3.2.1 Acquisition from Mock-Up Scans

Based on risk analysis conducted by the customs administrations, threat objects and their locations in the container were identified. Following their recommendations, a set of mock-ups was created with real threat items and simulants, combined with common goods (Figure 5). These were scanned using laboratory systems, and some with a cargo scanner, chosen as reference.

For some illicit items the incidence of the X-ray paths through the object largely influences the produced image. Therefore mock-up X-ray scans were performed with different object tilts so that the best projection could be selected depending on the vertical position of the object in the container.

Figure 5 Photograph of a container of apples containing hidden Plastex (left) and hand grenade (right), above, and X-ray image of this threat container, below.

3.2.2 Generation from Simulation Software

The main objective of the mock-up scans was to enlarge the variety of threat images. For the same purpose, simulation tools

were also used in order to generate X-ray images from 3D models of various types of threat items (e.g. weapons).

The acquisition geometry, source spectrum and detector parameters of the high energy scanner were defined in the simulation software. 3D models of different weapons were then loaded into the software environment and multiple projections were created (Figure 6).

Figure 6 3D CAD model (left) and simulated X-ray projection (right) of a weapon.

The strength of the simulation approach is to create easily a large set of images of an object from different viewpoints. This variety of images of a same object is essential for training learning algorithms for detecting specific threats. Figure 7 displays simulated images of a small weapon, a larger weapon and a bottle that could represent a chemical product used for explosive devices for instance. Each threat has been rotated from side view to top view by steps of 30°.

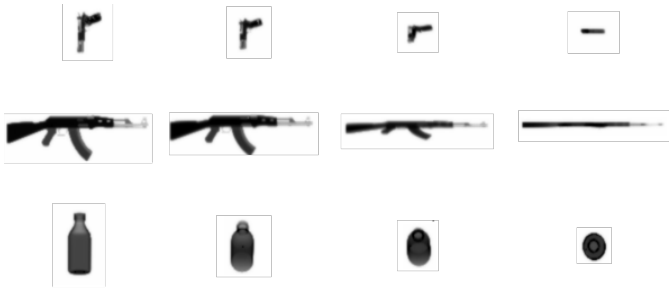

Figure 7 Simulated images of three different threats from multiple viewpoints.

3.3 Merging Threat Images with Historic Ones

The basic principle of X-ray imaging is the measurement of the X-ray photons which are attenuated when traversing matter. This process is modelled by the Beer-Lambert law, which can be approximated as follows:

$$I_{det} = I_0 \, e^{-\sum_{i=1}^{N} \mu_i \cdot x_i} \quad (1)$$

Where I_{det} is the beam intensity at the detection point after traversing N different materials, I_0 is the beam intensity at the initial point, μ_i and x_i are the linear attenuation coefficient and the thickness of each material, respectively. According to (1), the beam intensity at the detector point corresponds to the combination of the attenuation due to each material successively penetrated by the X-ray beam. It can be decomposed as:

$$I_{det} = \underbrace{I_0 \cdot e^{-\mu_1 \cdot x_1} \dots e^{-\mu_j \cdot x_j}}_{I_{bg}} \cdot \underbrace{e^{-\mu_{j+1} \cdot x_{j+1}} \dots e^{-\mu_N \cdot x_N}}_{e^{-\mu_{th} \cdot x_{th}}} \quad (2)$$

Where I_{bg} is the beam intensity attenuated by the background (non-illicit cargo without threat constituted of j materials) and the parameters μ_{th} and x_{th} represent the characteristics of the threat element (constituted of N-j materials).

Then, by injecting in (2) the additional measure of the incident beam intensity attenuated by the threat I_{th} it comes:

$$I_{det} = I_{bg} \cdot \frac{I_{th}}{I_0} \quad (3)$$

with:

$$I_{th} = I_0 \cdot e^{-\mu_{th} \cdot x_{th}} \quad (4)$$

According to (3), we can combine pixel to pixel the attenuation of the threat (threat image acquired as described in earlier subsection) to the grey value of the non-illicit cargo image to create an image of illicit cargo (Figure 8).

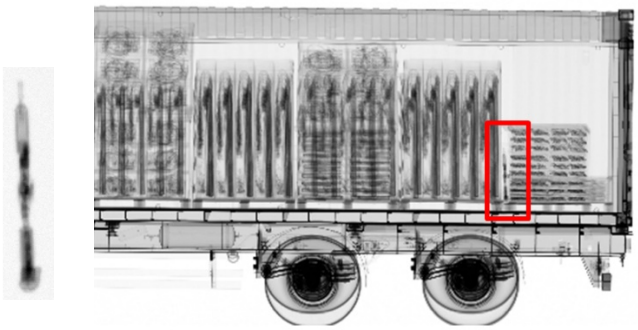

Figure 8 Simulated image of a weapon (left) inserted into a non-illicit cargo to create an artificial illicit cargo image (right).

The implemented tool allows the insertion of a same threat image multiple times at different positions in the background image and with different orientations. The major difficulty when performing the merging is in the selection of suitable and realistic spots for placing the considered threat.

A first set of illicit cargo images created artificially has been submitted to customs officers, who have assessed and validated the quality of the merging process.

3.4 Creating a Unified X-ray Image Standard

Upon visual inspection of X-ray images, the human brain can easily adapt to different systems, regardless the different parameter variations such as geometric deformations, textures, and levels of contrast or noise. This is not equally the case for automatic algorithms.

Given the large variety of X-ray scanners installed at border checkpoints, it is important that the acquired images are similar in terms of the permissioned parameters. As such, standardising these images enables an increase in the automatic detection performances. Therefore, all X-ray data can be converted into a standardised format and stored in a database, along with the results of the ATRs and useful annotations (Figure 9 centre). This standardisation enables the comparison between scans originating from different X-ray imaging systems. The database consists of set of approximately 30.000 scans as reference material, and new scans can be integrated continuously.

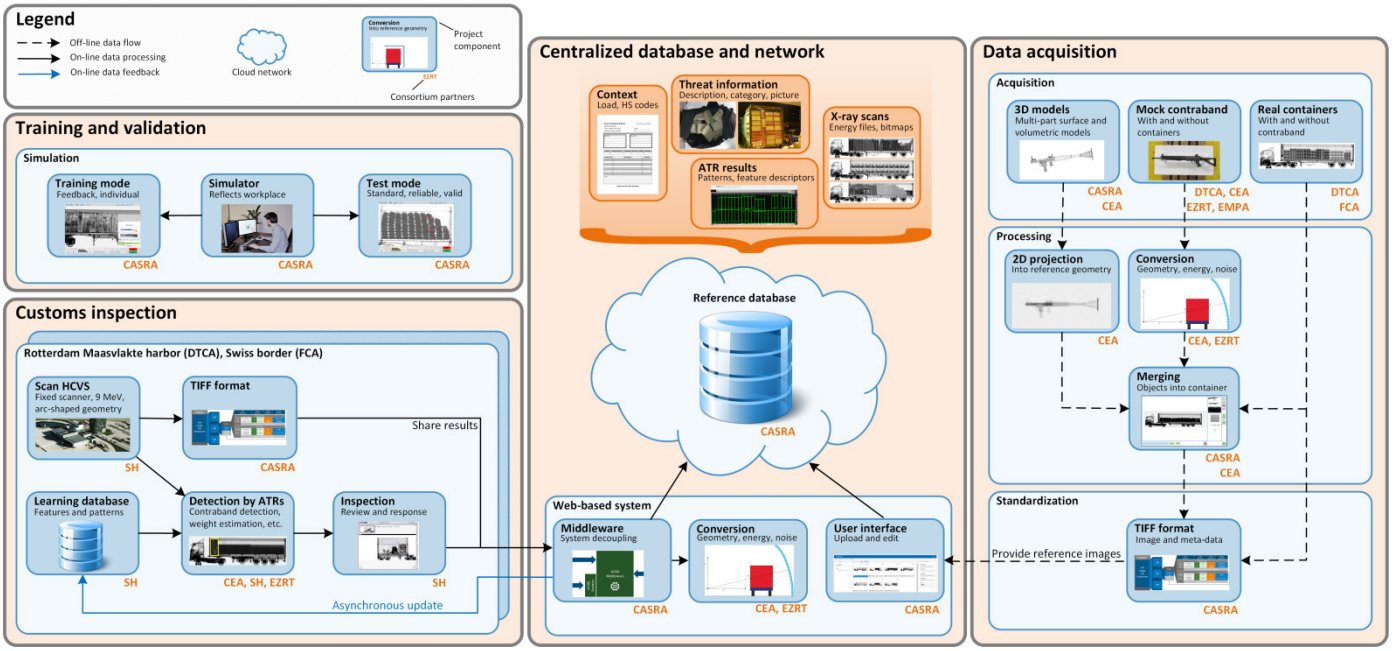

Figure 9 X-ray inspection procedure for border controls, with automated target recognition functions based on a centralised reference database.

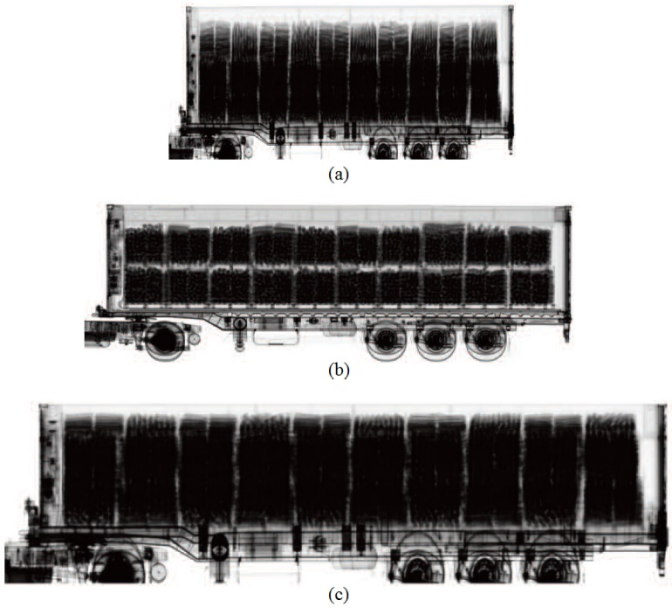

Figure 10 Real container scan with Euromax (a) and SH-HCVS (b) scanners. The Euromax scan was converted to the HCVS format (c).

Similarly, scanners with very different energy spectra such as mobile systems equipped with 2.5 MeV sources and stationary ones using 9 MeV accelerators produce very different images in terms of contrast and image quality [9]. Based on this analysis, it is not relevant to convert all scanner images to a unique reference configuration but for creating a homogeneous database, we propose to standardise images acquired with systems of energy in the range 4 MeV to 9 MeV. The strategy for the adaptation of contrast is based on the use of X-ray images of step wedges of different materials, which give a unique response curve for a given system. Using these images, we express, for a given thickness of material, the attenuation value of one system as a function of another. The equation of this curve corresponds then to the contrast conversion function, which is applied after the geometric conversion.

Finally, several noise reduction algorithms were evaluated in order to select the best one, *BM3D* [10] to reduce the noise to the level of the reference scanner, without affecting the image quality (e.g. the texture or the sharpness).

4. Customs Officers Training

information into consideration, or to ignore it when they believe that the ATR function has generated a false alarm. The waybill information is also provided to the officer, regarding the container contents.

The CBT software incorporates both training and testing modes. The training mode can be used for initial and recurrent X-ray image interpretation training using the large reference database. For each container image, the CBT asks the screening officer whether and where suspect goods are present. Following each image inspection, the officer is given feedback. When a screener correctly reports that an X-ray image contains an item that does not match the waybill or is illicit, the response is counted as a hit. If an incorrect illicit item present answer has been given, the response is categorised as a false alarm. Feedback on missing illicit items and correctly reporting that a container image is harmless is also provided. When an illicit item is present in the image, the feedback includes an additional window displaying the illicit item as a photograph and as an X-ray image. The training time and further details of the simulated scenario can also be examined. Upon completion of a training session, a summary feedback on detection performance in that session is provided. The testing mode is similar to the training mode but feedback is not provided. It can be used to measure X-ray image interpretation competency of customs officers and to conduct research for example on training progress and the value of ATRs.

5. ATR Algorithms Trained on Merged Threats

In comparison with the amount of data required to train and test ATR algorithms, a small sample of images containing illicit goods is available. Building a database derived from merging techniques is therefore crucial, especially for machine learning based algorithms where hundreds of thousands of images are often needed. Thus, a single sample can easily be projected according to different orientations and scales, increasing the variability of the dataset.

Our experience has shown that some differences may appear between the results yielded on artificially generated and real testing sets. Though, while tested on real data, ATR algorithms indicate highly satisfactory performances.

In the framework of the ACXIS project, two prominent ATR tools have been developed and trained on projected images: the Automatic Firearm Detection (Figure 12 (a)) and Reefer Unit Analysis (Figure 12 (b)) algorithms.

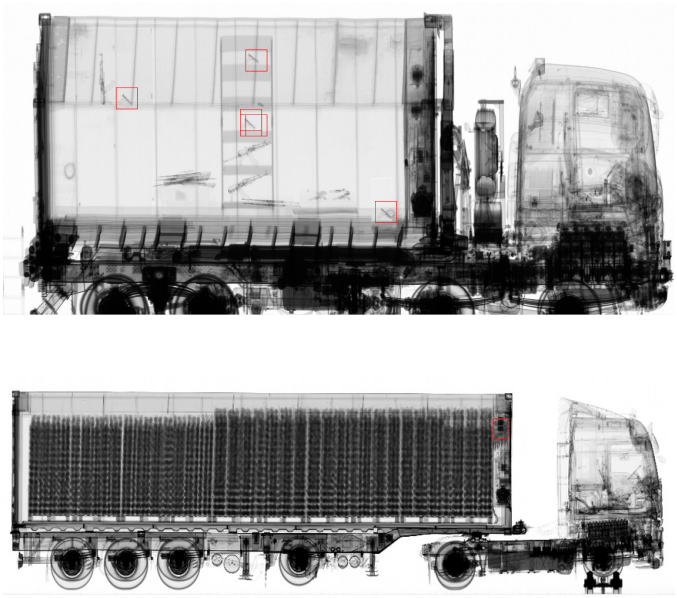

Figure 12 (a) Firearms automatically identified in the container scanned by an HCVM system (b) Narcotics automatically detected in the reefer unit, Rotterdam HCVS, 2016.

6. Conclusions

This work, which was part of the ACXIS project, developed a manufacturer independent reference database for X-ray images of illicit and non-illicit cargo, procedures and algorithms to uniform X-ray images of different cargo scanners and measurement parameters, and an automated identification method of potentially illicit cargo. Historic images of real detection scans, images of illicit cargo mock-ups as well as images of non-illicit cargo were integrated into the reference database. The resulting database was then used for the improved training and evaluation of customs' officers. The developed software incorporates ATR functions, which together with the impact of the systematic computer-based training is expected to confirm the benefits through a validation study. The foreseen results of the study will confirm that this software increases the success of border controls and reduces the required time necessary for cargo inspection.

Conflict of Interest

The authors declare no conflict of interest.

The article deals with the problem of increasing the accuracy of determination of aircraft's navigation flight parameters. Increasing the accuracy and sensitivity of navigation parameters determination will improve the efficiency of air conveyance by optimizing the flight trajectories and reducing the flight time and simultaneously will ensure the sufficient level of air conveyance safety. The main purpose of this article is to develop a polarimetric navigation method for determining the aircraft's coordinates during flight. This method can potentially increase the accuracy and sensitivity of navigation parameters determination. The article gives a detailed analysis of the existing methods and systems for determination of aircraft's navigation parameters, their advantages and the sphere of application. Also the polarimetric navigation method and the system for implementing this method are proposed. The system envisages the use of two measurement channels and consists of two main blocks: the radiation unit and the measurement unit. The practical implementation of the proposed navigation method and system includes the development, creation and use of the polarimetric navigation system. The results of system's mathematical modeling are given and the optimum parameters of the optical channel elements of the proposed system are determined based on these results. Further research in this area envisages the development and creation of the polarimetric navigation system as well as experimental verifications of the concept. Using a high-precision measuring method, such as polarimetric measurement method, to determine the aircraft's navigation flight parameters will significantly improve the safety and efficiency of the airlines industry.

1. Introduction

Modern transportation market is characterized by the dynamic development of the airline industry. This is due to increasing mobility of population, development of national and international tourism, increasing enterprise activity and globalization process. According to ICAO statistics annual increase in the volume of regular freight and passenger traffic is observed. Thus, for example, during 2015 [3] there was the increase in the volume of passenger traffic by 7.1% and increase in the volume of freight traffic by 1.7%.The main advantages of aviation operations that distinguish it among other types of transportation are a high speed, high reliability, better safety of cargo, the ability to deliver cargo to remote areas, the shortest traffic routes and others. The vast majority of transcontinental cargo and passenger transportation over long distances is carried out by air. There are main disadvantages of aviation operations such as the high cost, high consumption of materials and high power consumption, dependence on weather conditions.

One of the priorities for increasing the efficiency and safety of air traffic is to ensure effective and overall air navigation services [4]. Improving the quality of air navigation services will optimize routes and reduce the duration of flights. This will reduce some of the above mentioned disadvantages of air transportation. Air navigation services include the air traffic service, the radio-

*Corresponding Author: Arsen Klocan, PhD student, Department of Electronics and Computing Techniques, Faculty of Transport and Information Technology, National Transport University, 46/2, Kyiv Way Street, Boryspil city, 08300, Ukraine

technical support, the aeronautical information service and the meteorological service. This article will focus on radio-technical support aspects of air navigation services.

Radio-technical support should be understood to mean a set of measures aimed at the timely formation of information about air situation and its issuance to aviation's control point and aircraft's crews to provide navigation, takeoff and landing of aircraft [5]. Radio-technical support includes providing communication, navigation and surveillance. This article will focus on providing navigation of the aircraft's flight.

Air navigation (Aeronavigation) is the realm of science about the methods and means of driving the aircraft and determination of its movement parameters during the flight within the atmosphere. The aircraft's flight includes several main stages, such as, takeoff, climb, route flight, landing approach, landing and others. During the flight, the following navigational tasks are performed: programming of flight trajectory; determining the coordinates of the aircraft in space; determining the vectors of air speed, ground speed and wind speed; determining the flight time to point of call, turning points; determining maneuver in the horizontal and vertical planes during flight, approach, landing and other tasks. Accurate and timely determination of aircraft navigation parameters at each stage is a prerequisite for safe and efficient air transportation.

Aircraft's navigation parameters include parameters and their derivatives, which describe orientation, location and movement of aircraft in space and around center of mass. There are the main navigational parameters defined during the flight such as coordinates (geographical, polar), height (absolute altitude, height above ground, true height), heading (magnetic, true, great-circle), speed (indicated, airspeed, ground), attitude (roll, pitch and yaw angles) and others.

One of the promising directions to improve the efficiency of air transportation is the concept of free flight. This concept involves transferring operating choice of the route trajectory, flight speed and profile to aircraft crews [6].This will allow using airspace more rationally and flexibly. Applying this concept can increase efficiency and provide annual savings of several billion dollars by reducing fuel consumption and flight time. Applying of this concept involves the compacting of the flow of air transport in airspace. This, in turn, requires improving the accuracy of determination of the coordinates and position of aircraft in air space, as well as providing early warning about possible conflicts to ensure the necessary level of safety.

2. Problem Statement

The dynamic development of the airline industry, the air traffic volume growth and implementation of air traffic management concepts «Free Flight» lead to the necessity for compacting the flow of air transport in airspace and lead to potential reduction in air transportation safety because of aircraft collision at the critical density of aircraft in the air space. Improving safety with air transport flow compacting is possible by increasing the accuracy of determination of the aircraft's coordinates and by predicting aircraft motion trajectory for the near future. The analysis of the motion trajectories of aircraft which are in locally restricted space will allow providing air traffic regulation and safe deconfliction of aircraft in the airspace. Thus, there is a need to develop new or improve existing methods for determining the coordinates of the aircraft to ensure improvement of measurement accuracy. It is critical to improve measurement accuracy of aircraft coordinates in locally restricted space: in the zone of the airport, around turning point, near the intersection zone of air-route and in other zones of airspace with a high density of aircraft.

3. Review

To determine navigation parameters, different technical means which can be divided into autonomous and non-autonomous systems are used. The non-autonomous navigation systems define navigation parameters by using information which coming on board from outside. The autonomous navigation systems are characterized by the use of onboard equipment for navigation parameters determination.

All navigation technique depending on their physical principles of action can be divided into 5 main groups: geotechnical, inertial, radio, astronomical, lighting. Each of these groups has certain operating peculiarities and is used to define aircraft's leg.

Geotechnical navigation means are based on the different physical properties of the Earth and its atmosphere, which include the gravity force, Earth's magnetism and the earth magnetic field, terrain, pressure change with flight altitude changing, air velocity, thermal properties of the Earth and others. This group of navigation technical means refers to autonomous navigation systems and is characterized by low accuracy and sensitivity. This group includes magnetic and gyromagnetic compasses, magnetometers, gravitometers, a barometric altimeter, an air speed meter, correlation-extreme navigation systems and others. This group of navigation technical means was widely used at the beginning of aviation development, and now they are used as emergency devices.

Radio navigation means are based on the physical properties of artificial electromagnetic waves that propagate in space. This group of means refers to non-autonomous navigation systems: the source of radio waves (radio beacon) is needed for their work. This group of means is characterized by high precision work in any weather conditions, at any time of the day, and at different distances. This group includes a short range radio navigation system, a long range radio navigation system, the VOR system, the DME system, a radio altimeter and others. Radio navigation means are widely used in modern aircraft in different stages of flight, to perform various tasks.

Astronomical navigation means are based on the use of objective laws of relative position and the Earth's motion relative to the Sun, the Moon and other celestial bodies. This group of navigation technical means refers to non-autonomous navigation systems: visibility of celestial bodies is needed for their work. This group of means is characterized by high accuracy and is used exclusively for navigation tasks. Equipment of astronomical navigation means is used as an additional information source of aircraft position during flight over the ocean and in the North and South Poles. This group includes astronomical compasses, sextants and others.

Inertial navigation means are based on measuring of angle rate and linear accelerations caused by the action of non-gravitational force (engine thrust, atmospheric effect, lift component, control force and others). This group of means refers to autonomous navigation systems. Modern inertial means are characterized by relatively high accuracy and sensitivity, the accumulation of errors over time, the relatively small weight and size. This group includes fiber optic gyros, ring laser gyros, MEMS-gyros, attitude and

heading reference systems, inertial navigation systems and others. This type of navigation means is widely used in modern aircraft in different stages of flight, to perform various tasks.

Lighting and visual navigation means are intended to marking of visual cues and provide ground-based aircraft navigation. This group of means refers to non-autonomous navigation systems: for their work is needed earth-based system for marking of visual cues. Means of this group is mainly used at leg of takeoff and landing. This group includes light beacons, searchlights, laser instrument landing systems of direct vision, laser instrument landing systems on the dispersion effect and others.

The current stage of aerotechnics development is characterized by integrated utilization of navigation technical means with different physical principles. It permits to reduce the measurement error of navigation parameters significantly and reduce the adjustment time of navigation system.

Inertial and radio navigation systems and methods are widely used to determine navigation parameters during end route flight. Inertial navigation systems allow obtaining information about linear and angle accelerations on aircraft's board. Onboard system determines the angle of turn and covered distance in some system of coordinates, as well as calculates aircraft's navigation parameters, such as coordinates, heading, attitude, altitude, speed and others. Radio navigation systems provide determination of aircraft's coordinates by measuring distance and azimuth to radio beacon. The holistic use of inertial and radio navigation systems permit to increase the accuracy of determining the navigation parameters.

Consider radio navigation systems in more detail. . According to the measured navigation parameter radio navigation systems are divided into the azimuth-measurement navigation system, range-measurement navigation system, rho-theta navigation system, differential-range measurement navigation system and others.

The systems which provide the navigational information about the distance to the radio beacon on board of the aircraft refer to the range measurement navigation systems. Using this type of navigation systems allows determining aircraft coordinates by the distance to three DME-beacons or the distance to two DME-beacon and altitude.

Azimuth-measurement radio navigation systems are the systems which provide the navigational information about relative angular position of aircraft and radio beacon on board of the aircraft. Using this type of navigation system allows determining aircraft coordinates by the azimuths of two VOR beacons and altitude.

The systems that provide the navigational information about relative angular position of the aircraft and radio sources and about the distance to the radio beacon on board of the aircraft are defined as rho-theta navigation system. Using this type of navigation system allows determining aircraft coordinates by the azimuth and distance to radio beacon and altitude.

The differential-range measurement navigation systems are the systems that provide on board of the aircraft the navigation information about the location of aircraft by determining the difference of the distances to several radio navigation points. To determine the coordinates of the aircraft, it is necessary to have three (four) independent differences of the distances to two (three) beacons.

So to perform navigation tasks during the flight route the most widely used radio and inertial navigation means. The radio navigation means characterized by high precision work in any weather conditions, at any time of the day, and at different distances, but needs availability of radiowaves source - radio beacon. The inertial navigation means are autonomous and characterized by relatively high accuracy and sensitivity, the relatively small weight and size, but they accumulate the errors over time. Integrated utilization of inertial and radio navigation systems permit to increase the accuracy of aircraft's navigation parameters determining.

4. Problem Solution

Optical measurement methods are widely used in various fields of science and technology. Application scope of optical measurement methods has expanded significantly in recent years. This is due to their advantages. Optical measurement methods have the following advantages: noncontact measurement, non-destructive testing, high speed of measurements, high measurement accuracy and sensitivity, and others. One of the application directions of optical measurement methods for determining the aircraft's coordinates is the use of the optical gyroscopes: fiber optic gyroscopes and ring laser gyroscopes. Their operation principle is based on the Sagnac effect. This effect consists in the change of the phase difference of two oppositely directed light waves, which propagate in a closed loop at its turn around a normal axis. Optical gyroscopes are autonomous means and refer to inertial navigation means. They are characterized by high accuracy, sensitivity and stability, relatively small gyro drift - 0,001 degrees per hour. The disadvantages of ring laser gyroscopes include high power, the complexity of their production technology, relatively large mass and dimensions. The disadvantages of fiber optic gyros include inverse scattering, effect of temperature, vibration, magnetic and electric fields on the quality of their work.

One of the most sensitive optical measurement methods is polarimetric measurement method. It allows measuring the azimuth plane polarization with accuracy 0,0005° [7]. Polarimetric measurement methods involve measuring the polarization properties of radiation after interaction of polarized radiation with the objects: the degree of polarization, azimuth plane of polarization, ellipticity and others. The use of polarimetric measurement methods to solve navigation problems is possible through the use of an isotropic dielectric plane-parallel plate in the optical channel of measurement. The dielectric plate rotates the plane of polarization of the incident radiation depending on his angle of incidence.

This paper is an extension of work originally presented in IEEE 4th International conference « Methods and Systems of Navigation and Motion Control (MSNMC) » [8]. This article continues studying the issue of using polarimetry in aircraft navigation systems and is aimed at a wider and more detailed examination of the polarimetric technology possibility to solve aviation navigation tasks. Polarimetric techniques are understood to mean the totality processes of collection, accumulation, processing, transmission, storage and display of information. They use polarimetric methods and devices to obtain basic information about the object. This article proposes the polarimetric navigation method and system, which implements this method. The operation principle of the

method is based on Fresnel's formulas. The proposed method and system are based on the use of physical properties of artificial electromagnetic waves in the optical band, which propagate in space. The polarimetric navigation method and system are classified as non-autonomous and in accordance with the classification above they can be attributed to radio navigation means.

Rotating the polarization plane of polarized radiation after falling on isotropic planar dielectric plate with weakly absorbing material is explained by various transmittance and reflectance for p- and s-polarized beam components, which are described by Fresnel's formulas. Studies, presented in [1] and [2], confirm this statement and show that at falling of linearly polarized beam on the dielectric plate the reflected and refracted beams will also be linearly polarized, and the angle of polarization plane will depend on the angle of incidence.

The values of azimuth of polarization plane for the reflected and refracted beam that has passed through the two faces of the plate can be determined by the following formulas:

$$\varphi_r = arctg\left(-\frac{\cos(i-r)}{\cos(i+r)}\cdot tg\varphi_e\right),$$
$$\varphi_d = arctg\left(\cos^2(i-r)\cdot tg\varphi_e\right).$$

where φ_r – azimuth of polarization plane of the reflected beam,
φ_e – azimuth of polarization plane of the incident beam,
φ_d – azimuth of polarization plane of the refracted beam,
i – angle of incidence,
r – angle of refraction,

Thus, when polarized radiation falls on the isotropic dielectric plate, the polarization plane of the refracted beam, reflected beam and beam passing through the two faces of the plate rotates. The azimuth rotation of polarization plate depends on the incidence angle of radiation and the azimuth of polarization plane of the incident beam.

The use of polarimetric technologies to solve the aeronavigation tasks is as follows. The emitter, which is located on navigation beacon, emits linearly polarized radiation with a certain dispersion aperture in the vertical plane and the minimum dispersion aperture in the horizontal plane. The polarization plane of radiation rotates simultaneously with the rotation of radiation diagram. The meter located on board of the aircraft receives radiation from the navigation beacon, measures the polarization plane azimuth of the beam that has passed through the two faces of the plate and determine the angle of incidence and polarization plane azimuth of the incident beam. This polarization plane azimuth of the incident beam is directly associated/ connected with the navigation beacon bearing and angle of incidence depends on the relative navigation beacon bearing and distance to it, as well as pitch angle, yaw angle and altitude of the aircraft.

Consider the block diagram of the optical measurement channel shown in Fig. 1.

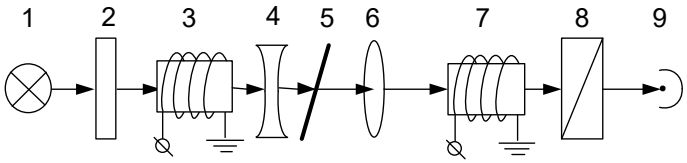

Figure 1. Block diagram of the optical channel

Radiation source 1 is intended to emit unpolarized light. The optical filter 2 is designed to filter radiation in order to highlight a certain wavelength. Faraday cell 3 is designed to polarize radiation and to rotate its plane of polarization according to the law of diagram rotation of beacon radiation. Scattering lens 4 is designed to dissipate polarized radiation with defined aperture dispersion. The dielectric plate 5 is designed to rotate the plane of polarization depending on the angle of incidence and polarization plane azimuth of the incident beam. It provides primary information about angle of incidence and polarization plane azimuth. Focusing lens 6 is designed to focus the polarized beam after dielectric plate on modulator 7. Analyzer 8 is designed to determine the plane azimuth of polarization radiation, which has passed through the dielectric plate. Photodetector 9 is designed to convert the intensity of radiation incident on it into an electrical signal. The resulted electrical signal is sent to the measurement unit for determining of polarization plane azimuth and incidence angle of radiation.

Accuracy measurement is defined by the relation of a signal to noise. The relation of a signal to noise for photodetector has the following appearance [7]:

$$\frac{S}{N} = \frac{U_s^2}{U_{TH}^2 + U_{SH}^2} = A_1(k_1+k_2)^2\cdot\Delta^2\cdot\frac{4\cdot P^2\cdot\sin^2 2\alpha}{\frac{U_{TH}^2}{A_2(k_1+k_2)^2}+1-P\cdot\cos 2\alpha}.$$

where S is signal; N is noise; U_S, U_{TH}, U_{SH} are voltages generated by signal, thermal and shot noises, respectively; A1, A2 are constants depending on the properties of the photodetector; k1, k2 are principal transmittances of polarizing prisms; Δ is system sensitivity; P is polarization degree of the light in the optical channel; α is the angular vibration amplitude of polarization plane, changing according to the periodic law: $\alpha = \alpha_0\Phi(t)$.

Using the polarimetric techniques to solve aeronavigation problems anticipates the use of polarimetric navigation system, which consists of two main units: radiation unit and measurement unit. Radiation unit is set on the beacon and designed to emit polarized beam with fixed value of polarization plane azimuth. At that the polarization plane azimuth depends on the direction of radiation. Measurement unit is set on the onboard and designed to measure the polarization plane azimuth of the passed beam and calculate navigation beacon bearing. Radiation unit has two channels and provides radiation of two linearly polarized beams with different wavelengths and polarization plane azimuths. Dependence of the polarization plane azimuth in the first and second channels (ϕ_{e1}, ϕ_{e2}) on radiation azimuth (θ) of the navigational beacon is shown in Fig. 2. Radiation unit consists of two identical channels, each of which is configured to corresponding channel of radiation unit.

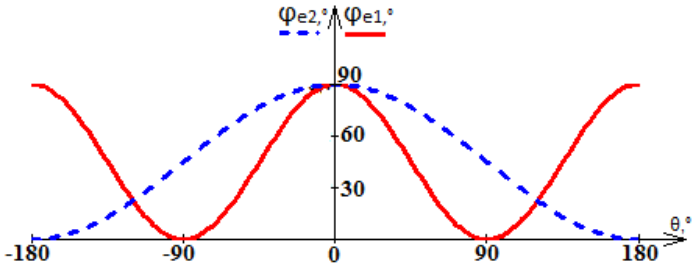

Figure 2. Dependence polarization plane azimuth on radiation station azimuth in the first and second channel

The block-diagram of one channel of polarimetric navigation system is shown in Figure 3. One channel of polarimetric navigation system includes radiation unit 1, measurement unit 2 and propagation medium 11. Unit 1 emits the polarized beam with certain polarization plane azimuth that passes through the propagation medium 11 and falls to the measurement unit 2 where the calculation of navigation beacon bearing takes place.

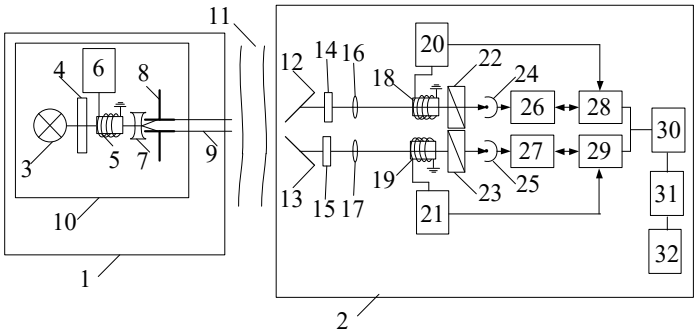

Figure 3. Block diagram of one channel of polarimetric navigation system

One channel of the radiation unit includes radiation source 3; monochromator 4; Faraday cell 5; sound generator 6; scattering lens 7, slit diaphragm 8. Both radiation channels are placed on the platform 10, which rotates. Monochromator 4 is designed to filter the incidence beam and miss out the wavelength on which the appropriate channel of measurement unit is tuned. Faraday cell 5 is designed for polarizing the beam and rotating its plane of polarization. Sound Generator 6 is intended to form control signals to the Faraday cell 5. Scattering lens 7 and a slit diaphragm 8 are designed for scattering plane-polarization radiation in the vertical plane with minimal divergence radiation angle in the horizontal plane. The platform 10 rotates around a vertical axis at constant frequency and provides changing the radiation direction of the beam 9. The beam polarization plane and platform rotate rotates simultaneously. This ensures communication of polarization plane azimuth and the radiation station azimuth. Two measurement channels differ by rotation frequency of the polarization plane: in the first channel it is equal to the speed of platform rotation, while in the second channel it is equal to the half of the platform rotation frequency.

The channel of measurement unit consists of planar dielectric plates 12 and 13, which are designed to rotate the polarization plane depending on the angle of incidence and polarization plane azimuth of the incident beam, it provides getting primary information about incidence angle and polarization plane azimuth; optical filters 14 and 15, which are designed to filter the incidence beam and miss out the wavelength on which the appropriate channel of radiation unit is tuned; focusing lens 16 and 17, which are designed to focus the radiation on the Faraday cell 18 and 19; Faraday cell 18 and 19, which are designed to modulate polarized radiation in an alternating magnetic field; sound generators 20 and 21, which are designed to form the control signals which are transmitted for Faraday cells 18 and 19; analyzers 22 and 23, which are designed to determine the polarization plane azimuth; photodetectors 24 and 25, which are designed to convert polarization plane azimuth into an electrical signal; narrow-band amplifiers 26 and 27, which are designed for amplifying electrical signal; synchronous detectors 28 and 29, which are designed to increase the measurement sensitivity and provide measurement "on zero signal"; microcontroller 30, which is designed for processing measurement results; storage unit 31, which is designed for collecting and storing measurement results; calculator 32, which is designed to perform mathematical calculations.

5. Result of Research

The paper represents the azimuth-measurement polarimetric method for determining the coordinates of the aircraft and the navigation system that implements the proposed method. Proposed navigation system allows measuring the relative angular position of the aircraft and navigation beacon. At that, aircraft's coordinates are determined by the azimuths of two beacons and altitude. The system consists of two channels. The polarization plane azimuth and incidence angle of radiation are defined in each channel. The value of polarization plane azimuth of incidence radiation in two channels determines the airplane bearing. The measured value of the incidence angle may be used in determining the altitude, pitch angle and station bearing.

In the process of mathematical modeling the dependence graph of the polarization plane azimuth of the refracted beam on incidence angle for different values of polarization plane azimuth of the incident beam (Fig. 4), the dependence graph of the measurement sensitivity on polarization plane azimuth of the incident beam (Fig.5), the dependence graph of the polarization plane azimuth of the refracted beam on the polarization plane azimuth of the incident beam for different values of the incidence angle (Fig. 6) were created. To determine the optimal incidence angle we created the dependence graphs of measurement sensitivity and refracted beam intensity on incidence angle on the same graph (Fig. 7). The incidence angle value of the intersection point is optimal incidence angle.

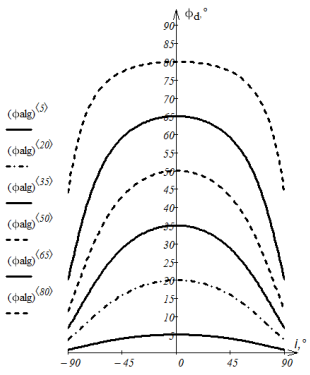

Figure 4.Dependence graph of the polarization plane azimuth of refracted beam on incidence angle

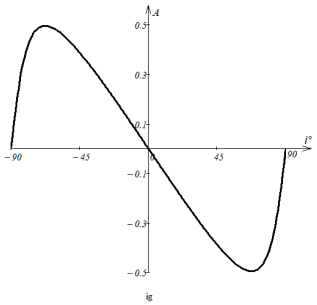

Figure.5 Dependence graph of the measurement sensitivity on polarization plane azimuth of the incident beam

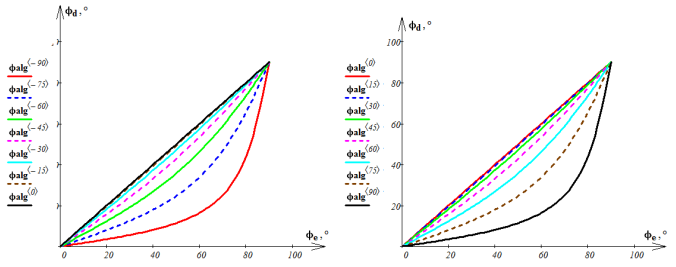

Figure 6. Dependence graphs of the polarization plane azimuth of the refracted beam on polarization plane azimuth of the incident beam

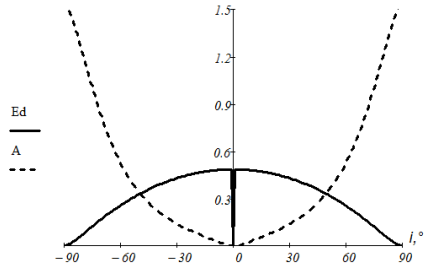

Figure 7 – Dependence graph of measurement sensitivity and refracted beam intensity on incidence angle

After analyzing the dependence graph of the polarization plane azimuth of refracted beam from incidence angle (Fig. 4), we conclude that the relationship is symmetric about the y axis and depends on the polarization plane azimuth of the incident beam. After analyzing the dependence graph of the measurement sensitivity on polarization plane azimuth of the incident beam (Fig. 5), we conclude that the relationship is symmetric about zero and has extremes. The graph shows that the highest sensitivity value provides polarization plane azimuth $\phi_e = \pm 68°$. After analyzing the dependence graph of the polarization plane azimuth of the refracted beam on polarization plane azimuth of the incident beam (Fig. 6), we conclude that the relationship is nonlinear and depends on the incidence angle. At that, the sensitivity of the measurement increases with the increase of the incidence angle. After analyzing dependence graphs of measurement sensitivity and refracted beam intensity on incidence angle on the same graph (Fig. 7), we conclude that the optimal incidence angle (i) equal $i = \pm 52{,}5°$. The optimal incidence angle is provided by installation of dielectric plate at an angle to the horizontal plane. Due to the fact that one measurement channel unit has two dielectric plates, it is proposed to establish one plate at an angle of 52.5 ° to the vertical plane and the second 52.5^0 angle to the horizontal plane.

6. Conclusions

The article deals with the existing methods for determining navigation parameters and the proposed azimuth-measurement polarimetric method for determining the coordinates of the aircraft. This method can potentially increase the accuracy and sensitivity of determining the navigation parameters. Also in the article the measurement system that implements this method is proposed. The proposed method and system can be used with azimuth-measurement and rho-theta navigation system for determining the aircraft's coordinates.

Distinction between the proposed system and optical gyroscopes lie in different principles of action: optic gyroscopes are autonomous means and polarimetric system is non-autonomous means, as well as lie in various physical operation principles: optical gyroscopes are based on the Sagnac effect and polarimetric navigation system is based on the Fresnel's formulas. Integrated utilization of optical gyroscopes and means of polarimetric navigation system will greatly increase the accuracy, sensitivity and reliability of information about aircraft's navigation parameters of flying.

The article also shows the results of mathematical modeling of the measurement channel. Optimal polarization plane azimuth of the incident beam and optimal incidence angle of radiation were determined during mathematical modeling. Calculations can be applied in the development and implementation of polarimetric navigation system. The practical implementation of the proposed method is to create a polarimetric navigation system and requires additional theoretical and practical research. This article reflects results of one theoretical research stage of the possibility to use the polarimetric technology for solving air navigation tasks.

A B S T R A C T

A new architecture of multi-standard transmitter that combines single and double frequency conversion is presented. The transmitter is able to generate waveforms of different cellular standards (GSM, UMTS, Wimax), LAN standards (Bluetooth, Zigbee, IEEE802.11 b/g) and Radio navigation standards (GPS, Galileo) as well. Depending on the selected standard and frequency, the transmitter routes the intermediate frequency signal, into direct or double conversion path. Optimization design techniques are introduced to manage multiple standards and efficiently enable them while reducing cost, size and weight of the resulting transmitter. Such a transmitter is aimed to be used as a backup solution for a broken network to reestablish and insure communication links for rescue operations.

1. Introduction

On January 12th 2010, an earthquake has devastated Haiti, causing approximatively 160.000 deaths [1]. One of the main reasons that worsen the disaster was some major failures in the wireless communications towers, located at Port-au-Prince, which hampered the emergency measures.

Disasters have no specific target location and no specific timing. One of the possible solutions to insure the communication between rescue and intervention units is to deploy Unmanned Aerial Vehicles (UAVs, a.k.a Drones) to restore the links with the wearable transmitters in case of emergency and to generate radio navigation signals when satellite signals are lost. As illustrated in Figure 1, an UAV equipped with a multi-standard transceiver will fly over the affected city to take over the communication system.

Existing mobile networks are heterogeneous and people own different devices supporting cellular standards (GSM, UMTS and Wimax), wireless personal and local area network standards (Bluetooth, Zigbee and IEEE802.11 b/g) as well as Radio navigation (GPS and Galileo). In this context, the UAV's transceivers have to support all available wireless communication standards and all operating frequencies. Therefore, there is a real need to a multi-standard transceiver that covers common wireless standards and automatically switches between different standards and frequencies whenever needed.

Some solutions have been already proposed. Indeed, Qualcomm transmitter in [2] serves different GSM variants (GSM850, Primary GSM, EDGE, Railway GSM, and GSM1800 & GSM1900). In [3], another architecture is proposed to generate GSM signals using Phased Locked Loops (PLLs) in the up-converters eliminating the additional filters traditionally used between the up-converter and the amplification bloc. This solution minimizes power consumption but is only applicable to constant envelope signals. Another architecture [4] was proposed for both constant and complex envelope signals. Each waveform is generated by a different configuration of I/Q modulators.

The proposed solution involves a new architecture that generates the RF signal using direct or double conversion, depending on the desired standard. In addition, an optimization

*Riadh Essaadali Aviat Networks and LACIME, 16847 Hymus Boulevard, Kirkland, Quebec, H9H3L4,
Email:Riadh.essaadali@aviatnet.com

technique is introduced to minimize the high number of RF filters and PLLs necessary to cover multiple standards and frequencies. Therefore, cost, size and weight are also minimized.

This paper is an extension of work originally presented in IEEE MILCOM2016 [5] and it is organized as follows: Section II outlines the basics of multistandard architecture optimization. The judicious filtering technique is detailed. After presenting the frequency plan of different standards to be served, two architectures with their different components will be presented. In the last section, both of architectures are validated by carrying out simulations with CAD software: Advanced Design System (ADS).

Figure 1 Artist point of view of a rescue operation using UAVs [1]

2. Multi-standard transmitter architecture definition and optimization

2.1. Basics of architecture optimization

The first step in the transmitter design is defining the architecture. Generally, the transmitter is divided into the following blocks: baseband part, frequency up-converter, RF filter, power amplifier and antenna. Modern architectures could be heterodyne, homodyne, polar and digital-IF. The digital IF which is heterodyne is the most used because of its perfect balance between I and Q signals. Its architecture is illustrated in Figure 2. Digital I and Q signals are combined in the baseband part. The resulting signal is converted by a digital to analog converter.

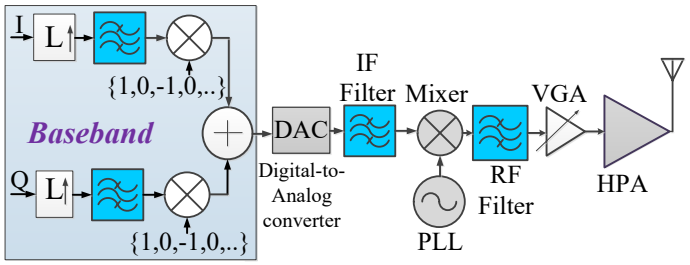

Figure 2 Architecture of digital IF (heterodyne) transmitter

The frequency f_{IF} of the signal at the IF stage is then up-converted to f_{RF}, at the output of the up-converter. In order to reduce the number of required filters, in a multi-standard transmitter, the upper side band signal located in $f_{RF} = f_{LO} + f_{IF}$ and the lower side band signal located in $f_{RF} = f_{LO} - f_{IF}$ are used. The mixing of the IF signal and the carrier produces the desired output signal, the image signal and the intermodulation products. As illustrated in Figure 3, the desired signal can be located either on the upper or lower sideband. Harmonics and inter-modulation products have the form $m*f_{LO}+n*f_{IF}$, and the critical harmonics are: $-f_{LO}+5f_{IF}, f_{LO}-3f_{IF}, f_{IF}, f_{LO}, f_{LO}+3f_{IF}, f_{LO}+5f_{IF}$. The IF-frequency f_{IF} is fixed whereas the PLL-frequency f_{LO} is tuned. If the signal is transmitted in the upper sideband, the filer should reject the nearest unwanted signal components f_{LO} and $f_{LO}+3f_{IF}$. In the same way, if the signal is transmitted in the lower sideband, the rejection of f_{LO} and $f_{LO}-3f_{IF}$ is required. This concept allows increasing the bandwidth of the RF filters, and therefore, it reduces their numbers.

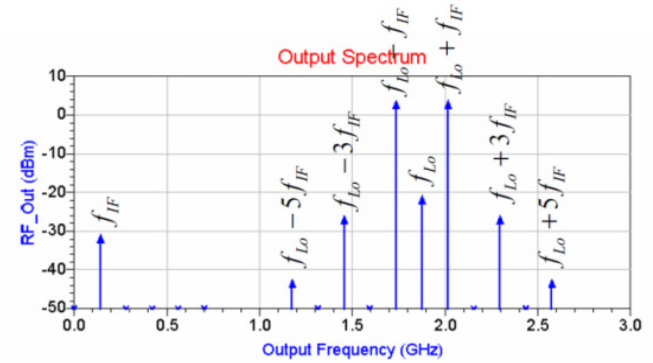

Figure 3 A typical output spectrum of the up-converter

Moreover, it decreases the frequency range that should be covered by the PLLs. Indeed, the sub-frequency band of the PLL that will cover the higher sub-band of the filter will be re-used to cover the lower sub-band of the filter. Figure 4 illustrates this concept. In conventional direct-conversion architecture, the maximum stop bandwidth of a filter is lower than f_{IF}. By using the optimization concept, the stop bandwidth of each RF filter is lower than $2f_{IF}$. An overview of this filtering strategy is given in Figure 5. The difference between the upside ($f_{StopHigh}$) and low side ($f_{StopLow}$) stop band frequencies of the RF filter should be at most equal to $2f_{IF}$. Two scenarios are included in Figure 5, the higher lateral band ($f_{LO1}+f_{IF}$) is filtered where f_{LO1} is the frequency generated by the local oscillator. In the second scenario, the lower lateral band ($f_{LO2}-f_{IF}$) is filtered by the same filter where f_{LO2} is the frequency generated by the local oscillator.

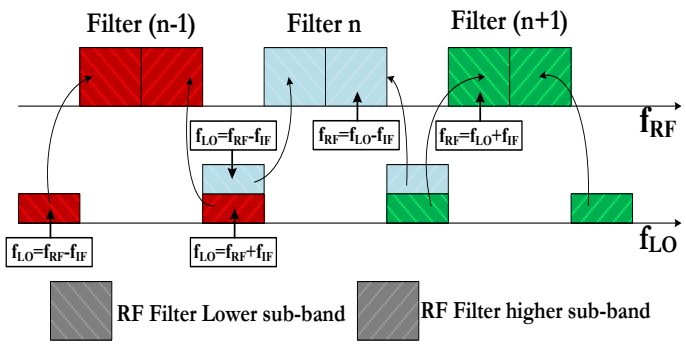

Figure 4 RF filters bands and the corresponding PLL frequency bands.

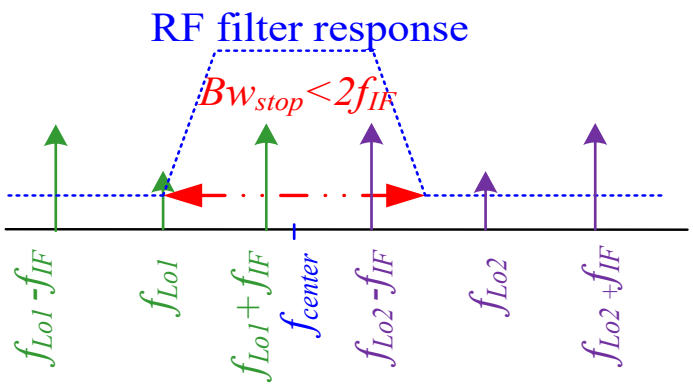

Figure 5 Judicious filtering technique.

2.2. Optimization of a Direct Conversion Multi-standard Transmitter

The frequency plan to be covered is shown in Figure 6. The second generation of a cellular communication standard (GSM) offers voice and low speed data transfer [6]. The need to add multimedia services at a very high-speed in wireless communication infrastructure has led to the development of the third generation such as UMTS and the fourth generation as Wimax [7]. Local and Personal wireless networks such as WLAN, Bluetooth and Zigbee have become very popular [8]. And satellite navigation systems were developed to enable precise and reliable positions for users. European Union launched a new positioning system called Galileo and United States of America have upgraded their satellite navigation system [9], [10].

The method consists on subdividing the whole frequency band into sub-bands, respecting the fact that the rejection bandwidth does not exceed $2f_{IF}$. Another point that should be considered is that closer the pass band is to $2f_{IF}$, the steeper the slope of the filter transfer function has to be. Therefore, the order of the filter increases and the number of resonators increases as well which increases the size of the RF filters. The rejection bandwidth should not exceed $2f_{IF}$. Thus, in order to reduce the number of required RF filters, The IF frequency f_{IF} should be high enough.

The maximum frequency that the afforded digital to analog converter can generate is 140 MHz. Thus, the transmitter requires 8 RF filters, each one having a bandwidth less than 2 fIF =2x140=280 MHz. the standards served by each RF filter are shown in Figure 7. Filter 1 covers the standards GSM, UMTS and Zigbee between 824 MHz and 960 MHz. Filter 2 covers GPS and Galileo signals. It has a bandwidth of 136 MHz centered at 1232 MHz. Filter 3 covers also GPS and Galileo signals between 1559 MHz and 1575 MHz. Filter 4 covers the standards GSM and UMTS between 1710 MHz and 1785 MHz. Filter 5 covers also the standards GSM and UMTS between 1805 MHz and 1990 MHz. Filter 6 covers the UMTS standard between 2010 MHz and 2170 MHz. Filter 7 covers Wimax, Bluetooth, Zigbee and WLAN standards between 2300 MHz and 2497 MHz. Filter 8 covers UMTS and Wimax standards between 2496 MHz and 2690 MHz.

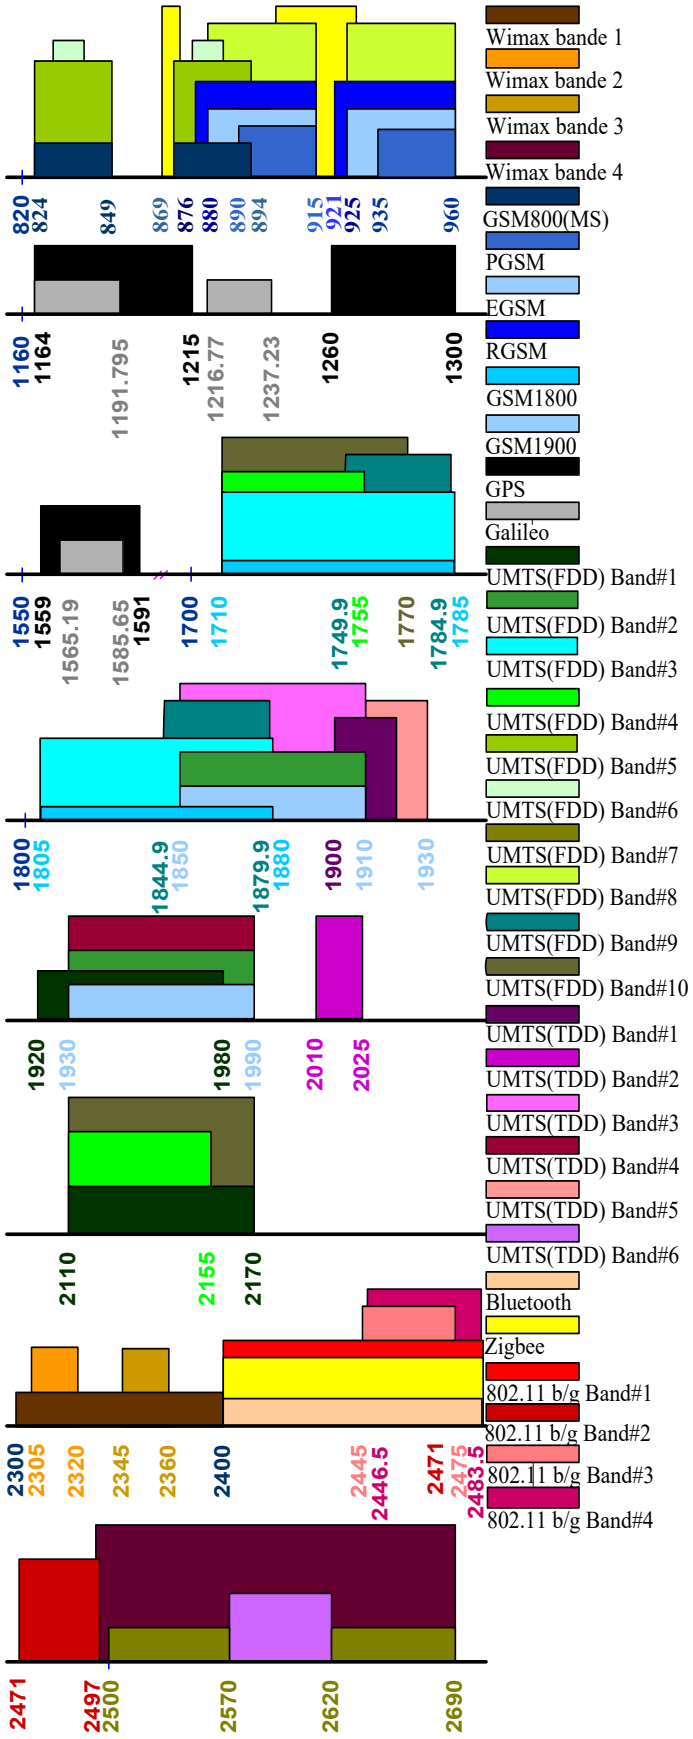

Figure 6 Frequency plan of the considered standards

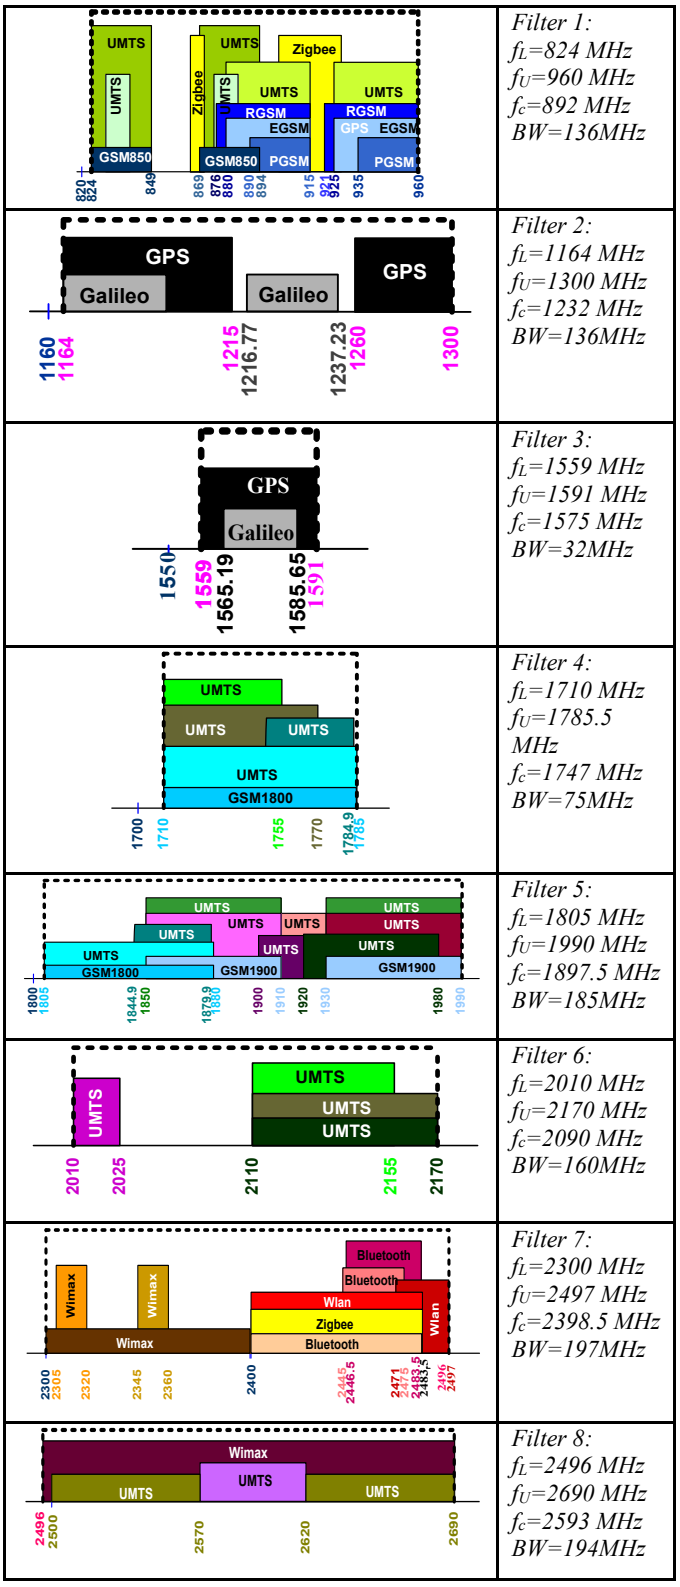

Filter 1:
f_L=824 MHz
f_U=960 MHz

f_U=2690 MHz
f_c=2593 MHz
BW=194MHz

Figure 7 RF filters specifications.

Figure 8 shows how the multi-standard architecture generates and processes the right signal. GPS signal is taken here as an example to illustrate the process. At the DAC output the FPGA generate the GPS signal that passes through an IF filter of 32 MHz bandwidth, centered at 140 MHz. This corresponds to the maximum pass band allowed by the whole set of standards. The filtered signal is then up-converted to the desired RF frequency using a Phase Locked Loop (PLL). A combination of a two digitally controlled SPDT and SP4T switches insures the routing of the signal to the GPS filtering path which is selected among 8 RF filtering arms. Finally, the filtered signal is amplified before transmission.

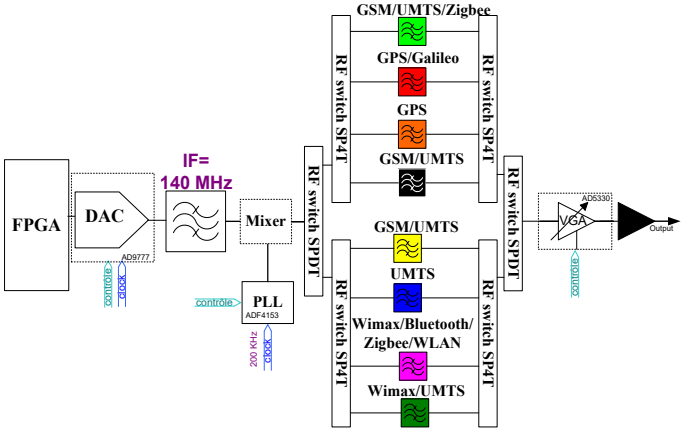

Figure 8 The proposed multi-standard transmitter architecture.

The frequency band covered by the voltage controlled oscillator used in the PLL depends on RF filter bandwidths. For a given filter having a central frequency f_c and a bandwidth BW, the frequency range is:

$[f_c - BW/2 - f_{IF} ; f_c - f_{IF}]$ if we choose $f_{RF} = f_{IF} + f_{LO}$, (1)

$[f_c + f_{IF} ; f_c + f_{IF} + BW/2]$ if we choose $f_{RF} = f_{LO} - f_{IF}$. (2)

Figure 9 shows the obtained frequency ranges to be covered by the frequency synthesizer.

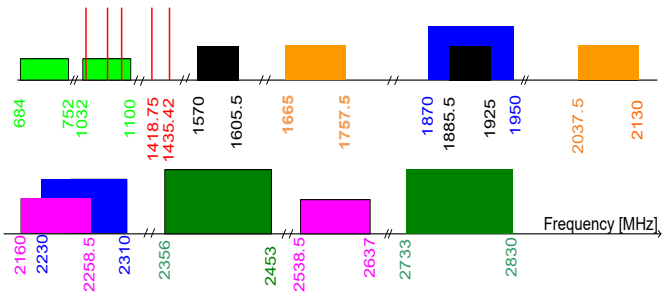

Figure 9 Frequency bands to be covered by the frequency synthesizer.

The mixer is selected primarily depending on its frequency band operation. The characteristics of the mixer are shown in Table 1. The frequency band of the LO port has to cover 824 and 2690 MHz. It has to exhibit a high IIP3 and a high 1dB compression point, as well as low insertion loss. Regarding those conditions, the best candidate is MACOM's ESMD-C50M mixer.

For the SPDT switch, many device candidates are possible. The Analog Devices' ADG918 exhibits the lowest insertion loss and return loss and offers the highest isolation and IIP3. For SP4T,

the Analog Devices'ADG904 fulfil the requirements. The specifications of the RF switches are presented in Table 2.

Table 1 Mixer main characteristics

Mixer Name	MACOM ESMD-C50M
RF band [MHz]	10-2950
IF band [MHz]	30 - 590
LO band [MHz]	10 - 2950
Conversion Loss [dB]	6.21
LO drive level [dBm]	13

Table 2 SPDT & SP4T main characteristics

Name	SPDT-ADG918	SP4T-ADG904
Freq band [MHz]	DC - 4000	DC-2700
Insertion Loss [dB]	0.8	1.1
Isolation [dB]	43	37
Retun Loss [dB]	26	27
IP_{1dB} [dBm]	17	16
IIP_3 [dBm]	36	31

The IF filter has to be centered at 140 MHz with a minimum bandwidth of 32 MHz. Low ripple, low insertion loss and low group delay are required. High stop band rejection and return loss are also needed. Oscilent's 820-IF140.0M is selected as it satisfies all the requirements. Its characteristics are presented in Table 3.

Table 3 IF Filter characteristics

Name	Oscilent820-IF140.0M
Center Freq [MHz]	140
Bandwidh [MHz]	34
Ripple (dB)	0.65
Group delay (us)	0.96
Rejection (dB)	60
Insertion Loss (dB)	22.2

The RF filter reponse depends on the characteristics of the chosen RF components, especially the frequency conversion bloc. The rejection level required to attenuate the level of f_{LO}, $f_{LO} \pm 3f_{IF}$ and of the other remaining intermodulation products should be determined to respect the out-of-band emission mask. A software simulation (ADS) is used to obtain the level of different harmonics and intermodulation products at the input of RF filters and at the output of the first stage of RF switches.

The common RF filter response is plotted in Figure 10. The attenuation A_{min} should be low in the filter passband between F_c-F_p and F_c+F_p. The term $A_{f_{Lo}}$ is the attenuation level needed to reject the oscillator signal. The frequency bands between F_c-F_p-f_{IF} and F_c- f_{IF} and between F_c+ f_{IF} and F_c+F_p+ f_{IF} correspond to the frequency range of the PLL frequency f_{LO}. The term A_{max} is the attenuation level to be achieved for the image frequency. The frequency bands between F_c-F_p-$2f_{IF}$ and F_c-$2f_{IF}$ and between F_c+$2f_{IF}$ and F_c+F_p+$2f_{IF}$ correspond to the frequency range of the image signal. The term $A_{f_{Lo}\pm 3f_{IF}}$ is the minimum level required to attenuate the intermodulation product located in $f_{Lo}-3f_{IF}$ and $f_{Lo}+3f_{IF}$. The frequency bands between F_c-F_p-$4f_{IF}$ and F_c-$4f_{IF}$ and between F_c+$4f_{IF}$ and F_c+F_p+$4f_{IF}$ correspond to the frequency range of the harmonic components $f_{Lo}-3f_{IF}$ and $f_{Lo}+3f_{IF}$ respectively. The term $A_{f_{Lo}\pm 5f_{IF}}$ is the minimum level required to attenuate the harmonics located in $f_{Lo}-5f_{IF}$ and $f_{Lo}+5f_{IF}$. The frequency bands between F_c-F_p-$6f_{IF}$ and F_c-$6f_{IF}$ and between F_c+$6f_{IF}$ and F_c+F_p+$6f_{IF}$ correspond to the frequency range of the harmonic components $f_{Lo}-5f_{IF}$ and $f_{Lo}+5f_{IF}$ respectively. The term $A_{f_{IF}}$ is the attenuation level of the IF component.

Different standards have an attenuation levels depending on the in- and out-of-band emission limits. The level of each harmonic components and undesired signals at the input of the RF filters are designed with a software simulation. The obtained harmonics and intermodulation products rejection levels for each filter are summarized in Table 4. The RF power amplifier is assumed to be linear to guarantee that the levels of the generated harmonics and intermodulation products generated by the up-converter relative to the signal level are kept to be similar after the amplification bloc.

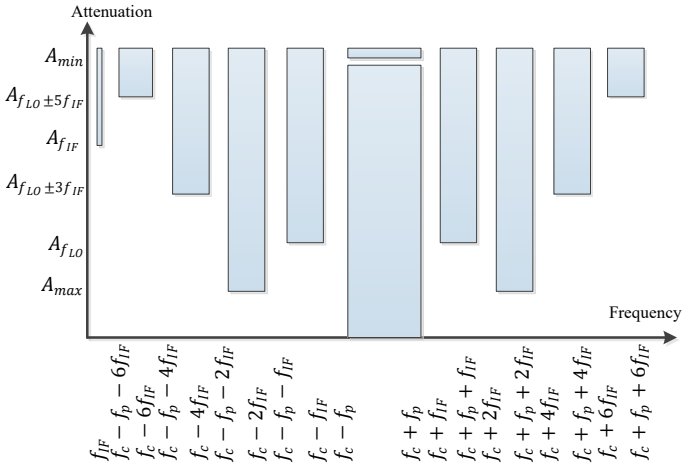

Figure 10 RF Filter response

Table 4 F_{LO} and $F_{LO}\pm 3F_{IF}$ rejections for each channel filter

Specification	Center Freq [MHz]	Pass band Freq [MHz]	$f_{LO}\pm 3f_{IF}$ rejection level [dB]	f_{LO} rejection level [dB]
Filter 1	892	136	80	59
Filter 2	1232	136	40	19
Filter 3	1575	32	40	19
Filter 4	1747.5	75	80	59
Filter 5	1897.5	185	80	59
Filter 6	2090	160	53	32
Filter 7	2398.5	197	52	31
Filter 8	2593	194	53	32

2.3. Optimization of a Multi-standard transmitter architecture using single/double conversion

The first architecture uses eight RF filters, two SPDT switches, four SP4T switches. This architecture is costly in terms of size. For optimization purposes, we have developed another architecture based on double conversion. Two stages are used to transpose the signal from an intermediate frequency to RF frequency.

In order to reduce further the number of required RF filters, The IF frequency fIF should be sufficiently high. The maximum frequency that the afforded DAC can generate is 140 MHz. The purpose is to cover the maximum standards with the minimum number of filters. The judicious filtering technique detailed in the section II.A is re-used to develop this architecture.

The first part of the spectrum is 824 –1300MHz. For this section of the spectrum, the direct conversion method with an IF frequency of 140 MHz (which leads to a maximum channel filter bandwidth of 280 MHz) gives good results in terms of rejections. However, the second section of the spectrum (1559 – 2690 MHz) requires at least six IF-filters to be entirely covered. To reduce the total size and cost of this previous setting, we use instead, a double conversion with a new IF-frequency that will be high enough to require at most two band-pass filters without being too close to the LO frequency. This prevents to generate harmonic interference.

In fact, the intermediate frequency is not fixed for this architecture, it is chosen in such a way that it does not exceed the third of the frequency of the phase-locked loop, $f_{LO}/3$. Indeed, at the output of each mixer at both frequency conversion blocs, the critical harmonics that should be filtered are $-f_{Lo}+5f_{IF}$, f_{IF}, $f_{Lo}-3f_{IF}$, f_{Lo}, $f_{Lo}+3f_{IF}$, $f_{Lo}+5f_{IF}$. These harmonics may disturb the judicious filtering technique when one of them, at least, falls within the frequency ranges between $f_{Lo}-2f_{IF}$ and $f_{Lo}+2f_{IF}$. The RF filter bandwidth is at most equal to twice the intermediate frequency

$$\max(f_{IF}) = \frac{2}{7} f_{LO} = \frac{2}{9} f_{RF} \quad (3)$$

$$\Delta f \le 2 * \min(f_{IF}) \quad (4)$$

Looking at Figure 6, the frequency bands of interest start at $f_{RF} = 824MHz$. According to (3), the maximum IF frequency is therefore 206 MHz. In one hand, if the carriers around 824 MHz are generated by double conversion, the maximum of the frequency at the output of the digital converter must be 51.5 MHz. In the other hand, if the signal is generated by direct conversion, the maximum of the intermediate frequency is 140 MHz and the first filter covers the frequency band between 824 MHz and 960 MHz. The bandwidth of the filter is 136 MHz and the minimum intermediate frequency f_{IF} is 68 MHz. The first filter bandwidth covers GSM, UMTS and Zigbee standards. The second filter starts at $f_{RF} = 1164MHz$. According to (3), the maximum IF frequency f_{IF} is therefore 291 MHz in the case of direct conversion. The bandwidth of the filter is 136 MHz therefore the minimum frequency is 68 MHz. The frequency bands to be covered which come just after the second filter start at frequency 1559 MHz. The corresponding maximum IF frequency is 389.75 MHz. The third filter covers the band 1559-1990 MHz. The maximum frequency and minimum frequency is therefore 215.5 MHz. The fourth filter covers the frequency band between 2010 MHz and 2690 MHz. The maximum intermediate frequency is 502.5 MHz and the minimum intermediate frequency is 340 MHz. Simulations using Advanced Design System (ADS) of Keysight technologies on this set up (see Simulation section) prove that the second stage IF frequency of 357.5 MHz is a good compromise and corresponds to a central frequency of an available intermediate filter. The maximum allowed channel filter bandwidth is 715 MHz. The filters 1 and 2 are used for the direct conversion whereas the filters 3 and 4 are used for the double conversion. Specifications of each RF filter are summarized in Figure 11.

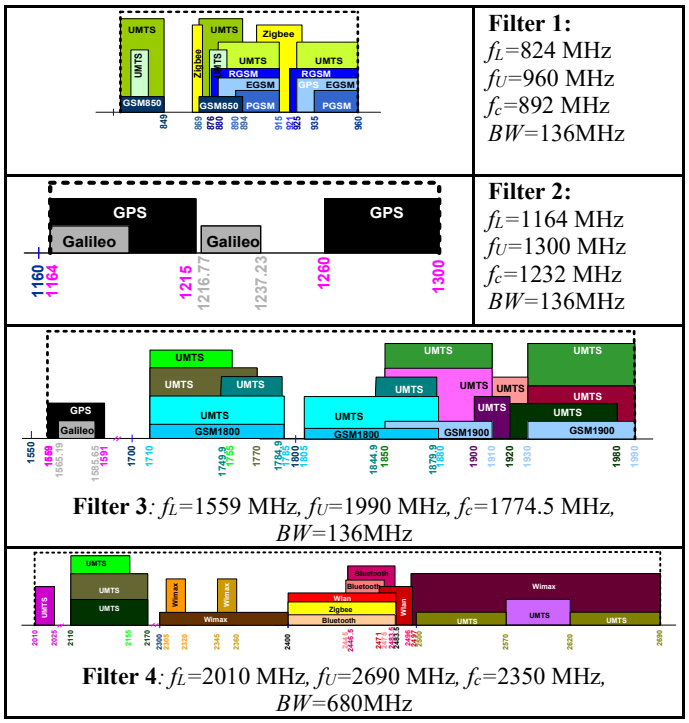

Figure 11 RF filters specifications.

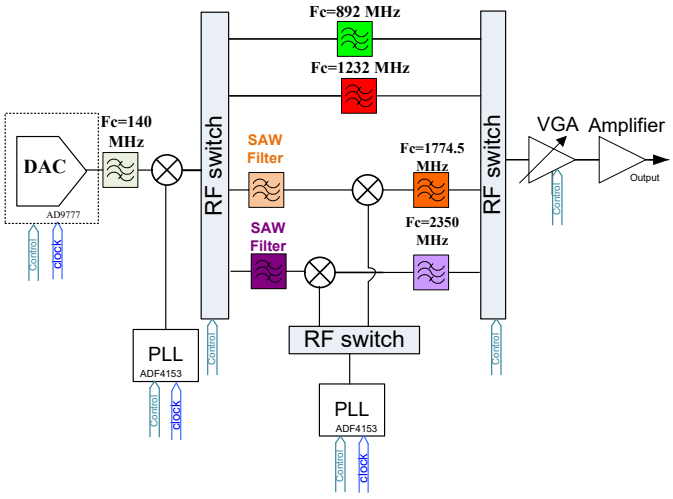

Figure 12 The proposed multi-standard transmitter architecture.

The global transmitter architecture is shown in Figure 12. The DAC output is filtered by an IF-filter with a 32 MHz bandwidth (corresponding to the maximum pass band of the GPS standards) centered at 140 MHz. The signal is then up-converted to a desired

RF frequency. Then, depending on the RF frequency, the signal is routed to either single or double conversion path. For the double conversion, two intermediate surface acoustic wave (SAW) filters centered at 357.5 MHz and having at least 32 MHz bandwidth are to be considered before the second up-conversion stage. The signal is then driven by a variable gain amplifier (VGA) depending on the standard and finally amplified by a high power amplifier (PA).

Figure 13 shows the obtained frequency for the local oscillators. The green bands of 684 – 752 MHz and 1032 –1100 MHz are the LO frequencies corresponding to the direct conversion path (filters 1 and 2). For double conversion path we use the up sideband frequency 497.5 MHz (357.5+140) because it is closer to the other required bands. The orange and purple bands corresponds to the LO frequencies of the second PLL for the 3rd and 4th filters respectively (low side band and higher side band).

In the frequency synthesizer's side, the frequency range to be covered by the Voltage-Controlled Oscillator (VCO) depends on the bandwidth of the filters. For a filter whose center frequency f_c is and the bandwidth is B_W , the frequency range to be covered by the VCO is between $f_c - B_W/2 - f_{IF}$ and $f_c - f_{IF}$ on the one hand and between $f_c + f_{IF}$ and $f_c + B_W/2 + f_{IF}$ on the other hand. Figure 13 shows the total frequency range to be covered by the RF frequency synthesizers. For the signals covered by the first two filters covering the frequency bands 824-960 MHz and 1164-1300 MHz respectively, the intermediate frequency f_{IF} is set to 140 MHz. In the path where the frequency transposition occurs twice, the intermediate frequency at the output of the analog-digital converter is fixed and is equal to 140 MHz. The signal generated by the converter is transposed to 357.5 MHz by the first block of the frequency synthesizer. The first frequency synthesizer should generate a frequency of 497.5 MHz or 217.5 MHz. The frequency 497.5 MHz is chosen because it is closer to the other frequency ranges. The second block of the frequency synthesizer serves to transpose the 357.5 MHz frequency signal to a RF signal that will be filtered by the third and fourth filters.

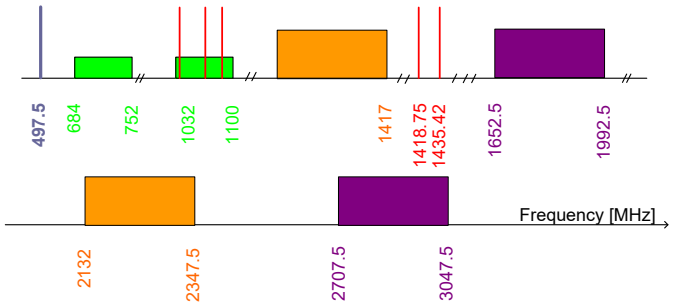

Figure 13 Frequency bands to be covered by the frequency synthesizer

Between the two mixers, a filter should be inserted. In the market, SAW (Surface Acoustic Wave) filters can be used. The third filter covers GPS, Galileo, UMTS, GSM and WLAN standards with a maximum channel width of 32 MHz. The fourth filter covers the UMTS, WIMAX, Bluetooth, Zigbee and WLAN standards with a maximum bandwidth of 28 MHz. The first and the second SAW are pass-band filters. The center frequency of the first SAW is located between 215.5MHz and 389.75 MHz and between 340 MHz and 502.5 MHz, for the second. Their bandwidth should be at least 32 MHz and 20 MHz respectively. Figure 14 illustrates the possible locations of IF channels to be filtered by the third and fourth filters, i.e, at the second frequency conversion bloc.

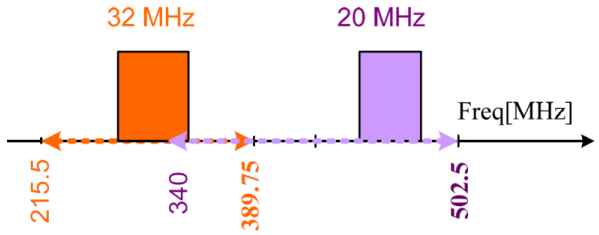

Figure 14 Possible frequencies of intermediate IF channels.

The folding of the two intermediate frequency ranges is considered as an optimization point if a filter that covers the frequency band between 389.75 MHz and 340 MHz is available. From the market, the chosen SAW filter is RFM SF2090C as its ripple, group delay and insertion loss are low and its out-of-band rejection is high. Its characteristics are in Table 5.

The modified transmitter architecture is illustrated in Figure 15. The transmitter includes an analog to digital converter, a mixer, phase locked loops, an SPDT type RF switch, two SP4T type RF switches, a variable gain amplifier and an RF amplifier block. The chosen mixer is MACOM's ESMD-C50M. Its main characteristics are listed in TABLE I. The RF switches ADG918 and ADG904 of analog devices are the best candidates. Their characteristics are in TABLE II. After the DAC, the IF filter (Oscilent's 820-IF140.0M) is inserted. Its characteristics are listed in Table 1.

Table 5 SAW IF filter characteristics

SAW filter Name	RFM SF2090C
Center freq [MHz]	357.5
Bandwidth [MHz]	35
Ripple [dB]	1
Group delay [ns]	55
Rejec-tion [dB]	40
Insertion Loss [dB]	12
Frequency Band [MHz]	340-375

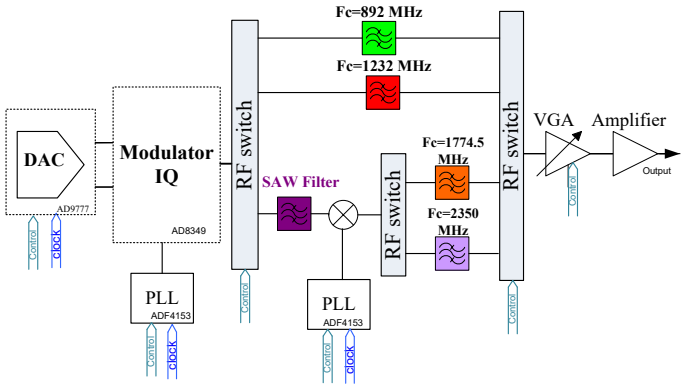

Figure 15 The architecture of single/dual multi-standard transmitter.

The out-of-band attenuations of the first second filters are determined based on the level of the harmonics at the output of the first mixer and the values of the center frequency and bandwidth. The center frequency of the first filter is 892 MHz, and its bandwidth is 136 MHz. The first filter covers GSM, UMTS and Zigbee standards. According to their various masks and spurious emissions cited, the rejection of the image frequency should be 80 dB and of the local oscillator should be 19 dB. The second filter covers the GPS and Galileo systems, the rejection of the image frequency should be 40 dB and of the component is 19 dB. For the third filter and the fourth filter, the levels of harmonics are obtained by carrying out a harmonic balance simulation. The level of harmonic components $f_{Lo}+f_{IF}$ and $f_{Lo}-f_{IF}$ is 10.79 dBm. The level of the local oscillator signal is -19.64. According to the Mask signal and out-of-band emission limits of GSM, UMTS, GPS and Galileo, the third filter should attenuate the image signal by 80 dB and the local oscillator component by 71.15 dB. The stop band of this filter is 720 MHz. The fourth RF filter has a bandwidth of 680 MHz. It covers UMTS, Bluetooth, Zigbee, WLAN and WIMAX standards. It should attenuate the signal at f_{Lo} by 44.15 dB and the image frequency by 53 dB.

3. Simulation

3.1. Simulation of the Direct Conversion Multi-standard Transmitter

To validate the concept, the multi-standard architecture is implemented in ADS, as shown in Figure 16. The RF filters, the RF switches, the mixer as well as the IF filter are implemented by using their models. The simulation allows checking whether the spurious signals are well rejected by the RF filters. All standards generated through the proposed multi-standard architecture are tested. And for each standard, many frequency step simulation runs were carried out. The output spectrum respects the out of band emission limits, in all simulated cases. The following test run is used as an illustration example.

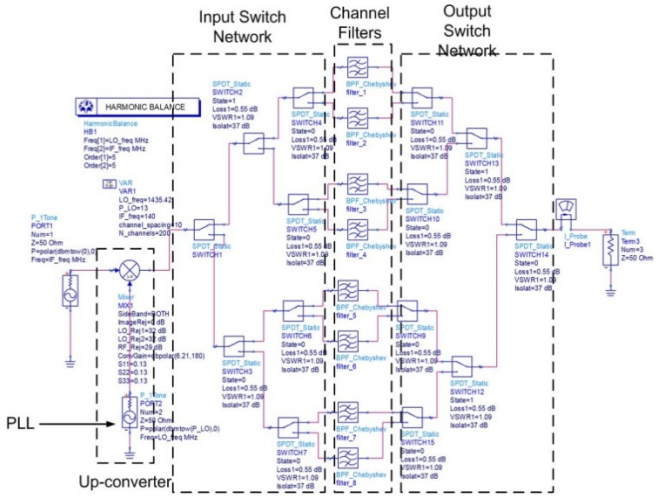

Figure 16 Validation of the direct conversion multi-standard transmitter architecture with ADS.

To generate a WiMAX signal at 2304 MHz, the RF switches are activated in a way that the signal is filtered by filter 7. The frequency of the signal that is generated by the PLL is $f_{Lo}=f_{RF}-f_{IF}=2164MHz$. The spectrum of the signal at the output of the transmitter for this case is illustrated in Figure 17.

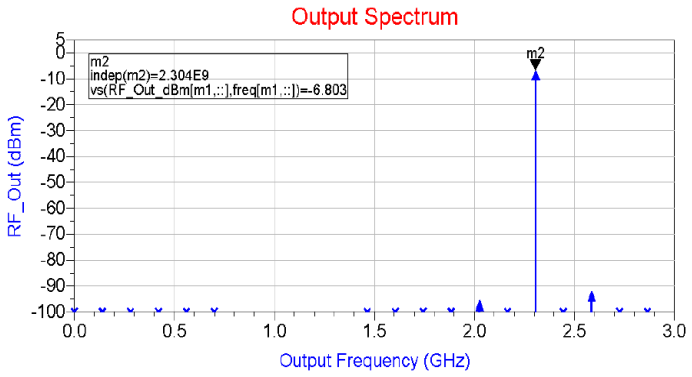

Figure 17 Spectrum of the signal at the output of the transmitter

3.2. Simulation of a multi-standard transmitter using single/ double conversion technique

After the selection of the RF components, the simulation of the second architecture is done using the Keysight–ADS simulator. The circuit diagram useful for completing the simulation in ADS is shown in Figure 18. The simulation consists in carrying out the spectral analysis at the output of the transmitter by varying the frequencies of the frequency synthesizers and adjusting the control parameters of the RF switches.

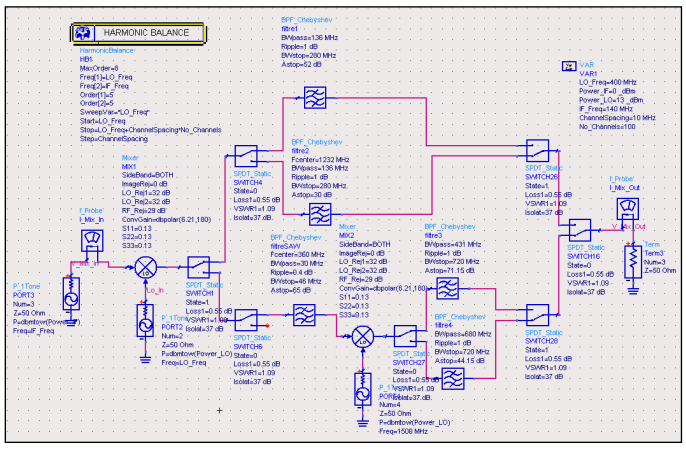

Figure 18 Validation of the multi-standard transmitter architecture using single/double conversion technique with ADS.

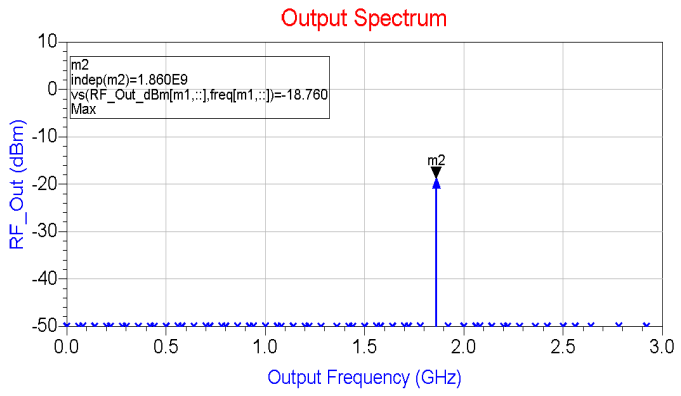

Figure 19 Spectrum of the signal at the output of the transmitter

For example, if the frequency of the first frequency synthesizer and of the second frequency synthesizer are adjusted to $f_{Lo1} = 497.5MHz$ and $f_{Lo2} = 2217.5MHz$. The different RF switches are tuned in a way that the RF signal passes through the third filter. At the output of the transmitter, the spectrum is shown in Figure 19.

4. Conclusion

In this paper, two new optimized architectures of a multi-standard transmitter have been presented. The first one is an heterodyne based architecture. The second combines single and double frequency conversion that allows further reducing the cost, size and weight of the transmitter. This transmitter is a part of a wireless radio that will be carried by an UAV reaching stricken areas after a disaster and therefore enabling and making easier efficient rescue intervention.

It has been shown, through simulation, that both of architectures can generate GPS and Galileo signals which are very critical for rescue operations and waveforms of different cellular wireless communication standards (UMTS, GSM and Wimax) along with waveforms of different local and personal area wireless network standards (Bluetooth, Zigbee and IEE802.11 b/g). The high number of different wireless communication standards and their operating frequency bands requires a high number of RF filters and PLLs. The first architecture is direct conversion. It uses an analog digital converter to convert the digital signal into an analog signal. The analog signal passes through an IF filter with a center frequency of 140 MHz. The filtered signal is mixed with a carrier to be transposed to an RF frequency. The RF signal may be the upper or lower sideband. The RF signal passes through an SP4T switch which points the RF signal to its corresponding RF filter. The first architecture uses eight RF filters. RF filters are partitioned and defined based on the judicious filtering technique. For each RF filter, the lower half of bandwidth serves to filter the upper side signal and the upper half of filter's bandwidth serves to filter the lower side signal. The second architecture is less expensive than the first. It uses fewer components. It uses two SAW IF filters, two mixers, two SP4T RF switches, an SPDT RF switch and four RF filters. The frequency range to be covered by the frequency synthesizers of the second architecture is between 497.5 MHz and 3047.5 MHz. As a logical perspective, the architecture can be further optimized. There is an opportunity to use a frequency doubler that allows using fewer RF filters and fewer RF frequency synthesizers.

Singular integral equations

ABSTRACT

The processes of reflection of three-dimensional electromagnetic waves by locally irregular media interfaces are investigated. The problem under study is mathematically reduced to the solution of a boundary value problem for the Maxwell equations in an infinite space with an irregular boundary. In order to develop a numerical algorithm, the potential theory and a special Green's function are applied to reduce the addressed boundary problem to an equivalent system of two hypersingular integral equations. This system is solved with the use of the approximation and collocation method. Special attention is focused on calculation of the kernels of these equations. Results of simulation of the currents induced on the irregularity and reflected field patterns in the resonance frequency range are presented.

1. Introduction

This paper is an extension of the work originally presented at the URSI Commission B International Symposium on Electromagnetic Theory (EMTS 2016) [1]. In this article we model the scattering of three-dimensional electromagnetic waves on a finite impedance section of a wavy surface separating two media. The scattering of electromagnetic waves by a wavy interface between two different media is an important problem for various applications. In this article we investigate the incidence of an arbitrary plane wave on a local inhomogeneity of the interface assuming sufficiently high conductivity of the underlying medium. The mathematical formulation of such problems reduces to that of solving a system of Maxwell equations in non-regular infinite regions. Depending on the polarization of the incident field, the boundary-value problems are reduced to independent systems of hypersingular integral equations solved by specially developed numerical algorithms utilizing a singularity isolating algorithm.

2. Mathematical model and numerical algorithm

2.1. Mathematical formulation of wave scattering problems

Let us assume that an interface between two media is situated in Cartesian coordinates x, y, z. The interface consists of two half planes Σ that are specified by the equation $y = 0$ and joined by an impedance cylindrical wavy section S that stretches along the z axis. The entire wavy section is located in the half-space $y \geq 0$. The surface S is specified by the equation $y=f(x)$, $0 \leq x \leq a$, $f(0) = f(a) = 0$, where a is the x length of irregularity S. Let $a = 2\pi$. The reflecting surface $S \cup \Sigma$ does not depend on z coordinate. Denote by D_1 the region over interface $S \cup \Sigma$ where the 3D incident electromagnetic field propagates. This region D_1 is characterized by permittivity ε_1, permeability μ_1, and the k_1 wave number $k_1^2 = \omega^2 \varepsilon_1 \mu_1$, where ω is the circular frequency (Figure 1). The time dependence is $\exp(-i\omega t)$.

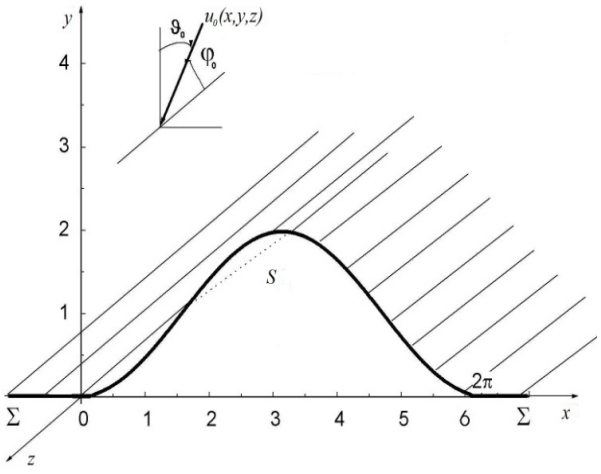

Figure 1: Geometry of perfecting surface

The field of the plane wave

$$\vec{E}_0(x,y,z) = \vec{E}_0 \exp(i\alpha_0 x - i\beta_0 y + i\gamma_0 z),$$
$$\vec{H}_0(x,y,z) = \vec{H}_0 \exp(i\alpha_0 x - i\beta_0 y + i\gamma_0 z),$$

$\alpha_0 = k_1 \sin\vartheta_0 \sin\varphi_0$ □ $\beta_0 = k_1 \cos\vartheta_0 \sin\varphi_0$, and $\gamma_0 = k_1 \cos\varphi_0$ is incident on the surface $S \cup \Sigma$ in region D_1. Here, φ_0 is the angle between axis z and the direction of the incident wave propagation. When $\varphi_0 = \pi/2$, we obtain a plane reflection two-dimensional problem. If $\vartheta_0 = 0$, we have the case of the normal incidence in the plane problem.

In region D_1 we seek for a solution to the homogeneous system of Maxwell equations

$$curl\,\vec{H}(x,y,z) + i\omega\varepsilon_1\,\vec{E}(x,y,z) = \vec{0},$$
$$curl\,\vec{E}(x,y,z) - i\omega\mu_1\,\vec{H}(x,y,z) = \vec{0},$$

which satisfies on the plane section Σ the condition of perfect conduction

$$\left[\vec{n} \times \vec{E}(x,y,z)\right] = \vec{0},$$

Leontovich condition on local section S with a finite conductance

$$\left[\vec{n} \times \vec{E}(x,y,z)\right] = -W_2\left[\vec{n} \times \left[\vec{n} \times \vec{H}(x,y,z)\right]\right],$$

$W_2 = \sqrt{\mu_2/\varepsilon_2}$. Here, ε_2 and μ_2 are the characteristics of the section S, $\vec{n} = (n_x, n_y, 0)$ is the outward normal to region D_1. The reflected field satisfies the radiation conditions at infinity.

We look for the total electromagnetic field in D_1 that has the same dependence on z as the incident field, that is

$$\vec{E}(x,y,z) = \vec{E}(x,y)\exp(i\gamma_0 z),\quad \vec{H}(x,y,z) = \vec{H}(x,y)\exp(i\gamma_0 z).$$

Then, the boundary condition on S can be represented as follows:

$$E_z(x,y) = \frac{W_2}{k_1^2 - \gamma_0^2}\left(-i\gamma_0 \frac{\partial H_z(x,y)}{\partial \tau} - i\omega\varepsilon_1 \frac{\partial E_z(x,y)}{\partial n}\right)$$
$$H_z(x,y) = \frac{1}{W_2(k_1^2 - \gamma_0^2)}\left(-i\omega\mu_1 \frac{\partial H_z(x,y)}{\partial n} + i\gamma_0 \frac{\partial E_z(x,y)}{\partial \tau}\right),$$

$\partial/\partial n = n_x\,\partial/\partial x + n_y\,\partial/\partial y$, $\partial/\partial\tau = n_x\,\partial/\partial y - n_y\,\partial/\partial x$ are the normal and tangent derivatives, respectively. Accordingly, boundary conditions on plane section Σ take the form

$$E_z(x,y) = 0, \qquad \frac{\partial H_z(x,y)}{\partial n} = 0.$$

We denote $u(x,y) = E_z(x,y)$, $v(x,y) = H_z(x,y)$, $\beta_1^2 = k_1^2 - \gamma_0^2$. Then the considered boundary value problem can be reduced to solving in region D_1 of the 2D homogeneous Helmholtz wave equation

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \beta_1^2\right)\left\{\frac{u(x,y)}{v(x,y)}\right\} = 0$$

with appropriate boundary conditions on Σ and S.

2.2. Reduction of the boundary problem for Helmholtz equations to the system of singular equations in case of E-polarization

In order to obtain a system of hypersingular integral equations equivalent to the boundary value problem for Helmholtz equation, we introduce Green's function $g^E(M,P)$, satisfying in region D_1 the inhomogeneous Helmholtz equation

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \beta_1^2\right) g^E(M,P) = -2\pi\,\delta(M,P),$$

the boundary condition for perfect conductor on half-plane Σ

$$g^E(M,P) = 0,$$

that have the form

$$g^E(M,P) = \frac{i\pi}{2}\left[H_0^{(1)}(\beta_1 r_{M,P}) - H_0^{(1)}(\beta_1 \hat{r}_{M,\hat{P}})\right].$$

Here, $H_0^{(1)}(x)$ is the zero-order Hankel function of the first kind; $r_{M,P} = \sqrt{(x_M - x_P)^2 + (y_M - y_P)^2}$, where $(x_{M,P}, y_{M,P})$ are coordinates of M and P points; $\hat{r}_{M,\hat{P}} = \sqrt{(x_M - x_P)^2 + (y_M + y_P)^2}$, $(x_P, -y_P)$ are the coordinates of the $\hat{P}$ point.

Applying in region D_1 the Green's formula successively to functions $u(M)$, $g^E(M,P)$, taking into account the radiation conditions and the properties of surface potentials, we obtain a system of two integral equations for unknown functions $\partial u(P)/\partial n$ and $\partial v(P)/\partial\tau$ on finite section S for E- polarization case:

$$\frac{ik_1 W_2}{2W_1\beta_1^2}\frac{\partial u(M)}{\partial n_M} + \frac{i\gamma_0 W_2}{2\beta_1^2}\frac{\partial v(M)}{\partial \tau_M} +$$
$$\frac{1}{2\pi}\int_S\left[\left(g^E(M,P) + \frac{ik_1 W_2}{W_1\beta_1^2}\frac{\partial g^E(M,P)}{\partial n_P}\right)\frac{\partial u(P)}{\partial n_P} + \right. \qquad (1)$$
$$\left.\frac{i\gamma_0 W_2}{\beta_1^2}\frac{\partial g^E(M,P)}{\partial n_P}\frac{\partial v(P)}{\partial \tau_P}\right] ds_P = -u_0^E(M),$$

$$\frac{1}{2}\frac{\partial u(M)}{\partial n_M}-\frac{1}{2\pi}\int_S\left[\left(\frac{\partial g^E(M,P)}{\partial n_M}+\frac{ik_1W_2}{W_1\beta_1^2}\frac{\partial^2 g^E(M,P)}{\partial n_M\,\partial n_P}\right)\frac{\partial u(P)}{\partial n_P}+\right.$$

$$\left.\frac{i\gamma_0W_2}{\beta_1^2}\frac{\partial^2 g^E(M,P)}{\partial n_M\,\partial n_P}\frac{\partial v(P)}{\partial \tau_P}\right]ds_P=\frac{\partial u_0^E(M)}{\partial n_M},\ M\in S, \qquad (2)$$

where $u_0^E(x,y)=\exp(i\alpha_0 x-i\beta_0 y)-\exp(i\alpha_0 x+i\beta_0 y)$. In the case of the *H*- polarization we can obtain a system of two integral equations for unknown functions $v(P)$ and $\partial u(P)/\partial\tau$ on finite section *S*.

2.3. The numerical algorithm for the solution of singular integral equations for the E-polarization

The systems of integral equations are singular and can be solved through reducing them to the complex system of linear algebraic equation by means of the collocation and approximation method.

To this end, we divide the interval $[0,a]$, on which the equation $y=f(x)$ of the irregular cylindrical surface S is defined, by points $x_i=ia/N,\quad x_0=0,\quad x_N=a$, into N equal parts. The points dividing the curve S have the coordinates $(x_i,f(x_i))$. Then we replace the integrals entering into the systems of equations (1), (2) with the sums of the integrals over the subintervals and set $M=M_{i+1/2},\quad i=1,...,N$, $M_{i+1/2}$ are collocation points. The sought solution on the section $S_{P_j,P_{j+1}}$, $j=0,...,N-1$, is approximated by a zero-order spline. As a result, we obtain a complex system of linear algebraic equations. When calculating the integrals over a section $S_{P_j,P_{j+1}}$, in which the integrand depends on either $g^E(M,P)$ or $\frac{\partial g^E(M,P)}{\partial n_P}$, we replace the integration with respect to s with the integration with respect to x by setting $ds_P=\sqrt{1+(f'(x))^2}\,dx_P$.

Note that the terms that enter the kernels of integral equations and depend on $g^E(M,P)$ have a logarithmic singularity when the arguments coincide. Therefore, when developing the numerical algorithm, this singularity is separated in an explicit form and the integrals containing it are calculated analytically.

The normal derivatives of the function $g^E(M,P)$ have no singularity when the arguments are equal, and

$$\lim_{P\to M}\frac{\partial g^E(M,P)}{\partial n_p}=\frac{1}{2}\kappa_0(M),$$

where $\kappa_0(M)$ is the curvature of the contour S at the point M.

The kernels of the system depending on $\frac{\partial^2 g^E(M,P)}{\partial n_M\,\partial n_P}$ have a strong singularity. In order to calculate the matrix elements that are integrals of the functions with a hypersingularity, it is necessary to develop a numerical algorithm. To this end, we preserve the integration over the arc s in these integrals. We defined the surface S in the form $x=x(s),\quad y=y(s)$. The outward normal to the domain D_1 we write in the form $\vec{n}=-y_s'\,\vec{i}+x_s'\,\vec{j}$, where $\vec{i}$ and $\vec{j}$ are the x and y unit vectors. Note that if the boundary of *S* is specified in the form $y=f(x)$, the relationship between the directional cosines $n_x;n_y$ of the outer normal $\vec{n}$ to D_1 is given by

$$y_S'=-n_x\sqrt{1+(f'(x))^2},\qquad x_S'=n_y\sqrt{1+(f'(x))^2},$$
$$n_x=f'(x)/\sqrt{1+(f'(x))^2},\quad n_y=-1/\sqrt{1+(f'(x))^2}.$$

We have

$$\int_{S_{P_j,P_{j+1}}}\frac{\partial^2}{\partial n_M\partial n_P}g^E(M_{i+1/2},P)ds_P=$$
$$\frac{i\pi}{2}\int_{S_{P_j,P_{j+1}}}\frac{\partial^2}{\partial n_M\partial n_P}H_0^{(1)}(\beta_1 r_{M_{i+1/2},P})ds_P-\qquad (3)$$
$$\frac{i\pi}{2}\int_{S_{P_j,P_{j+1}}}\frac{\partial^2}{\partial n_M\partial n_P}H_0^{(1)}(\beta_1 \hat{r}_{M_{i+1/2},P})ds_P.$$

To develop a special computing algorithm, every integrands is represented by a sum of two terms: the first one is the total differential of some function has been calculated analytically; the function in the second term has a logarithmic singularity and is integrated by separating this singularity in the explicit form, thereafter the corresponding integrals are calculated analytically.

In the first term $\partial/\partial n_M$ let us consider the component $\partial/\partial x_M$ (without the multiplier $i\pi/2$):

$$\int_{S_{P_j,P_{j+1}}}\frac{\partial^2}{\partial x_M\partial n_P}H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right)ds_P=$$

$$-\int_{S_{P_j,P_{j+1}}}\frac{\partial}{\partial n_P}\frac{\partial}{\partial x_P}H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right)ds_P=$$

$$-\int_{S_{P_j,P_{j+1}}}d\left(\frac{\partial}{\partial y_P}H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right)\right)-$$

$$\beta_1^2 \int\limits_{S_{P_j,P_{j+1}}} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right) y'_{S_P} d s_P + 4i \int\limits_{S_{P_j,P_{j+1}}} \delta(M,P) y'_{S_P} ds_P = -\frac{\partial}{\partial y_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P_{j+1}}\right) + \frac{\partial}{\partial y_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P_j}\right) - \beta_1^2 \int\limits_{S_{P_j,P_{j+1}}} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right) y'_{S_P} ds_P + 4i \int\limits_{S_{P_j,P_{j+1}}} \delta(M,P) y'_{S_P} ds_P. \quad (4)$$

The points M and P can coincide, hence, there is an integral of the Dirac delta-function.

Similarly let us consider the component $\partial / \partial y_M$ in the first term $\partial / \partial n_M$:

$$\int\limits_{S_{P_j,P_{j+1}}} \frac{\partial^2}{\partial y_M \partial n_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right) ds_P = -\int\limits_{S_{P_j,P_{j+1}}} \frac{\partial}{\partial n_P} \frac{\partial}{\partial y_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right) ds_P = \int\limits_{S_{P_j,P_{j+1}}} d\left(\frac{\partial}{\partial x_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right)\right) + \beta_1^2 \int\limits_{S_{P_j,P_{j+1}}} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right) x'_{S_P} d s_P - 4i \int\limits_{S_{P_j,P_{j+1}}} \delta(M,P) x'_{S_P} ds_P = \frac{\partial}{\partial x_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P_{j+1}}\right) - \frac{\partial}{\partial x_P} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P_j}\right) + \beta_1^2 \int\limits_{S_{P_j,P_{j+1}}} H_0^{(1)}\left(\beta_1 r_{M_{i+1/2},P}\right) x'_{S_P} ds_P - 4i \int\limits_{S_{P_j,P_{j+1}}} \delta(M,P) x'_{S_P} ds_P. \quad (5)$$

Using (4)-(5) and the recurrence relations for Hankel functions

$$\frac{\partial}{\partial x_P} H_0^{(1)}\left(\beta_1 r_{M,P}\right) = \beta_1 H_1^{(1)}\left(\beta_1 r_{M,P}\right) \frac{x_M - x_P}{r_{M,P}};$$

$$\frac{\partial}{\partial y_P} H_0^{(1)}\left(\beta_1 r_{M,P}\right) = \beta_1 H_1^{(1)}\left(\beta_1 r_{M,P}\right) \frac{y_M - y_P}{r_{M,P}},$$

we obtain the final formula for the calculation of the second normal derivative of the Green function [2].

2.4. Calculation of the reflected field pattern for the E-polarization

Using the solution to the system of integral equations (1)-(2) and taking into account the boundary conditions on the section S, we can obtain the integral representation for the field $u_1(M) = u(M) - u_0^E(M)$:

$$u_1(M) = \frac{1}{2\pi} \int\limits_S \left\{ \left[g^E(M,P) + \frac{i k_1 W_2}{\beta_1^2 W_1} \frac{\partial g^E(M,P)}{\partial n_P} \right] \frac{\partial u(P)}{\partial n_P} + \frac{i \gamma_0 W_2}{\beta_1^2} \frac{\partial g^E(M,P)}{\partial n_P} \frac{\partial v(P)}{\partial \tau_P} \right\} d s_P, \quad M \in D_1. \quad (6)$$

We introduce spherical coordinate frame $r, \overline{\vartheta}, \overline{\varphi}$, where angle $\overline{\vartheta}\ (-\pi/2 < \overline{\vartheta} < \pi/2)$ is measured from the y axis and angle $\overline{\varphi}\ (0 < \overline{\varphi} < \pi/2)$ is measured from the z axis. We seek for a representation of the scattered field for $|\vec{r}|_M >> |\vec{r}|_P$, $k_1 |\vec{r}|_M >> 1$. Following that, we introduce the notation $|\vec{r}|_M = \rho$. It can be shown that the following asymptotic relationships $r_{MP} \approx \rho - (\vec{r}_P, \vec{e}_M)$ and $\hat{r}_{M\hat{P}} \approx \rho - (\vec{\hat{r}}_{\hat{P}}, \vec{e}_M)$ are valid. Here, $\vec{e}_M$ is a unit vector oriented in the direction to point M; i.e. $\vec{e}_M = \vec{r}_M / \rho = (\sin\overline{\vartheta}\sin\overline{\varphi}, \cos\overline{\vartheta}\sin\overline{\varphi}, \cos\overline{\varphi})$. Taking into account the above relationships and asymptotic behavior of the Hankel function, we can obtain the asymptotic representations for $g^E(M,P)$, $\frac{\partial g^E(M,P)}{\partial n_P}$ in the form

$$g^E(M,P) \approx \sqrt{\frac{\pi}{2\beta_1\rho}} \exp\left(i\left(\beta_1\rho + \frac{\pi}{4}\right)\right) \times \left[\exp\left(-i\beta_1(\vec{r}_P, \vec{e}_M)\right) - \exp\left(-i\beta_1(\vec{\hat{r}}_{\hat{P}}, \vec{e}_M)\right)\right];$$

$$\frac{\partial g^E(M,P)}{\partial n_P} \approx \sqrt{\frac{\pi}{2\beta_1\rho}} \exp\left(i\left(\beta_1\rho + \frac{\pi}{4}\right)\right) \times \left[-i\beta_1(\vec{n}_P, \vec{e}_M)\exp\left(-i\beta_1(\vec{r}_P, \vec{e}_M)\right) + i\beta_1(\vec{n}_{\hat{P}}, \vec{e}_M)\exp\left(-i\beta_1(\vec{\hat{r}}_{\hat{P}}, \vec{e}_M)\right)\right] \quad (7)$$

and also for $u_1(M)$[3].

We call quantity $F^E(\overline{\vartheta},\overline{\varphi})$ that equals

$$F^E(\overline{\vartheta},\overline{\varphi})=$$

$$\frac{1}{\sqrt{\beta_1}}\int_S\Big[\Big\{\Big[\exp\big(-i\beta_1(\vec{r}_P,\vec{e}_M)\big)-\exp\big(-i\beta_1(\vec{\hat{r}}_{\hat{P}},\vec{e}_M)\big)\Big]+$$

$$\frac{k_1W_2}{\beta_1W_1}\Big[(\vec{n}_P,\vec{e}_M)\exp\big(-i\beta_1(\vec{r}_P,\vec{e}_M)\big)-$$

$$(\vec{n}_{\hat{P}},\vec{e}_M)\exp\big(-i\beta_1(\vec{\hat{r}}_{\hat{P}},\vec{e}_M)\big)\Big]\Big\}\frac{\partial u(P)}{\partial n_P}+$$

$$\frac{\gamma_0W_2}{\beta_1}\Big[(\vec{n}_P,\vec{e}_M)\exp\big(-i\beta_1(\vec{r}_P,\vec{e}_M)\big)-$$

$$(\vec{n}_{\hat{P}},\vec{e}_M)\exp\big(-i\beta_1(\vec{\hat{r}}_{\hat{P}},\vec{e}_M)\big)\Big]\frac{\partial v(P)}{\partial\tau_P}\Big]ds_P$$

the pattern of scattering field $u_1(M)$. Knowing the solution of the system of singular integral equations (1)-(2), we calculate the currents induced on the irregular surface and far-field pattern for the scattered field in the far zone [4].

3. Numerical results

The induced currents and reflected electromagnetic field patterns are calculated for *E*- polarization, $\varepsilon_2=50+4i$, contour S specified in the XOY plane by the equation $f(x)=1-\cos x$, $0\le x\le 2\pi$, $a=2\pi$.

Figure 2 shows the distribution of the calculated function of the induced current $I(x)=|\partial u(P)/\partial n|$ on the boundary S along the x axis for $ak_1=3\pi$, $a/\lambda=1.5$, where λ is the wavelength of the incident field. The results are obtained for various angles ϑ_0 and φ_0 of the electromagnetic wave incidence: (curve *1*) $\vartheta_0=0$, $\varphi_0=85^0$; (curve *2*) $\vartheta_0=30^\circ$, $\varphi_0=60^0$; (curve *3*) $\vartheta_0=45^\circ$, $\varphi_0=45^0$; (curve *4*) $\vartheta_0=60^\circ$, $\varphi_0=30^0$.

Figures 3-4 show for $ak_1=3\pi$, $a/\lambda=1.5$ reflected field pattern $|F^E(\overline{\vartheta},\overline{\varphi})|$ in polar coordinates for the range $-85^\circ<\overline{\vartheta}<85^\circ$ and fixed values of $\overline{\varphi}$. Curves *1-5* correspond to $\overline{\varphi}=85^\circ, 60^\circ, 45^\circ, 30^\circ, 5^\circ$. Figures 3-4 represent the results of calculations for the reflected field when a plane wave incident at the angles $\vartheta_0=0$, $\varphi_0=85^\circ$ (Figure 3) and $\vartheta_0=45^\circ, \varphi_0=45^\circ$ (Figure 4).

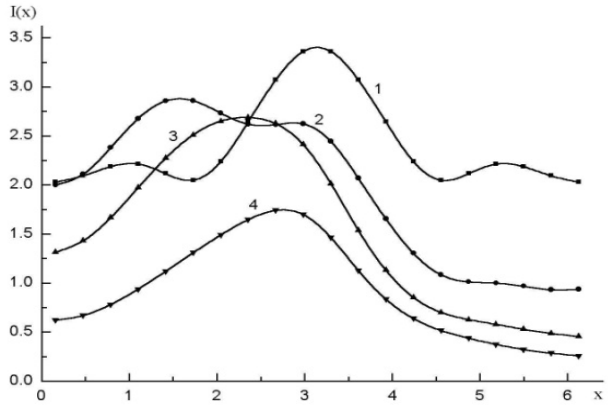

Figure 2

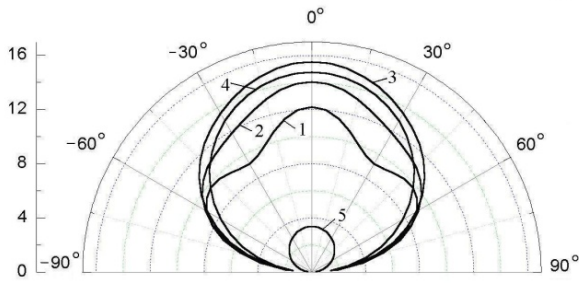

Figure 3

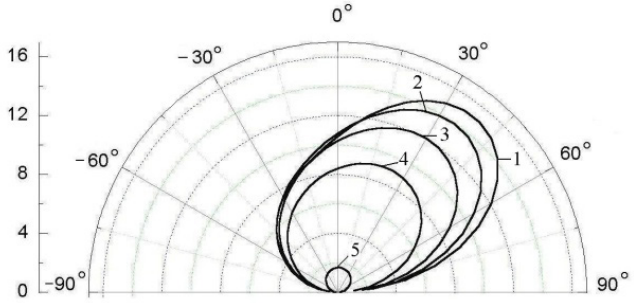

Figure 4

Further, the analogous results are presented on Figures 5-7 for $ak_1=5\pi$, $a/\lambda=2.5$.

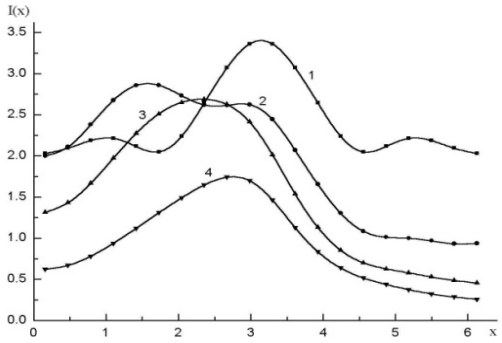

Figure 5

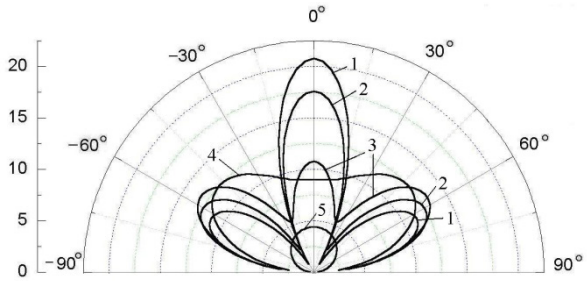

Figure 6

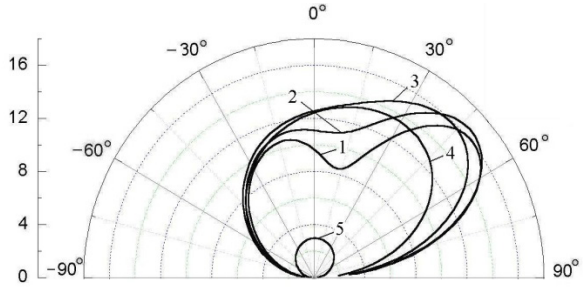

Figure 7

4. Conclusion

1. The exact model of plane electromagnetic wave incident on inhomogeneous conductive surface is investigated.
2. The problem is reduced to the system of singular integral equations. The analytic solution is provided for a singularity in the kernels of integral equations.
3. The numerical algorithm for calculation of scattering characteristics of incident electromagnetic field was developed and calculation examples were presented.

ABSTRACT

This article is an extended version of the study presented at the IEEE Ecuador Technical Chapters Meeting (ETCM)-2016. At that time, a methodological proposal was designed, implemented, and applied in a group of industrial plants for the management of the information security of the Industrial control systems (ICS). The present study displays an adaptation and improvement of such methodology with the purpose of aligning the proposal for the effective management of information security with the strategic objectives. The development of this study has been divided into three distinctive phases. Firstly, we induced the articulation of PMI-PMBOK v5 and ITIL v3 both for the management of the project and for the verification of risks in the IT services. Second, we applied a set of risk mitigation strategies based on international standards as NIST 800-82 and 800-30. Thirdly, we assembled the two mentioned phases in a Guide for standards-based instructions and security policies, which previously have been encouraged on NIST 800-82, 800-53 and 800-12. Hereby, we observed the reduction of incidents of information security, the correct delimitation of the functions of the direct responsible of the ICS and the improvement of the communication between the operative and technical areas of the involved companies. The results demonstrate the functionality of these improvements, especially in the context of the availability and integrity of information, which generates an added value to the enterprise.

1 Introduction

According to the Guide to Industrial Control Systems (ICS) Security NIST-2nd Revision [1], "threats to control systems may be originated from numerous sources, including hostile governments, terrorist groups, disgruntled employees, malicious intruders, complexities, accidents, and natural disasters as well as malicious or accidental actions by insiders. ICS security objectives typically follow the priority of availability and integrity, followed by confidentiality".

Facing these issues, the industry has proposed several studies as recommended by [2] where best practices and risk assessment of the ICS have been suggested. In [3] authors documented about Supervisory Control and Data Acquisition (SCADA) system security. In [4] enlightens the myths and facts behind Cyber security in ICS, while in [5] [6] [7] [8] [9], authors present issues, methods and countermeasures to the protection of information, control systems as well as automation. In [10] exposes the research about SCADA security in the light of Cyber-Warfare. In recent studies such as [11] examines the State of the Art in Cyber security risk assessment methods for SCADA systems. In [12] [13] proposes a study on efficiency of an Information Security Management System (ISMS) for ICS with compliance. In [14] presents a formal approach that automates the security analysis of ICS. In [15] explains a process of defense of securing ICS. In [16] presents a theory of security metrics in SCADA

https://dx.doi.org/10.25046/aj020313

and ICS including resilience. In [17] [18] [19] [20] [21] authors explore the ICS cybersecurity landscape including threats, vulnerabilities, intrusions and cyberattacks. In [22] discusses that the wireless systems in all ICS are subject to cybersecurity vulnerabilities. In [23]gives an analysis of behavior, time, and adaptation in the assessment of ICS Cybersecurity Risk. In all mentioned studies, general recommendation and analysis on the ICS were discussed, but unfortunately they missed to propose a management system of information security. The standards listed in the mentioned studies are predominantly: NIST 800-53, ISA 99, NERC, ISO 27001, ISO 27002 [24], ISO 31010, and ISO 27019.

Despite having controls and procedures in the management of information security of its ICS, the manufacturing companies, fail to reduce and resolve the incidents. In addition, there is little or no evidence of a complete vulnerability, threat and risk analysis of their critical assets and services. This may be attributed to the high level of sophistication of the ICS and the poor knowledge of the present personnel that manages and carries out such tasks [10].

Thus, the main contribution of this research has been to provide a methodology to manage information security in ICS. This has been focused on both, Information Technology (IT) professionals and manufacturing automation professionals. Its stages and methods have been consistently combined with the standards outlined above and are internationally used in traditional IT and ICS. Specifically, these contributions are: (1) Novel guides for the management of the project of implementation of the methodology; (2) Updated methodologies for risk assessment in IT services used in ICS; (3) Methodological procedures to encounter new risk mitigation strategies; and finally, (4) Methodological procedures to develop the manual of security standards and policies for ICS.

Based on the findings and conclusions presented by [24] [26], we agree and confirm that NIST fulfills all criteria needed and has been therefore chosen to be ideally for this study, besides the existence of two further interesting options such as the North American Electrical Reliability Corporation / Critical Infrastructure Protection (NERC / CIP). They represent a set of requirements designed to secure the assets required to operate in North America and the International Automation Society (ISA), being is a series of standards, technical reports and related information that defines procedures for Systems Automation and Control Electronics (IACS). Therefore, we have opted for a reliable standard like NIST stands for, which is not exclusively framed in the organization nor in the technical part only. This allows the possibility to manage in an effective and holistic way different areas that coexist in the SCI being: business, computing, electronics, automation, production processes and people. It is also recognized that NIST is internationally highly disseminated and its best practices exist supplementary information that may be available to the professional stakeholders of this project.

This document is an extended version of a previous conference presentation [27], which has been based specially on NIST. In this present article, areas of knowledge of the PMBOK and ITIL standards have been also included, which served to improve the management of the methodology implementation projects and in the risk analysis of the IT services operating in the ICS. Furthermore, we added detailed evidence and discussions of the results presented in [27].

The remainder of this paper is organized as follows: The conceptual framework that describes the theoretical foundation of this study is described in Section 2. Then, the adaptation and improvement of the methodology proposed is explained in section 3. Results and discusses of findings and their implications are displayed in Section 4. Finally, Section 5 closes with conclusions and some future research lines.

2 Theoretical Framework

This section comprises all the important theory and knowledge about the ICS, tools for IT architecture modeling and expert system validation method that have been used in this study:

2.1 Industrial Control Systems (ICS).

As reported by the Guide to Industrial Control Systems (ICS) Security of the National Institute of Standards and Technology (NIST) [1], the term Industrial Control System includes Supervisory Control and Data Acquisition (SCADA), Distributed Control Systems (DCS), as well as programmable logic controllers (PLCs). ICS are used in industries such as electricity, water distribution systems, wastewater, petroleum, natural gas, chemical, transportation, pharmaceutical, pulp, paper, food, automotive, aerospace, among many others. On the other side, SCADA systems are also used to control critical infrastructure. As stated by ENISA in [28] critical infrastructure such as electricity generation plants, transportation systems, oil refineries, chemical factories and manufacturing facilities means an asset, system or part thereof located in a country which is essential for the maintenance of vital societal or strategic functions, such as health, safety, security, economic or social well-being of people, and the disruption or destruction of which would have a significant impact (e.g. disruption to business operations and services but also potential damage and destruction of equipment). As a final point, DCS are used to control production systems within a local area such as a factory using supervisory and regulatory control. PLCs are used for discrete control for specific applications and generally provide regulatory control [1].

2.2 Security incidents in Industrial Control Systems.

The proliferation of connections that use the electromagnetic spectrum, combined with vulnerable source code and errors in configurations of automation systems expose the ICS to potential from cyberspace. Weak IT security policies and weaknesses in the security features of automation systems dramatically increase the risk of a successful cyber-attack [29].

Facing such issues, there are some organizations authorized to investigate and combat cybersecurity incidents. For instance, in the United States are the Cybersecurity Emergency Response Team (ICS-CERT) [30] and the Federal Bureau of Investigation (FBI). ICS-CERT in 2015, received and responded to several incidents reported by owners and manufacturers of industrial products in North America. Other reports considered are also those reported by manufacturers and suppliers of equipment, industrial systems, and information security solutions such as: ABB, Allen Bradley, Verizon [31], among others.

In the same context [27] [28] discloses the current maturity level of ICS-SCADA cybersecurity in Europe and identifies good practices handled by European Member States to improve this area. The first and second part of this study introduces the ICS-SCADA cyber security topic, explains the role of ICS-SCADA in critical sectors and summarizes the methodology of this research.

2.3 Guide for Industrial Control System Security NIST 800-82.

The NIST Industrial Control System Safety Guide 800-82 establishes some guidelines for the implementation of safety in ICS. The main reason for using the regulations for an ICS is that these increasingly adopt computer components in their design and operation. While some features are similar between traditional IT systems and ICS, it is fundamental to understand that they are unable to be handled in a similar procedure. ICS and IT include significant risks such as health, protection of human life, environmental damage, financial impact, production losses, etc., [1].

This document is the second revision to NIST SP 800-82 which has been published in March of 2015. Updates in this revision include: ICS threats and vulnerabilities; ICS risk management, recommended practices and architectures; current activities in ICS security; security capabilities and tools for ICS; Additional alignment with other ICS security standards and guidelines; new tailoring guidance for NIST SP 800-53, among others [1].

Risk is present, when the probability exists of an occurrence of a threat or any vulnerability. Threats are able to take advantage of vulnerabilities. In the case of a computer incident, for example, the magnitude of the potential impact results from a successful exploitation of vulnerability [32] and [33] should be determined. Risk assessment, in turn, is the process of identifying the risks of an organization's operations, assets, and individuals by evaluating the likelihood of an identified vulnerability having a potential impact. The risk assessment also has to compare the costs of such safety with those expenses or financial damages associated with a possible incident.

2.4 Guide to the Project Management Body of Knowledge (PMBOK® Guide)–Fifth Edition.

The Guide to the Project Management Body of Knowledge provides guidelines for the direction of individual projects and defines concepts related to project management. It also describes the life cycle of project managements and related processes, as well as the project life cycle. The PMBOK® Guide contains the globally recognized standard and guidance for the project management profession. By standard means a formal document that describes established standards, methods, processes and practices. Similar to other professions, the knowledge contained in this standard evolved from the recognized good practices of the professionals dedicated to the management of projects that have contributed to its development. Acceptance of project management as a profession indicates that the application of knowledge, processes, skills, tools and techniques may have a considerable impact on the success of a project [34].

2.5 IT Infrastructure Library (ITIL)

ITIL is part of a suite of best-practice publications for IT service management (ITSM). ITIL provides guidance to service providers on the provision of quality IT services, and on the processes, functions and other capabilities needed to support them. Organizations are encouraged to adopt ITIL best practices and to adapt them to work in their specific environments in ways that meet their needs. ITIL is not a standard that is mandatory to be followed, it is more likely a guidance that should be read, understood, and used to create value. The ITIL framework is based on the five stages of the service lifecycle, namely Service Strategy, Service Design, Service Transition, Service Operations and Continual service improvement [34] [35] [36].

2.6 Control Objectives for Information and Related Technology (COBIT).

The COBIT provides a comprehensive framework that supports enterprises to achieve their goals and deliver added value through effective governance as well as IT governance of the Organization. In this way, it supports organizations to create optimal value from IT, by maintaining a balance between realizing benefits and optimizing levels of risk and resource utilization. This allows IT and related organizations to be governed and administered in a holistic manner throughout the Organization. This includes the full scope of

all functional and business areas of responsibility, taking into account the internal and external interests of IT stakeholders.

3 Methodology Proposal.

3.1 Research Methodology

During this project, we have used the Action research Methodology [37], also known as participatory research which is a testing of theories developed to overcome an immediate on the job-difficulty. In short, action research means learning by doing. In this kind of approach first a solution is devised and evaluated, while depending of the results, a new solution may be constructed in order to try to achieve more sophisticated results. These processes are cyclically repeated until an acceptable performance has been obtained. In one of its formal stages it is established the gathering of pertinent data, material, methods, techniques, and so on for setting into testing periods. All data should be relevant to the problem. Therefore, it has been pertinent for us, to use PMBOK v5 and ITIL PRACTITIONER in their respective areas of knowledge called Communication. As collaborative instruments, workshops were developed with ICS experts as a focus group. The next stage has been to concern the developing plans for implementation of a theory.

The research has been carried out under real conditions of four industrial plants of the principal manufacturing enterprises in their markets. These have approximately 600 employees in the manufacturing area and some 400 more, in the administrative area. The four plants were comprised of two production lines containing four distributed control systems (DCS), 120 Allen Bradley and Siemens PLCs, 40 HMIs Allen Bradley, 48 desktop computers, 15 industrial applications using Rockwell Automation and Wonderware software (including 5 critical mission) and a Local and Wide area networks (LAN/WAN) with Cisco equipment and Checkpoint. Reference standards such as: NIST 800-30, NIST 800-82, NIST 800-53, NIST 800-12, PMBOK v5, ITIL v3, interviews, statistical processes and cost-benefit analysis have been used among the most important ones.

3.2 Modeling of IT frameworks & Methodological proposal.

In order to improve the methodology proposed in our previous study [27], we have considered the adaptation of other standards, referential frameworks, and management systems that are used in Information Technology (IT). With the purpose to understand the context, we have started by modeling the indicated in a hierarchical pyramid that is illustrated in Figure 1. In the base stand the standards used in traditional IT: COBIT, ISO 27000, PMBOK and ITIL. The second level of the pyramid holds NIST, NERC and ISA. At the third level is the proposed methodology. From bottom to top, these standards reveal ICS practitioners "how to do it?", while from top to bottom urges the question of: "what to do?"

Firstly, as part of the COBIT IT governance process, the "BAI01" (Building, Acquiring and Implementing, BAI), called Program and Project Management has been included. There, COBIT indicates "what to do?" According to this process, all the investment portfolio programs and projects are strongly recommended to be managed in a coordinated way and in line with the corporate strategy. In a similar case, chapter 13 of [34] indicates "what to do?" to identify project stakeholders. In the case of this proposed management, the "how to do?" procedure is indicated to discover the stakeholders required at each step of the implementation.

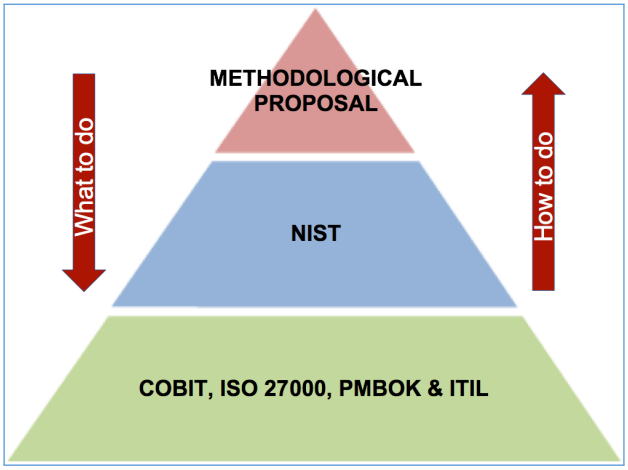

Figure 1: Modeling of IT frameworks & Methodological proposal

Secondly, [1] indicates "what to do?" to evaluate and mitigate ICS risks. In the case of the management proposal for ICS security, it is indicated "how to do it?"

Although COBIT, ISO27000, PMBOK and ITIL are not fully implemented in the case study, it is necessary to use some of their areas of expertise and refer them to fit the methodological proposal into a form, which is already worldwide established. This avoids the occurrence of inaccuracies of concepts that in the future may not articulate in the management of the information security at managerial, operational, and technical level.

3.3 Project to improve the methodological proposal

For the improvement of this methodology and because its implementation requires to perform a considerable amount of tasks with specific deliverables with a defined time, in which the quality of the information is fundamental, having some stakeholders in account, it has become necessary to include in the methodology standards in the field of project management, which help to keep critical success factors controlled (i.e. cost, quality, scope and time). The main

reason for adopting PMBOK [34] has been the better adaptability with NIST, its interdependence and the widespread diffusion that this standard has had in project management.

Prior the implementation of the methodology in an enterprise, several meetings with the responsible of the ICS must be realized. It starts with the collection of information that serves to identify and analyze stakeholders. In line with [34] this point plays a fundamental role in the development and success of a project. Later, a variety of points should be reviewed such as: names and position of who will be the project manager of implementation, identification of the problem to be solved, business need to solve the problem, justifications that lead to implement the methodology in the enterprise, levels of authority of Project Manager, risks that may exist in the implementation, opportunities that the enterprise has with this project, general deliverables, specific deliverables, and pre-allocated resources (i.e., financial, material and human resources). With all this information two documents need to be elaborated to begin the project of implementation of the methodology such as Project Charter and Power-Interest Matrix Stakeholder (see Figure 2). In consonance with [34] the Charter Project must be signed before beginning the implementation of the methodology in order to formalize the support and participation of the entire enterprise. The signers of the charter project are the Project Manager and the Chief Executive Officer (CEO), who is the first and most important stakeholder.

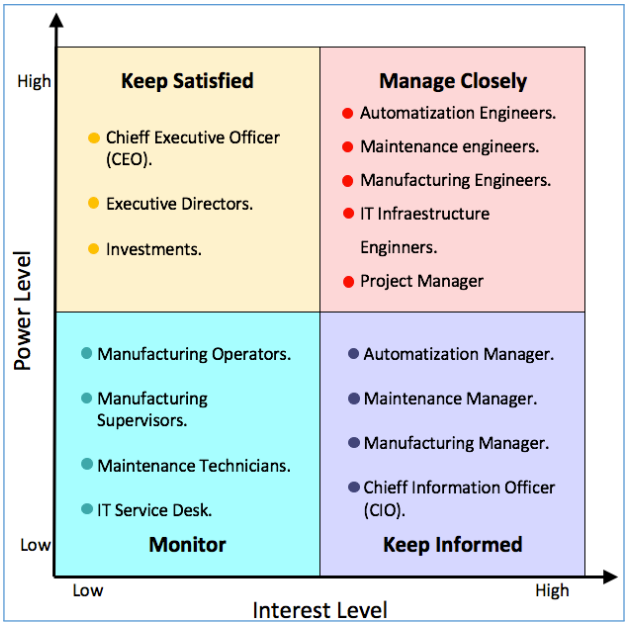

Figure 2: Power-Interest Matrix Stakeholders of the implementation project.

As stated in [34], the analysis of the power-interest matrix stakeholders illustrated in Figure 2, allows identifying who are the experts of the ICS. Moreover, there it's stated that all the workshops and meetings that are needed to obtain the information, which will be vital for the success of the implementation, must be carried out.

Figure 2 illustrates that these experts are those located in the quadrant entitled "Manage Closely" (e.g. Engineers of automation, maintenance, manufacturing, and IT Infrastructure Engineering Engineers). Shown in the "Keep Satisfied" quadrant, investors, executive directors, and the CEO will be placed, because they are only interested in the project for adequate results for the enterprise. Besides, in the "Keep Informed" quadrant, there are all those who are interested in implementing the methodology, but are not directly involved within. Finally, in the "Monitor" quadrant, the managers are placed in charge of monitoring what is being implemented and when the methodology is already in place to notify about the incidents and problems that may appear.

Given the experience gained in the implementations acquired by the research team, it is recommended to meet with the project implementation team and the Project Manager to assess progress and review the project's risk status once a week. As inputs, surveys should be carried out by the experts of each workshop and meeting, with whom the methodology is being implemented. In section 4, evaluation of results and discussion implies such behavior. In order to obtain the results of the surveys carried out by the experts, the following formula has been used (see equation 1):

$$P_m = \frac{\sum_{n=1}^{q} (R_m)_n}{q} \; (m=1,\ 2,\ 3,4) \qquad (1)$$

Where "P" is the average of the answers of question number "m"; "n" is the workshop session number; "q" is the number of the last workshop; and "R" is the qualification the expert gave to each question.

Once the adaptation and improvement of the proposed methodology is planned, starts the implementation of the methodology, being divided into three phases represented in Figure 3. A brief schematic description is provided below:

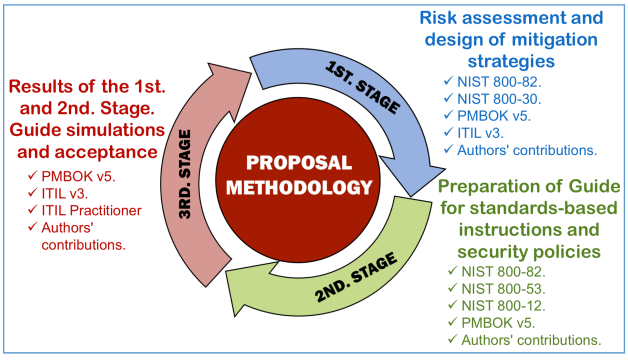

Figure 3: Stages of the methodology proposed, as adapted by [27]

Unlike the previous version presented in [27] and as illustrated in Figure 3, in this extended version, areas of knowledge of both PMBOK and ITIL have been added in blue colors in the three stages of the proposed methodology. In stage 1, the PMBOK, NIST

and ITIL stakeholder management were used to assess risks in ICS components and services, design of mitigation strategies, including the authors' contribution. In the second phase, only PMBOK stakeholder management are incorporated together with what NIST suggests in the preparation of the guide for standards-based instructions and security policies, as well as the contribution of the authors. Stage 3 includes PMBOK stakeholder management, ITIL service strategy catalogs, ITIL service design and communication management suggested by ITIL practitioner, and the authors' contributions.

3.4 Risk assessment and design of mitigation strategies for ICS

The first process in the methodology of risk management is the evaluation of threats and vulnerabilities, according to [1]. To perform such task, the subsequent steps are followed:

Step 1. The characterization of the system. In agreement with [34] it is determined with the whole system of hardware, software, connectivity, data, personnel support and execution processes. They also take into account the revision of existing documentation, the use of exploration tools, questionnaires and stakeholder interviews of the "Monitor" and "Manage closely" quadrants of the Power-Interest matrix (Figure 2).

Step 2. Identification of threats. For this step, we have drawn a table with sources based on threats [25], motivations, actions that would yield these threats and a comment of the stakeholders if necessary. Those responsible for conducting workshop sessions from step 2 through step 8 are the stakeholders of the "Manage closely".

Step 3. Identifying Vulnerabilities: Interviews were conducted, information related to recent incidents has been gathered and subsequently analyzed. Furthermore, documentation risks of the enterprise, I-CAT NIST database vulnerability, and security requirements were check-listed and later analyzed according to [35]. Although other ways to identify vulnerabilities have been available as proposed by [32], we have used a simplified version of the proposed methodology as suggested by [30].

Step 4. Analysis of Controls: A variety of control methods, control categories, and analysis techniques of control according to [24] were taken into account. The results have been documented due to the realization of workshops.

Step 5. Determination of Probability (P): The motivation of the source of threat (TM), the nature of vulnerability and the effectiveness of controls (EC) according to [24] were considered. In this respect:

1. If TM=High and EC=low, then P=1 (High).
2. If TM=medium and EC=medium, then P=0.5 (Medium).
3. If TM=low and EC=high, then P=0.1 (Low).

Step 6. Determination of Impact: The mission of the ICS has been to review the data criticality and to respect the sensitivity of the data and the information security [38] within the enterprise. In the present case study, the mission, the vision, the strategic plan of the enterprise and the documentation ISO 9001: 2015 held by the enterprise were analyzed.

Step 7. Risk Assessment (R): The risk assessment has been estimated according to the probability of threat sources (P) and the corresponding magnitude of the impact (I). Thus: R = P x I. The risk scale has been used by [24]: being HIGH when 100> value> 50, MEDIUM when 50> value> 10 and LOW when 10> value> 1.

Step 8. Recommended Controls: The recommended controls aim to reduce the vulnerability and risk level of the ICS and its data to an acceptable level for the enterprise, which needs to take into account the lowest possible costs and impacts.

Step 9. Documentation Result: A final report about the achieved results has been developed and afterwards addressed to the stakeholders, being rather systematic and analytical than accusatory in any form. However, finally in the present case study an executive summary has been elaborated and addressed to the CEO. Furthermore, the methodology for risk mitigation has been performed according to [24] (Figure 4).

In order to complement and verify that the ICS risk analysis has been accomplished, it is further recommended to use a risk assessment with respect of computer services in the ICS. Therefore, it is necessary to pick up the ICS services catalog as indicated [35] and [36]. To evaluate the risks in the IT services at ICS, a brainstorming session is held with the experts, without losing sight of the services catalog. In this way it is possible to analyze the probability and the impact in each of them, in the same way that it has been performed with the components of the ICS.

Regarding the data characteristics of the experimentation, we may point out, that for the accomplishment of the present study, confidentiality agreements have been signed with the enterprise of the case study. Consequently, this prevents the disclosure of detailed information on the characteristics of the components of their ICS. However, it should be stressed out, that regardless of the technology used, the proposed methodology would work properly as it has been focused on both management and technical criteria. Even so, the characteristics of the components have been better detailed described in the following points.

3.5 Preparation of the Guide for standards-based instructions and security policies

The security of an ICS according to [1] is based on a combination of effective security policies and a set of security controls configured properly. Such consider-

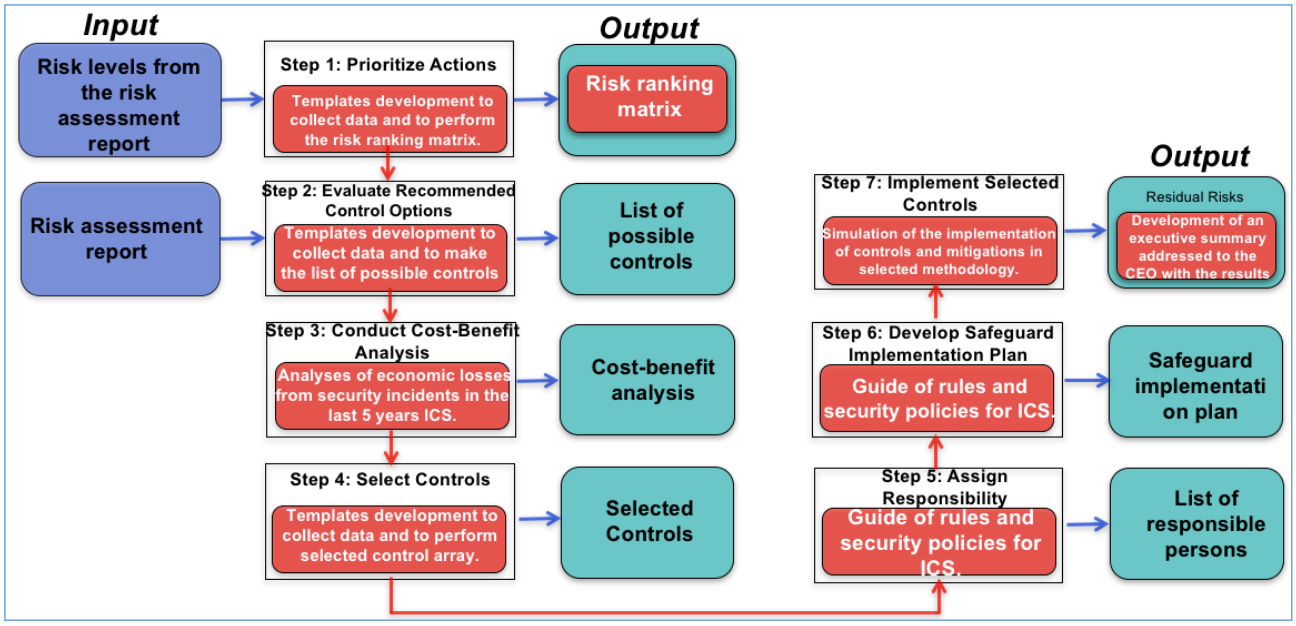

Figure 4: Risk Mitigation methodology conformity with NIST SP 800-30 [24], with Authors' contributions (in red) based on [27]

ations lead to the following five phases:

Phase 1: Meeting with the stakeholders (i.e., the "manage closely", "Keep informed" and "monitor" of the power-interest matrix, Figure 2). The purpose of these meetings is to encounter project requirements, implemented safety controls and other important documentation for the preparation of the manual. For this purpose the basic questions 5W-1H are used.

Phase 2: *Preparation of the guide*. As a reference has been taken of [1] [39] [40] [41], which serve as guidelines for developing security policies. In order to improve to structure the guide, it has been classified into three types of policies: being management, operational, and technical type, operational and technical. The stakeholders of the "manage closely" quadrant (Figure 2) are in charge of conducting the workshop sessions to elaborate phases 3, 4 and 5.

Phase 3: *Management type*. These are according to [1] security countermeasures to an ICS that focus on risk management and information security management: Evaluation of security and Authorization (CA), Planning (PL), Risk Assessment (RA), System and Services Acquisition (SA), and program Management (PM).

Phase 4: Operating Type. According to [1], these are security countermeasures for an ICS, which are executed and implemented mainly by people (i.e., stakeholders of all quadrants of the power-interest matrix, Figure 2): Personal Security (PS), physical and environmental protection (EP), Contingency Plan (CP), Maintenance (MA) and integrity of the information system (SI), media protection (PM), incident response (IR) and awareness training.

Phase 5: *Technical type*. According to [1], the technical types are security countermeasures to the ICS, which are primarily implemented and executed by the system through mechanisms containing hardware, software or firmware of the system: Identification and authentication (IA), Access Control (AC), Audit and Accountability (AU), System Protection and communications (SC).

4 Evaluation of Results and Discussion.

As indicated in section 3, this study includes the results of evaluations of experts' perceptions regarding the methodology implementation project. These were completed after each workshop session lasting between 60 and 120 minutes. This has been achieved by being informed of how the project is being implemented and better managing the risks related to its factors of success. The questions that were given for these evaluations were the following:

Question 1: Do you think that the time you took to collaborate in this workshop add value to the enterprise? Possible answers: Much (100%), Very (75%), little (50%), Very little (25%) and Nothing (0%).

Question 2: Do you think that the team that worked in this workshop provided all the necessary information? Possible answers: Yes (100%), something (50%) and No (0%).

Question 3: Do you agree that this workshop covered all aspects related to the scope of the project? Possible answers: Yes (100%), something (50%) and No (0%).

Question 4: How would you rate the time that has been used for this workshop? Possible answers: Very productive (100%), productive (75%), Normal (50%), Unproductive (25%) and Nothing Productive (0%).

Figure 5 reveals the averages of the answers to the questions asked in each evaluation according to each of the interested areas indicated in the "Manage Closely" quadrant of the Power-interest matrix indicated in section III: Maintenance, Process, Automa-

tion, and IT infrastructure of Figure 2.

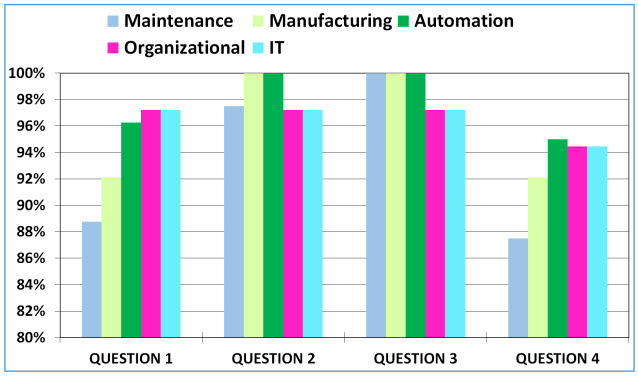

Figure 5: Averages of the scores of the expert's evaluations in the project.

Although the first and the fourth question are similar, it should be noted that the first one assesses whether there is added value to the enterprise or not. In contrast the fourth question assesses the productivity of the expert who has been present. The average answers to question 1 range from 88% to 97%, while the answers to question 4 range from 87% to 95%, respectively. This means that the experts are aware that their time in the implementation of this project gives value to the enterprise. However, it is not very productive or fun for them to spend any given time talking about the subject since their professional profile is more technical than administrative. These results allow important clues about how the project is performing in terms of the cost that the enterprise is investing in implementing such methodology. In addition, it demonstrates if there is any need to motivate the experts with an incentive, which may be analyzed later by the area of human resources and the project manager. In turn, these results indicate that there is a likelihood that the time-cost risks of project experts will be activated, as well as risks due to schedule delays due to fatigue or lack of interest. This information helps the project manager as well as the implementation team of the methodology. In current implementations, the subject of communication with stakeholders has been based on [42] and [34] and is being started in order to mitigate these project risks at the time of its execution.

The averages of the answers in question 2 indicate that the quality of implementation of the methodology is on track, since the corroborating ranks range from 97% to 100%. This question induces to the experts to unholy anything saved for them and to contribute with the vital information required. Also, it indicates to the Project Manager that the risks regarding the quality of the project are unlikely to be activated.

The answers to question 3, range from 97% to 100%, which indicates that the risks in scope are less likely to be activated.

After analyzing the results of risks of the implementation of the methodology, we have proceed to analyze the results of the risk assessment and design of mitigation strategies for ICS. These resulted in five visible threats, 15 vulnerabilities, 17 resulting risk and ten suggested mitigation strategies.

In this study, we assessed the risks from the perspective of ICS components and also of the informatics services. Therefore, the result of lifting the catalog of services according to [35] and [36] of the manufacturing process of the product "P" in the production line "L" is illustrated in Figure 6. There, they found 13 IT Services, 18 Information Systems and 26 informatics components. The risks found in the IT services coincided with items 1,2,6,8 and 9 mentioned in Table 2, and their mitigations would be the same as those analyzed with NIST. For other ICS manufacturing processes the same procedure may be performed.

As for the results obtained in the development of mitigation strategies, as mentioned in section 3, these are directly linked to the cost-benefit analysis presented to the enterprise (case study). Specifically, these indicate a deficiency in the management of the Information Security of this ICS, which forms it adequate to apply the proposed methodology.

Table 1 illustrates the considered variables. These indicate the investment costs of the implementation of the strategies versus the losses if the enterprise avoids the implementation of the methodology. Based on such calculations, the monthly cost of unavailability of the two production lines may reach between $ 109,000.00 in the first production line and $ 226,400.00 in the second production line. These calculations were obtained taking into account an hourly value of $ 5.01, with a total of 160 working hours per month. Total costs of implementation of mitigation strategies have reached up to $ 170,400.00 (i.e. estimated total costs of implementing technology, processes, and personnel requirements for the ten largest mitigations) compared to $ 1,422,760.00, which would be the cost of not implementing them. With these results, we follow that the best decision for the managers of these companies is the application of the proposed mitigation strategies. As mentioned in [38], it is confirmed that availability and integrity are more important than confidentiality in an ICS. Therefore, at this point we may suggest the development of a software application for the management of ICS that is able to evaluate the risks and the cost benefit of information security decisions in a fast and effective way.

The results of the simulations of the application of the above mentioned mitigations are listed in Table 2. The residual risk has been reduced in most cases from 100% to 10%, as well as the probability of execution of the threats. However, the impact remained almost unchanged. Simulations include only risks that would potentially have a high impact on SCI. The other minor risks should not be ruled out, but were carried out in a similar analysis, which produces a complete risk management in the ICS. Analyzing the whole context, we are able to appreciate that the continuous changes in the processes, the behavior of the people and the technology documented in this study, besides the in-

Table 1: Cost–Benefit Analisis

Number	Strategy/Control	Impact of implementation	Aditional costs/ investment	Impact of omited implementation	Aditional costs/ investment
1	Implentation of antivirus and firewall in the network ICS	MEDIUM	$24.000	HIGH	$81.750
2	Implementingan application, whic changes control and manages backups	MEDIUM	$20.000	MEDIUM	$226.400
3	Introduction of a security cameras system in control rooms	LOW	$24.000	HIGH	$60.000
4	Implementation of an application for asset management and inventory	LOW	$15.000	HIGH	$60.000
5	Acquisition of an additional PLC to quality control and later integration into the network	MEDIUM	$16.000	HIGH	$283.000
6	Introduction of an authentication a system (where possible) and daily backups	MEDIUM	$14.000	MEDIUM	$251.550
7	Physical access controls in control rooms	MEDIUM	$15.000	HIGH	$134.160
8	Introduction of a coordination procedure between Automation and IT	LOW	$2.400	HIGH	$45.000
9	Review of software licensing and other major equipment programs for the maintenance of ICS	MEDIUM	$24.000	HIGH	$226.400
10	Documenting algorithms and programs for changes of PLC	LOW	$16.000	MEDIUM	$54.500
			$170.400		**$1.422.760**

dications of [43], demonstrate that it is essential to mitigate and reduce the risks in an ICS. This leads to a risk assessment and mitigation strategy to be performed at least once a year.

For the Guide for standards-based instructions and security policies, the different formats and templates used by the enterprise for this type of documentation have been used. In order to carry out the evaluation of the Guide, a ten-person committee composed of management, technical and operational personnel (stakeholders of the quadrants: "manage closely" and "keep informed") was elected. This group had the task of reviewing, commenting, and proposing changes to improve the content of the policy manual. The collected responses were subsequently evaluated using statistical formulas and graphs (frequency, means, fashion, median, standard deviation and central tendency) as an evaluating tool to visualize the results (Figure 7). From a total of eleven data, the acceptance percentage has a median of 75%, an average of 79.09% and an acceptance for most questions of about 90% (fashion). In general, the Guide lists 18 clear and precise guidelines, which contain the point of view of management and the enterprise, thus considering all aspects of the management of the ICS safety guide. Therefore, it complies with what it stands for [12], where a policy also helps to reduce investment costs in technology control, induced by appropriate management processes and assigned functions.

Due to the Guide evaluation, the low values of about 55.24% may reflect poor judgment or knowledge of the contestants, in which an additional survey may be able to analyze its potential causes. Nonetheless, evidently users accept the Guide, allowing having high expectations that its application will significantly improve management and reduce potential future incidents.

In the Guide-induced simulations, ten stakeholders were consulted (i.e. from the "manage closely", "keep informed" and "monitor" quadrants, Figure 2). Figure 8 illustrates that out of a total of 100 data (ten questions asked to these 10 ICS stakeholders), the percentages of perception of policy compliance vary from

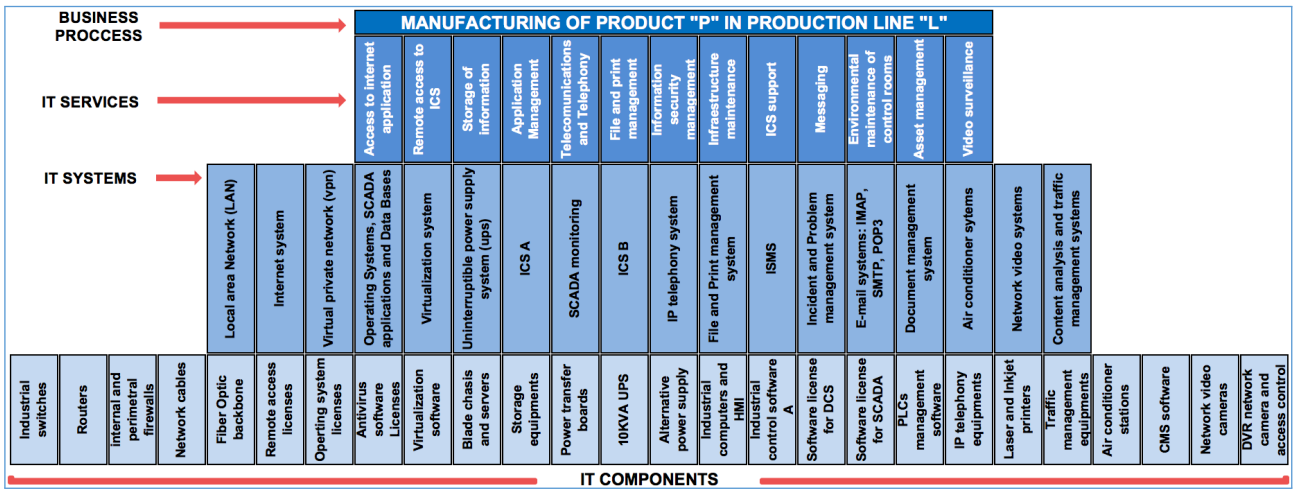

Figure 6: Services catalog of Industrial Control System.

Table 2: Results of The Simulation of Applications of Mitigation Strategies on ICS(The Top 10)

Item	Risk description	Probability	Impact	Risk	Strategy mitigation	Probability	Impact	Residual risk
1	Virus infection and malware network of ICS	1	100	100	Implementation of antivirus and firewall	0,1	100	10
2	Information loss and configuration errors in the ICS	1	100	10	Implementing an application for managing change controls and backups	0,1	100	10
3	Robbery of computers and devices of the ICS backup	1	100	100	Introduction of a camera security system in control rooms and workshops	0,1	100	10
4	Critical infrastructure lacking insurance policy	1	100	100	Implementation of an application for asset management and inventory	0,1	100	10
5	Damage of PLC of Quality Control in the 2nd production line (Outdated equipment)	1	100	100	Acquisition of an additional PLC for quality control, program support, and integration into the control network	0,1	50	5
6	Intentional alteration of information of the ICS	0,5	100	50	Introduction of an authentication system where possible and daily backups	0,1	100	10
7	Failures in ICS caused by unauthorized persons	0,5	100	50	Implementation of physical access controls	0,1	100	10
8	Improper acquisitions by outdated information security technology	5	50	50	Introduction of adequate and contemporary coordination procedure between Automation and IT	0,1	50	5
9	Inadequate sizing of technology resources in ICS maintenance	0,5	100	50	Regular software licensing review and other major equipment programs for the maintenance of ICS	0,1	50	5
10	Allen Bradley PLC Failure (control room 3)	1	50	50	Documenting Algorithms and programs for changes in the PLC	0,1	50	5

15% to 80%, while the average perception of compliance yielded an average of 41.05% and a median of 45%. Despite the negative trend shown in this figure, the slope (about 45 degrees) indicates a reliable distribution of the data collected for this analysis. On the other hand, as illustrated in Figure 8, 60 of the 100 questions answered are between the average (41.05%) and 80% of the fulfillment of perception. This may be considered as satisfactory values of the simulation. It is therefore thought that in the future stakeholders will support the improvement of the proposed methodology for the security of management information in ICS once they become familiar with such a procedure.

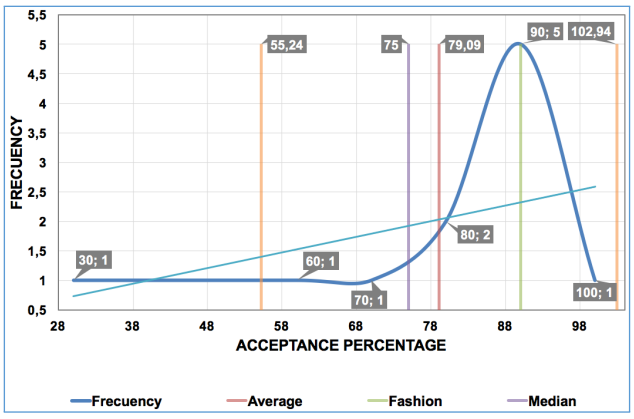

Figure 7: The statistical process, which results by the evaluation of the acceptance of the Guide for standards-based instructions.

In Figure 9 the perception of compliance with the application of the manual that are outside the range between 20.61% and 61.49% may result from the lack of judgment or even ignorance of the respondents regarding the Security of the ICS, since it is a contemporary and new topic for many professionals in the industrial field.

According to enterprise executives in this case study, the percentage of compliance with other policies and standards manuals of the organization vary in the range of 40% to 50%. This suggests that 40% is not a coincidence but the result of the organizational culture of such an enterprise. According to these results a proposal of a follow-up may rise, where the target may be of how an organizational culture has a potential impact or relation with the compliance of the rules and policies of an enterprise. Simultaneously, it should also be considered to propose the development of a software application that simulates the performance of the manual, in order to be able to determine the degree of information security management of an ICS that is a useful tool for the managers and stakeholders of the quadrant "Manage closely".

Finally, the proposed approach and the set of industry standards analyzed in this study have been complemented with each other. Therefore, the substantial difference is situated in the amalgamation and articulation of proven techniques, methods, and the adaptation of other standards, referential frameworks, and management systems that have been used in IT for both project management and industrial security in the same place where the facts are occurring. This allowed significant improvements to effectively and holistically manage the different and complex areas, which coexist in the ICS: business, computing, electronics, automation, production processes and people.

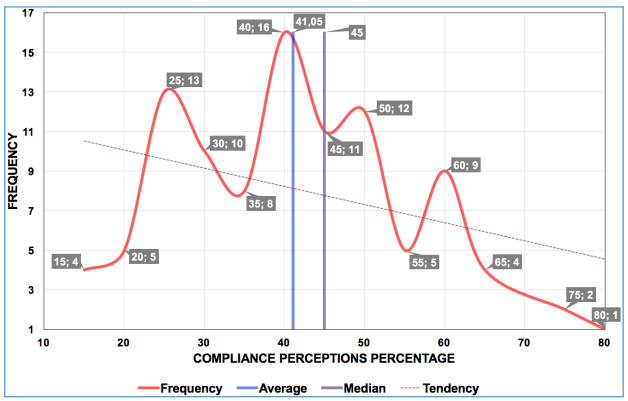

Figure 8: The statistical process, which resulted by the perception of the compliance of the Guide for standards-based instructions.

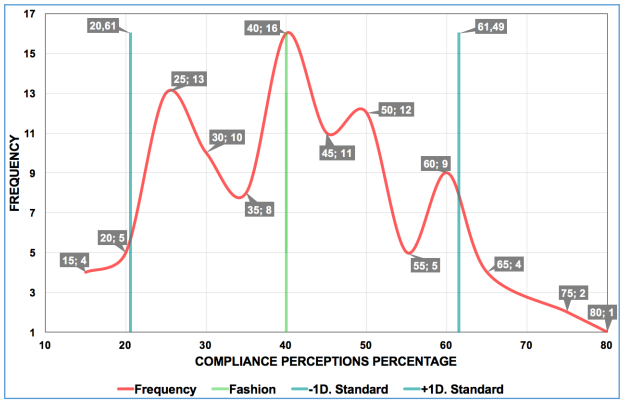

Figure 9: The statistical process, which results by the simulation of the application of the Guide for standards-based instructions.

5 Conclusions and Future Work.

Based on the results obtained, it is concluded that the set of mitigation strategies and the Guide for standards-based instructions and security policies for a manufacturing enterprise may achieve a reduction of 40% of security incidents in its ICS in the contexts of availability, integrity and confidentiality of information. At the same time, it is observed how the project of implementation of the methodology has been favorably accepted by the stakeholders creating motivation, collaboration and synergy in the areas that use, operate and manage the ICS. As for NIST 800, PMBOK, COBIT and ITIL, it has been perceived that they are highly strategic international standards, robust and in line with the management proposal presented for the ICS. That means that in turn, that the management proposal is perfectly articulated with the managerial, operational, technical areas of such enterprise. The proposed methodological process may be compared with ISO 27000 ISMS, being recommended to be used in manufacturing companies to manage information security in industrial control systems.

As future lines of studies, it is planned to combine the proposed methodology with DSS02, DSS03 and DSS04 of COBIT 5, the ITIL service operation stage, and a general guide of information security policies as well as norms throughout the enterprise according to ISO 27000, and NIST 800-82, in order to maintain proper management of traditional IT and ICS. In addition, the design and implementation of an information security incident response team (CSIRT) for ICS, based on NIST 800-61 as a framework and ITIL V3, has also been considered in order to analyze the involved computer services.

Conflict of Interest. The authors declare not to have any conflicts of interest.

Acknowledgment. We would like to thank Comercializadora San Remigio and in particular Engineer Rafael Simon (CEO) for allowing to apply the concept of this study and also the analysis of the required information for this research. This work has been partially funded by the Universidad de las Fuerzas Armadas ESPE within the research project entitled "Training Computational Platforms, Experimentation, Management, and Mitigation of Cyber security Attacks", Code: ESPE-2015-PIC-019.

Word segmentation

ABSTRACT

The unsupervised morphology processing in the emerging mutant languages has the advantage over the human/supervised processing of being more agiler. The main drawback is, however, their accuracy. This article describes an unsupervised morphemes identification approach based on an intuitive and formal definition of event dependence. The input is no more than a plain text of the targeted language. Although the original objective of this work was classical Arabic, the test was conducted on an English set as well. Tests on these two languages show a very acceptable precision and recall. A deeper refinement of the output allowed 89% precision and 78% recall on Arabic.

1 Introduction

This article is an extension of work originally presented in Proceedings of 4^{th} Saudi International Conference on Information Technology (Big Data Analysis) [1]. The article discusses one of the main challenges in computational linguistics is the identification of morpheme boundaries [2, 3, 4]. Boundary detection process plays a central role in extracting stems from words [5]. Moreover, the noisy infixes affect the performance of some tasks such as similarity computation [6, 7, 8]. The fascinating results of this process performed easily on specific examples made computer learning of language morphology a desirable approached for a long time; as are simple problems hiding dissuasive details. As a result of that, Zelig Harris [9] way of segmenting words into morphemes by only counting letters that may occur after a prefix and marking the picks seems to be the first approach published. Since that, investigations did not cease on building a model easily maintainable to grasp how words are coined in a human language. Benefits of unsupervised approaches step beyond avoiding costly human efforts on known languages. These approaches also have the advantage of being fast enough and to some extent language independent.

In Semitic languages [10, 11] such as Arabic, the challenge is even harder because of the irregularities, like mutations and diphthongs situations. Mutation means that one letter can be replaced by another to fit the pronunciation. Take the Arabic word "اضطجع" ([ADoTajaE]: lie-down)[1] comes from applying the pattern "افتعل" and then mutates the third letter "ت" ([t]: 3^{rd} Arabic letter) to "ط" ([T]: 16^{th} Arabic letter). This mutation also can be shown with a long vowel[2] deleted or replaced by another. For example, the past tense of the verb "قول" ([qawl]: say) is "قال" ([qaAl]: said) by mutating "و" ([w]: 27^{th} Arabic letter) into "ا" ([A]: 1^{st} Arabic letter), whereas the imperative form of the same verb is "قل" ([qul]: say) with the letter "و" ([w]: 27^{th} Arabic letter) deleted. The second situation, diphthong; means that two consecutive identical letters are merged into one letter. For example, the word "شد" ([$ad~]: pull) is originally "شدد" ([$adoda]).

The proposed approach is developed to the design of a fully computerized (i.e., unsupervised) extraction of the morphemes. In light of this goal, the approach uses simple and intuitive statistical feature extracted by reading a corpus of plain text with no tag to become able to identify the morphemes boundaries. The approach also was compared with an existed approach named Morfessor [13]. Although the original goal of this work was to address the much

[1] In this article, Arabic is represented in some or all of three variants according to context: "Arabic word" ([Buckwalter Arabic transliteration] [12]: English translation).

[2] Three Arabic letters have long vowels: "ى" or "ا" ([A]: 1^{st} Arabic letter), "و" ([w]: 27^{th} Arabic letter) and "ي" ([y]: 28^{th} Arabic letter)

richer vocabulary of the classical Arabic, the test was conducted on an English set as well. The results are a proof of concept that unsupervised techniques can accurately handle a morphology as complex as the one of a legacy Semitic language.

The study brings the following values:

1. A model: An intuitive but formal model was developed for morphology learning based on a simple interpretation of the probabilistic dependence [14] to segment a word into morphemes.

2. Languages

   - Classical Arabic: The performance of the model was reported on the morphology of the classical Arabic, which is the language of a huge legacy literature. Arabic morphology is more complicated than simple languages [15]. Because of these complex features, some of the methods widely used in many languages cannot be applied to Arabic [6, 11]. On the other hand, two known varieties of Arabic are classical Arabic and Modern Standard Arabic (MSA). MSA is based on the classical Arabic. However, MSA is used more in informal speech and can combine words borrowed from other languages that may not use Arabic rules. In contrast, the classical Arabic has been used to write literary legacy and traditional vocabulary. It contains purer Arabic words than MSA. Moreover, Arabic morphological and semantic rules are derived from the classical Arabic. At the same time, the researchers on Arabic are paying most of their attention to MSA. To the best of our knowledge, the only studies taking into account the classical Arabic are limited to religious texts.
   - Other Languages: The performance of the model was tested on a concatenative language namely English. It has a totally different degree of morphological complexity from Arabic [16].

3. Comparison: The performance of another word segmentation approach named Morfessor was reported on the same dataset.

4. Corpus: It is a language resource defined as a collection of texts stored in a machine-readable format. To assess the proposed approach, we had to build a corpus of classical Arabic texts authored in the period from 431 to 1104 (in Hijri between 130 b.h and 498 h) counting around 122M words in total and 1M distinct words.

The remaining parts of this article are organized as follows: Section 2 reviews existing methodologies on detecting morpheme boundaries. Section 3 introduces the proposed approach and explains its algorithm. Section 4 discusses the tests and the results it carried out. Finally, section 5 concludes with a summary of contributions and makes suggestions for future research work.

2 Applied Methodologies

One of the oldest published work on unsupervised word segmentation is due to Harris who suggested a process to break a phonetic text into morphemes [9] using only successors numbering. Bordag [17] partially relies on Letter Successor Variety (LSV) due to Zelig Harris [9, 2, 3] and combines it with a trie based classifier [18]. The approach is claimed to reach 67.48% F-measure. Bernhard [19] too combined the same principle of successors variation with a set of heuristics to filter out the less plausible segments. The F-measure is claimed to reach 60.81%.

One of the well-known systems in this area is Morfessor, developed by Creutz and Lagus [13]. Morfessor tries to capture the morpheme boundaries in a probabilistic model with simplistic features such as the frequency and the length of the morpheme. For comparison, we investigate this approach deeper in Section 4.1.4. Eroglu, Kardes, and Torun [20] tried to make Morfessor 1.0 accommodate the phonetic features of the Turkish language. By adding phone-based features the tried to measure the phonemic confusability between the morphemes. Their results are claimed to be better than Morfessor's for Turkish, Finnish and English. Pitler and Keshava [5] use the forward and backward conditional probability to build a list of substantial affixes. They report a 52% F-measure on their test set and 75% on the gold-standard.

A number of works depend on Markov Models (MM).Melucci and Orio [21] investigated the use of the Hidden Markov Models (HMMs). The evaluation though is done on a whole information retrieval system (extrinsic) [22]. Naradowsky and Toutanova [23] designed a model, which tries to exploit the alignment of morphemes in a source language to the morphemes in a target (machine translated to) language. With different settings of the model, the approach is claimed to reach 84.6 F-measure for Arabic.

Peng and Schuurmans [24] proposed a two-level hierarchical Expectation Maximization (EM) model. Their test set holds 10K words and their results are claimed to reach 69% F-measure. Poon, Cherry and Toutanova [25] use a log-linear model [26, 27] to capture the features inherent to the morpheme itself and its surrounding letters. The authors tested the approach on supervised and semi-supervised settings as well. The unsupervised settings reached a 78.1% F-measure for Arabic and 70% for Hebrew.

It is worth mentioning that, the actual list of similar works is longer. Thus, we limited the overview to the previous works only. Some of the extra works are in the surveys [28] and [29] that provided for the interested reader. In light of the proposed goal in this article, this section intentionally avoids supervised approaches [30].

On the other hand, other works in real environments use the segmentation technique in their approaches, such as document image retrieval systems [31, 32].

3 The Proposed Approach

The word *"unbreakable"* is coined by concatenating the prefix *"un"*, the stem *"break"* and the suffix *"able"*. The vocabulary, which suggests such segmentation, should contain other words with different combinations of prefixes, stems and suffixes (e.g. *"rebreakable"*, *"unbreaking"*...etc), which makes the occurrence of *"un"* have a weak dependence to the occurrence of *"break"* whose occurrence is also relatively independent of the occurrence of the suffix *"able"*. On the other hand, each morpheme is supposed to be inseparable from neither its first nor its last letter. The proposed approach (Dependence-Based Segmentation) is all about exploiting these two facts. A good formal modeling of these facts is the definition of the probabilistic dependence [14].

3.1 Segmentation Algorithm

Algorithm 1 iterates over the word W letter by letter and computes for every letter w_i two dependences: 1. the dependence of the prefix on w_i as its last letter, 2. the dependence of the suffix on w_i as its first letter where the prefix ends (inclusive) at w_i and the suffix starts (inclusive) at it. The difference then points to which of the two (i.e. the prefix or the suffix) is more attached to the current letter w_i. The algorithm keeps going until it encounters a change of the direction of the attachment. The change is done when the prefix depends on the preceding letter w_{i-1} more than the suffix does, and at the same time the suffix depends on the current letter w_i more than the prefix does. Then between the previous and the current letters a cutting point (CP) is marked.

3.2 Computation of the Dependence

The concept of dependence we use is symmetric [14]. In this context: *"the string depends on the letter"* means *"the letter depends on the string"* and vice versa.

We will call the dependence of a letter a on the prefix α: the forward dependence, and we denote FD(u) where u=αa is the prefix tailed by the letter under processing a. We call the dependence of the letter a on the suffix β: the backward dependence, and we denote BD(v) where v=aβ is the suffix headed by the letter under processing a. We also mark the beginning and the end of a word by respectively # and $. The forward dependence is then:

$$FD(u) = \frac{P(\alpha \rightarrow a)}{P(a)} \tag{1}$$

$$BD(u) = \frac{P(a \leftarrow \beta)}{P(a)} \tag{2}$$

Where $P(\alpha \rightarrow a)$ is the conditional probability:

$$P(\alpha \rightarrow a) = \frac{Count(\alpha a)}{Count(\alpha)} \tag{3}$$

and $P(a \leftarrow \beta)$ is the conditional probability:

$$P(a \leftarrow \beta) = \frac{Count(a\beta)}{Count(\beta)} \tag{4}$$

$$FD(u) = \frac{Count(\alpha a)}{Count(\alpha)P(a)} \tag{5}$$

$$BD(u) = \frac{Count(a\beta)}{Count(\beta)P(a)} \tag{6}$$

Where the probability of a letter a: P(a) is estimated by its normalized frequency in the corpus.

$$P(a) = \frac{Count(a)}{\sum_{b \in \mathcal{A}} Count(b)} \tag{7}$$

Where $\mathcal{A}$ is the alphabet. Count(α) expresses how often an n-gram α occurs in the corpus.

By the definition of the dependence measure [14], when both forward and backward dependencies at the same letter are lower than one, this means that the letter does not depend on the prefix or the suffix. Thus, we assigned zero to the difference's value and discarded this position from the segmentation process. This dependence is called a *negative dependence* [14].

After segmenting a word using the cutting points, we supposed that a morpheme with the least frequency among the other morphemes is a stem and the other morphemes are affixes.

Arabic example: The Arabic word "الكتابان" ([Al◦kitaAbaAk]: the two books) contains two cutting points as shown in Table 1. The first one occurs when the second letter "ل" is more dependence on the prefix "#ال" than the suffix "لكتابان$, while the third letter "ك" is more dependent on the suffix "كتابان$" than the prefix "#الك". The second position is the sixth letter "ب" when the dependence tendency is changed. Thus, these two cutting points "ال|كتاب|ان" produce the following morphemes: "ال", "كتاب" and "ان". Consequently, the morpheme "كتاب" is the stem depending on the frequency list in Table 3.

Negative dependence example: The Arabic word "كتيب" ([kutayb]: small book) does not contain any cutting point as the table 2 shows it. Consequently, the morpheme "كتيب" is the stem of the word. At the same time, we can note the second letter "ت" ([t]: 3^{ed} Arabic letter) has zero as its difference value. That means both forward and backward dependencies are less than one.

English example: Table 4 is a simulation of the algorithm on the word *"unbreakable"*. The difference at each letter ($FD(u)$-$BD(v)$) points a dependence direction of that letter. In other words, the positive difference means that the current letter w_i is more attached to the prefix $w_{1...i}$ than suffix $w_{i...n}$ and vice versa. The second letter *"n"* depends on the prefix *"#u"* more than it does on the suffix *"breakable$"*, where the third letter *"b"* depends on the suffix *"reakable$"* more than it does on the prefix *"#un"*. This change of the dependence direction makes the point *"un|breakable"* a cutting point. The same logic applies to the seventh letter

Algorithm 1: Word Morphological Segmentation

input : A word $W = w_0 w_1 \dots w_n$
output: Segments of word W
Cutting points: CP
foreach w_i *where* $0 < i \leqslant n$ **do**
  if $FD(\#\dots w_i) < 1$ **and** $BD(w_i \dots w_n\$) < 1$ **then**
    discard this point
  else
    if $FD(\#\dots w_{i-1})$-$BD(w_{i-1} \dots w_n\$) > 0$
    and $FD(\#w_0 \dots w_i)$-$BD(w_i \dots w_n\$) < 0$ **then**
      $CP \leftarrow CP \cup i$
$seg \leftarrow$ segment W at each i in CP
return seg

Algorithm 2: N-grams model construction algorithm

Input : A string of words W
Output: n-grams mapped to their frequency
foreach W *in string* **do**
  W ← '#'+W+'$'
  for $i \leftarrow 1$ *to* $|w|-1$ **do**
    for $j \leftarrow i+1$ *to* $|w|-1$ **do**
      if $w_{i\dots j} \in n\text{-}grams$ **then**
        $freq(w_{i\dots j}) \leftarrow freq(w_{i\dots j}) + 1$
      else
        $n\text{-}grams \leftarrow n\text{-}grams \cup \{w_{i\dots j}\}$
        $freq(w_{i\dots j}) \leftarrow 1$
return n-*grams* and $freq$

Table 1: Arabic example of the segmentation

i	u	FD(u)	v	BD(v)	Difference	Direction
1	ا#	0.991	الكتابان$	7.174	-6.182	↓
2	ال#	9.349	لكتابان$	9.153	0.195	↑
3	الك#	1.017	كتابان$	17.174	-16.157	↓
4	الكت#	0.716	تابان$	1.210	-0.494	↓
5	الكتا#	2.532	ابان$	0.544	1.987	↑
6	الكتاب#	12.067	بان$	1.552	10.514	↑
7	الكتابا#	1.366	ان$	1.865	-0.498	↓
8	الكتابان#	4.560	ن$	1.792	2.767	↑

Table 2: Example of the negative dependence

i	u	FD(u)	v	BD(v)	Difference	Direction
1	ك#	1.125	كتيب$	5.631	-4.505	↓
2	كت#	0.646	تيب$	0.349	0	0
3	كتي#	0.685	يب$	2.030	-1.344	↓
4	كتيب#	6.675	ب$	0.256	6.419	↑

Table 3: A frequency list of chosen words

Morpheme	Frequency	Morpheme	Frequency
un	1,986	ال	72,845
break	46	كتاب	47
able	1,426	ان	10,047

Table 4: English example of the segmentation

i	u	FD(u)	v	BD(v)	Difference	Direction
1	#**u**	0. 46	**u**nbreakable$	30.97	-30. 51	↓
2	#u**n**	6. 36	**n**breakable$	5. 84	0. 52	↑
3	#un**b**	1. 35	**b**reakable$	46. 70	-45. 35	↓
4	#unb**r**	1. 94	**r**eakable$	10. 45	-8. 51	↓
5	#unbr**e**	3. 11	**e**akable$	5. 01	-1. 90	↓
6	#unbre**a**	6. 79	**a**kable$	1. 68	5. 11	↑
7	#unbrea**k**	34. 71	**k**able$	1. 50	33. 21	↑
8	#unbreak**a**	5. 09	**a**ble$	7. 38	-2. 29	↓
9	#unbreaka**b**	46. 70	**b**le$	9. 89	36. 81	↑
10	#unbreakab**l**	9. 72	**l**e$	2. 76	6. 96	↑
11	#unbreakabl**e**	10. 02	**e**$	1. 15	8. 87	↑

"*k*" and the eighth letter "*a*". Therefore, the resulting morphemes will be: "*un*", "*break*" and "*able*". The least frequent morpheme is "*break*" by using Table 3. Consequently, the morpheme "*break*" is the stem.

4 Tests and Results

Before describing the test settings, we will list main steps, that we followed in the study:

1. Build the corpus. (see Section 4.1.1).
2. Make the normalization (see Section 4.1.2).
3. Generate the language model (see Section 4.1.3).
4. Test the proposed approach (see Section 4.1.4) using materials (see Section4.1.5).
5. Evaluate the performance by using the metrics (see Section 4.1.6).

4.1 Test Settings

4.1.1 Test Dataset

Arabic The purpose of the research, which drew our efforts to design this approach, was to address challenges in processing the morphology of the classical Arabic. Works we are aware of try to handle MSA. Actually, MSA is known to include a mixture of words borrowed from other languages and words just coined for the convenience, which usually breaks the classical Arabic rules. Correctly handling the classical Arabic brings three interrelated values: 1. The classical Arabic vocabulary is much richer in terms of pure Arabic words. 2. The Arabic rules in the morphological, grammatical and semantic levels amply documented since the eighth century have been designed on the basis of the classical Arabic. 3. A huge legacy literature is written in the classical Arabic, and most of the time standing beyond the scope of the supervised approaches designed for the MSA. The present corpus[3] gathers Arabic texts dating back from 431 to 1104 (130 b.h and 498 h). It contains around 122M words in total and 1M distinct words with an average size of 6.22 letters per word. Table A.1 in the appendix shows a sample of the index in Arabic that was published with our corpus. Such dataset is by itself a valuable resource for researches in NLP field.

English We obtained the English text by merging the two corpora "wiki" and "news"[4]. This resulted in more than 1M unique words and more than 8M words in total, having an average size of 8.00 letters per word.

4.1.2 Normalization

The normalization process is frequently used to transform text into an approved form, which aids in reducing the noise and sparsity in the text. In present work, the following normalization was applied to the Arabic words:

1. The removal of diacritics.
2. The substitution of all variants of Hamza "ء" ([ˊ]) with the form "ء" ([ˊ]).
3. The substitution of the letter "آ" ([|]) with "ءا" ([ˊA]).

4.1.3 Language Model

The proposed language model extracts all possible q-grams from a word of n length, where q rises from one to n. Then it assigns each gram to its occurrence in the corpus. Algorithm 2 explains the extraction. Table A.2 in the appendix shows the n-grams of the two example words "الكتابان" and "*unbreakable*".

4.1.4 Test Process

Morfessor 2.0[5] and the proposed approach (Dependence-Based Segmentation) are run over the same corpus, then three samples of 100 words each are randomly picked out of the whole segmented corpus. The results of these approaches are evaluated manually. Precision, recall and F-measure of the cutting points are then recorded. This is repeated on each of the four settings combinations where each setting combines one of two occurrence settings with one of two affix settings.

Occurrence Settings

- Distinct: To build the language model, the approach used distinct words, i.e. each word in the corpus occurs one time.
- Plain: The number of occurrences is taken into account during building the model, i.e. a word may occur more than once.

Affix Settings

- Raw: Results sample is picked randomly with no restriction.
- Non-empty affix: Samples are picked randomly only among words for which the proposed approach has carried out at least one cutting point. For a number of words, the segmentation simply did not identify any cutting point. Most of them were because of the scarcity of the stem or stem.affix remaining combination. We then tried to assess the impact of such cases on the performance and how accurate the identified cutting was.

It is worth noting that our objective was to address the challenge of segmenting the classical Arabic words. To the best of our knowledge, there is no suitable gold standard for TA. We had to build ourselves the set of words. Then we proceeded to the manual segmentation of three different randomly picked samples for each setting.

[3] https://sourceforge.net/projects/classical-arabic-corpus/

[4] http://corpora.informatik.uni-leipzig.de/download.html

[5] One of our objectives is to keep the process entirely unsupervised. Thus, we used the latest version without using any optional parameters to discard any semi-supervised extension.

4.1.5 Test Platform

We used the following materials to test the proposed algorithm:

- Operating system: Ubuntu 12.04, 64-bit.
- Programming language: C++.
- Compiler: GCC 4.9.0.
- Database management system: MySQL Server 5.5.43.
- C++ external Library: libmysqlcppconn-dev 1.1.0-3build1 to connect C++ with MySQL server.
- CPU: Intel(R) Xeon(R) CPU E5530 @ 2.40GHz * 16.
- RAM: 6 GB for RAM and 12 GB for Swap.

4.1.6 Performance Metrics

For evaluating, we used three metrics: recall, precision and F-measure [33], where we took into account a number of cutting points during the evaluation.

1. Recall: This metric measures how many correct positions are found among all the existing correct positions. The higher the recall, the more correct positions are found and returned.

$$Recall = \frac{correct\ cutting\ points\ in\ the\ result}{all\ correct\ cutting\ points\ in\ the\ sample}$$

2. Precision: Precision measures how many positions are actually correct among all the positions that the algorithm found. The high precision indicates that the algorithm found significantly the correct positions more than incorrect positions.

$$Precision = \frac{correct\ cutting\ points\ in\ the\ result}{all\ found\ cutting\ points\ in\ the\ result}$$

3. F-measure: A weighted average of the recall and the precision is measured.

$$F - measure = 2 * \frac{Recall * Precision}{Recall + Precision}$$

4.2 Result

4.2.1 Arabic Results

Compared to the English, the results of the proposed approach (Dependence-Based Segmentation)are clearly lower on Table 5. The two obvious causes might be the irregularities in Arabic morphology and the typos in the test set. The latter is confirmed by results obtained when the sample is restricted to the words with a relatively high frequency (thresholded) as shown in Figure 1. Thresholded denotes an additional filter applied to *non-empty affix* sample, where a segmentation is picked only if the affix reappears in more than 1K other segmentations. It is worth noting that we omitted this filter in the English tests because we observed a rise in values of the standard deviation between the three samples. It has fluctuated around 0 to 29 words. Reasons for this deviation need to be investigated more closely in a separate work, and we paid our attention in this work to Arabic results.

Another reason affects the performance which is the lack of a dataset. The proposed approach works totally with the unsupervised method and depends only on the count of words in the corpus. However, it is difficult to include all possible derivatives in the corpus. For example, the derivative "الإجحافات" ([Al◦<ij◦HaAfaAt]: the prejudices) appears one time in the dataset; that is, there is no other derivative that appears in the dataset without the prefix "ال", for instance. Indeed, the word "إجحافات" would be more dependent on the prefix "ال" and the proposed approach does not learn that the prefix "ال" can be cut off from the word "الإجحافات" as shown at the top of Table 6. This problem will be removed if we add the word "إجحافات" into the dataset. The approach then finds the segmentation position "ال|إجحافات" as it appears at the bottom of Table 6.

The segmentation seems to be the best when the word counts are omitted (distinct). This seems to be due to the diversity of affixed in the classical Arabic. Indeed some stems/affixes may not appear more than once in the whole corpus (e.g. "كجخف" ([kajux◦f])as a deep sleep).

Surprisingly, Morfessor was unable to detect any boundary. The expected reason is that Morfessor may not be able to deal effectively with non-Latin letters, such as Arabic letters. We then evaluated Morfessor using Buckwalter Arabic transliteration [12]. Despite the simplicity of the proposed approach, the results of Morfessor is close to the results of the proposed approach especially after applying the filter.

Running the proposed approach over the whole corpus resulted in around 1,805,231 morphemes and 596,358 distinct morphemes with an average size of 5.94 letters per morpheme.

4.2.2 English Results

With no restriction on the results sample, Morfessor outperforms the proposed approach (Dependence-Based Segmentation) in terms of precision where the latter has a better recall as shown in Table 7 . This matches well the results given in [34]. The low recall of Morfessor explains the worsening of its performance with affixed words while the proposed approach improves. The F-measure shows that the overall performance of the proposed approach is better as shown in Figure 2.

When the counts of the words are involved in the computation of the dependence, Morfessor improves. The dependence-base's precision increases too, where its recall worsens.

Table 5: Arabic results

5 Conclusion and Future Work

We investigated the use of an intuitive yet formal definition of event dependence in the detection of morpheme boundaries. The initial target of our work was the classical Arabic, which is a Semitic language recognized to have a complex morphology and a vocabulary richer in pure Arabic words than the Modern Standard Arabic (MSA). The test also was conducted on an English set as well. Results on the classical Arabic and on English have been compared to the results of another unsupervised complicated segmentation approach so-called Morfessor that initially designed for European languages. As simple and elegant as is the proposed approach (Dependence-Based Segmentation) , it seems to be more committed to the recall where the latter's precision is better on English words. This has been confirmed when the evaluation focused on affixed words. On Arabic, Morfessor could not identify boundary. The results are a proof of concept that unsupervised techniques can decently handle a morphology as complex as the one of a legacy Semitic language like Arabic.

In addition, required for the evaluation, we carefully built a pure classical Arabic dataset. Where such linguistic resource is abundant in languages like En-

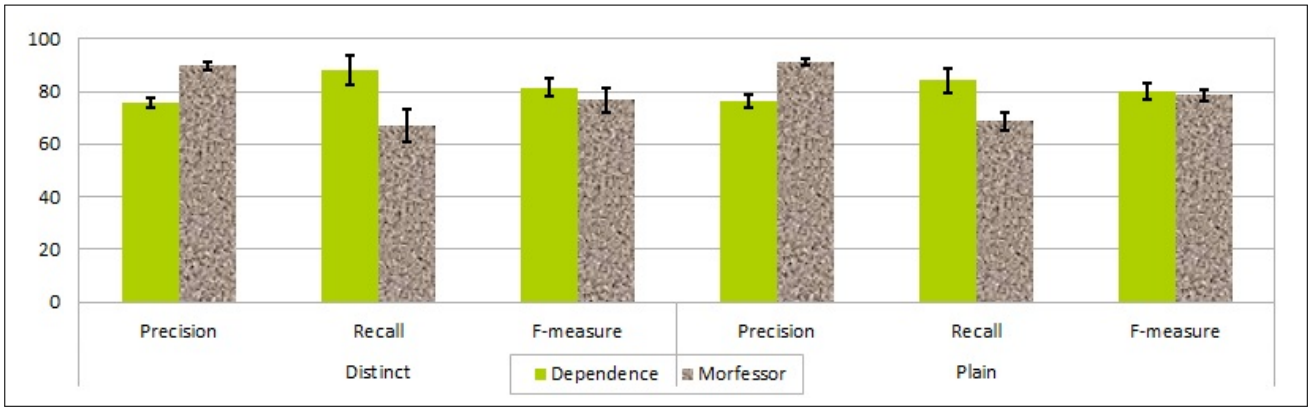

Figure 2: English results of the two approaches

glish, we are not aware of any other classical Arabic dataset.

One of the things made possible by morpheme boundaries identification is the automated word generation. The segmentation of a small set of well-chosen words will result in a set of diverse morphemes. The generation of new words is then a proper concatenation of the resulting morphemes. The challenge is then two folds: to build a suitable word-set of a decent size, which allows an accurate segmentation and a wide coverage of the different morphemes, then to find the appropriate concatenation strategy to minimize the number of irrelevant words.

ABSTRACT

Analysis of Arabic language has become a necessity because of its big evolution; we propose in this paper a rule based extraction method of Arabic text to solve some weaknesses founded on previous research works. Our approach is divided on preprocessing phase, on which we proceed to the tokenization of the text, and formatting it by removing any punctuation, diacritics and non-letter characters. Treatment phase based on the elimination of several sets of affixes (diacritics, prefixes, and suffixes), and on the application of several patterns. A check phase that verifies if the root extracted is correct, by searching the result in root dictionaries.

1. Introduction and Related Works

Arabic is a Semitic language spoken by more than 400 million people as a native language and ranked at the seventh position of Internet users in 2010. However, the task of performing the retrieve of information of Arabic language is very problematic, because of many aspects, such as: polysemy, irregular and inflected derived forms, various spelling of certain words, various writing of certain combination character, short vowels (diacritics) and long vowels, and the spectacular availability of affixes in the Arabic words [1, 2]. Different methods and approaches have been introduced to retrieve Arabic information [2, 3, 4, 5, 6].

To study Arabic morphology effectively, we divide words in Arabic into three self-contained categories as follows:

- ✓ اِسْم: It includes nouns, pronouns, adjectives, adverbs, etc
- ✓ فِعْل: Verbs
- ✓ حَرْف: Particles, articles, and conjunctions

Particles are completely unpredictable; they don't fall into the templatic system (i.e. they have no patterns) nor do they undergo any morphophonemic changes. They are what they are and must be memorized. The up side is that there are relatively few of them in the language – within one hundred.

Nouns and verbs do fall into the templatic system and have very systematic morphophonemic rules that govern them. This includes the study of how verbs are conjugated, how they move from pattern to pattern to enhance their meanings, how the participles and other nouns are derived, how nouns pluralize, etc.

Each declinable noun and each verb is made up of a certain set of base letters, called its root: جذر. (Nouns that are always indeclinable (such as pronouns) usually don't follow this system).

Verbs can have either 3 base letters, or 4. Nouns can have 3, 4 or 5. Now these base letters can be augmented with extra letters, and they can be dropped or changed due to morphophonemic rules as well.

Particles - The third part of speech in Arabic mentioned above is the particle. The meaning of a particle is often understood in the context of the sentence and words before and after the particle. The sign of the particle is that it does not accept the signs of nouns or verbs.

Analyzing Arabic text was treated by many researchers, all of them tried to extract an exact root or stem from a word, there is two ways to treat a text; morphological analyze, which consist to find roots, and there are statistical stemmers that group word variants using clustering techniques.

The first approach of morphological analyze is manually constructed dictionaries based on roots, Kharashi and Evans worked with small text collections, for which they manually built dictionaries of roots for each word to be indexed [7]. Tim

*Corresponding Author : Soufiane FARRAH, 46 Rue 17 Hay Anigret, No +212663782432, Email: f.soufiane@gmail.com

Buckwalter developed a set of lexicons of Arabic stems, prefixes, and suffixes, with truth tables indicating legal combination [1].

Nehar [5] and Taghva [8] introduces new stemming techniques that do not rely on any dictionary, the first one is based on the use of transducers. Nehar [5] proposed also a heavy stemmer that does not use any dictionary of roots. Khoja and R. Garside [2] developed a dictionary-based stemmer, and Larkey [5] developed a Java program based on their own Arabic stemmer that will develop and evolve to take in count some nouns and verbs categories described in the previous paragraph. Taghva [8] proposed IRSI Arabic Stemmer Algorithm, which does not use a Root Dictionary. ISRI stemmer per-forms better than the other approaches on the shorter title queries. For the long texts and narrative queries, stemming made a difference: the Khoja, ISRI, and Light stemmers were significantly better than not stemming. Ghwanmeh [9] presents an Arabic root-based algorithm based on patterns. This stemmer is restricted to native Arabic words that consist of four or more Arabic alphabets.

All algorithms mentioned before have some weaknesses. In this paper, we will prove that the best way of stemming is the one that have a strong preprocessing phase, and it is based on both "patterns check" and "root list".

This paper is an extension of work originally presented in conference [10].

In fact, we present the weakness in Heavy and Light Stemming Algorithms and we try to propose some new solutions for each point treated, then we will compare results of our new stemmer with other ones.

In section II, we present the different areas for improvement in Arabic text classification, in section III we present our approach, and in section IV we present some tested examples and, compare our solution with others.

2. Improvement Areas in Arabic Classification

Light stemming algorithms removes suffixes, and prefixes from words, producing a form of word called "stem" [11], there was many versions of the light stemming algorithms and the last one is light10 [12]. This algorithm after removing punctuation and non-letters, diacritics, Hamza from letter "أ", he replaces final letter "ة" with letter "ه" and then replace final letter "ى" with letter "ي". After that, the algorithm search in irregular word list to find out if the word exists on this table or not. Then the algorithm removes the letter "و" from the beginning of the words if the length of the word is more than three characters, because it considers that this letter is usually a conjunction.

This step generates several errors on stem extraction, I give below some examples:

Word	Stem extracted by Light10
وَبِيل	بيل
وُجُوب	جوب
وَرِيث	ريث

Table 1. Morphology of Arabic Word

As we can see, when removing the letter "و" from the beginning of those words, we change the meaning of the word, for the first word "وَبِيل" it means calamitous; disastrous, and when we remove the letter "و" the word means torch.

In Khoja's Approach, and TC system proposed by M.Hadni, A.Lachkar and S. Alaoui Ouatik in [13], and also in Mohammed N. Al-Kabi who proposed evolution of Khoja's algorithm [14], we find this same issue, so in our algorithm we will take care of this point and we propose to check if the word doesn't exist in the list of words that begins by 'و', and then remove diacritic 'و' (primarily weak vowels), this list is constituted manually and must be maintained regarding the evolution of Arabic language.

The second point we have improved is removing the letter "أ", in Light Approach, Khoja's Approach and M.Hadni's one, this letter is deleted because it is considered as a prefix. The issue is when this letter is a part of word as for the word "أباح" which means "permit", and when we delete it the word means "confide", to solve that, we built a list of words that starts with letter "أ".

The third point we involve in this paper is the stemming of five nouns (أب, أخ, حمو, فو, ذُو), those nouns are excluded from the other single nouns per the syntactic case. They have other marks to indicate them syntactic cases that the other doesn't have. The single noun always depends on rules to indicate its syntactic cases but the five nouns are contradicting those rules. The five nouns aren't depending on al Harakat (vowelization on system) rather than the letters. They have preconditions to be different from other single nouns:

- It has to be adjunct to another noun in other words there must be a noun after it that is genitive noun.
- The noun after must not be (ي) that indicates the speaker [15].

Therefore, for our algorithm, we handle the fives nouns separately.

It is true the orthography in Arabic is less ambiguous and more phonetic with the use of diacritics. For example, a word can be written using the same characters and be pronounced differently. The main purpose of diacritics including vowel marks, known as Harakat a phonetic is to provide, "حركات" aid to show the correct pronunciation. Arabic vowel marks include Fatha "فتحة", Kasra "كسرة", Damma "ضمة", Sukun "سكون", Shadda "شدة" and Tanwin "تنوين". The pronunciation of these vowel marks are represented in Table 2 below:

Double Constant	No Vowel	Tanwin			Vowel		
ـّ shadda	ـْ Sukun	ـٍ in	ـٌ un	ـً an	ـِ Kasrah	ـُ Ḍammah	ـَ Fatḥah

Table 2. Arabic Diacritics

However, in Modem Standard Arabic (MSA), vowel marks are not usually included in printed and electronic text, and the understanding and correct pronunciation of the word is determined within its context by the reader, so we decide not to remove (if it exists), the vowels as a step on preprocessing phase.

3. Important Steps

The method we propose is based on preprocessing step, treatment and check steps, here is a description of each one:

3.1. Preprocessing

In this step we proceed to:

- Divide text into words
- Format the word by removing any punctuation, diacritics and non-letter characters
- Check if the word is a stop word (3)

(3) This step consists on eliminating (very frequent) words that contain no or little information to help discriminate the text they occur in. A large list of stop words are used (Table 3).

إن	أنما	إنما	بعد	ضد
أحد	إلى	في	من	حتى
تلك	كذلك	التي	وهو	به
لكن	عن	منذ	على	وكان

Table 3 Stop Word

3.2. Searching in strange words list

In this step our algorithm will check if the word is a part of strange words (it is a word that comes from another language than Arabic, and used in the modern Arabic language especially), those words exists in a list of Strange words constituted manually (Table 4).

ألمانيا	فرنسا	ديسمبر	أوروبا	إفريقيا
اكلنيكي	ميكانيك	ناهوند	أوباما	بنكيران

Table 4 Strange Words

If the word exists the algorithm returns the word, otherwise the treatment continues.

3.3. Check if the word exists in the list of words that begins by "و":

The stemmer removes letter "و" ("and") from the beginning of the words if the length of the word is more than three characters, and if the word doesn't exist in the list of "Words_begins_by_Waw.txt", because many common Arabic words begin with this character.

ومي	وقر	وصب	وخط	وخض
وهث	وكز	وعع	وغي	وغف

Table 5 Words starting with *"و"*

3.4. Check if the word exists in the list of words that begins by "ال"

The stemmer removes letter "ال" from the beginning of the word if the length of the word is more than three characters, and if the word doesn't exist in the list of "Words_begins_by_AL" (table 6), because many common Arabic words begin with this character.

أتم	أبط	أبض	أبر	أبب
أول	أوض	أوش	أمس	أذي

Table 6 Words starting with "ال"

3.5. Normalization

The third step in the stemmer is normalization of the words. Normalization process in the proposed stemmer is the similar to the normalization process in Light10 stemmer which runs as following:

- Remove Hamza from letter "أ" (Replace " أ إ آ" with "ا")
- Replace final letter "ة" with "ه".
- Replace final letter "ى" with "ي".

3.6. Removing prefixes and suffixes

This step consists of removing the prefixes and suffixes from the words

س	و	ب	ل	لل
وا	ها	كما	تما	هما
نا	كن	تن	كم	تم
هم	هن	ين	ون	تا

Table 7 Prefixes and Suffixes

3.7. Check if the word matches any of the patterns

The last step after deleting the prefixes and suffixes of the words is correcting any word that its meaning changed. In some cases, a letter in the pattern of the word is deleted affecting the process of root extraction, like in the word.

In (فعل) which is the pattern of (رأى), the letter "أ" is deleted, and in the present tense of pattern (فعل) is (يفعل) which is introduced to (يرأى) and not (يرى). If we take (يرى) as a present verb, the past will be (رى) so the letter ' ع ' is deleted for this reason becoming (يفل) instead of (يفعل).

There are three rules which apply in the stemmer for correcting some words their meaning was affected:

1. Adding "ي" to the end of the word if the suffix "يه" is deleted
2. Adding "ه" to the end of the word if the suffix "ته" is deleted
3. Replacing the letter "ئ" to the end of the word by "ء" if the suffix of the word is deleted.

4. Detailed Algorithm

To implement our algorithm, we have used Java code program, based on Khoja's one.

These are the schema of our algorithm:

```
{
    // check if the word consists of two letters:
    if ( word.length ( ) == 2 )
        if the word consists of two letters, we treat two cases:
```

- A root consisting of two letters (though I can't think of any!)
- A letter was deleted as it is duplicated or a weak middle or last letter.

```
    // if the word consists of three letters
    if( word.length ( ) == 3 && !rootFound )
```

- If the last letter is a weak letter or a hamza, then check for last week words list.
- If the second letter is a weak letter then check for second week words list.

```
// if the word consists of four letters
if( word.length ( ) == 4 )
   // check if it's a root
```

- Check on the list of four letters root.

```
// if the root hasn't yet been found
if( !rootFound )
{
   // check if the word is a pattern
```

- Try and find a pattern that matches the word

```
}
// if the root still hasn't been found
if ( !rootFound )
{
   // check for a definite article, and remove it
   word = checkDefiniteArticle ( word );
```

- look through the vector of definite articles search through each definite article, and try and find a match
- Check to see if the word is a root of three or four letters
- If the word has only two letters, test to see if one was removed
- If the root hasn't been found, check for patterns/ check for suffixes/ prefixes

```
}
// if the root still hasn't been found
if ( !rootFound && !stopwordFound )
{
   // check for the prefix waw
   word = checkPrefixWaw ( word );
```

- Check to see if the word is a stopword
- Check to see if the word is a root of three or four letters, that begin by 'waw'
- If the word has only two letters, test to see if one was removed
- if the root hasn't been found, check for patterns
- Check for suffixes
- check for prefixes

```
}
// if the root STILL hasnt' been found
if ( !rootFound && !stopwordFound )
{
   // check for suffixes
   word = checkForSuffixes ( word );
}
// if the root STILL hasn't been found
if ( !rootFound && !stopwordFound )
{
   // check for prefixes
   word = checkForPrefixes ( word );
```

- Check to see if the word is a stopword
- Check to see if the word is a root of three or four letters.
- If the word has only two letters, test to see if one was removed
- if the root hasn't been found, check for patterns
- Check for suffixes
- check for prefixes

```
}
return word;
}
```

5. Results

The stemming result of the word will be correct, if the output form of the word is the same as the target form of the word. Otherwise, the result of the word will be incorrect. We have used Khoja's java code and we applied our approach on it. This program take in input a text file and returns in output a list of words theirs stems and the type of the each word. We have used as a first test a list of 524 words that begins by "waw" letter, we give below results of our stemmer comparing it to Khoja's one.

	Khoja's Stemmer	Our Stemmer : EST.Stemmer
Number of words used	524	534
Stemmed words	96,75 %	98,85 %
Not Stemmed words	3,25 %	1,15 %

Table 8 Results Comparison

Figures below shows the running result of both stemmers:

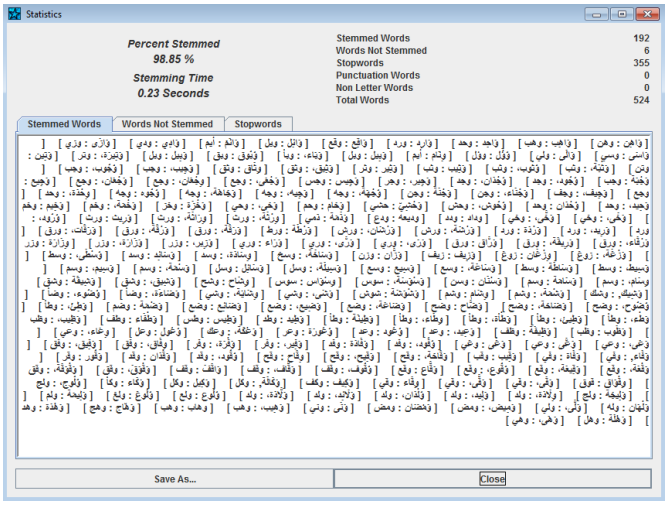

Figure 1 EST.Stemmer

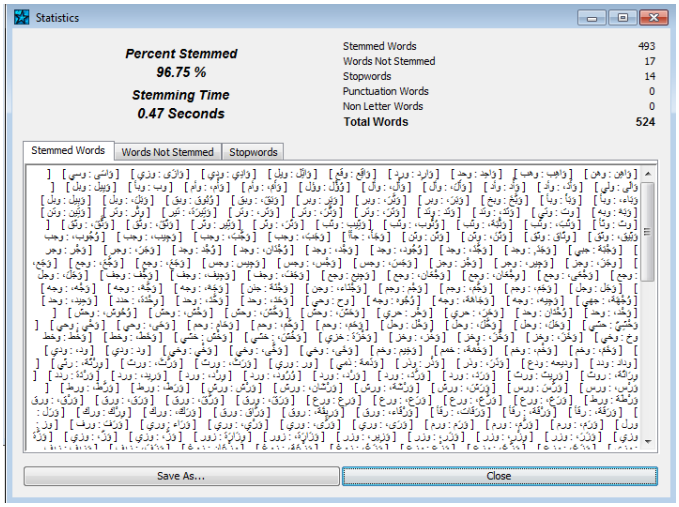

Figure 2 Khoja's stemmer

A second test that we have done with an article that contained 1418 words, results are presented in the table below:

	Khoja's Stemmer	Our Stemmer: EST.Stemmer
Number of words used	1418	1418
Stemmed words	93,16 %	93,23 %
Not Stemmed words	6,84 %	6,77 %

Table 9 Results Comparison

Since the text didn't contain words that begins by "waw", some strange words, and five nouns, the difference between the two results is not large.

EST.Stemmer is able solve some cases, for example if we take وَسَمَة ، وَسَامَة.

With Khoja's stemmer we have as stemmed text:

Word	Stem	Type
وَسْمَة	سمي	ROOT
وَسَامَة	سوم	ROOT

Table 10 Results Example

With our algorithm EST.Stemmer:

Word	Stem	Type
وَسْمَة	وسم	ROOT
وَسَامَة	وسم	ROOT

Table 11 Results Example

We have also review and modify stop word list to solve some issues detected is our tests, for example we have added 'ففي' and 'منهم' in this list.

6. Conclusion

In this paper we proposed new methods to improve the detection of the stem for Arabic language. Indeed, specific cases related to the five nouns and words starting with a vowels are processed successfully by the algorithm.

In the future work we will test the accuracy of our algorithm and compare it with Light and Heavy stemmers.

Least Mean Square algorithm

ABSTRACT

In general, the imbalanced dataset is a problem often found in health applications. In medical data classification, we often face the imbalanced number of data samples where at least one of the classes constitutes only a very small minority of the data. In the same time, it represent a difficult problem in most of machine learning algorithms. There have been many works dealing with classification of imbalanced dataset. In this paper, we proposed a learning method based on a cost sensitive extension of Least Mean Square (LMS) algorithm that penalizes errors of different samples with different weights and some rules of thumb to determine those weights. After the balancing phase, we apply the different techniques (Support Vector Machine [SVM], K- Nearest Neighbor [K-NN] and Multilayer perceptron [MLP]) for the balanced datasets. We have also compared the obtained results before and after balancing method. We have obtained best results compared to literature with a classification accuracy of 100%.

1. Introduction

Learning algorithms from imbalanced data has attracted a significant amount of interest in recent years. This is because in real world, imbalanced data exist in many applications, such as fault diagnosis [1], medical diagnosis [2], intrusion detection [3,4], text classification [5,6], financial fraud detection [7], data stream classification [8], and soon. In those applications, there are often one or some minority classes possessing very few samples compared with the other classes. And most of time, the "small" classes are more important than those "large" ones. Because of the unbalance data distribution of imbalanced learning problems, it is often difficult to obtain good performance for most cases by using traditional classifiers where a balanced distribution of classes is assumed and an equal misclassification cost for each class is assigned. As a result, traditional classifiers tend to be overwhelmed by the majority classes and ignore the minority ones, which is not acceptable in many real applications [9, 10].

Most previous works focused on the binary classification problems [11]. The others [12, 13] also tried to employ the multi-class data and define the class with a small number of data as the minority class while the other data are merged in to the majority class. Al though the minority class can be recognized by classifiers, the artificial majority class might be more likely to be misclassified. The knowledge of imbalanced data is complex especially when we solve the multi-class problems, since the amounts of some data classes are the same or similar to each other, which increases the difficulty to artificially select the minority class. The imbalanced learning problems can be summarized as two categories: absolute imbalance and relative imbalance [14]. The absolute imbalance occurs in the situation when the minority instances are significantly scarce and implicit, whereas the dataset with relative imbalance can show explicit data distribution but still rare quantity for minority examples. The characteristic of rare instances exists in the typical imbalance where the limited representative data lead to difficult learning regard less of between class imbalances. The other form of imbalance is within-class imbalance. It concentrates on the representative data distribution for the sub- concepts with in a class. The within-class imbalance problem seems to be more difficult than the datasets with the concepts in a similar characteristic [15, 16].

The works to be cited in Section 2 clearly show that most techniques cited in the literature were not able to find the best effective ways to address minority data.

In this paper, the learning method based on a cost-sensitive extension of Least Mean Square (LMS) algorithm is proposed to solve the imbalanced learning problems, and that penalizes errors of different samples with different weights, which increase the

classification rate. In order to validate our empirical study, we have chosen three different algorithms from different paradigms of data mining, including Multilayer Perceptron (MLP), Support Vector Machines (SVMs) and the K-Nearest Neighbour (K-NN) as an Instance-Based Learning approach. We have also compared the results obtained before and after balancing the different datasets by the adopted LMS.

The rest of the paper is organized as follows. State of Art is presented in Section 2, it reviews several techniques applied for problems with imbalanced datasets. Next, section 3 presents the different techniques (MLP, SVM and K-NN) and our proposed method (LMS). In Section 4, the experimental work is presented also the obtained results are discussed and compared to other works in literature. Finally, Section 5 concerns conclusions and outlines possible directions for future research.

2. State of art

A variety of solutions has been proposed to address the imbalanced learning. To understand this issue comprehensively, most of the state of the art methods are generalized as the following categories. A critical and comprehensive survey on imbalanced learning can be found in [17].

Random oversampling for minority instances and under sampling for majority instances can facilitate change of the distribution for original dataset [18]. The data formed under sampling using K- Nearest Neighbor (K-NN) [19] is also presented. To overcome the disadvantages of the basic sampling methods, Such as, risk of overfitting for oversampling approach and risk of a loss of information for undersampling method, the Synthetic Minority Oversampling Technique (SMOTE) [20] is used. It selects one from the nearest neighbors for each original minority example, and generate synthetic minority data, based on the linear interpolations between the original examples and randomly selected nearest neighbors. Borderline Synthetic Minority Oversampling Technique (Borderline-SMOTE) [21] generates only synthetic data for the minority instances near the border rather than every original minority instance. Adaptive Synthetic (ADASYN) [22] is proposed to adaptively create the different quantities of synthetic data corresponding to the density distribution. Parallel Selective Sampling (PSS) technique [23] is proposed to select data from the majority class to reduce imbalance in large datasets. The PSS is a filter method, which can be combined with the Support Vector Machine (SVM) classification. The PSS-SVM showed excellent performances on synthetic datasets, much better than SVM. Other sampling strategies are integrated with ensemble learning techniques [24, 25] to address the imbalanced learning issue. The Synthetic Minority Oversampling Technique in boosting (SMOTEBoost) [26] algorithm is achieved via combining SMOTE with Adaboost.M2 (Adaptive Boosting.M.2.). Ranked Minority Oversampling in boosting (RAMOBoost) [27] adjusts the sampling weights of minority class examples based on the data distributions [16]. Other weighting approaches are proposed to overcome the problem of imbalanced datasets. The Least Mean Square (LMS) [28] algorithm is proposed to penalise errors of different samples with different weights and some rules of thumb to determine those weights. After the balancing phase, different classifiers (Support Vector Machine [SVM], K-Nearest Neighbour [K-NN] and Multilayer Perceptron [MLP]) are applied for the new balanced dataset. In addition, the results obtained by the LMS method are compared with the results obtained by the sampling methods (Under-sampling, Oversampling and SMOTE). Other local strategies are proposed to address the within-class imbalance issue of positive data sparsity, by directly adjusting the induction bias of specificity-oriented learning algorithms. The k Rare-class Nearest Neighbour (KRNN) algorithm [29] is proposed, where dynamic local query neighbourhoods are formed that contain at least k positive nearest neighbours and the positive posterior probability estimation is biased towards the rare class based on the size and positive distribution in local regions.

The goal of cost-sensitive learning [30- 33] is to calculate the costs for misclassification through different cost matrices. The Adaptive Cost sensitive boosting (AdaCost) [34] adopts the cost-sensitive learning with boosting. Cost-sensitive decision tree [35] can prune the scheme for imbalanced data with misclassification costs through specifying decision threshold. Cost-sensitive neural network models [36, 37] are also widely applied for imbalanced learning [16].

The kernel-based learning approaches include many state-of-the-art techniques for the application of data mining domain [38-41]. A Granular Support Vector Machines-Repetitive Undersampling (GSVM-RU) algorithm [42] carries out the iterative learning procedure based on GSVM. Kernel-Boundary Alignment (KBA) [43] is proposed to modify the kernel matrix via a kernel function based on the distribution of imbalanced data. There is another typical kernel-based learning algorithm for maximizing Area Under Curve (AUC) of the Receiver Operating Characteristic (ROC) graph [16, 44].

The active learning methods [45- 47] are traditionally adopted to handle the special issues relevant to training data without class labels (unlabeled data). As mentioned in [48], the criteria of termination for active learning methods are investigated to apply for the class imbalance issues on Word Sense Disambiguation (WSD) through maximal confidence and minimal error [16].

3. Materials and Methods

A brief description of the used algorithms is reported below:

3.1. Classification techniques used

In this work, we have used a K-Nearest Neighbor (K-NN) as a statistical machine, a Support Vector Machine (SVM) as a kernel machine, and a Multi-Layer Perceptron (MLP) as a neural network. Brief descriptions of these algorithms are already reported in literature [49].

3.2. Least Mean Square algorithm

The Least Mean Square (LMS) algorithm which is also called the stochastic gradient algorithm is relatively easy to implement and is based on a simple concept, it was introduced by Widrow and Hoff in 1960 [50].

The LMS algorithm is an adaptive algorithm, which uses a gradient-based method of steepest decent. LMS algorithm uses the estimates of the gradient vector from the available data. LMS incorporates an iterative procedure that makes successive corrections to the weight vector in the direction of the negative of the gradient vector, which eventually leads to the minimum mean square error.

Compared to other algorithms LMS algorithm is relatively simple; it does not require correlation function calculation nor does it require matrix inversions [51].

In the LMS algorithm, the squares of mean quadratic errors are minimized by solving a system of linear equations. In this paper, to remedy the problem of the learning of the imbalanced dataset, we used a cost-sensitive extension of Least Mean Square algorithm that penalizes errors of different samples with different weights.

LMS algorithm formulation

We are given a training set which consists of n independent identically distributed samples which is described by [50- 53]:

$$S = \{(x_1, y_1), \dots (x_n, y_n)\} \quad (1)$$

Where $x_i \in R^d$ and $y_i \in \{-1, 1\}$, $i = 1,2 \dots, n$. The classification consists of finding a hyper-plane $w.x + b = 0$ where $W \in \mathbb{R}^d$ and $b \in \mathbb{R}$.

The solution for the least mean square algorithm classification can be found by solving the following constrained minimization problem:

$$min_w \frac{1}{n}\sum_{i=1}^{n}(Y_i - W.X_i)^2 \quad (2)$$

The LMS algorithm is probably the most popular adaptive algorithm that exists because of its simplicity.

From the method of steepest descent, the weight vector equation is given by:

$$w_{i+1} = w_i + \frac{1}{2}\mu\,[-\nabla(E\{e_i^2\})] \quad (3)$$

Where μ is the step-size parameter and controls the convergence characteristics of the LMS algorithm; e_i^2 is the mean square error between the beam former output Y_i and the reference vector which is given by,

$$e_i = y_i - x_i^T w_i \quad (4)$$

The gradient vector in the above weight update equation can be computed as

$$\begin{aligned}\nabla(E\{e_i^2\}) &= \partial J\,[w_i]/\partial w_i \\ &= -2E\{x_i\, e_i\} \\ &= -2P + 2R\, w_i\end{aligned} \quad (5)$$

In the method of steepest descent, the biggest problem is the computation involved in finding the values P and R matrices in real time. The LMS algorithm on the other hand simplifies this by using the instantaneous values of covariance matrices P and R instead of their actual values i.e.

$$\begin{aligned}\widehat{R_\iota} &= x_i x_i^T \\ \widehat{P_\iota} &= x_i y_i\end{aligned} \quad (6)$$

These are simply the estimated instantaneous correlations.

Therefore, the weight update can be given by the following equation,

$$w_{i+1} = w_i + \mu\,[\,\widehat{P_\iota} - \widehat{R_\iota} w_i\,] \quad (7)$$

$$= w_i + \mu\, x_i\,[\,y_i - x_i^T w_i\,] = w_i + \mu\, x_i\, e_i \quad (8)$$

Note that w_i is a random variable [since each new iteration i, w_i depends random processes of x_i and y_i.

Therefore, the LMS algorithm can be summarized in following equations [53]:

- Filter output: $Y_i = w_i^T x_i$
- Error: $e_i = y_i - x_i^T w_i$
- Update filter Weight: $w_{i+1} = w_i + \mu\, x_i e_i$

The LMS algorithm is initiated with an arbitrary value $w(0)$ for the weight vector at $i = 0$. The successive corrections of the weight vector eventually leads to the minimum value of the mean squared error.

μ is the step-size parameter and controls the convergence characteristics of the LMS algorithm :

- If μ is chosen to be very small then the algorithm converges very slowly.
- A large value of μ may lead to a faster convergence but may be less stable around the minimum value.

The LMS algorithm is very simple: it requires only 2L + 1 multiplications and 2L additions by iteration, where L is the number of filter coefficients.

4. Results and discussions

4.1. Medical datasets

We have used five medical datasets from UCI database [54]. In order to validate the proposed methods on each one, we chose a subset of these datasets providing a heterogeneous test bench. These five datasets are Pima Indian Diabetes, Wisconsin Breast Cancer (WBC), Wisconsin Diagnostic Breast Cancer (WDBC), Liver disorder and Appendicitis. The main characteristics of these datasets are depicted in Table 1.

Table 1. Characteristics of the medical datasets.

Dataset	Classes	Attributes	Instances	Min. class	Maj. class
Pima	2	8	768	268	500
WBC	2	9	683	137	546
WDBC	2	31	569	212	357
Liver disorder	2	6	345	145	200
Appendicitis	2	7	106	21	85

4.2. Employed classifiers

In this subsection, we describe how we adjust some parameters of these techniques and how we estimate the classification reliabilities.

The K-NN algorithm requires no specific set-up. We test values of k $\{1, 3, 5, 7\}$ and we choose the value providing the best performances on a validation set according to a fivefold cross validation. We estimate the reliability of each classification act on the basis of information directly derived from the output of the expert and analyzing also the reasons in the feature space giving rise to unreliable classification. For further details, we may refer to [49, 55].

We test a SVM algorithm with a Gaussian radial basis kernel. Values of regularization parameter C and scaling factor σ are selected within intervals $[1;\ 10^4]$ and $[10^{-4};\ 10]$, adopting a log scale to sample the two intervals. The value of each parameter is

tuned using a fivefold cross-validation on a validation set. The reliability of a SVM classification is estimated as proposed in [56], where the decision value of the classifier is transformed in a posterior probability [49].

We use a MLP algorithm with a number of hidden layers equal to half of the sum of features number plus class number. The number of neurons in the input layer is fixed by the number of the features whereas we chose two neurons in the output layer. The reliability is a function of the values provided by neurons in the output layer [49, 55].

4.3. Statistical metrics

To assess the predictive ability of constructed models, five statistical evaluation methods were employed and they are defined as follows:

1) The correct classification rate (CC %): is the recognition rate;

$$CC = (TP + TN)/(TP + TN + FP + FN) * 100 \quad (9)$$

Where true positives (TP) denote the correct classifications of positive samples; true negatives (TN) denote the correct classifications of negative samples; false positives (FP) denote the incorrect classifications of negative samples into the positive samples; and false negatives (FN) denote the positive samples incorrectly classified into the negative samples.

2) Error rate (E %):

$$E = (FP + FN)/(TP + TN + FP + FN) * 100 \quad (10)$$

3) Sensitivity (SE %): the percentage of positive samples which are correctly classified;

$$\mathrm{SE} = \mathrm{TP}/(\mathrm{TP} + \mathrm{FN}) * 100 \quad (11)$$

4) *S*pecificity (SP %): the percentage of negative samples which are correctly classified;

$$SP = TN/(TN + FP) * 100 \quad (12)$$

5) Gmean (%): It provides a simple way to evaluate the model's ability to correctly classify the minority and majority class by the combination of Sensitivity and Specificity into a single metric. Gmean is considered as a measure of the balanced accuracy and is defined as:

$$\mathrm{Gmean} = \sqrt{\mathrm{Sensitivity} \times \mathrm{Specificity}} \quad (13)$$

4.4. Statistical performance of different classifiers combined with LMS

In order to validate the influence of LMS on the different classifiers (MLP, SVM, K-NN), it is interesting to compare the performances of MLP, SVM and K-NN techniques in the two cases (with and without LMS). However, selecting objective statistical metrics are used to estimate the performance of different classifiers. Indeed, for the imbalanced classification problem, the overall classification accuracy is often not an appropriate measure of performance given that a trivial classifier that predicts every sample as the majority class could achieve very high accuracy in extremely skewed domains. In the present work, instead of the complicated metrics, five intuitive and practical measures (correct classification rate, error rate, Sensitivity, Specificity and Gmean) were adopted to estimate the current classifiers based on the following reasons: first, both Sensitivity and Specificity provide a class-by-class performance estimate, making one easily investigation on the predictive ability of a classification method for each sample class, especially the predictive ability for the interesting minority classes; second, Gmean is a combination of both Sensitivity and Specificity, which indicates the balance between classification performance on the majority and minority classes. A poor performance in prediction of the positive (interesting) samples still leads to a low Gmean value, even if the negative samples are classified with high accuracy, which is a common case for imbalanced dataset. The comparative study results are summarized in table 2.

The classification of the different imbalanced databases used in this work involves four steps:

- Step 1: application of the different techniques (SVM, K-NN and MLP) on imbalanced data.
- Step 2: application of the LMS algorithm to remedy the imbalance of data.
- Step 3: application of the different techniques (SVM, K-NN and MLP) on obtained balanced data.
- Step 4: comparison between results obtain successively in first and second step.

We notice from these experiments that the classification performances (CC, SE, SP, and Gmean) increase after balancing databases by using the least mean square algorithm.

We remark that before balancing the different datasets, the minority class is hardly recognized by the different classifiers (MLP, SVM and K-NN). However, after balancing these imbalanced databases, the performance is improved significantly with the employment of LMS algorithm as illustrated in table 4; by increasing the Sensitivity, the specificity, the correct classification rate, and the Gmean. Therefore, we have obtained the best classification performances. We can say that the classifiers have a good recognition of the minority classes and the majority classes, since in our experimentations the samples of the minority classes and the majority classes are correctly classified (TP and TN will increase / FN and FP will decrease after balancing).

Behavior of descriptors before and after balancing approach

To validate the influence of LMS on the different techniques (MLP, SVM and K-NN), we compare the values of descriptors before and after balancing. So we take a miss-classified case from the minority class before balancing the different databases (PIMA, WBC, WDBC, liver disorder and Appendicitis); and we apply the LMS algorithm, where each descriptor is weighted by a coefficient, and the same case was correctly classified (see figure1).

We notice also from this figure1 (a) that some descriptors in PIMA dataset remain unchanged (D1, D5, D7) however the rest has changed in a certain percentage which enhance the importance of the attributes. Also in the other used databases (WBC, WDBC, liver disorder and Appendicitis) we have obtained some changes in the different descriptors (figure1 (b), (c), (d), (e)).

Table 2. The obtained performances before and after balancing of the different imbalanced dataset on the testing base

Datasets	Classifiers		CC (%)	E (%)	SE (%)	SP (%)	Gmean (%)
PIMA	MLP Classifier	MLP	73.85	26.15	51.28	83.52	65.44

4.5. Comparative study with related works

In this section, we have compared the classification accuracies of our method with other methods applied to the same database:

Works tested on PIMA database

Table 3 gives the classification accuracies of our method and other methods applied on the PIMA database.

Table.3 classification accuracies obtained with our method and other classifiers in literature (PIMA)

Method	Classification Accuracy (%)
GSVM [57]	74.15
WLTSVM [58]	76.78 ±0.35
MLP with LMS	**99.24**
SVM with LMS	**99.23**
K-NN with LMS	**100**

L. Gonzalez-Abril and al. have proposed a new Support Vector Machine method (called GSVM), which is specially designed for bi-classification problems its objective was balanced accuracy between classes [57]. For the evaluation of the results, (L. Gonzalez-Abril and al.) have used many databases (23) and obtained an accuracy of 74.15% for Pima dataset. Y.Shao and al. proposed an efficient Weighted Lagrangian Twin Support Vector Machine (WLTSVM) for the imbalanced data classification, they use different training points for constructing the two proximal hyperplanes [58], they achieve 76.78 ±0.35% of accuracy. In this work, as can be seen from the results (Table. 3), our method (MLP with LMS, SVM with LMS and K-NN with LMS) gave excellent classification accuracy.

Works tested on WBC database

Table 4 gives the classification accuracies of our method and other methods applied on the WBC database.

Table.4 classification accuracies obtained with our method and other classifiers in literature (WBC)

Method	Classification Accuracy (%)
S- AIRS [59]	96.91
WLTSVM [58]	96.30±0.31
MLP with LMS	**99.56**
SVM with LMS	**99.12**
K-NN with LMS	**100**

Wang and Adrian proposed a hybrid method by combining Synthetic Minority Over-Sampling Technique (SMOTE) and Artificial Immune Recognition System (AIRS) to handle the imbalanced data problem that are prominent in medical data . This approach denoted as S- AIRS [59]. They obtain 96.91% accuracy. Y. Shao and al. proposed WLTSVM [58] and they achieve 96.30± 0.31% of accuracy. In this study, as can be seen from the results (Table. 4), our approach obtain the best classification accuracy with the different classifiers.

Works tested on WDBC database

Table 5 gives the classification accuracies of our method and other methods applied on the WDBC database.

Table.5 classification accuracies obtained with our method and other classifiers in literature (WDBC)

Method	Classification Accuracy (%)
S- AIRS [59]	96.52
K-NN with resampling [60]	98.42
MLP with LMS	**100**
SVM with LMS	**100**
K-NN with LMS	**100**

Wang and Adrian proposed a hybrid method S- AIRS [59]. Their approach obtained 96.52% accuracy. G. NAGA RAMADEVI and al. applied the five classifiers K-NN, SVM, Logistic Regression, C 4.5 and Random Forest on original four breast cancer datasets with and without resampling technique, they compare the obtained performances before and after resampling datasets [60]. They obtain the best accuracy with 98.42% by using K-NN and resampling method. In this work, as can be seen from the results (Table. 5), our approach obtain the best classification accuracy.

Works tested on Liver disorder database

Table 6 gives the classification accuracies of our method and other methods applied on the Liver disorder database.

Table.6 classification accuracies obtained with our method and other classifiers in literature (Liver disorder)

Method	Classification Accuracy (%)
DGC+ [61]	67.44
GSVM [57]	71.07
MLP with LMS	**100**
SVM with LMS	**100**
K-NN with LMS	**99.13**

Alberto Cano and al. proposed an algorithm called weighted Data Gravitation Classification (DGC+) that compares the gravitational field for the different data classes to predict the class with the highest magnitude. The proposal improves previous data gravitation algorithms by learning the optimal weights of the attributes for each class and solves some of their issues such as nominal attributes handling, imbalanced data performance, and noisy data filtering [61]. They achieve 67.44% of accuracy. L. Gonzalez-Abril and al. proposed GSVM method [57]; they obtained an accuracy of 71.07%. In this work, as can be seen from the results (Table. 6), our approach obtain the best classification accuracy with the different classifiers.

Works tested on Appendicitis database

Table 7 gives the classification accuracies of our method and other methods applied on the appendicitis database.

Table.7 classification accuracies obtained with our method and other classifiers in literature (Appendicitis)

Method	Classification Accuracy (%)
DGC+ [61]	84.09
BSMAIRS [62]	92.5926
MLP with LMS	**100**
SVM with LMS	**100**
K-NN with LMS	**94.29**

Alberto Cano and al. proposed a DGC+ algorithm [61] and they achieve 84.09% of accuracy. Kung-Jeng and al. developed a hybrid classifier approach, they combine Borderline Synthetic Minority oversampling technique (BSM) and Artificial Immune Recognition System (AIRS) as global optimization searcher with the nearest neighbor algorithm used as a local classifier. This approach denoted as BSMAIRS. For the evaluation of the results, Kung-Jeng and al. have used a fivefold cross validation strategy and they have obtained five accuracies; the best one obtained with 92.5926% [62]. In this study, as can be seen from the results (Table.7), our approach obtains an excellent classification accuracy.

5. Conclusion

In this paper, we proposed a learning method based on a cost sensitive extension of least mean square algorithm that penalizes errors of different samples with different weights. This approach is used to overcome the problem of imbalanced data, it gives high weights for the samples of the minority classes.

The proposed approach was applied on five medical datasets from UCI database to assess its performance. Experimental results revealed that LMS algorithm performed better (achieved higher performance values) than the other balancing methods. It shows clearly the advantage of LMS when we handle the imbalanced data. Moreover, the results showed that the combination of LMS with different techniques (MLP, SVM and K-NN) can enhance classifier performance, particularly in terms of accuracy.

We propose that our approach will be applied for multiclass datasets, also the LMS algorithm will be tested on other intelligent methods based techniques such as fuzzy logic in order to increase the interpretability of the results. Also we can extend the ratio of the minority class to majority class in order to do a study in this situation. Our approach will be proposed to overcome the disadvantages of the basic sampling methods. Because the LMS algorithm that penalizes errors of different samples with different

weights. However, this approach does not eliminate the instances of the majority class and does not add the instances of the minority classes. We can conclude that, this method keeps the same database.

A B S T R A C T

The importance of Modelling Methods Engineering is equally rising with the importance of domain specific languages (DSL) and individual modelling approaches. In order to capture the relevant semantic primitives for a particular domain, it is necessary to involve both, (a) domain experts, who identify relevant concepts as well as (b) method engineers who compose a valid and applicable modelling approach. This process consists of a conceptual design of formal or semi-formal of modelling method as well as a reliable, migratable, maintainable and user friendly software development of the resulting modelling tool. Modelling Method Engineering cycle is often under-estimated as both the conceptual architecture requires formal verification and the tool implementation requires practical usability, hence we propose a guideline and corresponding tools to support actors with different background along this complex engineering process. Based on practical experience in business, more than twenty research projects within the EU frame programmes and a number of bilateral research initiatives, this paper introduces the phases, corresponding a toolbox and lessons learned with the aim to support the engineering of a modelling method. "The proposed approach is illustrated and validated within use cases from three different EU-funded research projects in the fields of (1) Industry 4.0, (2) e-learning and (3) cloud computing. The paper discusses the approach, the evaluation results and derived outlooks.

1. Introduction

This paper is an extension of work originally published in 2016 IEEE 20th International Enterprise Distributed Object Computing Workshop (EDOCW)[1]

The importance of Modelling Method Engineering is equally rising with the importance of Domain Specific Conceptual Modelling Methods and individual modelling approaches. In addition to existing (de-facto-) standards (e.g. Business Process Model and Notation (BPMN)[2], Decision Model and Notation (DMN)[3], Case Management Model and Notation (CMMN)[4]), a growing number of groups around the world design their individual modelling-methods (in accordance with the definition of such a method by [5], [6]for a variety of application domains.).

This is often seen as necessary, when model-based approaches are transferred in new application domains and hence require adaptations for modelling methods. A simple sample can demonstrated using the well-known standard for business process BPMN. Although BPMN can be used to design a administrative process, such as sending an invoice, it cannot be used to design a simple production process like producing a chair. The successor relation that indicates that one activity follows the other does not have properties like distance to the station, which is not necessary when sending an invoice, but is of utmost importance, when producing a chair. When analysing more complex scenarios like a car manufacturer shop floor (we faced in projects DISRUPT [60], GO0DMAN [65]), the adaptation requirements for a modelling language like BPMN becomes quite complex. Hence, providing well-known model-based approaches requires the adaptation by e.g. introducing the concept “distance” between two activities.

Challenging question is, how to support the generation of modelling tools that can range from a minor adaptation like the one introduced above, till the complete realisation of totally new modelling approach like a cyber threat modelling for cloud computing .

The authors of [8] believe that supporting the automatic generation of modelling tools can open a new quality in

Email: nesat.efendioglu@boc-eu.com

information systems development for engineers and customized design as well as encourage the use of modelling languages that are fitting to the custom needs. Often customer needs are defined by desired features like visualisation, querying, simulation or configuration and transformation, which are applied onto the model. Individual solutions enable the generation of light-weighted solutions with targeted provision of features that reduce the developers' aversion against overloaded modelling languages and inflexible or expensive modelling tools.

The engineering of such modelling tools is a result of the so called "conceptualization process of modelling methods", which is disseminated by the world-wide community of OMiLAB[10]. The complexity lies in the mapping of language artefacts and their corresponding functionality to concrete implementable and deployable modelling tools. In addition, knowledge domains are divided into more refined and specialized subdomains, where each domain needs to be characterized by its own abstraction and refinement of concepts from the so-called "real world" objects from the "subject under study". Hence, in order to capture the relevant semantic primitives that address domain specific needs, it is necessary to involve both the method engineers as well as domain experts. Today, there are different approaches, guidelines and practices for the development of modelling tools available that do not consider the full lifecycle from the design and collaborative development of a modelling tool, which unavoidably leads to limitations and inconsistencies in the conceptualization [7]. We, hence, propose a guideline and corresponding tools supporting method engineers along the conceptualization process supporting all phases and ensuring collaboration among involved stakeholders.

Karagiannis proposes in [6] the Agile Modelling Method Engineering (AMME) framework. Authors of [9] propose the Modelling Method Conceptualization Process that based on AMME and guides the method engineers during conceptualization. The same authors in [35] propose a toolbox that supports this process. The work at the hand introduces an extended version of this toolbox so-called "Modelling Method Conceptualization Environment" as well as introduces corresponding services. Hence the paper introduces a product-service-system proposal for modelling method conceptualisation. Moreover the paper evaluates this product-service system in three European Research projects, and one additional in the context of an in-house research project, and discusses evaluation results.

In this respect, the remainder of the paper is structured as follows: Section 2 briefly presents results of our state of the art analysis from [9], revisits AMME, the Modelling Method Conceptualization Process. Section 3 outlines the toolbox Modelling Method Conceptualization Environment with an emphasis on new extension to ADOxx Library Development Environment, so-called ADOxx-JAVA-MM-DSL. Section 4 presents Modelling Method Conceptualization Services, Section 5 introduces evaluation cases and discusses the evaluation results, while Section 6 concludes the paper and gives an outlook on future work.

2. State of the Art in Modelling Method Definition and Development Approaches

We published the initial version of this state of the art analysis in [9]. In this paper, we revisit shortly it for completeness reasons.

We analyse modelling standards from five well-known standardization organizations, which provide intensively used industry modelling standards in last decade; (1) OASIS (www.oasis-open.org), (2) OMG (www.omg.org), (3) Open Group (www.opengroup.org), (4) W3C(www.w3.org) and (5) WfMC(www.wfmc.org). It is highly possible that each organization follows same or similar approach and technologies to specify standards within its organization. Therefore, we assume that, it would be enough selecting control samples from each standardization organization in order to understand, which approach they are following, which tools they are using to define modelling standards. As the control samples we select UBL [39], ebXML BPSS [40] and WS-BPEL [53] from OASIS; BPMN [2] CMMN [4] and DMN [3] from OMG; ArchiMate® [42] from Open Group; OWL [44], SPARQL [45] and WSDL [46] from W3C, finally XPDL [47] from WfMC.

We investigate, how the modelling language of modelling standards has been specified. We focus on four aspects specification of (1) abstract syntax-, (2) semantic- and (3) notation (concrete syntax) of the modelling languages as well as (4) samples provided to ease to understand modelling language specification and its usage.

The results of the analysis are presented in Table 1. In respect of abstract syntax specification organization used (1) graphical approaches and/or, (2) formal textual approaches and/or textual informal approaches. All of organizations utilize UML-Class Diagram [41] to specify abstract syntax of most of their modelling languages. In addition to UML-Class Diagram all standardization institute use natural language to specify the abstract syntax. Additionally, in order to ensure interoperability between systems using the given modelling standard and collaboration among parties utilizing the standard, most of the organizations attach importance to formal textual specification of abstract syntax either using with BNF [48] or XSD [49].

It seems that, regarding to specification of semantics there is no standard/approach used commonly by all organization. W3C uses formal languages such as RDF [50], Z Notation [54] [51] and standard mathematical notation. However, most of the organizations utilize semi-formal keywords defined in RFC-2119 [52] in order to define requirement level and constraints. Additions to these, all organizations use natural language to specify semantics of all modelling standards.

Regarding to specification of notation (concrete syntax), obviously the modelling standards, which have been developed preferentially in the first place for human interpretation, precise has concrete syntax that is illustrated with images and described with natural language. On the other side, the standards, which have been developed for machine interpretation, have concrete syntax specified with formal textual approaches. Mostly, XSD is utilized for specification of concrete syntax of these standards. Finally, all the organizations choose to introduce features of their modelling standards with samples. The samples can be found in either in form of graphical or textual models.

According to analysis results, for the specification of selected modelling standards, the UML (UML Class Diagram) has been mostly utilized to specify the meta-model of the modelling language.

Table 1 Figure 1 Approach, standards and artifacts used to specify modelling languages in control samples

		Abstract Syntax			Semantics			Notation			Sample
		Graphical	Textual (formal)	Textual informal)	Formal Languages	Semi-formal Languages	textual (informal)	Graphical	textual (formal)	textual (informal)	
OASIS	Universal Business Language (UBL)	UML-Class Diagram	BNF	Natural Language			Natural Language		XSD	Natural Language	Sample Graphical Models
	The eBusiness eXtensible Markup Language (ebXML) Business Process Specification Schema (BPSS)		XSD	Natural Langauge		RFC-2119			XSD	Natural Language	Sample Textual Models
	Web Services Business Process Execution Language (WS-BPEL)	UML-Class Diagram	XSD	Natural Language		RFC-2119			XSD	Natural Language	Sample Graphical Models
OMG	Business Process Model and Notation (BPMN)	UML-Class Diagram	XSD	Natural Language		RFC-2119; WS-BPEL	Natural Language	Image	XSD	Natural Language	Sample Graphical Models
	Case Management Model and Notation (CMMN)	UML-Class Diagram	XSD	Natural Language		RFC-2119	Natural Language	Image		Natural Language	Sample Graphical Models
	Decision Model and Notation (DMN)	UML-Class Diagram	XSD; BNF	Natural Language			Natural Language	Image		Natural Language	Sample Graphical Models

2.1. UML as a Modelling Method Design Approach

As UML is utilized for specification of most of modelling standards in our set, we extend our literature research to analyze UML as a prominent modelling method, which is used during create and design phases of the conceptualization process. The pragmatic objective of this analysis is to understand if UML - in the context of modelling method design - covers all requirements for creating and designing a modelling method, or if there are any shortcomings that we have to consider during the development of our approach.

Glinz evaluates UML in [56] as a requirement specification language. He states that definition of requirements with UML Use Case Diagrams is possible but Use-Case-Diagrams alone are not sufficient. Definitions of concrete functional and non-functional requirements as well as definition of relation between the concepts in domain specific modelling method and requirements are not possible. The authors of [58] indicate the same problem and propose again a UML-based solution to define non-functional requirements and relation between the components in system by combining constructs from UML Class Diagram and UML Component Diagram. Hence the first shortcoming needs to be considered in our approach is;

1. Definition of functional and non-functional requirements and their relation between the concepts in modelling methods.

According to Selic [59] the domain specific modelling languages specify different viewpoints of a complex system. Hence, the complex system should be represented from different viewpoints and some features will be presented in several viewpoints. Moreover the language, presumably, will support multiple viewpoints for different sub-domains, which means language should allow use of different abstract and concrete syntax. With UML Class Diagrams the whole meta-model (abstract syntax) of language can be fragmented. But depicting all alternatives of abstract syntax together can make the class diagram very complex and hard to read. To the best of our knowledge the UML does not offer definitions of different concrete syntax for same concept of modelling language. Hence the next shortcomings are

2. Fragmenting whole meta-model into individual meta-models composing concepts for different sub-domains and still be able to define link between concepts in different individual meta-models
3. Having another abstraction layer to represent modules and layers of modelling language as well as relation among them without representing complexity of abstract and concrete syntax
4. Assigning different concrete syntax to the concepts in modelling language.

According to authors of [55], nowadays, models are used to elaborate design decisions, sort out different concepts and exchange the ideas in mainstream software development. They state the importance of traceability during the transformation of information, communication of decisions etc. from design into implementation and vice versa. They indicate that in order to establish the traceability the support of modelling environment is as essential as the approach itself. To the best of our knowledge UML itself does not support such traceability. Then the next shortcoming is:

5. Traceability of information (e.g design decisions, changes, suggestions etc.) during the knowledge exchange among experts within design phase and also from design to implementation vice versa.

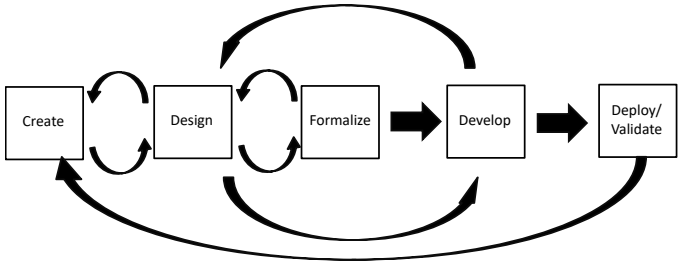
Karagiannis and Kühn in[5][57] argue that modelling methods have three major components (1) Modelling Language, (2) Modelling Procedure and (3) Mechanisms & Algorithms. Hence besides the modelling language of domain specific modelling method, we have to consider also designing modeling procedure and mechanisms & algorithms during the design of a modelling method. The design of modelling procedure and mechanisms & algorithms can be possible with using UML (e.g UML Activity diagram for design of the modelling procedure and if we consider description of mechanism and algorithms as sequence of object interactions and message exchange, the UML Sequence diagram can be used for description of mechanism and algorithms). Hence we would not see any shortcoming in UML for this issue. But in order to emphasize requirement of ability to design modelling procedure and mechanisms & algorithms besides the modelling language of a domain specific modelling method and requirement, and requirement of having corresponding supportive modelling environment, we would list this issue here rather as a general requirement than shortcoming of UML that we have to consider in our approach. Hence last but not least;

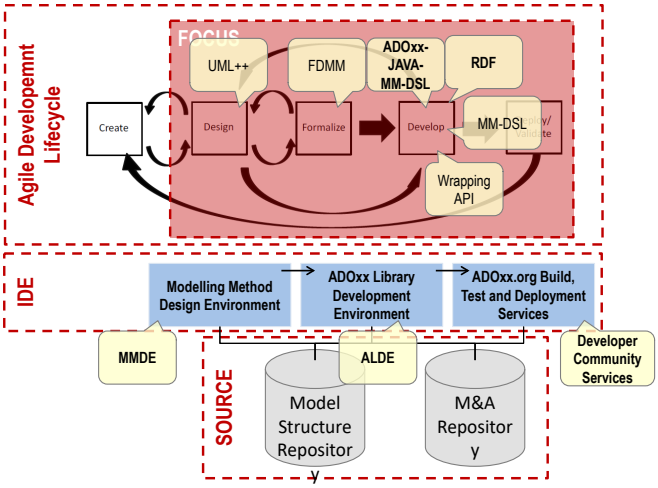
6. Possibility to design modelling procedure and mechanisms & algorithms of a domain specific modelling language.

2.2. Agile Modelling Method Engineering and Conceptualization Process

Having roots in software engineering, as it is in agile software development, during the modelling method engineering, involved stakeholders need procedures, structures and supportive tools allows high iterative process with as less as possible bureaucracy, and offers agile value and follows principles in Agile Manifesto [37]

AMME is proposed in [6] to support modelling method engineering during propagation and evolution of modelling requirements. The OMiLab Lifecycle [10] instantiates AMME and defines the internal cycle of a modelling method conceptualization with five phases; (1) “Create” as a mix of goal definition, knowledge acquisition and requirements elicitation activities that capture and represent the modelling requirements; (2) “Design” specifies the meta-model, language grammar, notation and functionality as model processing mechanisms and algorithms; (3) “Formalize” aims to describe the outcome of the previous phase in non-ambiguous, formal representations with the purpose of sharing results within a scientific community; (4) “Develop” produces concrete modelling prototypes and finally (5) “Deploy/Validate” involves the stakeholders in hands-on experience and the evaluation process as input for upcoming iterations.





Due to the involvement of several stakeholders with varying knowledge backgrounds, perspectives and different objectives, in the conceptualization of a modelling method, the authors of [9] propose so-called Modelling Method Conceptualization Process (as depicted inFigure 1) by adding additional feedback channels into the OMiLab Lifecycle between: (1) Create and Design, to prove, if the designed modelling language covers the identified application scenarios and considers the identified requirements; (2) Design and Formalize to ensure formal approval of modelling language, as well as (3) Design and Develop - to improve modelling language in earlier stages before it is released and deployed.

3. Modelling Method Conceptualization Environment

The work at hand introduces the "Modelling Method Conceptualization Environment from ADOxx.org. A toolbox (as its high-level architecture depicted in Figure 2) that initially has been introduced in [35] and that instantiates the above-mentioned conceptualization process and supports method engineers during each phase. The only exception is that of the "Create" phase, as this part is regarded as the most creative phase and standard tools and methods (also in some cases pen and paper can be the most appropriate tools) shall be freely selected. Modelling Method Conceptualization Environment proposes a combination of tools in sense of Integrated Development Environment (IDE), such as the Modelling Method Design Environment (MMDE, available to download and install at [11]) for the Design, the ADOxx Library Development Environment (ALDE) for Formalize and Develop, Adoxx.org Build, Test and Deployment Services (available at [22]) for Deploy/Validate Phases.

As depicted in Figure 3, typical application scenario would be; during the create phase domain experts and method engineers come together, define goal of modelling method, acquire and elicit requirements, in design phase method engineers with tight collaboration of domain experts specifies the meta-model, language grammar, notation and processing functions on MMDE, as method engineers formalize design of modelling method collaboratively and commit on ALDE, developer(s) based on that formalization implements concrete modelling toolkit prototype within ALDE and ADOxx Development Toolkit. Developer(s) uploads the prototype into ADOxx.org build server, semi-automatic service behind starts with completeness check, building installation package, testing of installation package and optionally deploy it on selected developer's space to allow to download the toolkit, to be tested and validated by community members, so to get feedback from them or the build services simply sends a link to corresponding owner to download and/or share the modelling toolkit.

It is worth to mention that one of the objectives is to provide loosely coupled tools, so involved actors have the flexibility to decide to use one, a combination of tools from the toolbox or even use other appropriate tools of their choice, (e.g. method engineer uses MMDE during the Design Phase, but formalize the modelling

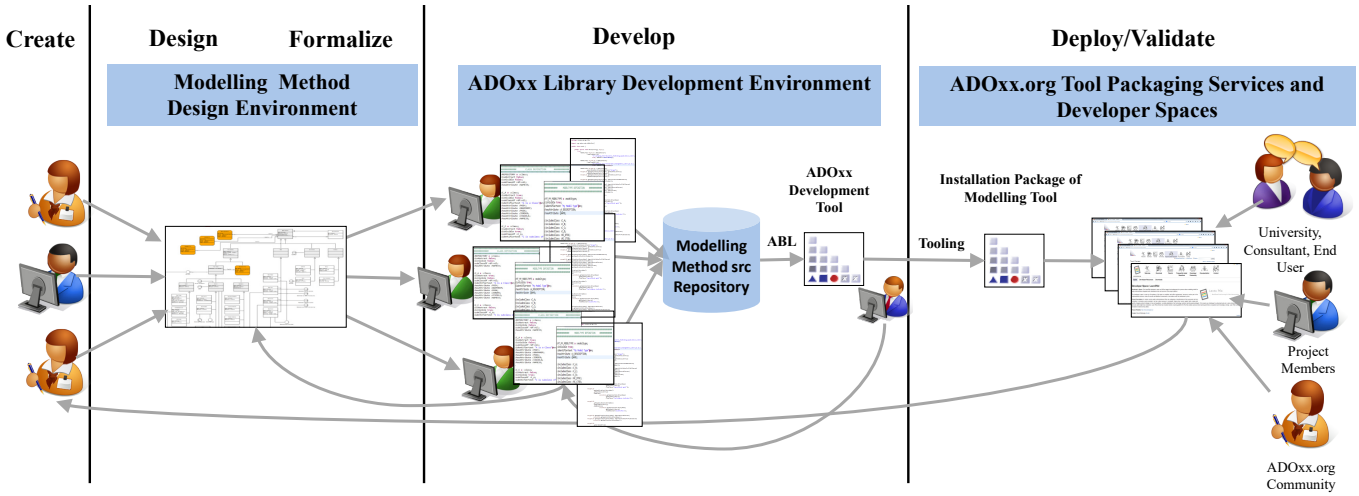


Figure 3 Life-cycle within Modelling Method Conceptualization Environment from Users' Perspective

method design with mathematical models or use another development tool during the Develop Phase and deploys them at the Developer Spaces and enable validation).

In the following sub-sections current abilities of the tools from the environment are shortly presented.

3.1. Modelling Method Design Environment

The Modelling Method Design Environment (MMDE) is itself a modelling tool to design other modelling methods. MMDE has been implemented based on lessons learned from results of the state of the analysis, which is discussed in pervious chapter, and from the experience of the authors, who have been involved in more than 20 modelling method/tool development projects for varying domains. Based on these lessons learned, UML [12] has been identified as a starting point. Hence, the MMDE takes a subset of UML and extends it with required concepts and functionalities in order to overcome the following challenges (**Ch**), which are introduced after the state of the art analysis: **Ch1**-Definition of functional and non-functional requirements and their relation between the concepts in modelling methods; **Ch2**-Fragmenting the whole meta-model into individual meta-models composing concepts for different sub-domains and still be able to define links between concepts in different individual meta-models; **Ch3**-Having another abstraction layer to represent modules and layers of modelling language as well as relation among them without representing the complexity of abstract and concrete syntax; **Ch4**-Assigning different concrete syntax to the concepts in modelling language; **Ch5**-Possibility to design modelling procedure and mechanisms & algorithms of a domain specific modelling language.

To overcome **Ch1**, "Requirements" model type (as depicted in Figure 4) is implemented that allows the elicitation of requirements, specifying their status as well as dependencies among them. The described requirements in this model type can be referenced to (a) all the modelling classes modelled in the related model type "Meta-Model" classes, (b) graphical notation (concrete syntax) definitions modelled in the "Graphical Notation" model type, (c) the "Modelling Stack" definition and (d) to the functionalities modelled in "Mechanisms & Algorithms" models.

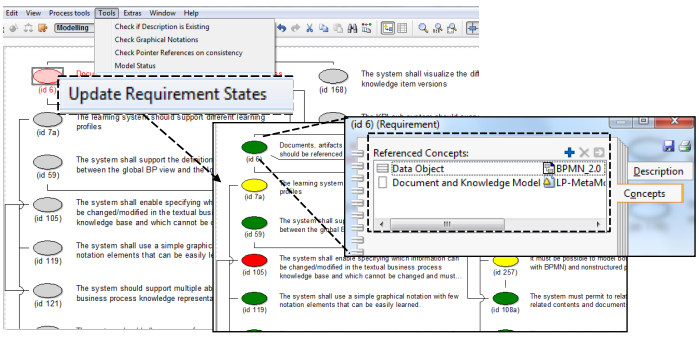

Figure 4 . Example: Requirement Model before and after Updating the Status of Requirements

For **Ch2** and **Ch3,** we extend the class diagram from UML (as depicted in Figure 5) with concepts, so method engineers can differentiate between class and relation class as well as relate different meta-models (-fragments) with each other using "Weaving" techniques as they are introduced in [8] [9].

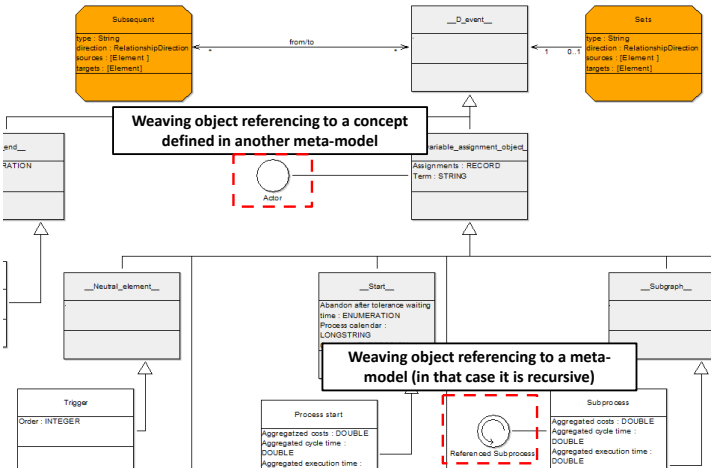

Figure 5 A sample meta-model showing usage of weaving concept

The modularization and layering of modelling language is essential to avoid complexities during the design of domain specific modelling methods [15][16] Hence, we propose representation of the Modelling Stack as the "Meta-models Stack model type (as depicted in Figure 6) allowing method engineers to differentiate meta-models in sense of different model types that target different fragments of the system.

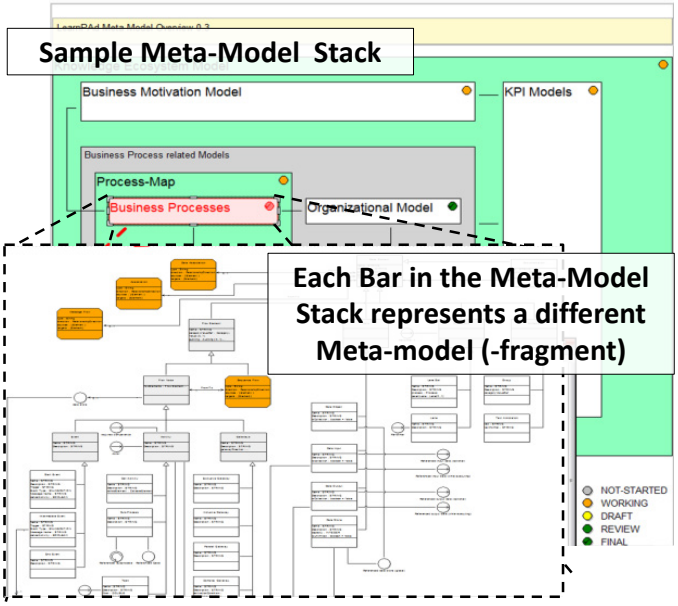

Figure 6 A Sample Meta-model Stack Model

In order to target Ch4 and specify a proper graphical representation (concrete syntax) of each concept in a meta-model, we introduce another model type called "Graphical Notation" model type (as depicted in

Figure 7) allows definition of concrete syntax of model types with specifying graphical representations for each constructs in meta-models. This model type allows the description of graphical representations with the assignment of concrete images in PNG, JPG or Bitmap format including a description of the functionalities in the notation (e.g. attribute-value dependent visualization, context related views)

End Event		As the name implies, the End Event indicates where a Process or Choreography will end.
Activity		An Activity is a generic term for work that company performs in a Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process Model are: Sub-Process and Task, which are rounded rectangles. Activities are sed in both standard Processes and in Choreographies.
Gateway		A Gateway is used to control the divergence and convergence of Sequence Flows in a Process and in a Choreography. Thus, it will determine branching, forking, merging, and joining of paths. Internal markers will indicate the type of behavior control.

Figure 7 Sample Graphical Notation Model

In order to target Ch5 to define the applicable modelling technique as steps and corresponding results we propose a model type called "Modelling Procedure" model type". The Modelling Procedure Model Type (as depicted in

Figure 8) allows method engineers to define the steps with their required inputs and produced outputs, as well as the sequence of steps based on the input – output relationships, in order to introduce case specific proper usage of their modelling method.

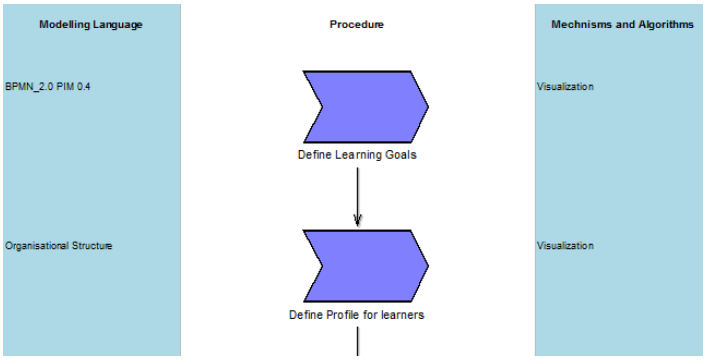

Figure 8 A Sample Modelling Procedure Model

Based on this procedural view, concrete Mechanisms and Algorithms, can be derived and depicted as Sequence and Component Diagrams from UML (therefore these diagram types has been implemented as model types in MMDE). Further details about MMDE can be found in [9]

3.2. ADOxx Library Development Environment

The ADOxx Library Development Environment (ALDE) aims to enable parallel development of modelling tools libraries based on the designs deriving from Design Phase, merging different libraries and ensuring maintainability. As an experimental prototype ALDE is uses the Resource Description Framework (RDF) as a format for data interchange [17]

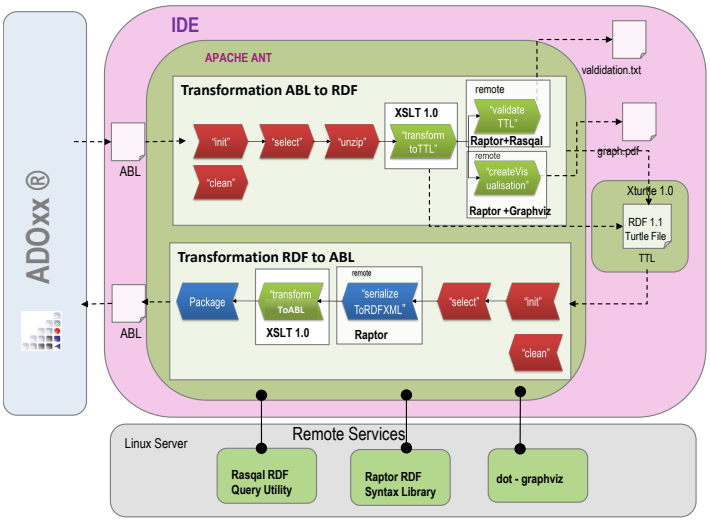

Figure 9 Architecture of ADOxx Library Development Environment (ALDE)

The Figure 9 depicts the architecture of ALDE. It is a development environment based on the Eclipse IDE [18] and includes a meta-meta-model defined in RDFS, the ALDE vocabulary. Having the vocabulary and utilizing Apache Ant® [19] as a build mechanism, the environment enables the definition of the transformation processes from ADOxx Library Languages to RDF and vice versa. Moreover ALDE serializes libraries in an arbitrary RDF format; for the prototypical realization RDF Turtle [20] has been used (the Figure 10 depicts code snippets produced by the environment) and includes the RDF XTurtle Editor developed by [21]. Having libraries in RDF Turtle format and a RDF Turtle Editor available, method engineers can adapt declaratively and script libraries collaboratively using standard functionalities of source-code management systems. Merging several libraries or integration of parts of libraries in each other becomes possible. On the other hand, ALDE includes verification services to ensure that the newly developed, edited or merged libraries are consistent with ADOxx platform requirements.

Figure 10 Snipper of Class and Model Type Definitions in ALDE in RDF

The new extension to ALDE is a new DSL based on Java, which has a working title of "ADOxx-JAVA-MM-DSL". The ADOxx-JAVA-MM-DSL is developed according to feedback on

previous version of toolbox, which are presented and discussed in [35].

The ADOxx-JAVA-MM-DSL is a framework that creates several abstraction layers over the ADOxx Library Language (ALL) format, the ADOxx internal language that describes a meta-model [64]. Each layer simplifies and adds features to the bottom one. The framework gives, the possibility to operate and easily perform modification on a meta-model without dealing with its complexity. In order to assure that, an internal structure is managed that represents the ALL structure. This internal structure can be imported from an existing ALL meta-model.

All the constraints and rules present in the ALL syntax are managed, so the framework can guarantee that only syntactically valid ALL conform meta-models can be loaded and generated. The whole internal structure is an instance of java classes, so operations and definitions on the meta-model's concepts can be done using the java features. Parallel to that, additional utilities are integrated in order to bridge the gap between the development phases:

- The compilation to the ALL meta-model to its binary format ABL: The ALL is a text based language used to describe a meta-model, in order to be imported and be usable in ADOxx it need to be compiled in its binary format ABL. A conversion engine is integrated into the framework. In such a way it is possible to automatize a previously manual step, required in order to create an automatized flow between formalization and development phase.
- The importing and deployment of the compiled meta-model in the form of ABL file, into a ADOxx Database: In order to create the respective modelling environment based on the created meta-model, is required to import the ABL compiled meta-model into the Database used by ADOxx. After this step the modelling environment relative to that meta-model can be executed and opened simply specifying at the launch time, the newly created database. The framework contains a feature that automatizes such a process, generating the Database and launching the modelling environment relative to the created meta-model. This step bridges the gap between formalization and development phase.

As depicted in Figure 11, the framework can be divided into three abstraction layers and two transversal layers of primitives and general features:

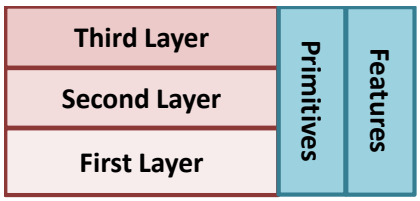

Figure 11 Layers of ADOxx-JAVA-MM-DSL

The first abstraction layer is a package of java classes that exactly reflect the structure of the ALL syntax. This layer is responsible for converting each class in its ALL representation and applies syntax rules. Due to its closeness to the ALL syntax, working directly with this layer is difficult. The advanced of creating a meta-model using this layer instead using directly the ALL syntax is that all possible errors derived from miss-spelling and unhallowed sequences will be avoided, but the complexity in the definition of the meta-model remain the same as the ALL.

The second abstraction layer abstracts all the concepts of the First layer to a more design friendly way, providing the possibility to work directly with the concepts of Libraries, Classes, Relations and Attributes. These concepts are more familiar to method engineers that are familiar with the interactive development approach directly in the ADOxx Development Toolkit. This abstraction layer defines also some semantic rules over the syntactic rules provided by the first layer. The entire concepts created at this level will be mapped to the relative concepts at the first layer in order to reflect the ALL syntax. At this level, certain helpful features are also implemented, such as the possibility to merge two or more libraries or to import one or several classes from a library to another.

The third abstraction layer is a factory layer and contains predefined methods that generate empty libraries as a starting point for the definition of specific meta-models with classes and relations. The main entry point of the framework is also at this layer with the possibility to explore all the features of the development environment.

The transversal primitives layer gives a formal representation of all the primitives allowed in the ALL syntax. The primitives are used at every level in order to define data such as Identifiers or Attribute Values;

The transversal features layer contains functions used at every level and the ALL parser. The parser is the component that allows an ALL to be read from a file and being instantiated and loaded into the framework in order to be extended or modified.

The ADOxx-JAVA-MM-DSL supports following three scenarios:

Definition of a meta-model from scratch: Using the third abstraction layer, it is possible to generate an empty ADOxx library that is the best starting point to create own specific meta-model. Starting from that object the method engineer can add Classes and Relations and their respective Attributes to the meta-model by writing pure java code. Once the java code is executed, it generates the ALL file and/or compile it in the ABL file and/or directly create the ADOxx Database and execute the prototype of newly developed modelling toolkit based on defined meta-model.

Extension or modification of an existing meta-model: Using the parsing module of the transversal layer, it is possible to load an ALL file into an instance of the java classes present in the second and First layer of the developer environment. After the ALL have been loaded is possible to extend, modify or manage it in the same way as creating from scratch. Certain methods to find specific Libraries, Classes, Relations and Attributes that the method engineer wants to work with are available. As in the previous scenario, after the java code is executed generates the ALL file and/or compile it in the ABL file and/or directly create the ADOxx Database and execute the prototype of newly developed modelling toolkit based on defined meta-model

Merging of two or more meta-model in one: This scenario is a particular case of the first two. In particular, with using the framework, it is possible to merge two or more meta-model. As it is in a sample snippet depicted in

Figure 12, thanks to the features present in the second layer is possible to import the whole concepts from a meta-model to

another or do a fine-grained import of specific concepts from each meta-model to another one. It is possible to import a class from a meta-model to another managing automatically all its dependencies like the presence of Super Classes. The merging scenario is supported in order to minimize the conflict that may rise in the merging of two incompatible meta-models, providing useful information to method engineer regarding how to correct occurred conflicts.

```
package caxman_merge_lib;

import org.adoxx.ado.ADOUtils;

public class Main {

    public static void main(String[] args) {
        try {
            ADOAllFile mainLib = ADOLibFactory
                    .loadFromAblFile(
                            "D:\\merging_test\\Business_Modelling_Application_Li
                            true, ADOUtils.adonisAblKey);

            ADOAllFile secondLib = ADOLibFactory
                    .loadFromAblFile(
                            "D:\\merging_test\\Performance_Management_Library_0.
                            true, ADOUtils.adoxxAblKey);

            ADOAllFile mergedLib = ADOLibFactory
                    .generateADOxxTotalEmptyLibrary("Merged");
            mergedLib.getApplicationLibraryNew().getDynamicLibrary()
                    .addADOxxEmptyDefaultClasses();
            mergedLib.getApplicationLibraryNew().getStaticLibrary()
                    .addADOxxEmptyDefaultClasses();

            mergedLib.getApplicationLibraryNew().importClassesAndRelations(
                    mainLib.getApplicationLibraryNew());

            mergedLib.getApplicationLibraryNew().importAttributeProfileClasses(

3.3. Adoxx.org Build, Test and Deployment Services.

Adoxx.org Build, Test and Deployment Services [38] are web-based services that allow method engineers of the ADOxx community to build verified, professional and installable distribution packages that can be distribute to interested stakeholders. The service combines and validates all available inputs, integrates all elements, compiles the necessary artefacts and signs the outcomes and creates the actual installer as a download archive.

As a collaboration space for the development and deployment phases, the concept of "Developer Spaces" has been introduced in ADOxx.org [23]. These spaces enable sharing of intermediate/release results, discussing development resources from all pre/past phases in the form of source code, snippet, examples and distribution packages with the community.

4. Modelling Method Conceptualization Services

In addition to the development tools described in the previous chapter, an appropriate service support is foreseen to support the modelling method engineers. The services are provided on the ADOxx.org portal, supporting a community of more than 1.300 modelling method engineers world-wide.

1. **Download:** For the download, ADOxx.org provides the Meta Modelling Platform ADOxx in combination, Installation Instructions, Frequently Asked Questions, Startup-Package as well as a set of more than 30 available application libraries, which can be used to start with.
2. **Get Started:** For getting started, ADOxx.org provides important readings, provides a Forum that is structured according active communities, lists tutorial and training events that are offered free of charge, provides tutorial material for both the students – in form of guide samples and slides – as well as for the trainer – in form of a trainer handbook and offers tutorial videos and webinars.
3. **Development and Support:** For the development, ADOxx.org provides aforementioned tools and additional developer utilities, 3rd parties add on like but not limited to simulation, documentation, dashboards or Web-APIs. A collection of 200 graphical representations that introduce the major elements conclude the development support.
4. **Community:** For collaborative development within the ADOxx.org community a map is provided indicating the ten laboratories – nine in Europe, one in Asia, indicating the hot spots of developers, the participating research institutes, a set of 24 modelling tools as a result of [66], and development spaces that enable a collaborative development and enable the use from solutions and tools from other projects.
5. **Documentation:** A complete specification and documentation is offered, where each relevant element of the modelling method is (a) explained based on the corresponding theory, (b) introduced with hand-on samples, (c) demonstrated with real-world scenarios, (d) mapped to forum entries of the community and finally (e) supported with tools where possible.

The operation of this service centre is provided via the portal, social media like Twitter, Facebook and LinkedIn, or via email. In justified cases an onsite support is possible, where either the method engineer is trained, supported or critical implementation steps are performed by the ADOxx.org service centre.

5. Evaluation

Given that usually each modelling method engineering case differs from each other in sense of complexity of domain, variety of aspects to be targeted, number of involved actors, to calculate quantified evaluation means is difficult, and – to best of our knowledge - there is no similar conceptualization environment, hence, it is difficult to bench-mark our proposal and quantify the

evaluation and provide statistically objective results. On the other hand, the most important tangible and objective evaluation result would be deployed and ready to use modelling toolkits, specification of modelling methods and communication of community members as proofs of concept. Those proofs of concepts for each are online and freely accessible (with exception of in-house project case). The links to access those proofs of concepts for each case are provided under regarding sub-section below.

The conceptualization environment introduced above has been applied in four different cases for evaluation: three EU-funded research projects in the domain of multi-stage manufacturing, eLearning and cloud computing and additionally in an in-house development project, in the area of decision modelling extensions. These cases have been selected since the involved partners have varying profiles and expertise in given domains, in development and in modelling method engineering. In the following sub-section we introduce the cases and their requirements in method engineering manner.

Case 1: Conceptualization of a Modelling Method for E-Learning: The FP7 project Learn PAd [24] proposes a process-driven-knowledge management approach based on conceptual and semantic models for transformation of public administration organizations into learning organizations. Learn PAd proposes a model-driven collaborative learning environment. In this case, 4 domain experts and method engineers have been involved. In addition, two developer teams, each consisting of 4 developers worked on the implementation of the tool. The results of the conceptualization process of this modelling method can be found at Learn PAd Developer Space [25], as well as the developed prototypes [26] can be downloaded and feedback can be given.

Case 2: Conceptualization of Modelling Method for Cloud Computing: The H2020 project CloudSocket [27] introduces the idea of Business Processes as a Service (BPaaS), where conceptual models and semantics are applied to align business processes with Cloud-deployed workflows [28]. In this case, 6 domain experts and method engineers have been involved, as well as two developer teams, one with 5 developers, the other one with 2 members. The results of the conceptualization process of this modelling method can be found at CloudSocket Developer Space [29], as well as developed prototypes [30] can be downloaded and feedback can be given.

Case 3: Conceptualization of Modelling Method for holistic Manufacturing System Management:

The H2020 project DISRUPT [60] deals with the integration of innovative technologies into a holistic manufacturing system and optimization of production flow. The DISRUPT projects needs a modelling method to describe manufacturing system from supply-chain level down to shop-floor level. In this case 2 domain experts, one requirement engineer and one method engineer have been involved. Preliminary results can be found on DISRUPT Developers Space [61].

Case 4: Integration of existing BPMN and DMN Modelling Methods: The in-house project requires integration of an already implemented DMN Modelling Method into existing BPMN 2.0 realization as part of a commercial product. In this case, 3 domain experts and method engineers, and a team of two developers have been involved.

The evaluation process was enacted in the following steps: (1) Provisioning: the tools -of the toolbox have been provided to the stakeholders in the involved cases. (2) Team Formation: representatives, - of the stakeholders in the project created development teams consisting of domain experts and method engineers following the conceptualization process and developing tools individually. (3) Feedback Phase: individual results have been consolidated periodically through video conferences and workshops, constituting the evaluation results.

Feedback on MMDE.

Pro: It is possible to specify requirements and dependencies among them as well as tracing them; (2) to define modelling language fragments and modules, (3) layering the modelling language with navigational constructs; (4) definition of syntax, semantic and assignment of notation (concrete syntax); (5) definition of weaving among construct in different meta-models; (6) assignment of (multiple-) graphical notation (concrete syntax); (7) explicit definition of modelling procedure;

Contra: It is not possible to define application scenarios and use cases, and design results can be exchanged solely using ADOxx specific formats or as static content (image, PDF or HTML). Hence, double effort in the design and in the formalisation and or development is currently necessary.

Outlook: The MMDE is currently updated, to offer an XML export, which then can be transformed into different formats like the one that is used for the ADOxx-Java-MM-DSL.

In addition, several improvements on the modelling language are implemented to (a) enable the design of user scenarios, (b) better describe the features of the modelling method and their corresponding components as well as (c) enable a more detailed representation of the method procedure enabling the mapping from components and the corresponding elements of the modelling method.

Feedback on ALDE.

Pro: it is possible to transform libraries in a machine as well as human interpretable format, ability to use reasoning algorithms, due to standard semantic formats; reduces complexity to edit, merge and maintain libraries.

Contra: To take over results from Design Phase require manual steps.; it re-quires different transformation scripts for different meta-modelling technologies (such as ADOxx, EMF).

Outlook: The semantic-based verification of meta model is seen as a useful extension of the ADOxx-Java-MM-DSL, hence an integration will be experimented. However, we see the necessary skill level for the meta model developer currently as inappropriate and tend not to follow this path.

Feedback on ADOxx-Java-MM-DSL:

Pro: It is possible to merge libraries and start libraries from scratch. Furthermore, the code base can be stored and versioned in a versioning system enabling several developers in parallel to work on one library. Built scripts enable the automatic generation and deployment of the tool.

Contra: The current code maturity needs improvement and documentation, enabling also non specialists to handle the tool.

Outlook: This tool will be further improved and tested in two EU-H2020 research projects and will consequently be taught at the

ADOxx.org Training Days and Webinars to achieve the required maturity.

Feedback on ADOxx.org Tool Packing Services and Developer Spaces.

Pro: It is possible to have an installation package to distribute to interested stake-holders, building your own community around the modelling method, and get feed-back from them.

Contra: Setting up and handling issues of a certain Developer Space involves certain manual steps, such, as the interested stakeholder has to send an e-mail to the administrator with a request of an own Developer Space.

Outlook: This tool packaging service will be stepwise opened, so that the developer can also include own software components, which are then composed into a single tool package.

6. Conclusion and Outlook

In this paper we introduce a toolbox instantiating the Modelling Method Conceptualization Process, which supports agile modelling method engineering. The toolbox has been evaluated through an analysis of four different cases: three EU research projects and one in-house project. The evaluation results put forward that having an approach and a corresponding toolbox following the idea of model-driven engineering approach is effective in terms of transferring knowledge from the analysis of requirements up to the development of solutions. Being three main tools, MMDE, ALDE and ADOxx-Java-MM-DSL, prototypes that are at about Technology Readiness Level 5, hence lack of full integration or automatic data exchange ability, and the need of manual steps building Developer Spaces came out as major limitations of the toolbox. As an outlook the following items derived from the evaluation as future work: (1) currently we are evaluating development alternatives of DSLs with using Xtend [62] or RDF; building on existing work [63] in the field and integrating it into ADOxx-Java-MM-DSL, (2) enabling graphical modelling method design to transform into machine understandable format, (3) formalization of modelling method design using mathematical models such as FDMM [33] or Proof of Concept prototyping, (4) automatization of tooling services and deployment onto developer spaces, (5) full integration of tools within a holistic development environment.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This work has been partly supported by European Union's Horizon 2020 research and innovation programme within the projects DISRUPT(www.disrupt-project.eu) under grant agreement No: 723541 and CloudSocket (www.cloudsocket.eu) under grand agreement no: 644690.

ABSTRACT

Vehicular ad-hoc networks (VANETs) are still more challenging to overcome even if they have been widely studied during the last decades. The routing mechanism is the essentially relevant issue in this field. Indeed, it must strictly to be adapted to specific and unique characteristics such as the high mobility of the vehicles, the dynamic nature of network topology as well as the high link breakage probability. In this paper, our objective is to improve the greedy perimeter stateless routing protocol (GPSR) as being the most promising position-based mechanism. However, according to the impact of position information on routing decision, our proposed approach defined by GPSR+PRedict protocol ensures that each vehicle estimates its own position for the near future. Afterwards, through extensive experiments, we show the ability of the GPSR+PRedict to overcome the observed problems and to enhance the overall performance of the traditional GPSR approach. The simulations are carried out on both highway and urban scenarios by using NS-2 and VanetMobiSim simulators.

1. Introduction

Vehicular ad-hoc network (VANET) is a new class of mobile ad-hoc network (MANET) that has emerged through the advances of wireless technologies and automotive industry [1]. This application field has become the core of the intelligent transport systems (ITS) in order to enhance road safety and improve comfort of road users [2, 3]. In addition, VANET's main features are [4]: traffic monitoring, traffic control, increasing visibility in dangerous intersections, detection of collisions and real time traffic calculation. Moreover, other applications apart from intelligent transport reside on providing connectivity to network or any communication between vehicles (e.g. games, chats or file exchange).

VANET behaves distinctly when compared to the other infrastructureless networks. Indeed, it is distinguished by specific and unique characteristics, especially, the huge mobility of the vehicles and the instability of network topology [5-7]. Consequently, a series of constraints and challenges including security, quality of service (QoS), and routing mechanism should be raised to meet the needs of aforementioned VANET features [8]. For that reason, different proposals and research studies are booming in order to achieve better results than the previously proposed solutions.

To be part of such network and be able to exchange messages smoothly either between vehicles (vehicle-to-vehicle communication (V2V)) or between vehicles and roadside infrastructure (vehicle-to-roadside communication (V2R)) [9], the intelligent vehicle represents the main application. Nevertheless, it must be equipped with some electronic tools namely, wireless communication devices, environmental perception devices (e.g. radars, cameras…), geographic positioning systems (e.g. GPS) [10, 11], and a platform for processing incoming and outgoing information. Figure 1 shows some of these intrinsic equipment [12, 13]. This paper is based

on purely V2Vad-hoc communication architecture, but it could be easily adapted to V2R communication with only simple changes.

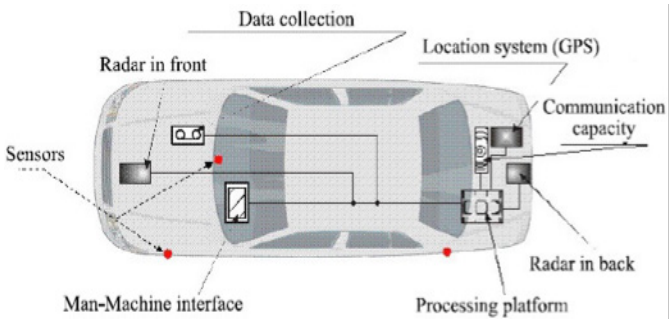

Figure 1: Illustration of different components of an intelligent vehicle [13]

Within this ever-changing vehicular ad-hoc network, messages must be transmitted smoothly from a vehicle to another in order to reach their final destinations. Hence, a routing protocol should be used to ensure inter-vehicular communications in an efficient manner. Exposed to the difficult constraints of vehicular networks, the obvious question is how to ensure routing with a satisfying quality of service (i.e., short delay, minimum lost packets and low overhead).

VANET routing protocols history starts with MANET protocols [14-18]. Unfortunately, these latter cannot achieve a good performance when they are used directly in high challenging environment like VANET. Therefore, many researches focus on adapting these protocols in order to be suitable for VANETs [19-22]. The geographical routing protocols [23-25] are considered as the most stable and functional schemes for VANET's large-scale areas compared to the topology-based routing protocols [26]. The Greedy Perimeter Stateless Routing (GPSR) is a typical example of protocols based on geographical location[27], where each node uses the current information of its position, the position of its neighbors and that of the final destination to make the routing decision.

Considering three significant points, namely, 1) the interest that presents the location's information and vehicles' movement on the both vehicular networks and geographic protocols, 2) the unemployment of amount information, namely, speed and direction given by GPS, 3) the problems observed in geographic protocols as link breakage, it would be advantageous to exploit all these information together to estimate future positions and to consider them during decision process of routing protocols.

In this context, a new geographical routing protocol based on GPSR is proposed. The improvement is mainly defined by using supplementary information to estimate the location of vehicles in the near future. This estimated future position will be included in the periodic message (hello packet) in order to be taken into account in the decision of the best next hop.

The rest of the paper is organized as follows: Section 2 summarizes the related works of routing protocols over VANETs. In Section 3, we provide a brief overview of GPSR protocol. Section 4 describes fully the design of our proposed GPSR+PRedict routing protocol. Simulation settings are presented in section 5, while section 6 shows the effectiveness of GPSR+PRedict via simulation experiments. Finally, the section 7 concludes the study and provides a number of recommendations.

2. Related Work

Actually, there are a lot of studies that are interested to the MANET routing protocols adjustment for being used in VANET environments effectively [28]. Additionally, most of researchers are gathering on the point that the geographical routing protocols are the most suitable for vehicular network [26, 29, 30]. Hence, our attention was directed towards one of the protocols belonging to this class: the famous GPSR protocol. GPSR protocol selects the shortest possible route to destination; however, it may suffer from a higher packet error rate due to the poor link quality or the high break link probability.

To this end, many improvements have been recommended. The authors of [31] proposed the cross-layer weighted position-based routing (CLWPR) to improve the efficiency of geographical routing protocol in vehicular network. The proposed algorithm utilizes information about link layer quality and positioning from navigation to anticipate the characteristics of an urban environment. Compared to the default GPSR, CLWPR demonstrates significantly better performance in terms of packet delivery ratio and end-to-end delay metrics. In the same context, authors of [32], designed an enhanced GPSR protocol and presented its performance for both urban and highway scenarios. The novelty resides on the fact that they used weight calculation to select best neighbor (best next hop). To compute this weight, they used location and velocity information as well as link quality metrics extracted during the hello messages receipt to produce routes that improve the performance of the network. Their proposed protocol achieves higher packet delivery ratio for the network, lower end-to-end delay, while keeping the energy consumption at the same low levels of GPSR. Furthermore, a grid-based predictive geographical routing protocol (GPGR) has been proposed by the researchers of [33]. Indeed, they used a map data to generate the road grid and to predict the moving position during the relay node selection process. Thus, it was noticed that the GPGR protocol reduces the possibility of link breakage and avoids falling on local maximum situation in urban scenarios. Moreover, authors of [33] suggested a new concept based on vehicles movement prediction. In fact, they estimated the Link Stability (LS) for each neighboring vehicle before selecting the next hop for data forwarding/sending. In this way, movement prediction-based routing (MOPR) protocol determines the most stable communication link of the network in terms of communication lifetime with respect to the movement of vehicles. Afterward, they selected the most stable route from the source till the destination.

To the best of our knowledge, all these approaches have been beneficial in most scenarios, but they concentrate all the required calculation on the forwarder during best next hop process or at the moment of receiving beacon packets, which can affect desperately the network's performance. In addition, in most of these aforementioned enhancements, there is a radical change in the process of choosing the best next hop of the default GPSR using more complicated calculations.

For that reason, we propose in our study to filling the observed gaps and to enhance even more the routing process while retaining the basic mechanism of GPSR protocol. Thus, our new GPSR+PRedict routing protocol does not include direction and speed knowledge in the hello packet, but it includes the estimated future position calculated according to this knowledge. Thereby, each vehicle is able to anticipate the state of its neighborhood in the near future. Our idea is directed regarding both highway and urban areas.

3. Overview of GPSR

GPSR was originally created for MANET, but quickly adapted to VANET [27]. It is one of the most known examples that approve the concept of position based routing. GPSR protocol switches between two forwarding strategies depending on the situation of communicating nodes. Usually, when node needs to send packets, it uses the first forwarding strategy defined by greedy forwarding strategy (GFS). In case of failure (i.e., there is no neighbor with least distance to the destination except the transmitter node itself), GPSR bypasses the problem by using the second strategy known by perimeter forwarding strategy (PFS). Figure 2 illustrates the behavior of GPSR.

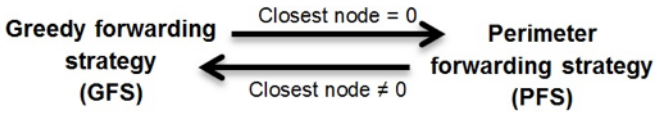

Figure 2: Communication strategies of GPSR

3.1. Maintain strategy

In GPSR, before choosing the best path to route a data packet, each node in the network must know its neighbors and their positions. Hence, the nodes flood the network by sending hello packets (beacon packets) containing current position and an identifier. Indeed, each node periodically shares a hello packet with the existing nodes within its own range radio, and simultaneously collects the information sent by these nodes. Due to the beacon packets exchanges, each node can build its own table of neighbors thanks to the collected information, and can maintain it according to the next beacon packets.

3.2. Routing strategy

In greedy forwarding strategy (see figure 3), the best next hop is selected based on the optimal path, i.e., it always selects the progressively closer node to the destination. This process is repeated at each intermediate neighbor until the intended destination is reached. With this routing decision, the packet can reach the destination through the optimal path in the aspect of distance. However, sometimes the forwarder vehicle has the shortest distance to destination compared to all its neighbors. In this context, there are two cases. In the first one, the final destination is under the radio range of transmitter vehicle; therefore, packet is forwarded directly. The second case is when the final destination is not accessible in a one hop, so it is impossible to use the GFS. Thus, the PFS is used in order to solve this problem (see figure 4). The PFS algorithm recovers by routing around the perimeter of the region until arriving at a node closer to the destination. At this moment, the GFS takes over.

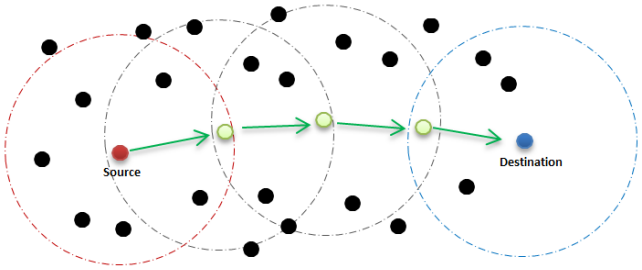

Figure 3: Greedy forwarding packets of GPSR

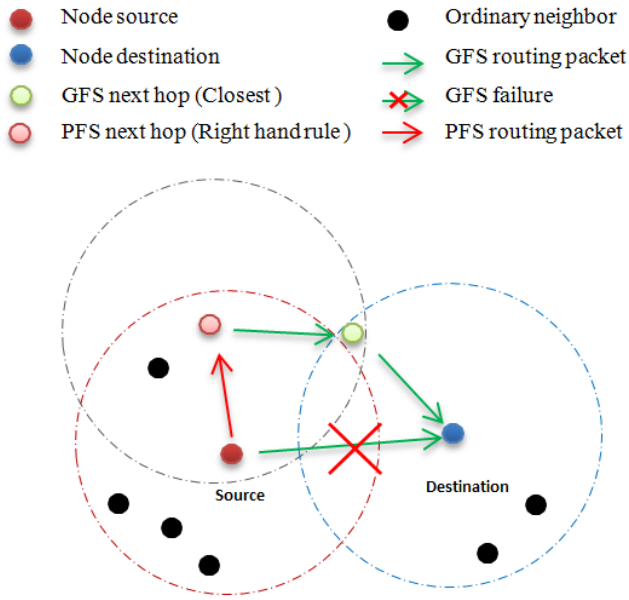

Figure 4: Coping with gap encountered thanks to perimeter forwarding strategy in GPSR

3.3. Benefits and Drawbacks

The most important advantage of GPSR, distinctly from the other proactive and reactive protocols, is the fact that the vehicles can get the exact movement information (e.g. geographic position, speed and movement direction) according to a positioning system like GPS or GALILEO. In addition, the one-hop propagated information over the topology, leading to know the geographic position of every single neighbor, minimizes more or less the network overload which is advantageous especially in dense networks. However, regarding the greedy routing strategy, the vehicle often chooses the best next hop in the distance aspect. Nevertheless, without considering speed or moving direction while researching the best next hop, the GPSR protocol could lead to wrong packet forwarding decisions, which may cause packet loss. Moreover, the link breakage problem can also affect the quantity of delivered packets, particularly in highway environment. Actually, when node receives a beacon packet to update its list of neighbors, it computes the best next hop, then it forwards packet. So, during this process, the selected neighbor can be out of the transmission range and the packet cannot reach it because of high network's mobility. In order to solve these problems that lead to performances degradation, we thought that it would be appealing, in terms of QoS, to improve the routing strategy. The enhancements are mainly based on the estimation of the future position of all participating nodes in routing operation. In the next section, a deep description of all proposals is provided.

4. GPSR+Predict

4.1. Motivation

GPSR+Predict has been conceived on the basis of three significant aspects: First, the importance of node's localization in geographic protocols. Second, the information available in GPS but not exploited by GPSR. Third, the various problems

encountered, for example, high breakage link probability due to the great mobility with different speeds, bad routing decisions due to opposite directions of vehicles, or inaccuracies in the prediction of the driver's direction at intersections.

In our point of view, it is constructive to propose a new greedy routing mechanism that estimates positions of the vehicles in the near future and takes this information into consideration to make smart routing decision.

4.2. Prediction the near future position

With the proposed protocol, each node uses its geographical position, its speed and its direction to estimate its position in a near future. This future position is attached to the hello packets and recalculated at each sent of periodic hello packet. In this way, node continuously has a prediction of future state of the network.

Moreover, unlike the basic GPSR, where the sender node simply searches the nearest neighbor to the destination when it needs to forward a data packet, that of the "GPSR+PRedict" searches firstly if the destination is in its list of neighbors. If it is the case, the packet data is sent directly to the destination, if not, then the sender searches the best next hop in terms of distance by using the estimated future position of neighbors. In fact, GPSR+PRedict practices this strategy in order to know the neighbors that will still or not in sender's neighborhood. Thus, it will make a smarter routing decision by avoiding several bad situations such as link breakage.

The choice of the prediction model is fundamental because it does not affect only the quality of prediction but also the speed and time of the calculation. In fact, there are different mathematical extrapolation methods with different levels of complexity allowing the estimation of future positions of vehicles [35-37]. For this study, we have opted to use a method based on previous positions, direction and speed. This technique is basic with very little intricacy so that the hello packet size does not involve the network overhead (i.e., it does not incur much bandwidth or computational power).

As mentioned above, this model exploits previous positions $\boldsymbol{X_{t0}}$ and velocity $\vec{\boldsymbol{V}}(\boldsymbol{X_{t0}})$. The velocity vector is calculated by using the current speed and heading direction of a vehicle (see equations (1) and (2)).

$$\vec{\mathbf{V}}(\mathbf{X_{t0}}) = \mathbf{dX_{t0}} * \mathbf{Speed} \quad (1)$$

$$\vec{\mathbf{V}}(\mathbf{Y_{t0}}) = \mathbf{dY_{t0}} * \mathbf{Speed} \quad (2)$$

Where dX_{t0} and dY_{t0} are a unit vector that indicate the direction of the vehicle at time t_0.

Therefore, the future position from any node can be calculated with the following equations (3) and (4):

$$\mathbf{fut(X_{t0})} = \mathbf{X_{t0}} + \vec{\mathbf{V}}(\mathbf{X_{t0}}) * \Delta\mathbf{T} \quad (3)$$

$$\mathbf{fut(Y_{t0})} = \mathbf{Y_{t0}} + \vec{\mathbf{V}}(\mathbf{Y_{t0}}) * \Delta\mathbf{T} \quad (4)$$

Where ΔT is the time between two hello packets.

4.3. Optimization

The highlight is to improve routing mechanism by assisting GPSR protocol to make smarter routing decisions and to better choose the suitable neighbor as next hop while maintaining the basic search process of best next hop. Also, we aim to optimize the calculation processing of GPSR and to not concentrate all the processing on the router of the data packet.

From most existing prediction approaches applied to the geographic protocols, the direction and the speed are added then sent in the hello packets. Hence, the nodes do not predict the future positions only after receiving these hello packets or during the research of the next best hop process, i.e., each node must traverse its entire neighbors list and make the required calculation to estimate the future position of each neighbor. This procedure causes two mainly drawbacks: the first is that each node has a lot of calculations to perform, while the second resides on the fact that the same calculation is repeated by several nodes (shared neighbors). As consequence, this strategy of prediction is not optimal and can affect the performance and the QoS especially in dense networks. We have addressed this problem by proposing the idea that each node in the network exploits its information (position and velocity) and estimates its future position in advance, then includes the result in the hello messages (see table 1). In this way, the calculations will be dispersed over the network and will be performed only once by the concerned node.

Through GPSR+PRedict protocol, when a node broadcasts the beacon packet to the other vehicles within its radio range, each vehicle that receive this hello packet, stores all information in its neighbors list. Therefore, the current and the future positions information are available to be used while computing best next hop. The illustration of both hello packet and neighbors list used in GPSR+PRedict is shown respectively in tables 1 and 2 taking the node1 at time t_0 as example.

Table 1: Format of hello packet

ID node	Geo-coordinates of node		Future position estimated of node	
1	X_{t0}	Y_{t0}	$fut(X_{t0})$	$fut(Y_{t0})$

Table 2: Format of neighbors list

ID neighbors	Geo-coordinates of neighbors		Future position estimated of neighbors	
1	X_{n1_t0}	Y_{n1_t0}	$fut(X_{n1_t0})$	$fut(Y_{n1_t0})$

Figure 5 summarizes all that has been explained concerning our improved greedy routing strategy. It represents the sending process of the hello packets and that of the data packets as well.

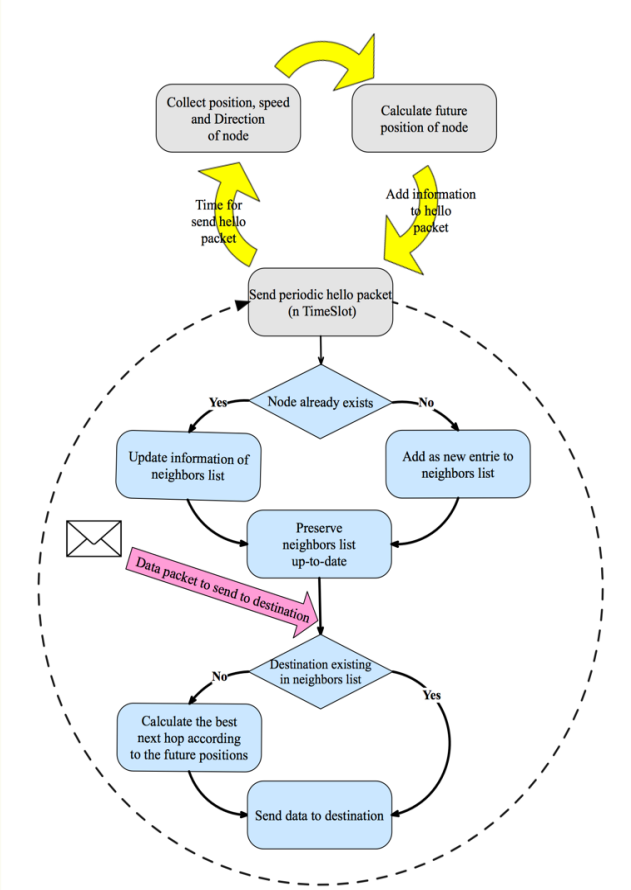

Figure 5: Greedy strategy of new GPSR+PRedict protocol

Our interest to improve the GPSR's routing mechanism is clearly motivated by the three cases presented respectively in figures 6, 7 and 8. It should be noticed that the default GPSR routing mechanism forms the red route (red arrows) where there is often breakage links, while the GPSR+PRedict routing mechanism forms the optimal green route (green arrows).

From figure 6, according to the default greedy strategy, the source node chooses the node A as the next hop since it is the closest one to the final destination. Nevertheless, the packet will be lost since the direction of A is different from that of the destination. The proposed mechanism forms the green route and avoids the problem of opposite directions that will occur in the red route in a very short amount of time.

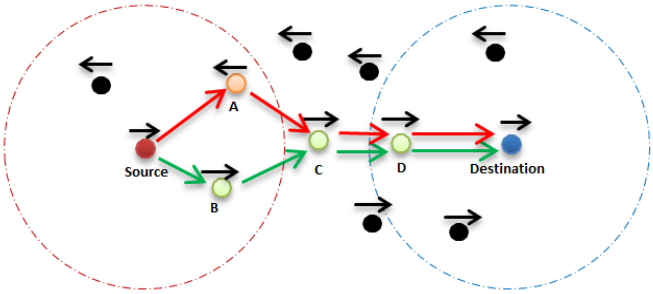

Figure 6: Problem of opposite direction in GPSR

Another problem is overcome as shown in figure 7: the problem of out of the radio range. In fact, according to the default GPSR forwarding process, when the highly mobile node marked by A is chosen as the next hop to send data packet to the final destination, it will be out of the range before the starting of transmission. In regards to GPSR+PRedict, it anticipates link breakage problem, which certainly will occur, and avoids it by selecting the node B as the next hop.

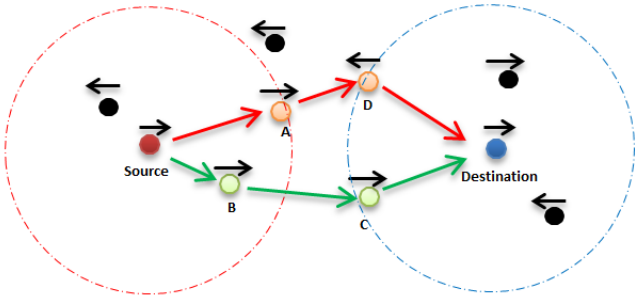

Figure 7: Problem of out of radio range in GPSR

In figure 8, considering that the vehicle B is much faster than A, so the vehicle B will exceed the vehicle A in a very short period of time. With GPSR+PRedict forwarding process, the source expects this situation since it has a future position estimated of its neighbors A and B. Consequently, the source chooses the node B as next hop instead of node A in case of classical GPSR. Thus, the speed problem is bypassed.

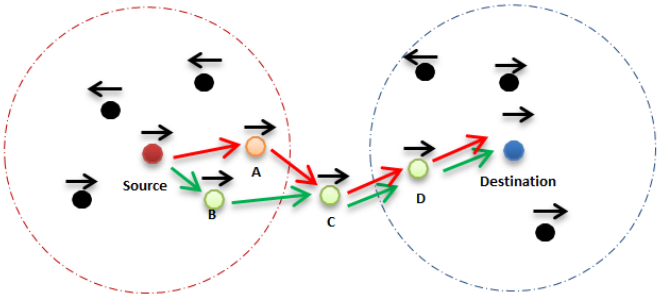

Figure 8: Problem of speed in GPSR

5. Simulations settings

5.1. Parameters of simulation

In the literature, various tools have been implemented to perform experimental studies. In this paper, we used NS-2 software which is the most employed simulator to study the protocol's performance [38]. Additionally, VanetMobiSim is used as a realistic mobility traffic generator [39, 40], where vehicles travel according to an Intelligent Driver Model with Lane Changes (IDM-LC). VanetMobiSim simulator is considered as the most efficient mobility modeling framework. Indeed, itis widely used to simulate realistic automotive motions at a macroscopic and microscopic level. Here, we have used this software to generate both of realistic mobility models and realistic urban/highway traffic environments. The output mobility trace obtained from VanetMobiSim is directly used as input in NS-2.

In order to evaluate the effectiveness of our enhancement, we have opted to compare our GPSR+PRedict and the default GPSR protocol in highway and urban scenarios since they are two

different milieus with a very distinct infrastructures and traffic rules. Each scenario is designed by varying the number of vehicles from 50 to 350 vehicles and keeping data traffic sources number at15 connections. The "TwoRayGround" model is employed as propagation model. The protocol MAC sets according to the IEEE 802.11p standard, and operates at 5.9 GHz on a 10 MHz control channel (CCH). The PHY data rate is configured to 6 Mbps, which is the minimum value to safe the communication [41]. The couples' source/destination were randomly selected and all nodes exchange beacon packets every 5 seconds (i.e., hello period) according to those protocols. Table 3 shows the common configuration parameters for the following set of experiments.

Table 3: Network parameters for both highway and urban scenarios

NS2.33 network simulator	
Parameter	**value**
MAC Layer	802.11p
Propagation Model	Two-Ray-Ground
Radio range	250 meters
Traffic model	CBR/UDP
Hello Period	5s
Hello Timeout	50 s
Time Simulation	500 s
Packet Interval	1 pkt/s
Packet Size	512 octets
Number of traffic	15 connections
Number of vehicles	50, 100, 150, 200, 250, 300 and 350
Routing Protocols	GPSR+PRedict and GPSR

5.1.1. *Urban scenario*

For urban scenario, a space of 1000*1000 meters^2 is randomly generated. It consists of various intersections, two-way road, and different density of vehicles in motion with variation speed between 20 and 60 km/h. Figure 9 illustrates the urban topology used for our experiments, while table 4 shows the parameters of the mobility scenario.

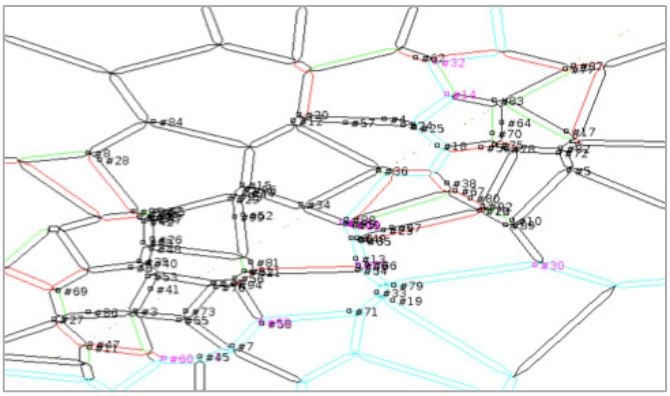

Figure 9: Urban topology randomly generated by VanetMobiSim

Table 4: Urban mobility model parameters

VanetMobiSim mobility generator: urban scenario	
Parameter	**value**
Mobility model	IDM-LC
Space area	1000*1000 meters^2
Vehicle speed	20 to 60 km/h
Traffic light	10
Number of lanes per direction	2

5.1.2. *Highway scenario*

In this subsection, a highway scenario over 700*5000 meters^2 is randomly generated. It consists of two-way road, i.e., two lanes per direction, without any traffic lights. Different density of vehicles is driving at speeds varying between 80 and 120 km/h. Figure 9 illustrates an example of the highway topology used for our simulations, while table 5 shows the parameters of the mobility scenario.

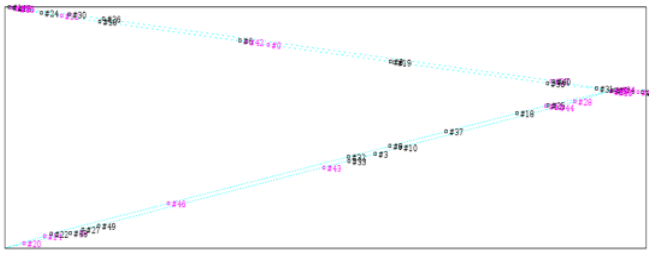

Figure 10: Highway topology randomly generated by VanetMobiSim

Table 5: Highway mobility model parameters

VanetMobiSim mobility generator: highway scenario	
Parameter	**value**
Mobility model	IDM-LC
Space area	700*5000 meters^2
Vehicle speed	80 to 120 km/h
Traffic light	0
Number of lanes per direction	2

5.2. *Metrics*

In order to evaluate and assess the performance of the simulated routing protocols, we use the following metrics:

Packet Delivery Ration (PDR): corresponds to the ratio between the number of packets of data correctly received by the destinations and the number of packets sent by the sources; this latter allows revealing whether a protocol is able to send all outgoing data packets. The final equation of PDR shown in (5):

$$\boldsymbol{PDR = \frac{\sum Received\ Packets}{\sum Sent\ Packets}} \quad (5)$$

End-to-End delay average (E2E) is defined as the average time that a data packet takes to travel from the source to the destination vehicle. It represents the main parameter that must be improved during the evaluation of a routing protocol. A good protocol must have an end-to-end delay average as low as possible. Its calculation is as follows in equation (6):

$$E2E = \frac{PacketTransmissionTime}{\sum Received\ Packets} \quad (6)$$

Throughput: it measures the flux or the quantity of data traveling over a communication channel per unit time, usually expressed in bits per second or packets per second. We use the following equation (7) to calculate the average throughput:

$$Throughput = \frac{Size\ of\ ReceivedPacket}{TimeReception - TimeSending} \quad (7)$$

Route-costs is calculated by dividing the total number of bytes of the routing packets that (includes forwarded routing packets and control packets as well) and the total amount of the received data (see equation (8)).

$$Routecosts = \frac{\sum Size\ of\ TransmittedRoutingPackets}{\sum Size\ of\ ReceivedDataPackets} \quad (8)$$

Normalized routing Load (NRL) defined as the total number of routing packets transmitted per data packet. It calculated by dividing the total sum of routing packets that sent (includes forwarded routing packets as well) by the total number of data packets received as follows in below equation (9):

$$NRL = \frac{\sum TransmittedRoutingPackets}{\sum ReceivedDataPackets} \quad (9)$$

6. Simulation Experiments

Initially, the objective of our experiments is to evaluate the effectiveness of our improved protocol, taking into account the impact of node density regarding routing quality of service. Therefore, we varied the number of vehicles to 50, 100, 150, 200, 250, 300 and 350 respectively, while keeping number of connections fixed at 15 connections. In order to guarantee the credibility and reliability of the experimental results, we respectively made 10 time experiments during 500 seconds for each simulation. The simulations result in both highway and urban are presented in figures 11 to 20, in which we illustrate the packet delivery ratio, the average end-to-end delay, the throughput, the route-costs and the normalized routing load for GPSR+PRedict and default GPSR.

In figures 11 and 12, default GPSR seems to have worst performance in both scenarios, while our proposed GPSR+PRedict gives good values. This is because GPSR+PRedict anticipates in advance the changes of vehicles localizations. Thus, it avoids the problems caused by the high mobility of the vehicles and the dynamic nature of the topology. In the highway scenario, our approach remarkably improves the PDR compared to the default GPSR since the GPSR mismanages the very high mobility of vehicles.

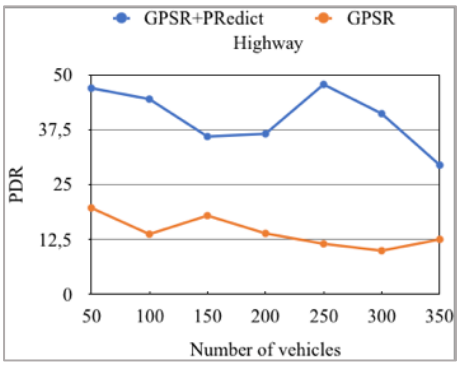

Figure 11: Packet Delivery ratio VS nodes density in highway scenario

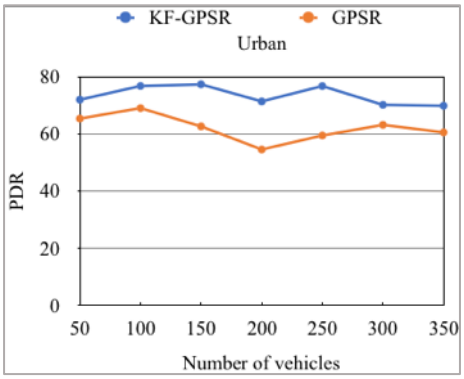

Figure 12: Packet Delivery ratio VS nodes density in urban scenario

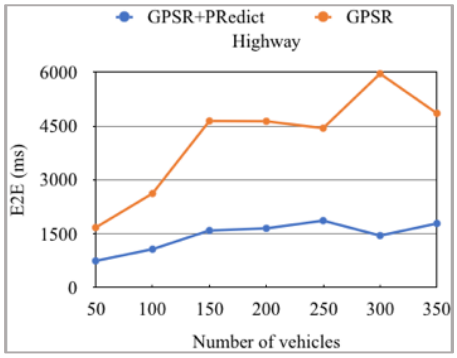

Figure 13: End-to-end delay VS nodes density in highway scenario

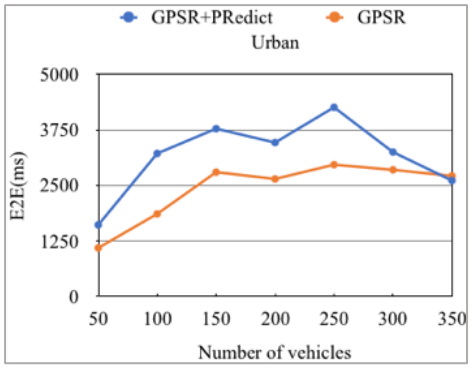

Figure 14: End-to-end delay VS nodes density in urban scenario

In figure 13, regarding the highway scenario, it can be noticed that the classical GPSR has the longer average end-to-end delay due to the outdated location information that results very probably data loss. While, GPSR+PRedict decreases End-to-end delay since it avoids the wrong routing decisions by using future position estimated, hence, the routed data packet will have less chance to be lost. In contrast to the urban scenario (see figure 14), we note that our enhanced protocol has the worst end-to-end delay. This is probably because of two things: its higher PDR compared to the default GPSR, and the mobility of vehicles, which is relatively inferior in this environment than in the highway.

Figures 15 and 16 present the flow in function of density. Both figures show that our improved GPSR+PRedict has higher flow than default GPSR. This can be explained by the fact of the good receipt of data packets. As we see, the performance of default GPSR is very low compared to our approach especially in the highway scenario. This is probably because of these bad routing decisions since it does not take into account the high mobility of vehicles, and this is clearly seen from the significant drop shown in figure 16.

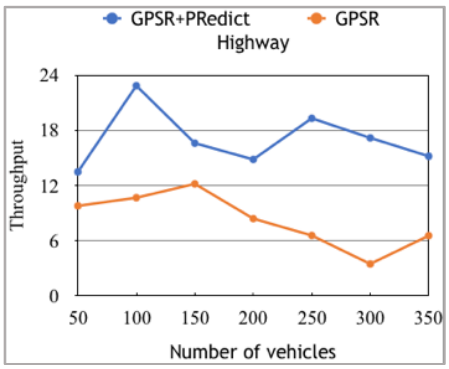

Figure 15: Throughput VS nodes density in highway scenario

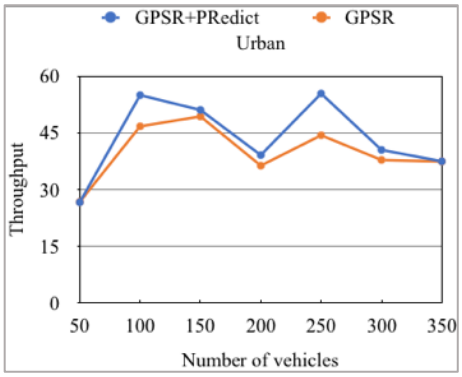

Figure 16: Throughput VS nodes density in urban scenario

Figures 17 and 18 illustrate the cost of routing according to the number of moving vehicles respectively in both highway and urban scenarios. The simulation results show that GPSR+PRedict guarantees low cost of routing compared to the default GPSR in highway scenario (see figure 17). The improved protocol suffers less from link breakages, which conduct to less packet loss and less routing cost. As for results of urban scenario presented in figure 18, GPSR+PRedict has a very slight rise in cost of routing compared with default GPSR. These values can be justified by the high PDR of GPSR+PRedict in the same scenario.

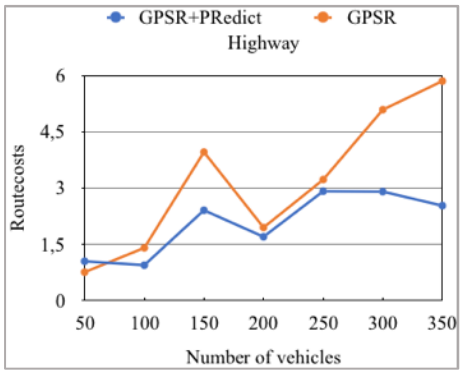

Figure 17: Route-cost VS nodes density in highway scenario

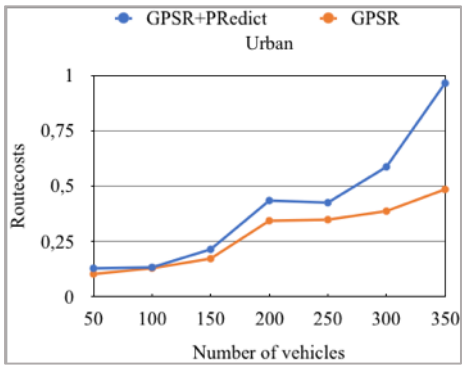

Figure 18: Route-cost VS nodes density in urban scenario

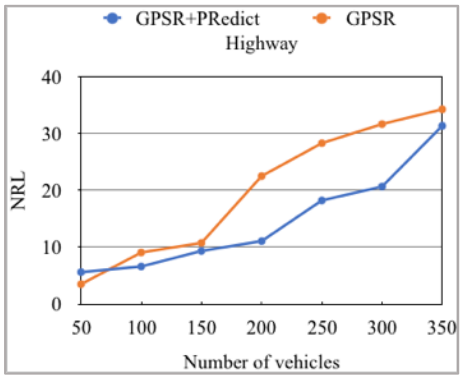

Figure 19: Normalized routing load VS nodes density in highway scenario

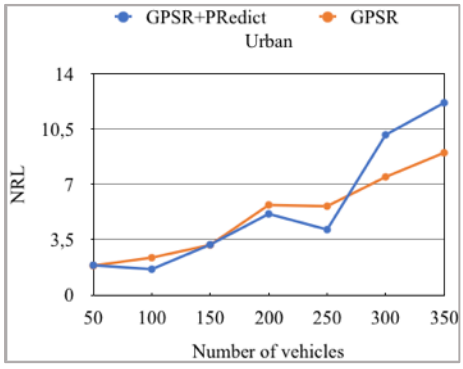

Figure 20: Normalized routing load VS nodes density in urban scenario

In regards of density, the normalized routing load increases when there are more router packets in the network. As shown in figures 19 and 20, the NRL proportionally increases with the number of vehicles. In The highway environment (figure 19) the performance evaluation shows that GPSR+PRedict outperforms GPSR in term of the normalized routing overload rate. As for the urban environment, presented in figure 20, our enhanced GPSR+PRedict improves the NRL for almost all the tested cases. In fact, default GPSR marks slight results than the GPSR+PRedict, especially in very dense network.

Regarding comparison of the obtained results for both routing protocols, it is clear that the proposed enhancement GPSR+PRedict practically guarantees better performance in all simulations compared to default GPSR.

The enhancements of GPSR protocol that are made in order to adapt it to the specific characteristics of VANET, have shown their gains especially in highway environment where mobility and topology are instable. Indeed, we notice a significant progress with all metrics in all cases compared to default GPSR. Meanwhile, in urban environment where mobility and topology are relatively less dynamic, our approach improves quietly packet delivery ratio, flow and normalized routing load. However, for average end-to-end delay and route-costs, the default GPSR is better, but the deficit is quite small and tolerable. Therefore, the proposed enhancement is a strong candidate to implement with GPSR.

7. Conclusion and Perspectives

In this paper, a new routing approach is developed in order to guarantee a high quality of service in VANET areas. The novelty resides on the simplicity of design and identity preserved of the original GPSR protocol. In fact, GPSR+Predict routing protocol exploits in a simple and optimized way node movement information, namely the position, the direction and the speed, to estimate vehicles localization in the near future. This predicted future position will be included in the hello packet and diffused periodically among neighbors, hence, it will greatly contribute to make a smart routing decision and to better select the appropriate next hop.

Our simulations using different frameworks (NS-2, VanetMobiSim) are directed respectively in both highway and urban environments with taking into account the impact of density. The results show that GPSR+PRedict has the ability to preserve and to increase the performance of the vehicular network. Moreover, it indicates that the proposed technique avoids relatively various problems resulting from the delicate properties of this type of networks. Indeed, it achieves a higher packet delivery ratio, a low end-to-end delay, a low routing cost, a low routing overhead and a high throughput, practically in all scenarios.

For future work, we plan to enhance the accuracy of prediction to be more near to reality, and to carry out more enhancement considering QoS on large environments. Furthermore, it should be noted that the proposed approach is appropriate for constant bit rate traffic (CBR); we plan to extend the approach to other types of applications, for example, streaming in multimedia application.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper presents the synthesis of a dynamic space vector modulation for power matrix converters so that it is possible to implement a universal modulator that provides a control algorithm dynamically optimized according to the requirements for the matrix converter.

1. Introduction

In recent years the three-phase to three-phase matrix converter has received considerable attention as an alternative to hard and soft switching dc link converters. This paper is an extension of work originally presented in International Symposium on Electronics and Telecommunications ISETC '16 Twelfth Edition [1]. The SVM (space vector modulation) control strategy for matrix converter offers the best performance, maximal voltage gain and controllable input displacement factor. There are several possible SVM algorithms focused first on reducing energy losses or optimizing the parameters for output voltage and input current [2]. The optimum choice of one of the SVM techniques is a complex task because these requirements are contradictory since reduced power losses mean a reduced sampling frequency leading to a degree of large distortion of waveforms generated by the matrix converter. So for choose correctly a control technique it is required a prior accurate knowledge of the specific conditions which the matrix converter will operate and the characteristics of semiconductor devices which implement the bidirectional switches [3]. Therefore, depending by the operation mode of the power circuit and the conditions imposed by the nature of the load it is useful an implementation of an universal algorithm enabling the transition from an reducing energy losses mode to a very low distortion of the generated waveforms mode and possibility to operation intermediate regimes between them. For this reason it is necessary to implement a digital modulator circuit that allows switching from one SVM algorithm to another without major modifications of the hardware control circuit.

2. Space Vector Modulation

The matrix converter consists of nine bidirectional switches that connect the three outputs with each of the three inputs, as shown in Figure 1. The converter being supplied by a voltage source, the three input phases can't be short-circuited, and the load having generally a mainly inductive character, the load current can't be interrupted. Because of these constraints the nine switches can generate only 27 permitted combinations. The SVM control algorithm uses 21 of these combinations, a number of 18 combinations, A122- A133; B212-B313 and C221-C331 which connect two output phases at the same input, called active states and a number of 3 combinations Z111-Z333 with all three outputs connected at the same input, called passive states of the matrix converter. To analyze the SVM modulation applied to a three-phase system x1, x2, x3, the space vector X of the system can be used, represented in the complex plan according to the transformation:

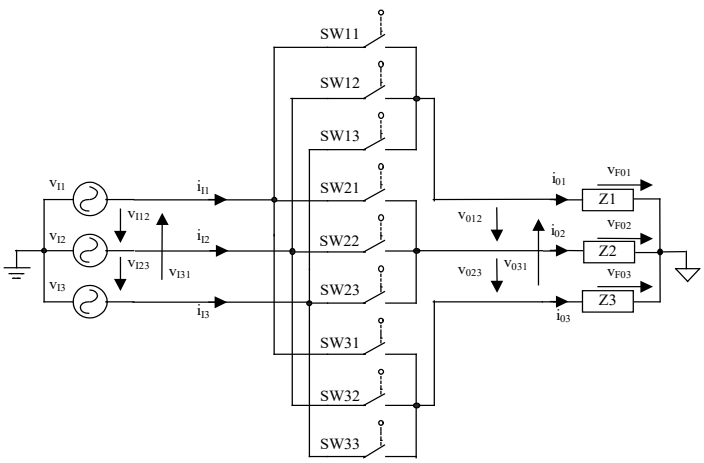

Figure 1: The matrix converter switch layout

$$\underline{X} = Re(\underline{X}) + j\, IM(\underline{X}) = 2/3\,(x_1 + \underline{a}\,x_2 + \underline{a}^2 x_3) \quad (1)$$

where $\underline{a} = e^{j\,2\pi/3}$.

According to this transformation the desired output line voltages space vector is $\underline{V}_{0LW}$ which rotates with the ω_0 angular speed, and the desired input phase currents space vector is $\underline{I}_{IW}$ which rotates with ω_I angular speed as shown in Figure 2 and Figure 3 respectively.

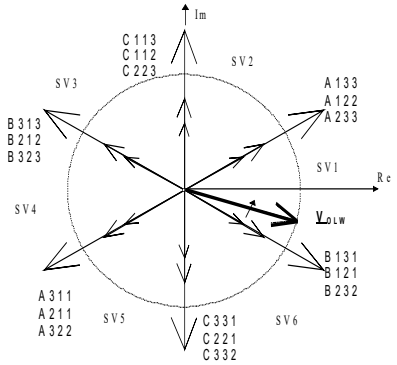

Figure 2: Output voltage SVM vectors diagram

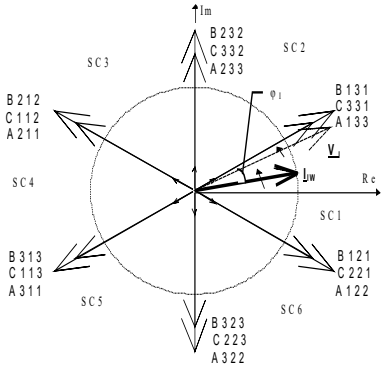

Figure 3: Input current SVM vectors diagram

The circular trajectories of these vectors can be divided in six voltage and current sectors, *SV* and *SC* respectively. If *Ts* time interval is short enough so that the reference vectors $\underline{V}_{OLW}$ and $\underline{I}_{IW}$ do not change significantly, the mean vector space result from different combinations of stationary space vector and null corresponding input voltage line will be equal with the reference vector in this time. Simultaneously it must be performed the desired phase difference between the input current reference space vector and the input voltage space vector, through various combinations of stationary and null space vector corresponding to input currents. The best approximation of spatial reference vector at a time, can be done using vectors that have direction adjacent with the reference space vector [2]. The principle is shown in Figure 4a and Figure 4b, where *a,b* and *m,n* are adjacent directions for output voltage reference space vector and input current reference space vector, respectively. In Figure 4c and Figure 4d it is shown how to choose the vectors for SV1 and SC1 active sectors. In this way from the 21 matrix converter permitted states, in any moment only four active states uniquely established and one of the passive states can simultaneously synthesise the two reference vectors [4]. The order of these active states and the passive state required in a sampling period are chosen so that the number of switches is minimum. Using the trigonometric laws, the normalised time intervals in a sampling period *Ts*, corresponding to the four active states can be established:

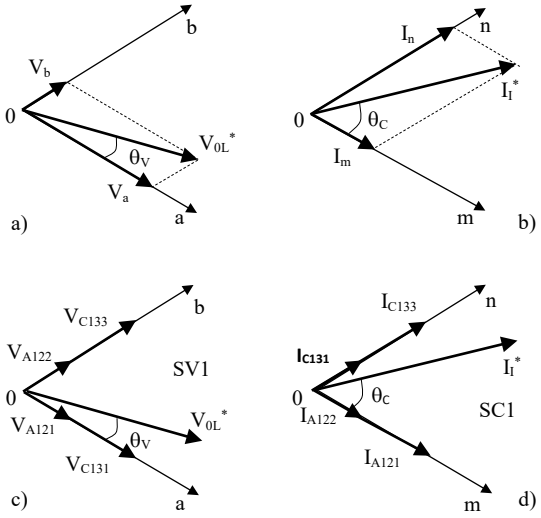

Figure 4: The space vector modulation principle

$$h_{am} = \frac{2}{\sqrt{3}} * (\frac{V_{OL}}{V_{IL}}) * \frac{\sin(\pi/3 - \theta_V) * \sin(\pi/3 - \theta_C)}{\cos(\varphi_I)} \quad (2)$$

$$h_{an} = \frac{2}{\sqrt{3}} * (\frac{V_{OL}}{V_{IL}}) * \frac{\sin(\pi/3 - \theta_V) * \sin(\theta_C)}{\cos(\varphi_I)} \quad (3)$$

$$h_{bm} = \frac{2}{\sqrt{3}} * (\frac{V_{OL}}{V_{IL}}) * \frac{\sin(\theta_V) * \sin(\pi/3 - \theta_C)}{\cos(\varphi_I)} \quad (4)$$

$$h_{bn} = \frac{2}{\sqrt{3}} * (\frac{V_{OL}}{V_{IL}}) * \frac{\sin(\theta_V) * \sin(\theta_C)}{\cos(\varphi_I)} \quad (5)$$

where $h_{am}=T_{am}/T_S$, $h_{an}=T_{an}/T_S$, $h_{bm}=T_{bm}/T_S$, $h_{bn}=T_{bn}/T_S$ an and $1-h_{am}-h_{an}-h_{bm}-h_{bn}=h_z$ [2].

For example, the relation between output and input voltages is

$$\left[v_0^*\right]=\begin{bmatrix} v_{01}^* \\ v_{02}^* \\ v_{03}^* \end{bmatrix}=\begin{bmatrix} 1 & 0 & 0 \\ h_z & h_{am}+h_{bm} & h_{an}+h_{bn} \\ h_{am}+h_{an}+h_z & h_{bm} & h_{bn} \end{bmatrix}\cdot\begin{bmatrix} v_{11} \\ v_{12} \\ v_{13} \end{bmatrix} \quad (6)$$

for *SV1* and *SC1* active sectors. This fact means that the normalised time intervals h_{am}, h_{an}, h_{bm}, h_{bn}, h_z represent the transfer functions for the SVM control strategy.

3. SVM1-SVM3 Versions of Space Vector Modulation

For a three-phase voltage supply for a given three phase output voltages and input phase shift between current and voltage, the association between active SVM and permitted matrix converter states is unique (Table 1). If you know the T_S, then periods T_{am}, T_{bm}, T_{an}, T_{bn}, can be calculated with relationships (2)-(5). In the time interval T_z the matrix converter can pass in any of the passive states. The order in which matrix converter switches from one state to another, within the time T_S, does not affect the local average value of voltages and currents [2],[5]. Basically, choosing between passive states and the order in which the converter switches from one state to another, does not affect the fundamental components of generated waveforms, but it determines the number of commutations required per unit time and the spectral characteristics of generated waveforms. Generally it is intended that the arrangement of the matrix converter states matrix in a sampling period T_S is made such that are necessary as few commutations when passing from one state to another. For example if the active sectors are *SV1* and *SC1* respectively, then from Table 1, the correlation between active states and switching states is *am, bm, an, bn* and *A121, A122, C131, C133* respectively. If a sampling period will use the SVM sequence *am - bm - bn - an -z* , then this corresponds to sequence *A121 -(1)- A122 -(1)- C133 -(2)- C131 -(1)- Z111-(1)-...*, if the z state is associated with Z111state. It is noted that in this case 6 switching are required within the sampling period T_S. If it is kept the same SVM sequence and combination of active sectors is SV1-SC2 then the sequence becomes *C131 -(1)- C133 -(1)- B233 -(1)- B232 -(3)- Z111-(1)-...* which means that required 7switching/T_S. But if the SVM combination is changed as follows *bm - am - an - bn -z* , then we have the next switching sequence: *C133 -(1)- C131 -(2)- B232 -(1)- B233 -(1)- Z333-(1)-...*, if zero state is associated with *Z333* state. It is noted that in this case it is required 6switching/T_S too. Generalizing for all possible combinations it is obtained the Table 2 association which can be easily implemented in a digital control system. Depending on the combination of the active sectors at a time, we define the complementary logical variables *Pa* and *Pb*, as follows:

$$Pa=(SV1+SV3+SV5)(SC1+SC3+SC5)+(SV2+SV4+SV6)(SC2+SC4+SC6) \quad (7)$$

$$Pb=(SV1+SV3+SV5)(SC2+SC4+SC6)+(SV2+SV4+SV6)(SC1+SC3+SC5) \quad (8)$$

Table2: Sequence SVM states and voltage current sectors association for 6switchings/T_S

Active Sectors	SVM States Sequence
SV1-SC1 SV1-SC3 SV1-SC5 SV2-SC2 SV2-SC4 SV2-SC6 SV3-SC1 SV3-SC3 SV3-SC5 SV4-SC2 SV4-SC4 SV4-SC6 SV5-SC1 SV5-SC3 SV5-SC5 SV6-SC2 SV6-SC4 SV6-SC6	*am - bm - bn - an -z*
SV1-SC2 SV1-SC4 SV1-SC6 SV2-SC1 SV2-SC3 SV2-SC5 SV3-SC2 SV3-SC4 SV3-SC6 SV4-SC1 SV4-SC3 SV4-SC5 SV5-SC2 SV5-SC4 SV5-SC6 SV6-SC1 SV6-SC3 SV6-SC5	*bm - am - an - bn -z*

This SVM version can be changed if the passive state *z* is placed at the beginning of the sampling period *z- am- bm- bn -an* for *Pa =1* and *z- bm- am- an- bn* for *Pa =0* or *z- an- bn- bm- am* and *z- bn- an- am- bm* for *Pa=1* and *Pa=0*, respectively. The combination of the SVM sequences and the matrix converter states can be easily implemented by some memory circuits. The variant thus obtained will be referred to as SVM1. This principle

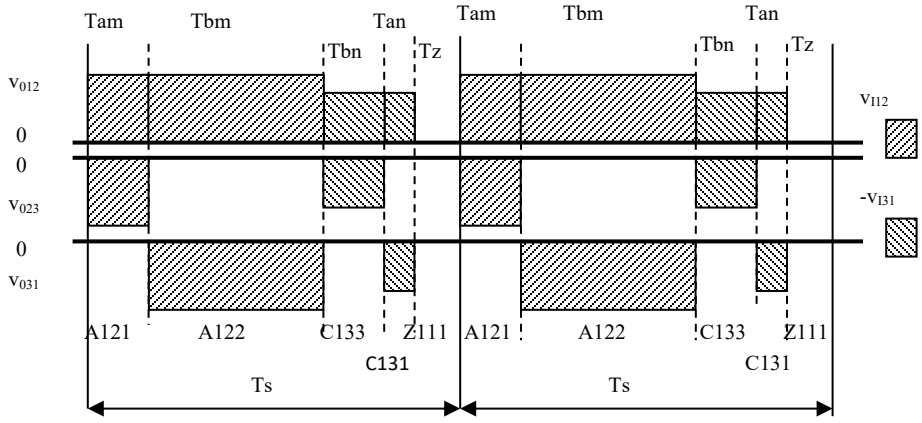

Figure 5: Line output voltage generation in the sampling period for SVM1 algorithm

is shown in Figure 5 for a sampling period. Again 6 switchings/T_S are necessary if for *Pa =1* the SVM sequence is *an- bn- bm- am - z* and for *Pa =0* it is *bn- an- am- bm- z* . Tis s SVM1a algorithm. The SVM1 version can be modified if the zero state is at the beginning of the sequence *z- am – bm –bn – an* for Pa=1 and *z- bm – am – an - bn*. for Pa=0. This is SVM1b algorithm.

By modifying the SVM1 algorithm in the same way we can get the algorithm SVM1c ie *z- an – bn –bm – am* for Pa=1 and *z- bn – an – am - bm*. for Pa=0. Again 6 switchings/T_S are necessary if the passive state is placed between active states*: bm- am- z- an- bn* and *am- bm- z- bn- an* for *Pa =1* and *Pa =0* or *bn- an- z- am- bm* and *an- bn- z- bm- am* for *Pa =1* and *Pa =0* synthesizing another algorithms named SVM1d and SVM1e respectively. A further reduction in the number of commutations can be made by combining certain type of previous algorithms. These new combinations will be named SVM2. A first additional reduction in the number of commutations can be done if for three consecutive sampling periods the SVM sequences will be *SVM1b - SVM1e - SVM1* or *SVM1c - SVM1d - SVM1a*, versions thus obtained are called SVM2a and SVM2b. For example, for SVM2a and *SC1-SV1* active sectors the SVM sequence will be *z- am- bm- bn- an- bn- an- z- am-bm- am- bm- bn- an- z* for *Pa =1*, which means that the number of commutation will be reduced with 5.5%. It can also be reduced the number of switching whether to combine two types of SVM1 sequences for two consecutive sampling periods in sequences *SVM1-SVM1c, SVM1a-SVM1b* and *SVM1d-SVM1e,* synthesizing the control techniques SVM2c, SVM2d and SVM2e, respectively. For example for SVM2c and SV1-SC1 active sectors, if Pa =1 the matrix converter sates will be *A121-(1)-A122-(2)-C133-(1)-C131-(1)-Z111-(0)-Z111-(1)-C131-(1)-C133 -(2)-A122-(1)-A121-(0)-* therefore it means that two consecutive sampling periods requires 10 switching so that the average switching requires 5switchings/T_S. This means a 16% reduction in the necessary number of commutations.

Another direction is optimization techniques to control the dominant harmonics, movement of these to high frequencies, for the same sampling frequency, without increasing excessive the switching losses. This can be achieving using symmetrical waveforms to the center of the sampling period [3]. Variants proposed in the literature accomplishes this balancing around the passive state, which is placed in the center of the sampling period, being framed by the active states that are divided into equal time intervals placed at the beginning and the end of the sampling period. To minimize the number of necessary switching sequences the implementation of SVM sequences proposed in this paper are *am/2- bm/2- bn/2- an/2- z- an/2- bn/2- bm/2- am/2* for *Pa =0* and *bm/2- am/2- an/2- bn/2- z- bn/2- an/2- am/2- bm/2* for *Pa=1*. This version is named SVM3. For this type of algorithms, the converter switches between 9 states during a sampling period, so the minimum number of commutations required is 8switching/T_S. If the SVM sequences are *an/2- bn/2- bm/2- am/2- z- am/2- bm/2- bn/2- an/2* for *Pa =0* and *bn/2- an/2- am/2- bm/2- z- bm/2- am/2- an/2- bn/2 for Pa =1* then are necessary 8switching/TS too. This is named SVM3a algorithm. For SVM3 the output voltage is symmetrical around "big" pulses, while for SVM3a it is symmetrical around "low" pulses for angle θ_C=0-30° in each current sector and vice versa for θ_C =30-60°. În [4] it is suggested that maintaining symmetry around the “big” or “small” voltage pulses regardless of the angle θ_C this can improve the quality of spectral waveforms generated at the converter output matrix. If for θ_C =0-30° will be used SVM3a and for θ_C =30-60° will be used SVM3, then at any time the output voltage waveform will have a shape symmetrical around “small” voltage pulses. This is SVM3b technique. If it is used SVM3 for θ_C =0-30° and SVM3a for θ_C =30-60°we will have symmetry around „large” pulses. This is SVM3c. An improvement of the quality of the frequency spectrum for the waveforms generated by the matrix converter can be obtained by alternating "big" voltage pulses with "small" voltage pulses keeping the symmetry of the output voltages [4]. In order to implement this technique it is necessary to control all switchings between nine states that requires 10 switching/T_S which results in an increase of 66% in the number of switching per unit time. To implement this technique it is necessary to control all switching between nine states. But if in a sampling period is chosen the sequence *bn/2- an/2- z/2- am/2- bm- am/2- z/2- an/2- bn/2* for *Pa =1* and *an/2- bn/2- z/2- bm/2- am- bm/2- z/2- bn/2- an/2* for *Pa =0* or *bm/2- am/2- z/2- an/2- bn- an/2- z/2- am/2- bm/2* and *am/2- bm/2- z/2- bn/2- an- bn/2- z/2- bm/2- am/2*, for *Pa =1* and *Pa =0* respectively then it is possible to reduce the

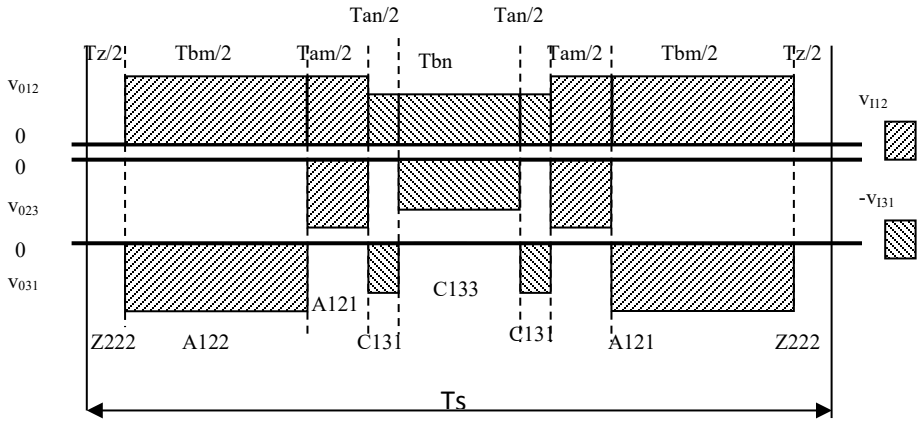

Figure 6: Line output voltage generation in the sampling period for SVM3d algorithm

number of commutation to 8commutations/T_S. This is SVM3d algorithm. If the sequences are *z/2-bn/2- an/2- am/2- bm- am/2- an/2- bn/2- z/2* for Pa=1 and *z/2-an/2- bn/2- bm/2- am- bm/2- bn/2- an/2- z/2* for Pa=0 then we obtain version SVM3e. For angle θ_C=0-30°, SVM3d generates symmetrical waveforms around the „small" voltage pulses like in Figure 6 and SVM3e around "big" voltage pulses, and θ_C =30-60° we have a reversed situation. If for θ_C=0-30° we will use SVM3e and for θ_C =30-60° we will use SVM3d, then at any time the output voltage waveform will be symmetrical around "high" pulses and the algorithm will be named SVM3f. If for θ_C=0-30° we will use SVM3d and for θ_C =30-60° we will use SVM3e, then at any time the output voltage waveform will be symmetrical around "small" pulses and the algorithm will be named SVM3g. If in a sampling period it is chosen the sequence *bn/2- an/2- z/2- am/2- bm- am/2- z/2- an/2- bn/2* for Pa =1 and *an/2- bn/2- z/2- bm/2- am- bm/2- z/2- bn/2- an/2* for Pa =0 we will obtain SVM3h. If for Pa =1 and Pa =0 we will have *bm/2- am/2- z/2- an/2- bn- an/2- z/2- am/2- bm/2* and *am/2- bm/2- z/2- bn/2- an- bn/2- z/2- bm/2- am/2* respectively then we will obtain SVM3i. These algorithms are characterized by 8 switchings/T_S too, the waveforms being symmetrically around the center of tha sampling period. The output voltages consist of alternative "high" and "small" voltage pulses set apart by intervals of "zero" voltage. Combining SVM3i and SVM3h in the same manner we will be obtain SVM3i and SVM3k characterized by waveform that are symmetrical around only the "high" pulses or only around the "small" voltage pulses. A detailed analyses of these algorithms will be presented in a future paper.

4. Implementation of the SVM1-SVM3 Modulator

Whichever you choose to control SVM algorithm, a computer system will determine the value of transfer functions h_{am}, h_{an}, h_{bm}, h_{bn} şi h_z, at T_S time intervals. These transfer functions are then transformed into *S11-S33* switching functions, which controls the ON/OFF states of the 9 bidirectional switches. To convert these transfer functions in PWM switching functions are sufficient four timers TM1-TM4. For this calculus it is necessary to know the modulation index $m=V_{0L}/V_{0L\,max}$ *or* $V_0/V_{0\,max}$, space vector angles θ_C şi θ_V and input phase angle. Analyzing the proposed variants of SVM algorithm previous proposed it is noted that according to the sequence of matrix converter switching states are 12 possible combinations of timer intervals TM1-TM4, according to the timeframes $T_{am}=h_{am}\cdot T_S$, $T_{bm}= h_{bm}\cdot T_S$, $T_{an}= h_{an}\cdot T_S$, $T_{bn}= h_{bn}\cdot T_S$ and $T_z=h_z\cdot T_S$. These combinations, denoted *CTV1-CTV12* are presented in Table 3. For example for *CTV1* combination the logical signals *ST1-ST4* at the outputs of timers will be like in Figure7. The switching functions *S11-S33* associated with switches of the matrix converter are calculated based on the combinations of *CTV, SV, SC* variables and auxiliary variables *Pam, Pbm, Pbn, Pan and Pz* calculated based on the five possible states of the signals *ST1-ST4*. For example switching function formula for *S11* is given by equation (9).

$$S11 = Pam\ ((SC1+SC2)(SV1+SV2+SV3)+(SC4+SC5)(SV4+SV5+SV6))+Pbm\ ((SC1+SC2)(SV1+SV2+SV6)+(SC4+SC5)(SV3+SV4+SV5))+Pbn\ ((SC1+SC6)(SV1+SV2+SV6)+(SC3+SC4)(SV3+SV4+SV5))+Pan\ ((SC1+SC6)(SV1+SV2+SV3)+(SC3+SC4)(SV4+SV5+SV6))+Pz\ (Saz1\cdot(SC1+SC4)+Saz2\cdot(SC3+SC6)+Saz3\cdot(SC2+SC5)) \quad (9)$$

Formula (10) is an example calculation for auxiliary variable *Pam*

$$Pam = ST1\cdot ST2\cdot ST3\cdot ST4\cdot(CTV2\cdot CTV9)+\overline{ST1}\cdot ST2\cdot ST3\cdot ST4\cdot(CTV1\cdot CTV6\cdot CTV10)+\overline{ST1}\cdot\overline{ST2}\cdot ST3\cdot ST4\cdot(CTV3\cdot CTV5)+\overline{ST1}\cdot\overline{ST2}\cdot\overline{ST3}\cdot ST4\cdot(CTV4\cdot CTV7\cdot CTV12)+\overline{ST1}\cdot\overline{ST2}\cdot\overline{ST3}\cdot\overline{ST4}\cdot(CTV8\cdot CTV11) \quad (10)$$

Saz1-Saz3 variables are associated with the passive states *z* of the converter.

CTV12	T_{bn}	$T_{bn}+T_{an}$	$T_{bn}+T_{an}+T_z$	$T_{bn}+T_{an}+T_z+T_{am}$

The output voltage waveforms and the frequency spectrum for SVM1 algorithm using S11-S33 switching functions generated with the universal modulator are presented in Figure 8, Figure 9 and Figure 10.

5. Conclusion

In this paper it was presented a dynamic algorithm that enables the implementation of a universal SVM1-SVM3 modulator to control the matrix converters. In this way it is possible to choose different control options that are optimized for reducing energy losses or to control the dominant harmonics. A more detail comparative analysis of these algorithms will be presented in a future work.

Keywords:
AFPM motor
Optimal control above nominal speed

ABSTRACT

The axial flux permanent magnet synchronous motor (AFPM motor) using magnet bearings instead of ball-bearings at both two shaft ends could allow rotational speed of shaft much greater than nominal speed. One of the solutions to increase motor speed higher than its nameplate speed is reducing rotor's pole magnetic flux of rotor (Ψ_p). This paper proposes a method to boost the speed of AFPM motor above nominal speed by adding a reversed current i_{sd} of (Ψ_p).

1. AFPM Motor

1.1. Structure

In terms of structure, the AFPM motor has its own particular specialists, in details, the stator module may include several types: A single module has one winding set and a dual module has two sets of winding sharing a common core and back-to-back establishment. Similarly, a single rotor module includes only one permanent magnet on one side, and in dual module one, both sides have permanent magnets leaning against each other.

In this research, an object with two single module stator outside and one dual module rotor inside is designated as shown in Figure 1.

1.2. Principle of Operation

When a three-phase voltage is granted to stator coils, different currents are generated (including current i_q) flowing inside, they will interact with the magnetics of rotor to generate torque (M) and the currents in phase windings (component i_d) of stator generate thrust and drag (F) based on the principle of the electromagnet. Thanks to special structure and above-mentioned operating principle, the rotor of the motor will not generate axial displacement although both ends of the shaft have magnetic bearings. It allows the absence of additional axial movement block of the rotor, therefore, the motor structure is being compact. Due to the way of winding roll, the rotational magnetic field generates torques M_1 and M_2 on the same direction on the rotor shaft and generates thrust-drag forces $F1$ and $F2$ between the rotor and the stator on opposite direction. The total torque ($M=M_1+M_2$) is the summation of the torques but the total force is the difference of the axial attractive forces ($F=F_1-F_2$).

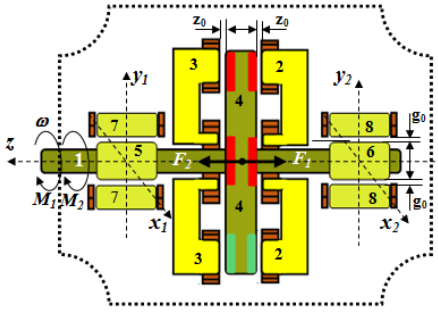

***Figure 1**: The AFPM motor section with magnetic bearing at both ends integrated (1: The shaft; 2, 3: the stator and the winding of left side and right side of motor; 4: the permanent magnetic rotor of motor; 5, 6: the magnetic bearing rotors on left and right sides; 7, 8: the stator and the winding of magnetic bearing on left and right sides; z_0, g_0: the nominal gaps between the rotor and stator of motor with magnetic bearings)*

From the structure and the principle of operation mentioned above, AFPM motor can be considered as two motors that have a common rotor or share a common sharp.

2. Mathematical Model of the AFPM Motor

According to [1, 2, 3], the mathematical model of AFPM motor was developed in *dq* coordinate system, as presented on (1). The indicator 1 and 2 are present for the left side motor and right side motor, respectively.

$$\left.\begin{aligned}
u_{sd1} &= R_s i_{sd1} + L_{sd1}\frac{di_{sd1}}{dt} - \omega_s L_{sq1} i_{sq1} \\
u_{sq1} &= R_s i_{sq1} + L_{sq1}\frac{di_{sq1}}{dt} + \omega_s L_{sd1} i_{sd1} + \omega_s \psi_p \\
u_{sd2} &= R_s i_{sd2} + L_{sd2}\frac{di_{sd2}}{dt} - \omega_s L_{sq2} i_{sq2} \\
u_{sq2} &= R_s i_{sq2} + L_{sq2}\frac{di_{sq2}}{dt} + \omega_s L_{sd2} i_{sd2} + \omega_s \psi_p \\
m_{M1} &= \frac{3}{2} z_p \left[\psi_p i_{sq1} + i_{sd1} i_{sq1}(L_{sd1} - L_{sq1})\right] \\
m_{M2} &= \frac{3}{2} z_p \left[\psi_p i_{sq2} + i_{sd2} i_{sq2}(L_{sd2} - L_{sq2})\right] \\
m_{\Sigma} &= m_{M1} + m_{M2} = m_m + \frac{J}{z_p}\frac{d\omega}{dt} \\
F_{\Sigma} &= k_1(i_{2d} - i_{1d}) + k_1(i_{2d} - i_{1d})z - k_2 z
\end{aligned}\right\} \quad (1)$$

$$k_1 = 2\frac{\mu_0^2 N^2}{g_0^2}\psi_p; \quad k_2 = 2\frac{\mu_0}{S_p g_0}\psi_p^2.$$

The stucture of AFPM motor as methematical model (1) is presented in Figure 2.

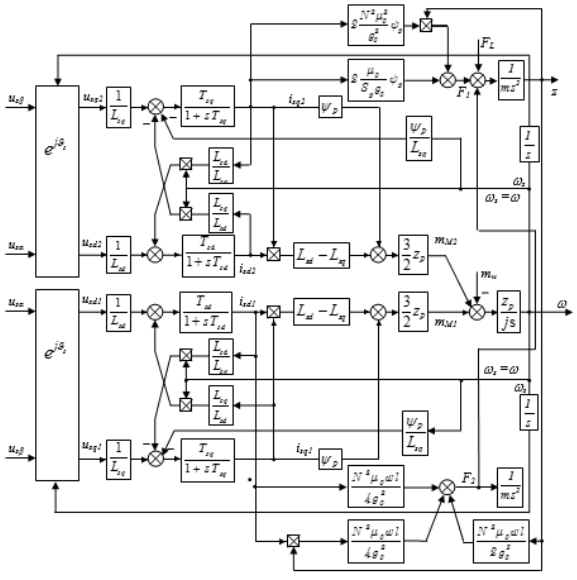

***Figure 2**: Structure diagram of AFPM motor*

3. The voltage, current and magnetic space vectors of APFM motor in two working areas.

The voltage, current, and magnetic space vector of AFPM motor in two working areas are presented in Figure 3 [1, 5, 7]. From (1), it is clearly seen that the torque of AFPM motor includes two parts: the major part with multiplication $\psi_p i_{sq}$ and the reactive part due to the difference of stator inductance (L_{sd}-L_{sq})≠0). In all operating condition, the AFPM motor must produce a sub-torque to compensate the reactive part. The clear existence of the reactive part normally neglected in classical control solutions. Ignoring that component helps to simplify control system and can be accepted in reality within nominal rotational speed, because in that range i_{sd}=0 (Figure 3a). On the contrary, in the speed range above the base speed, in order to speed up, the flux must be reduced by applying a negative current i_{sd}. The motor is now in flux weakening mode, the current is proportional to the rotor's speed (Figure 3b). This leads to the reactive component of the torque is significant and it can't be ignored.

When the motor's speed is adjusted to above base speed, frequency is greater than the nominal frequency $f_{đm}$ but its voltage cannot exceed the nominal voltage $U_{đm}$. The maximum value of voltage is $U_1 = U_{đm}$. The motor's electromotive force expression shows that the flux is inversely proportional to frequency, this is equivalent with the case that the flux of a DC motor is reduced to speed up.

Unlike the synchronous motor with the permanent magnet attached inside the rotor and reluctance synchronous motor, the AFPM motor operating in nominal speed *range* maintains the current i_{sd}=0. Therefore, we only consider the range of above nominal speed.

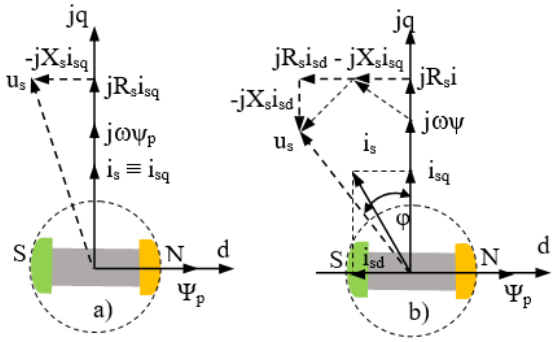

***Figure 3**: State vector of voltage, current and the magnetic flux of AFPM motor in two working areas: a) Under nominal speed; b) Above nominal speed.*

4. Calculating the critical values of voltage and current:

Before introducing a variety of control strategies, we need to consider the limitation of current and voltage [4, 5]. The limitation of current vector:

$$i_s = \sqrt{i_{sd}^2 + i_{sd}^2} < i_{sm} \quad (2)$$

The current limit of (2) is a circular with radius i_{sm} in plane of (i_{sd}, i_{sq})

The voltage limit vector: From the formula of the voltage at steady state neglecting the resistance of stator:

$$u_{sd} = -\omega_s L_{sq} i_{sq}; \; u_{sq} = \omega_s L_{sd} i_{sd} + \omega_s \psi_p$$

The fundamental maximum phase voltage of stator is determined by the DC-link voltage:

$$|u_s| = \sqrt{u_{sd}^2 + u_{sd}^2} < u_{sm} \quad (3)$$

Where: u_{sm} is the maximum DC voltage applied to the inverter.

$$u_s^2 = u_{sd}^2 + u_{sd}^2 = (\omega_s L_{sq} i_{sq})^2 + (\omega_s L_{sd} i_{sd} + \omega_s \psi_p)^2 \quad (4)$$

$$\frac{u_s^2}{\omega_s^2} = (L_{sq} i_{sq})^2 + (L_{sd} i_{sd} + \psi_p)^2 \quad (5)$$

From (3) and (4), ignoring the stator resistances in the steady state, the currents i_{sd}, i_{sq} are defined. Substitute them into (1), the motor torque is obtained:

$$m_M = k_1 \left(\frac{u_s}{\omega_s}\right) cos\varphi - k_2 \left(\frac{u_s}{\omega_s}\right)^2 sin 2\varphi \quad (6)$$

$$k_1 = \frac{3z_p}{2}\psi_p \left(\frac{(L_{sd} - L_{sq})}{L_{sd}} - \frac{1}{L_{sq}}\right); \quad k_2 = \frac{3z_p}{2}\left(\frac{L_{sd} - L_{sq}}{L_{sd} L_{sq}}\right)$$

where: φ is angle between stator voltage vector u_s and the q axis.

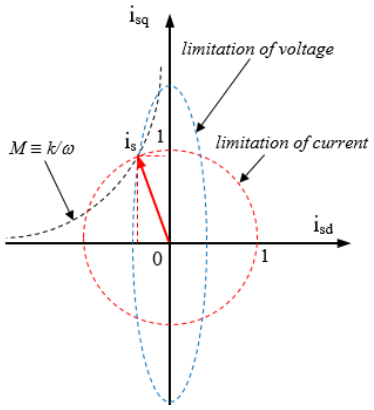

Figure 4: *The limits and the optimal point of torque of the AFPM motor above nominal speed*

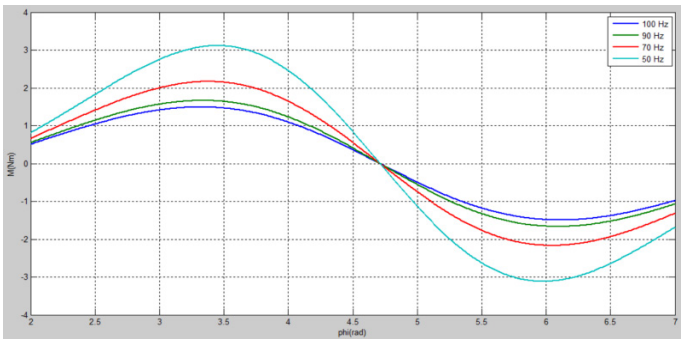

Figure 5*: Simulation result of the motor torque with DC voltage U=400 V;*

Figure 5 shows that if frequency is increased to speed up the motor to above base speed, the flux along with *d* axis will be decreased. However, if φ is maintained at 60° then the motoring torque will be maximum.

5. Control design for AFPM motor

5.1. General control scheme

In term of structure, AFPM motor is completely different from conventional motors; its control scheme includes two different control loops: rotor displacement control loop (attractive force control) and speed control loop (motoring torque control). The general control scheme of AFPM motor is shown in Figure 6 [1, 3].

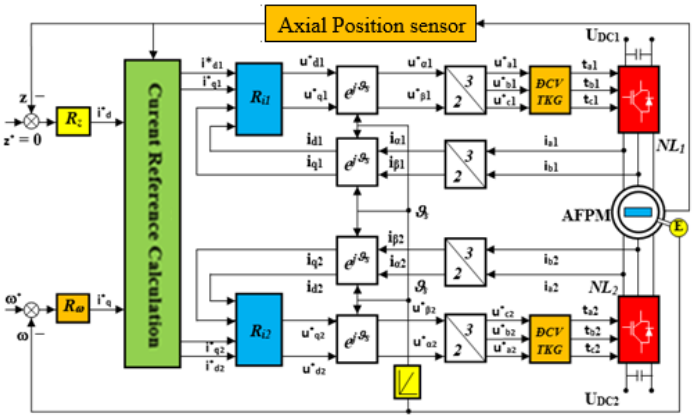

Figure 6: *Vector control structure of AFPM motor*

Vector control of AFPM motor is based on the analysis of the motor's instantaneous currents into two components: the direct component i_d and the quadrature component i_q. The direct component generates the attractive forces and the quadrature component generates the motoring torques. By this way, the control scheme of AFPM motor becomes similar to that of a DC motor.

The rotor displacement along *z* axis from its equilibrium point can be detected by displacement sensor. The detected value is compared to the reference value z^* and the difference is inputted to the R_z controller. The reference z^* is always set to make the rotor in-between the two stators at the equilibrium point. The output of R_z is used to compute the current reference i_d^* . The reference i_{d1}^* and i_{d2}^* of the two stator windings can be calculated by using the compensating current i_{d0}: $i_{d1}^* = i_{d0} + i_d^*$; $i_{d2}^* = i_{d0} - i_d^*$; i_{d0} can be zero or a small value around zero.

The rotor speed detected by the encoder is compared with the speed reference, the difference is fed to the speed controller R_ω. The output of R_ω is used to determine the *q*-axis reference current i_q^*. The *q*-axis reference current of the two stator windings i_{q1}^* and i_{q2}^* is then calculated similar to i_d.

Control design implemented for AFPM motor includes following loops:

5.2. Current control

Most of the modern AC motor drives have a control structure comprising an internal current control loop. Therefore, the drive system characteristic depends on the quality of applied current control strategy [1, 3, 4, 5]

The main task of the current control loop is to make the motor's currents follow the reference signals. By comparing the measured currents with the reference currents, the current control loop generates switching states for the inverter in order to decrease the current errors. In general, the current control loop performs two tasks: error compensation (reduce current error) and modulation (determine switching states).

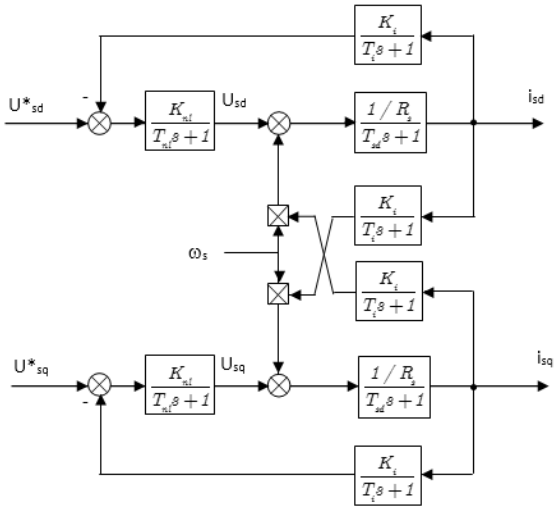

***Figure 7**: The current control loop of AFPM motor*

The current control loop of AFPM motor as mentioned in Figure 7 is extracted from Figure 2 and following formulas:

$$\begin{aligned} i_{sd} &= (u_{sd} + i_{sq}.w_s.L_{sq})W_{sd} \\ i_{sq} &= (u_{sq} - i_{sd}.w_s.L_{sd})W_{sq} \end{aligned} \quad (7)$$

$$\begin{aligned} i_{sd} &= \frac{1}{1 + W_{sd}.W_{sq}.w_s^2.L_{sd}.L_{sq}}(W_{sd}u_{sd} + w_s.L_{sq}.W_{sd}.W_{sq}.u_{sq}) \\ i_{sq} &= \frac{1}{1 + W_{sd}.W_{sq}.w_s^2.L_{sd}.L_{sq}}(-w_s.L_{sd}.W_{sd}.W_{sq}.u_{sd} + W_{sq}u_{sq}) \end{aligned} \quad (8)$$

$$W(s) = \frac{W_i.W_{nl}}{1 + W_{sd}.W_{sq}.\omega_s^2.L_{sd}.L_{sq}}\begin{bmatrix} W_{sd} & \omega_s.L_{sq}.W_{sd}.W_{sq} \\ -\omega_s.L_{sd}.W_{sd}.W_{sq} & W_{sq} \end{bmatrix} \quad (9)$$

Where: $W_{sd} = \frac{1/R_s}{T_{sd}s + 1}$; $W_{sq} = \frac{1/R_s}{T_{sq}s + 1}$;

$$W_{nl} = \frac{K_{nl}}{T_{nl}s + 1}; W_i = \frac{K_i}{T_i s + 1}.$$

The formulas (7), (8), (9) show that interactive actions exist in current control loop. To obtain desire quality of the closed system, the modulus optimum criterion is applied:

$$W_m(s) = \frac{1}{1 + 2T_s s + 2_{sd}.T_s^2 s^2} \quad (10)$$

Before applying the modulus optimum criterion, the current control loop must be decoupled.

Decoupling regulators are defined as follows:

$$W_R(s) = W_m(s)(1 - W_m(s))^{-1}.W(s) \quad (11)$$

$$T_s = T_{si} = 2T_i = 0,002 \quad .$$

Hence, T_σ^2 can be ignored. After that, transfer functions of the decoupling regulators for the current control loop can be determined.

$$\begin{aligned} W_R(s) &= \frac{1}{4T_i.K_{nl}K_i}\begin{bmatrix} L_{sd}(1 + \frac{1}{T_{sd}s}) & \frac{-\omega_s.L_{sq}}{s} \\ \frac{\omega_s L_{sd}}{s} & L_{sq}(1 + \frac{1}{T_{sq}s}) \end{bmatrix} \\ &= \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \end{aligned}$$

$$\left.\begin{aligned} R_{11}(s) &= \frac{1}{4T_i.K_{nl}K_i}L_{sd}(1 + \frac{1}{T_{sd}s}) \\ R_{12}(s) &= \frac{1}{4T_i.K_{nl}K_i}\frac{\omega_s L_{sd}}{s} \\ R_{21}(s) &= \frac{1}{4T_i.K_{nl}K_i}\frac{-\omega_s L_{sd}}{s} \\ R_{22}(s) &= \frac{1}{4T_i.K_{nl}K_i}L_{sq}(1 + \frac{1}{T_{sq}s}) \end{aligned}\right\} \quad (13)$$

Insert the decoupling regulators into the current loop diagram in Figure 7 we have the decoupled diagram as shown in Figure 8.

5.3 Axial displacement control

For simplicity, assume that the radial movement of the rotor is supported by two ideal radial magnetic bearings. Thus, the axial displacement and the radial displacement are independent, and can be expressed as follows [1, 2, 3, 4]:

$$F - F_L = m\ddot{z} \quad (14)$$

where m is the weight of the motion part and F is the axial force.

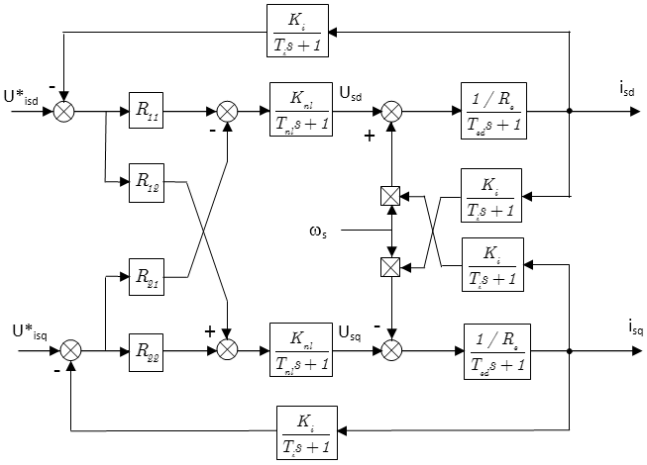

***Figure 8**: Decoupled current control loop*

The equation (15) is obtained by substituting (1) into (14):

$$m\ddot{z} + F_L = k_1(i_{2d} - i_{1d}) + k_1(i_{2d} - i_{1d})z - k_2 z \quad (15)$$

$$k_1 = 2\frac{\mu_0^2 N^2}{g_0^2}\psi_p; \; k_2 = 2\frac{\mu_0}{S_p g_0}\psi_p^2.$$

It is easy to see that this system is unstable. To make the system stable, a controller with derivative component is used. The axial displacement control loop is shown in Figure 9.

The axial displacement control loop contains the transfer function of the current control loop. Since the torque load is usually undefined, so it is regarded as an external interference.

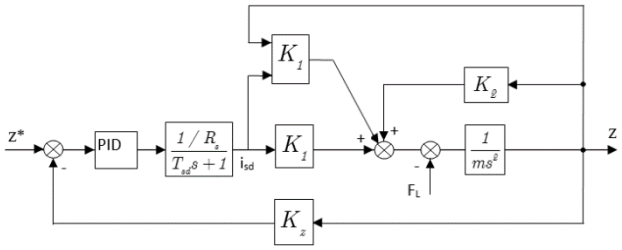

***Figure 9**: Axial displacement control loop*

To eliminate the steady state error, a PID controller is used.

$$G_{cz}(s) = K_P + \frac{K_I}{s} + K_D s \qquad (16)$$

The system will be stable if the controller parameters satisfy the following conditions:

$$\begin{cases} K_P > \dfrac{K_2}{K_1 K_z} \\ K_I < \dfrac{K_D\left(K_1 K_P + K_2\right)}{m} \\ K_I > 0 \\ K_D > 0 \end{cases} \qquad (17)$$

4.4 Speed control

For all types of electric motor, the difference between electromagnetic torque M and torque load M_L causes the acceleration of the rotor according to the mechanical characteristic of the motor drive. The rotational motion equation can be written as follows [1, 3, 4, 5]:

$$M - M_L = J\frac{d\omega}{dt} \qquad \frac{\omega}{M - M_L} = \frac{1}{Js} \qquad (18)$$

M can be controlled by the q-axis current i_q as shown in (1); thus, the speed control loop is depicted in Figure 10.

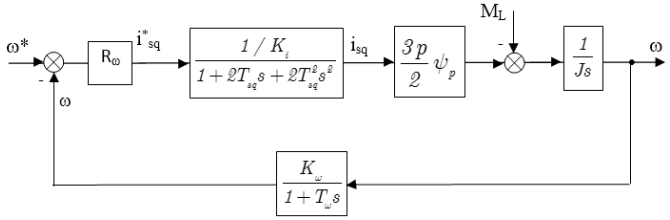

***Figure 10**: Speed control loop*

Similar to the axial displacement control loop, the speed control loop also includes an inner current control loop and a fixed motor transfer function. Due to the uncertain load, in the first step M_L is regarded as an external disturbance of the system. The influence of the speed measurement is usually included in the equivalent time constant of the current control loop.

Hence, the closed-loop transfer function can be expressed as follow:

$$W_K(s) = \frac{R_\omega W_0}{1 + R_\omega W_0} = \frac{KR_\omega}{s(T_s's+1) + KR_\omega} \qquad (19)$$

Apply the symmetrical optimum criterion for the speed control loop:

$$W_C(s) = \frac{1+4T_s s}{1+4T_s s+8T_s^2 s^2+8T_s^3 s^3}$$

Equalizing (19) and (20), we have:

$$\frac{KR_\omega}{s(T_s's+1)+KR_\omega} = \frac{1+4T_s s}{1+4T_s s+8T_s^2 s^2+8T_s^3 s^3}$$

Choose: $2T'_s = T_s$, solve the above equation we have:

$$R_\omega = \frac{1+4T_s s}{K8T_s^2 s} = \frac{1}{8KT_s^2 s} + \frac{1}{2KT_s}$$

6. Quality evaluation by numerical simulation

6.1 Specifications of the motor and simulation parameters

$R_s = 2{,}3\ \Omega$; $L_{sq} = 9{,}6.10^{-6}$ H; $L_{sd} = 8{,}2.10^{-6}$ H;

$T_{sq} = 4{,}2.10^{-6}$; $T_{sd} = 3{,}56.10^{-6}$; $\Psi_p = 0{,}0126$Wb;

$Z_p = 1$; $g_0 = 1{,}7.10^{-3}$ m; $m_{rotor} = 0{,}235$kg;

$J_r = 0{,}0000082$ kgm^2; $\mu_0 = 4\pi$ x 10^{-7} H/m;

Knl = 5; $K_i = 1$; $T_i = 0{,}001$; $K_\omega = 0{,}00417$;

$T_\omega = 0{,}1$; $T_{s\omega} = T_\omega + 2T_i$; $2T'_s = T_{s\omega}$.

6.3. Simulation results

+ When the motor operates at the nominal speed: $n = 3000$ rpm; $m = 0{,}08$ Nm; displacement $z = 0$

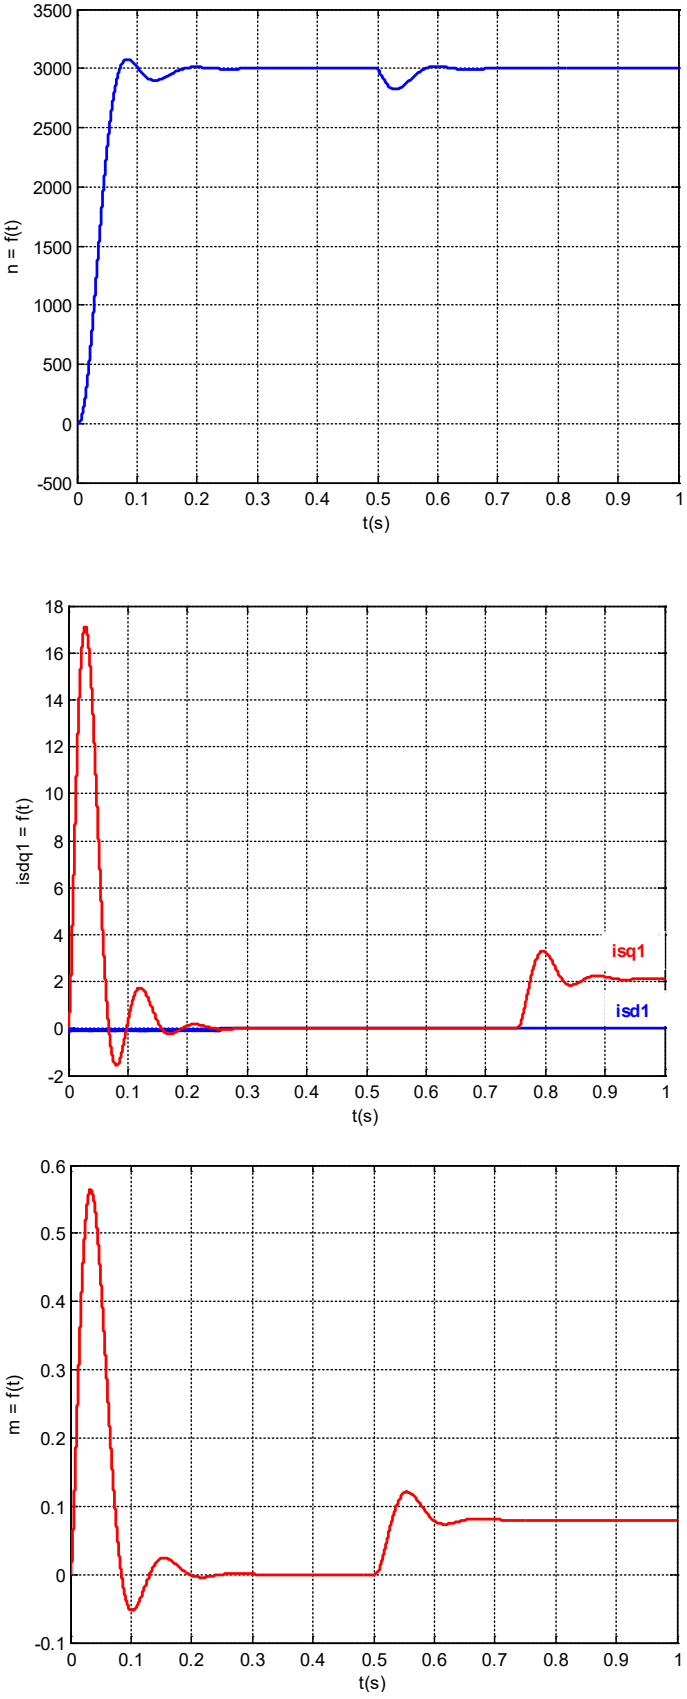

***Figure 12**: Characteristics of AFPM motor when it operates at the nominal speed and no axial force: n = 3200 rpm, displacement z = 0; the torque m (has the same shape as the current i_{sq}); i_{sd} = 0*

+ When the motor operates above the nominal speed: n = 4000rpm; m = 0,08Nm; $z \neq 0$

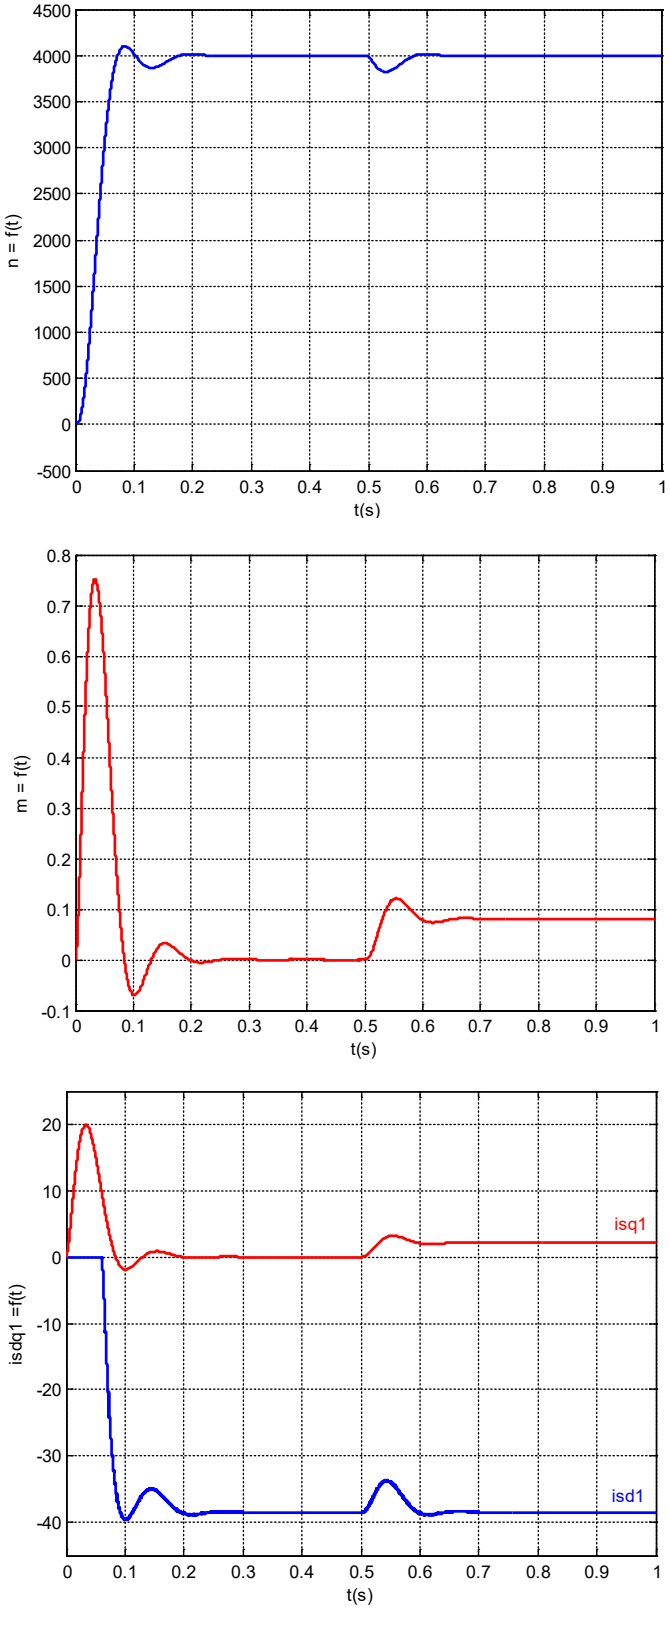

***Figure 13**: Characteristics of AFPM motor when it operates above the nominal speed: n = 4000 rpm, z ≠ 0; the torque m (has the same shape as the current i_{sq}); i_{sd} has large negative value.*

7. Conclusions

The AFPM motor with special structure is used in combination with magnetic bearings to form a system which includes two control loops: the speed control loop and the rotor displacement control loop (with assumtion that the magnetic bearings fullfil their nominal functions). By using rotor flux oriented control method, some results are firstly achieved:

- Speed control above the nominal speed is attained by flux weakening thank to apply a current i_{sd} opposite in direction with the flux ψ_p while sustaining the torque.

- The rotor is always kept at the center of the motor by the rotor axial displacement control loop.

- Further research need to be implemented in order to improve the control quality and sustain the optimal torque when the flux is weakened.

- Experimental study on the AFPM motor.

ABSTRACT

This study investigates the synchronization issue of multiple robot manipulators in the presence of time delay. Since several previous works based on synchronization task neglect the communication delay, in this paper we develop a finite time stability based on a Lyaponov functional for synchronization of a networked robotic system where time delay exists during the communication between robots. To this effect, we consider a second order sliding mode control (SMC) combined with the cross coupling concept in order to ensure the position synchronization of networked robot manipulators. Furthermore, the stability of the proposed controller with communication's delay has been proved. Simulation results illustrate satisfactory performances which prove the efficiency of the proposed approach.

1 Introduction

Over the past few decades, an increasing interest has been noticed on the interconnected systems in several fields of research [1, 2]. In fact, cooperative and coordinated control have attracted several research communities such as: biology [3]; artificial intelligence [4]; wireless sensor networks[5, 6]; control of mobile robot[7, 8]; spacecraft [9, 10]. The synchronized control of robot manipulators has been firstly presented in [11, 12]. Subsequently, further research results on the synchronization of robot manipulators have been published [13, 14]. It is recognized that the existing synchronization works as aforementioned are all for motion control. In this context, motion synchronization of multi agent systems has attracted much attention in various applications including the industrial assembling, automatic control of multi agent systems such as the control of robot manipulators [15, 16].

As an illustration, in [17] position synchronization of multiple motion axes has been studied. Motion synchronization has also been used in more complex mechanical systems especially the nonlinear robot systems. Furthermore, where flexibility and maneuverability are highly recommended [13, 18, 19], with the increasing complexity of evolved and specific applications, manipulability can't be fulfilled by a simple robot. For this reason, the use of cooperative schemes for multiple robots can present a better solution to realize more robust multi agent system controls, where each robots operates cooperatively, and receives feedbacks from each others to achieve a consolidated goal [11, 20].

Furthermore, most of the real systems are known by nonlinearities such as robotic field. For this reason, the formulation for robust control laws is required,in the sense that it is able to ensure the system stability and the robustness via external disturbances and parameters variations [21, 22]. Otherwise, several control methods have been used to synchronize various complex systems such as: adaptative control [23, 24]; sliding mode control(SMC) [25, 26, 27]; neural networks [28] etc.

Among several dynamic behaviors, the synchronized motion control and the stability of complex nonlinear systems are considered between the most important research topics during several years [29, 30]. The mutual synchronization of robotic systems without time delay has been absolutely studied by several communities [11, 13]. Nevertheless, and due to the importance of cooperative research using multiple agents and within its wide range applications, the control algorithm suffers from some disturbing factors that can't be neglected such as time delays communication, communication interruption, packet collisions etc. Time delay communication is commonly

*Marwa Fathallah, Sfax–Tunisia, fathallahmaroua@gmail.com

https://dx.doi.org/10.25046/aj020321

known in biological and physical networks, owing to the finite velocity of communication as well as traffic congestions [31, 32, 33]. In multi–agent robotic systems, the time delay is only considered at the level of the information arriving to a robot and coming from sensors of its neighbors, while information from its own sensors is processed immediately.

The presence of this communication constraint makes the dynamical behaviours more complicated, can lead to undesirable transient response, reduces the performances of the networked systems or even the instability of the system [33, 34, 35]. Referring to the cross-coupling technique, several works have been suggested to improve the performances of the synchronization of multi axis motions [36, 37]. Later on, [38] proposed a control algorithm in order to synchronize networked systems in the presence of time delays [39, 40]. In the light of what was said, we present in this paper a synchronizing SMC algorithm for the control of a time delayed multi agent system in order to prove the effectiveness and the stability of the proposed approach.

1.1 Contribution

The subject of this paper is to realize the motion control of complex networked robotic systems in the presence of time delays.
Since the robot requires an interaction with its environment to achieve its goal, and in the absence of a suitable sensor, the robot remains blind. For this reason, and in order to reproduce human capacities for perception and action in robotic systems, researchers adopt the integration of data from a surveillance camera.
This camera is a great way to provide security to the target location. Nowadays, the surveillance cameras can also be set to be motion activated, recording footage when motion triggers them. Many range of cameras also includes outdoor security cameras and wifi cameras in order to effectively control the monitoring task.
Therefore, a second order sliding mode strategy has been considered and exhibited on a 3 degrees of freedom($3DOF$) surveillance camera system, where we focus on the manipulative arm managing the camera movements.
Then, to guarantee the overall vision of the proposed framework, we combine a muli robot manipulators, where each robot must synchronize its movement with other teammates using the cross-coupling approach .
The main goal of this work is to realize a common and performant motion control task of multi-agent robot manipulators based on the cross coupled second order sliding mode approach design, by reducing the chattering impact, and achieving robust communication between agents which make the system stronger against disturbances, uncertainties, breakdowns and also able to compensate the existence of communication delay.

2 Second Order Sliding mode controller

2.1 Preliminaries

Sliding mode control is a robust nonlinear strategy [41, 46, 47]. Such Variable Structure Control (VSC) is considered as a discontinuous feedback approach where its design is divided into two parts: the reaching phase (system trajectories are forced to reach a specific surface in the state space then to remain on it) and the sliding phase (Figure 1).
The Sliding Mode approach is developed using the Lyaponov Theory in order to ensure the convergence to the sliding surface ($s(x) = 0$):

$$S^T \dot{S} < 0 \tag{1}$$

where the sliding surface S is chosen as:

$$S(x) = Y(x - x_d) \tag{2}$$

in which: x_d is the desired trajectory and Y is a matrix chosen such away x acheives x_d.
The structure of the proposed controller is composed of two terms:

$$u = u_{eq} + \Delta u \tag{3}$$

where u_{eq} is the equivalent control which ensure the "reaching phase" and Δu is the corrective term used to avoid all deviations from the sliding surface.
The expression of the equivalent term can be deduced from the following equation:

$$\dot{S} = F(x) + G(x)u = 0 \quad \mapsto \quad u_{eq} = -[G(x)]^{-1}F(x) \tag{4}$$

where $F(x)$ and $G(x)$ are defined by the affine state equation of a nonlinear system ($\dot{x} = f(x) + g(x)u$).
Moreover, the corrective term can be described as follows:

$$\Delta u = -[G(x)]^{-1} W \text{sign}(S) \tag{5}$$

where W is a definite positive matrix.

2.2 Second Order Sliding Mode Control

As it is mentioned above, this robust approach suffers from the undesirable chattering phenomenon [14, 34] induced by the corrective term Δu, whose impact is manifested by the existence of perturbing high switching frequencies in the control inputs [21, 42]. More precisely, this problem involves fast and sudden changing control signals which lead to low accuracy and even damage the mechanical parts. Therefore, several methods have been developed in order to overcome this annoying phenomenon [22].
In this context, the second order sliding mode approach presents an enhancement of the classical SMC by the introduction of a filtering action in the controller.
Such an action greatly reduces the major drawback of

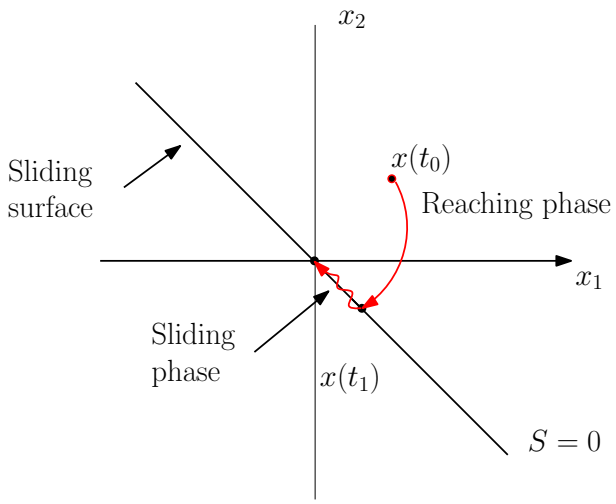

Figure 1: Phases of Sliding Mode Control

the simple SMC which is the chattering phenomenon. Hence, the second order SMC has been considered as the most useful among the high order SMC thanks to its relative simplicity of application, compared to the higher order controls [43, 44, 45].
Then, the sliding surface derivative of the second order SMC approach has been modified as follows :

$$\dot{s_i} = \sigma_i \quad \mapsto \quad \Delta u_i = [Wg(x)]^{-1}\sigma_i \tag{6}$$

The new description of the dynamic control behavior can be written as follows:

$$\begin{cases} \dot{s_i} &= \sigma_i \\ \dot{\sigma_i} &= -a_0\, s_i - a_1\, \sigma_i + v_i \end{cases} \tag{7}$$

where a_0, a_1 are positive scalars and v_i is a variable control of SMC. This study presents multi-input-multi-output systems. Furthermore, the expression of $\dot{\sigma_i}$ can be deduced from the equality $A(p) = 0$ of the following Hurwitz polynomial (which its roots have negative real parts) :

$$A(p) = (p + \mu)^2 \tag{8}$$

where μ is a positive scalar.
In order to ensure the stability, the representation (7) can be reformulated as the condensed form:

$$\dot{Z}_i = \phi Z_i + \Gamma v_i \tag{9}$$

in which:

$$\underbrace{\begin{pmatrix} \dot{s_i} \\ \dot{\sigma_i} \end{pmatrix}}_{\dot{Z}_i} = \underbrace{\begin{pmatrix} 0 & I \\ -\mu^2 I & -2\mu I \end{pmatrix}}_{\phi} \begin{pmatrix} S_i \\ \sigma_i \end{pmatrix} + \underbrace{\begin{pmatrix} 0 \\ 1 \end{pmatrix}}_{\Gamma} v_i \tag{10}$$

where 0 is the null matrix, I is the identity matrix and the discontinuous term v_i is given by .

$$v_i = -Q \text{ sign } (\Gamma^T L S_i) \tag{11}$$

where $Q = [q_1, q_2, ..., q_n]$ and L are positive definite matrix.

3 Mutual SMC synchronization algorithm

3.1 Mathematical model

A robotic manipulator arm designed to be equipped with a surveillance camera system presents the adopted dynamic model of this study (Figure 2).

Using the Lagrangian formulation, the motion equation of a manipulator robot "i" can be written as: [46]

$$M_i(q_i)\ddot{q_i} + C_i(q_i, \dot{q_i})\dot{q_i} + G_i(q_i) = \tau_i \tag{12}$$

where:

- $q_i(t) \in \mathbb{R}^n$ is the measured articulation vector of the manipulator (joint position),
- $\dot{q_i} \in \mathbb{R}^n$ is the velocity vector,
- $\ddot{q_i} \in \mathbb{R}^n$ is the joint acceleration vector,
- $M_i(q_i) \in \mathbb{R}^{n \times n}$ is the symmetric uniformly bounded and positive definite inertia matrix,
- $C_i(q_i, \dot{q_i})\dot{q_i} \in \mathbb{R}^n$ represents the vector expressing Coriolis and centrifugal forces,
- $G_i(q_i) \in \mathbb{R}^n$ is the vector of gravitational torques,
- $u = \tau_i \in \mathbb{R}^n$ denotes the control torque.

3.2 Cross Coupling technique

In this work, we take into consideration the synchronization of multiple robot manipulators. In this context, we propose decentralized control laws for n robots manipulators for which each robot synchronizes its position with the other neighbor agents and track the same desired trajectory. Specifically, using the synchronization approach, manipulators are controlled in a synchronous manner so that the tracking errors and the synchronization errors converge

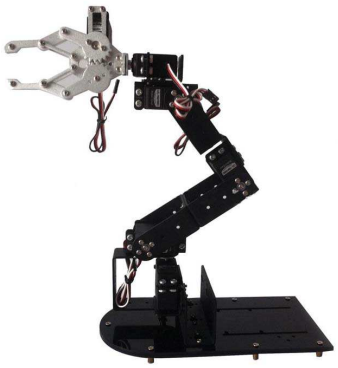

Figure 2: Example of 3*DOF* robot manipulator

to zero where the synchronization error is considered to be a differential position between coordinated agents. In order to achieve a coordinated control motion, an effective synchronization method namely the Cross Coupling concept is carried out where the whole multi-robot manipulators is used as a unique generalized system [47, 48, 49].
The cross coupling design was firstly introduced by [2], then its concept has been used mainly for machine tools [50, 51]. Later on, it has been applied in the robotic fields by [52]. The main idea of such a procedure is to create a global error of the model [36, 53].
In the light of what was said, the tracking error can be written as follows:

$$\eta_i(t) = q_i(t) - q_d(t) \tag{13}$$

where $q_d(t) \in \mathbb{R}^n$ denotes the desired position.
The vector η_i will give insight on the joint positions convergence to the desired trajectory. The proposed cross coupling concept suggests a suitable synchronization error which is defined as follows:

$$\begin{aligned}\xi_i(t) &= \textstyle\sum_{j\neq i}^{p} \Lambda_{ij}[q_i(t) - q_j(t-\tau)] \\ &= \textstyle\sum \Lambda_{ij}(q_i(t) - q_d(t)) - \sum \Lambda_{ij}(q_j(t-\tau) - q_d(t-\tau)) \\ &\quad + \textstyle\sum \Lambda_{ij}(q_d(t) - q_d(t-\tau)) \\ &= \textstyle\sum \Lambda_{ij}\eta_i - \sum \Lambda_{ij}\eta_j(t-\tau) + \sum \Lambda_{ij}[q_d(t) - q_d(t-\tau)]\end{aligned} \tag{14}$$

where Λ_{ij} is a symetric positive definite matrix which reveals an idea about the communication quality between the i^{th} and j^{th} agents.
Thus, in order to attain a robust controller for multi robot systems, and to ensure a synchronous trajectory tracking in the presence of communication data delay, we define the following global error expression (for robot i):

$$\varepsilon_i = \eta_i + \int_{t_0}^{t} \xi_i(\alpha) d\alpha \tag{15}$$

where we note that this error expression includes both synchronization error and trajectory tracking error defined above.
Then, its derivative can be considered as follows:

$$\dot{\varepsilon}_i = \dot{\eta}_i + \xi_i \tag{16}$$

Let's define the sliding mode surface :

$$s_i = \dot{\varepsilon}_i + \lambda_i \varepsilon_i \tag{17}$$

where $\lambda_i > 0$. Then, we obtain:

$$\dot{\eta}_i = -\xi_i - \lambda_i \varepsilon_i + s_i \tag{18}$$

Having in mind the expression of (14), we obtain the following expression:

$$\begin{aligned}\dot{\eta}_i = &-\textstyle\sum \Lambda_{ij}\eta_i + \sum \Lambda_{ij}\eta_i(t-\tau) \\ &-\textstyle\sum \Lambda_{ij}[q_d(t) - q_d(t-\tau)] - \lambda_i \varepsilon_i + s_i\end{aligned} \tag{19}$$

In order to simplify the previous expression, we define:
$d_i = \sum \Lambda_{ij}[q_d(t) - q_d(t-\tau)]$.
Thus:

$$\dot{\eta} = A\eta + B\eta(t-\tau) + d - \Lambda\varepsilon + S \tag{20}$$

where:

$$A = \begin{pmatrix} -\sum \Lambda_{1j} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & -\sum \Lambda_{nj} \end{pmatrix}, \quad \eta = \begin{bmatrix} \eta_1 \\ \eta_2 \\ \vdots \\ \eta_n \end{bmatrix}$$

$$B = \begin{pmatrix} 0 & \sum \Lambda_{12} \cdots & \sum \Lambda_{1n} \\ \sum \Lambda_{21} & \sum \Lambda_{23} \cdots & \sum \Lambda_{2n} \\ \vdots & \ddots & \vdots \\ \sum \Lambda_{n1} & \cdots & 0 \end{pmatrix}, \; S = \begin{pmatrix} s_1 \\ s_2 \\ \vdots \\ s_n \end{pmatrix}$$

$$d = \begin{pmatrix} d_1 \\ d_2 \\ \vdots \\ d_n \end{pmatrix}, \; \Lambda = \begin{pmatrix} \lambda_1 I & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n I \end{pmatrix}$$

The equivalent control expression can be deduced from the equality $\dot{s}_i = 0$ then, we obtain:

$$u_{eq_i} = M_i[\ddot{q_d} - \dot{\xi}_i + \lambda_i(\xi_i + \dot{\eta}_i)] + C_i(q_i, \dot{q}_i)\dot{q}_i + g_i(q_i) \tag{21}$$

3.3 Theorem

The control law:

$$u = u_{eq_i} + \Delta u \tag{22}$$

where: u_{eq_i} is expressed in equation (21) and Δu is given by:

$$\Delta u = NR^{-1}[N\varepsilon - P\eta - \Lambda S - KsignS] \tag{23}$$

with N is a diagonal, symmetric definite positive matrix which stabilities the proposed system composed by n manipulators.
Remembering that for the Second Order Sliding Mode Control, the sliding surface becomes $\dot{s}_i = \sigma_i$ and taken into consideration equation (17), we obtain:

$$\ddot{q}_i - \ddot{q}_d + \sum \Lambda_{ij}(\dot{q}_i - \dot{q}_j) + \lambda_i[\dot{q}_i - \dot{q}_d + \sum \Lambda_{ij}(q_i - q_j)] = \sigma_i \tag{24}$$

Retaking the mathematical model equation (12) and substituting it in the previous equation gives:

$$\begin{gathered}\sigma_i = M_i^{-1}[\tau_i - C_i(q_i,\dot{q}_i)\dot{q}_i - G_i(q_i)] \\ +\sum \Lambda_{ij}(\dot{q}_i - \dot{q}_j) + \lambda_i[\dot{q}_i - \dot{q}_d + \sum \Lambda_{ij}(q_i - q_j)] - \ddot{q}_d\end{gathered}$$

And consequently,:

$$\begin{gathered}\tau_i = C_i(q_i,\dot{q}_i)\dot{q}_i + G_i(q_i) + M_i[\ddot{q}_d - \sum \Lambda_{ij}(\dot{q}_i - \dot{q}_j) \\ -\lambda_i[(\dot{q}_i - \dot{q}_d) + \sum \Lambda_{ij}(q_i - q_j)] + \sigma_i]\end{gathered} \tag{25}$$

4 Proof of the Stability Analysis

In order to prove the stability of the considered multi agent system, a first Lyaponov function is chosen as follows:

$$V_1 = \eta^T P \eta \tag{26}$$

Its derivative yields:

$$\dot{V}_1 = \eta^T(PA + A^T P)\eta + 2\eta^T P(B\eta(t-\tau) + d - \Lambda\varepsilon + S) \tag{27}$$

The second function is expressed as:

$$V_2 = \int_{t-\tau}^{t} \eta^T H \eta \, d\alpha \tag{28}$$

where:

$$\dot{V}_2 = \eta^T H \eta - \eta(t-\tau)^T H \eta(t-\tau) \tag{29}$$

Then and in order to simplify the expression of $\dot{V}_1 + \dot{V}_2$, we firstly compute the sub −equation:
$2\eta^T PB\eta(t-\tau) - \eta(t-\tau)^T H\eta(t-\tau)$.

So, we denote that $\zeta_1 = \rho_1\eta(t-\tau) - \frac{1}{\rho_1}D^{-1}B^T P\eta(t)$

Consequently:

$$\begin{gathered}\dot{V}_1 + \dot{V}_2 = \eta^T(PA + A^T P)\eta + 2\eta^T P(d - \Lambda\varepsilon + S) \\ +\eta^T H\eta - \zeta_1 D\zeta_1 + \rho_1^2 \eta^T PBD^{-1}B^T P\eta \\ +\frac{1}{\rho_1^2}\eta(t-\tau)^T D\eta(t-\tau) - \eta(t-\tau)^T H\eta(t-\tau)\end{gathered} \tag{30}$$

After that, we regroup all terms of the previous equation:

$$\begin{gathered}\dot{V}_1 + \dot{V}_2 = \eta^T(PA + A^T P + H + \rho_1^2 PBD^{-1}B^T P)\eta \\ -\zeta_1^T D\zeta_1 - \eta(t-\tau)^T(H - \frac{1}{\rho_1^2}D)\end{gathered}$$

where H and D are positive definite matrix while P, N are symetric positive matrix.
It's obvious from the previous equation that there are three terms relative to d, ε and S which should been developed. Consequently:

$$2\eta^T Pd = -\zeta_2^T\zeta_2 + \rho_2^2\eta^T\eta + \frac{1}{\rho_2^2}d^T P^2 d$$

in which:

$$\begin{cases}\zeta_2 = \rho_2\eta - \frac{1}{\rho_2}Pd \\ -2\eta^T\Lambda\varepsilon = -\zeta_3^T\zeta_3 + \rho_3^2\eta^T\eta\frac{1}{\rho_3^2}\varepsilon^T\Lambda^T\Lambda\varepsilon\end{cases}$$

where $\zeta_3 = \rho_3\eta - \frac{1}{\rho_3}\Lambda\varepsilon$.

In the sequel, we introduce new terms V_3 and V_4 to complete the stability verification of the proposed synchronized control schemes such that:

$$\begin{cases}V_3 = \varepsilon^T N\varepsilon \\ V_4 = S^T RS\end{cases} \tag{31}$$

The differentiation with respect of time gives:

$$\begin{cases}\dot{V}_3 = 2\varepsilon^T N(s - \Lambda\varepsilon) = -\varepsilon^T(N\Lambda + \Lambda^T N)\varepsilon \\ -2\varepsilon^T Ns \\ \dot{V}_4 = 2\dot{S}^T RS\end{cases} \tag{32}$$

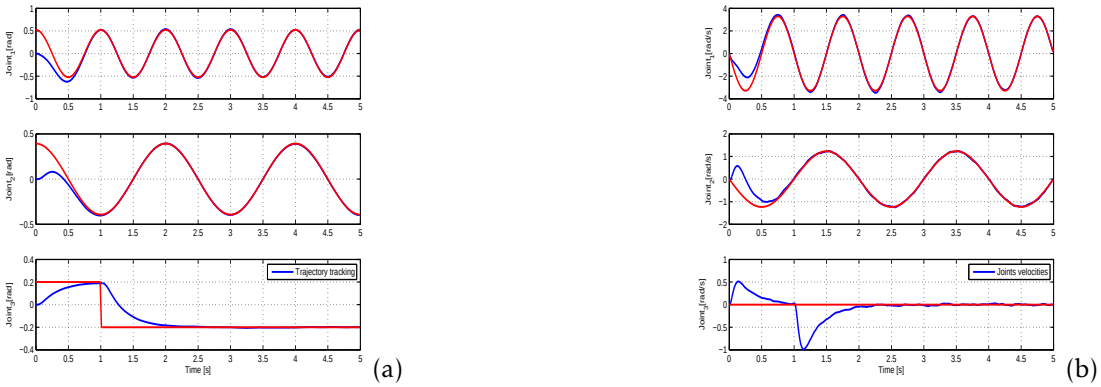
Therefore, we develop the following terms:

$$\begin{cases}2\eta^T PS = -\zeta_4^T\zeta_4 + \rho_4^2\eta^T\eta + \frac{1}{\rho_4^2}S^T P^2 S \\ -2\varepsilon^T NS = -\zeta_5^T\zeta_5 + \rho_5^2\varepsilon^T\varepsilon + \frac{1}{\rho_5^2}S^T N^2 S\end{cases} \tag{33}$$

in which $\zeta_4 = \rho_4\eta - \frac{1}{\rho_4}PS$ and $\zeta_5 = \rho_5\varepsilon + \frac{1}{\rho_5}NS$.

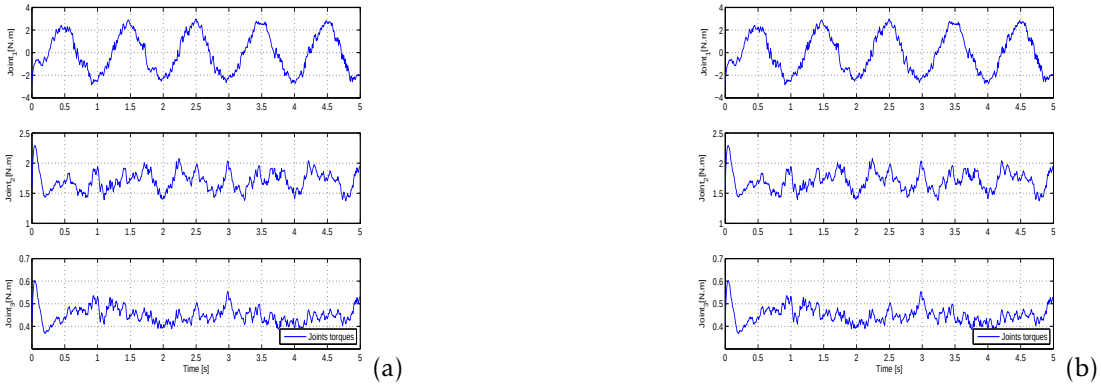
Finally, the derivative of the global Lyaponov function
$V = V_1 + V_2 + V_3 + V_4$ yields:

$$\begin{gathered}\dot{V} = \eta^T(PA + A^T P + H + \rho_1^2 PBD^{-1}B^T P + \rho_2^2 I + \rho_3^2 I \\ +\rho_4^2 I)\eta - \zeta_1^T D\zeta_1 - \zeta_2^T\zeta_2 - \zeta_3^T\zeta_3 - \zeta_4^T\zeta_4 - \zeta_5^T\zeta_5 \\ -\eta(t-\tau)^T(H - \frac{1}{\rho_1^2}D)\eta(t-\tau) - \varepsilon^T(N\Lambda + \Lambda^T N \\ +\rho_5^2 I - \frac{1}{\rho_3^2}\Lambda^T\Lambda)\varepsilon + 2S^T(R\dot{S} - N\varepsilon + P\eta) + \frac{1}{\rho_2^2}d^T P^2 d\end{gathered}$$



(a) (b)

Figure 3: Simulation in the presence of external disturbances: (a) Positions evolutions in the presence of low measurement noises, (b) Velocities evolutions in the presence of low measurement noises



(a) (b)

Figure 4: Simulation in the presence of external disturbances: (a) Torques evolutions of the SOSMC, (b) Measured torques evolutions of the SOSMC

Assume that $\dot{S}$ is defined as follows:

$$\dot{S} = R^{-1}[-N\varepsilon - P\eta - \Lambda S - KsignS] \tag{34}$$

Hence, remember that N, P, Λ, K are positive definite matrices, and assume that they verify the following conditions:

$$\begin{cases} H > \frac{1}{\rho^2} D \gg I \\ PA + A^T P + H + \rho_1^2 PBD^{-1} B^T P + (\rho_2^2 + \rho_3^2 + \rho_4^2) I \\ N\Lambda + \Lambda^T N > \frac{1}{\rho_3^2} \Lambda^T \Lambda \\ 2S^T (R\dot{S} - N\varepsilon + P\eta) + \frac{1}{\rho_2^2} d^T P^2 d = -2S^T \Lambda S < 0 \\ -2K \mid S \mid + \frac{1}{\rho_2^2} d^T P^2 d < 0 \end{cases}$$

The stability is confirmed if:
$\rho_1^2 PBD^{-1} B^T P \ll PA + A^T P$ and the term $\frac{1}{\rho_2^2} d^T P^2 d$ is considered as small bounded so that it can be neglected.
Consequently, we obtain:

$$\dot{V}_i \leq 0$$

Finally, this confirms the stability of the overall system.

5 robustness via measurement noises effect

In order to test the robustness of the proposed controller via uncertainties, an additive measurement errors have been introduced.
Then the measured state can be expressed as follows:

$$x_m(t) = x(t)(1 + b_1(t)) = x(t) + \Delta x(t)$$

where b_1 is an additive bounded measure noise such that:
$\|b_1(t)\| \leq d_1$, and d_1 is a positive constant.
The level of the error effect has been varied from the lower impact to be gradually more intense, aiming to verify the controller's capacity to withstand such disturbances. At the beginning, low noise has been yield (we fluctuate the perturbation from 5 percent to 20 percent), we notice that the positions and the velocities evolutions still remain on the sliding surface which prove the robustness and the insensibility of the second order sliding mode control via disturbances (Figure 3). Then, the level has been increased (almost 30 percent), and in this case, the noise start to affect the tracking evolution of the system(Figure 5b and Figure 6b).
It is obvious from Figure 4 that there is a similarity between the real torques and the measured ones, this

Table 1: Joints parameters

Table 2: Control parameters

Control Parameters	Values
Λ_{ij}	0.8
ω	20
$timedelay$	0.2

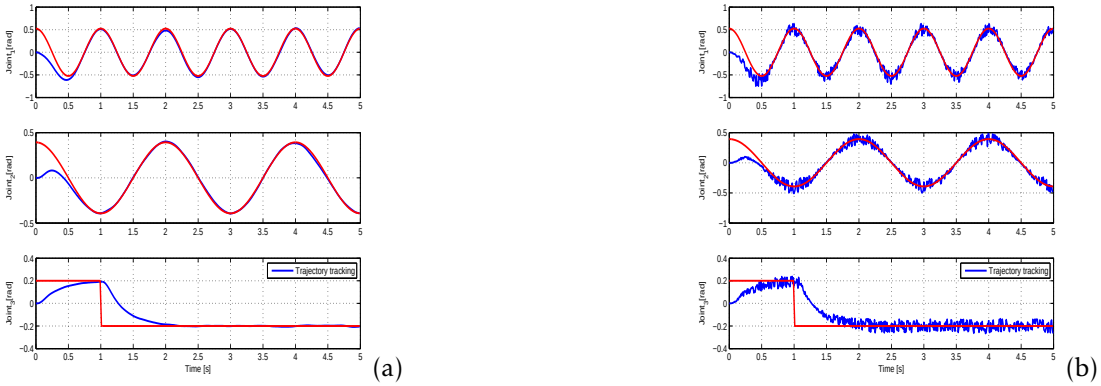

Figure 5: Simulations in the presence of external disturbances: (a) Positions evolutions in the presence of high measurement noises, (b) Measured Position evolutions in the presence of high measurement noises

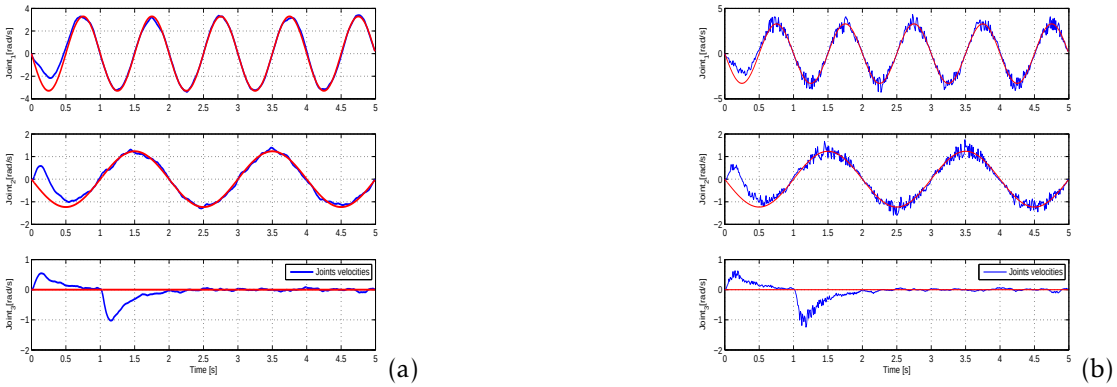

Figure 6: Simulations in the presence of external disturbances: (a) Velocities evolutions in the presence of high measurement noises, (b) Measured Velocities evolutions in the presence of high measurement noises

means that although the system suffers from external disturbances, the evolution of the applied torques do not record any notable increase, subsequently, no additional power consumption needed.

The aim of the comparison between real and measured simulations (Figure 5 and Figure 6) is to prove that the proposed controller exerts a satisfactory compensation action affecting the trajectory tracking and the velocity. This compensation becomes lower while increasing the disturbance effect, and it becomes unable to manage high imposed disruptions, i.e. starting from the presence of 30 present of errors applied to the system. Nevertheless, at this level the proposed controller has still resist to perturbations, and seen that the level of this disruption is relatively high, it can be then considered as a sufficient control, and proves its robustness via external disturbances.

6 Simulation Results

In this work, a second order SMC is applied to a networked multi–agent robotic system for a trajectory tracking control task. Indeed, the use of several cameras managed by manipulator robots and controlled by the proposed decentralized control law, allows the interaction of each robot with other agents in the networked system in order to make an overall vision about its environment. Thanks to the cross coupling concept, each agent is able to communicate and exchange information with its neighbors. The desired trajectory is expressed by:

$$q_d(t) = \begin{bmatrix} q_{d1}(t) \\ q_{d2}(t) \\ q_{d3}(t) \end{bmatrix} = \begin{bmatrix} \frac{\pi}{6}\sin(1.5\pi t) \\ \frac{\pi}{4}\sin \pi t \\ \frac{\pi}{2}\sin 4\pi t \end{bmatrix}$$

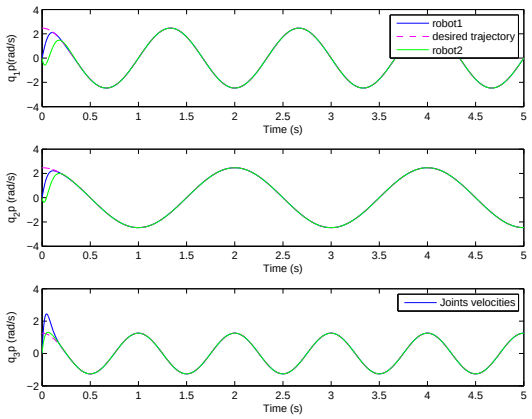

Figure 10: Velocity evolution of the synchronized robots

Parameters of the proposed system model used in simulation are illsutrated in Table 1 and control parameters values are given in Table 2.

Concerning the parameters μ_i and λ_i, they are defined as follows:

$$\lambda_i = 2\begin{pmatrix} 1.125 & & 0 \\ & 1.45 & \\ 0 & & 1.12 \end{pmatrix}$$

$$\mu_i = \begin{pmatrix} 3 & & 0 \\ & 4 & \\ 0 & & 5 \end{pmatrix}$$

Simulation results show the robust synchronization and the smooth evolution in the trajectory tracking based on the second order SMC. The original SMC torques evolutions and the second order SMC ones are shown in Figure 7*a* and Figure 7*b* respectively.

It is obvious from the Figure 7*a* that the classical sliding mode control suffers from the chattering phenomenon whose impact is reflected by the appearance of disrupting high switching frequencies (oscillations). Specifically, the problem consists of rapid and sudden changing control signals which lead to a low control accuracy. On the other side, Figure 7*b* demonstrates that the second order SMC seems to be smooth and able to reduce the chattering phenomenon.

Besides, the presence of time delay between the cooperative robots is slightly reflected during the simulation as shown in Figure 8 and Figure 10 respectively. It may be said otherwise that the communication time delay between robots is clearly compensated and the position synchronization based on the cross coupling concept is obvious, predominately in the (Figure 8). The presence of undesirable phenomenon namely chattering in control torques of each agent is avoided in Figure 9.

7 Conclusion

In this paper, the stability analysis of multi robot manipulator systems with a constant communication delay has been demonstrated. The main goal of this study is to compensate the delayed communication impact and to realize the synchronization between different robots of the system. So the proposed controlled system has succeeded to achieve a performing motion control task in the presence of loss of information during robot's communication, perturbations and also in the presence of delayed communication data. Simulation results show that the multi robots system can achieve the desired motion control task even with presence of a constant time delay.

Fault tolerant control (FTC)
Fault detection and diagnosis (FDD)
Observer bank

ABSTRACT

This paper focuses on studying the problem of fault tolerant control (FTC), including a detailed fault detection and diagnosis (FDD) module using observer banks which consists of output and unknown input observers applied to a continuous stirred tank reactor (CSTR). The main objective of this paper is to use a FDD module here proposed to estimate the fault in order to apply this result in a FTC system (FTCS), to prevent a lost of of the control system performance. The benefits of the observer bank and fault adaptation here studied are illustrated by numerical simulations which assumes faults in manipulated and measuring elements of the CSTR.

1 Introduction

The performance of a closed-loop system can be altered by a failure in one of its components, and in some cases can lead to an instability of the control system, causing major damage to it. The goal of fault tolerant control (FTC) is to prevent deterioration of the system, by means of a controller with the ability to compensate faults, by correcting the control action.

An active fault tolerant control systems (AFTCS) have basically two subsystems: a module for fault detection and diagnosis (FDD) and another one for reconfigurable control (RC). The detection and isolation of faults is an important research area in process control due to the improvements that it can be reached in terms of safety and reliability of the plant. For this purpose, several model-based methods for generation of residue, mainly based on observers, are proposed for different authors [5, 15, 8, among others]. However, there are another model-based methods, such as parity equations or stable matrix factorization [6] that were explored by several authors [17, 16, among others].

Firstly, the paper focuses on studying the problem of fault detection and diagnosis using observer banks that they include output and unknown input observers [5, 4]. The main objective is the fault estimation by means of diagnostic module, and then a fault-tolerant control system is developed, to prevent a bad performance [13, 2, 18, among others].

This article focuses on the design issues of FDD module and FTC system applied to a CSTR where an exothermic chemical reaction take place, using a mathematical model presented by several authors as [21, 9, 1, among others] and whose parameters were adopted according to [11]. The simulations show how output and unknown input observers can quickly detect faults in sensors and actuators, estimate the magnitude of the occurred faults and thus quickly correct the control action, for preserving stability and performance of the control system.

This paper is organized as detailed bellow. Section 2 presents the basic theoretical concepts associated with the observer banks here proposed. Then, in section 3 the general scheme of an active FTC and the adopted strategy for recovering performance is presented. Subsequently, section 4 shows the

improvement achieved by using proposed observer banks for fault detection and isolation, by numerical simulations. Finally, in section 5 the conclusions are presented.

2 Fault detection by means of observer banks

2.1 Problem statement

Consider a linear time invariant (LTI) system under the state space representation, with actuators and sensors additive faults as follows:

*Corresponding Author: Martin F. Pico, Universidad Nacional del Litoral, Facultad de Ingeniería Química, S3000, Argentina, martinpico@gmail.com

https://dx.doi.org/10.25046/aj020322

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t) + F_u f_u(t) \\ y(t) &= Cx(t) + F_y f_y(t) \end{aligned} \tag{1}$$

where $A \in \Re^{n\times n}$, $B \in \Re^{n\times q}$ y $C \in \Re^{m\times n}$ are the matrices of state, control and output respectively, $x \in \Re^n$ is the true value of the state vector, $u \in \Re^q$ is the input vector, $y \in \Re^m$ represents the outputs of the system, F_u and F_y are inputs and outputs faults distribution matrices, $f_u(t)$ and $f_y(t)$ are the inputs and outputs additive faults, respectively.

Under a unified framework, the system (1) can be expressed as,

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t) + Lf(t) \\ y(t) &= Cx(t) + Mf(t) \end{aligned} \tag{2}$$

where$f(t) \in \Re^v$ with $v = m + q$, is a actuators and sensors faults representation such that,

$$f(t) = \begin{bmatrix} f_u \\ f_y \end{bmatrix} \tag{3}$$

$L \in \Re^{n\times v}$ y $M \in \Re^{m\times v}$ are actuators and sensors faults matrices, which may written as $L = [B\ 0_{n\times m}]$ and $M = \begin{bmatrix} 0_{q\times m} & I_{m\times m} \end{bmatrix}$.

The goal is to estimate f_u and f_y as soon as possible such that, the monitored data are quickly corrected and at the same time the closed loop control system is able to correct the fault. Consequently, it is possible to prevent that the system is positioned outside the desired operating point or worse, become unstable.

Output observers

For fault detection and isolation (FDI) purposes, the estimation of all states is not required, it is sufficient to estimate of the output variables. For this reason, an output observer[1] is appropriate for FDI [8].

The dynamic of this observer (Fig. 1) is,

$$\dot{z}(t) = Fz(t) + Ju(t) + Ky(t) \tag{4}$$

where $z \in \Re^s$, s denote the observer order which may be the same, greater or lesser than the order of the system (n).

As it shown in Fig. 1, the observer output is the residue

$$r(t) = Wz(t) - Vy(t) \tag{5}$$

where the following conditions must be satisfied [14],

$$\begin{aligned} \Re(\lambda(F)) < 0; \\ KC = TA - FT \\ J = TB \\ WT + VC = 0 \end{aligned} \tag{6}$$

where $\Re(\lambda(F))$ denote the eigenvalue real parts of the F matrix.

According with [14], if these design conditions are satisfied, the dynamic errors and residues are,

$$\dot{e}(t) = Fe(t) - TLf(t) + KMf(t) \tag{7}$$

$$r(t) = We(t) - VMf(t) \tag{8}$$

with

$$e(t) = z(t) - Tx(t) \tag{9}$$

where the residuals depend on faults.

In order to isolate faults, a set of structural or directional residues is designed using this approach. Thus, the design of a structural residue set for sensor faults is straightforward. For example, if the output vector $y = (y_1, ..., y_m)$ is rewritten as $(y_1, ., y_{i-1}, y_{i+1}, .., y_m)$, the residue will be insensitive to the fault of the $i - th$ sensor.

Contrary to the above, to isolate faults in the actuators through structural residues is not straightforward, but can be solved by means of *unknown input observers* (UIO).

2.2 Unknown input observers

This subsection is based on the work of Hou and Müller [7] who proposed to design an observer whose dimension is $(n - q)$ for the purpose of detecting additive actuator faults. To do this, consider the LTI system (1) where A, B, C, F_u are constant matrices with appropriated dimensions. Furthermore, assume that $m \geq q$ and, without loss of generality, $rank(F_u) = q$ and $rank(C) = m$.

Under this assumption, it is possible to choose a nonsingular matrix T as

$$T = [N\ F_u], \tag{10}$$

with $N \in \Re^{nx(n-q)}$.

$$\begin{aligned} \dot{\bar{x}}(t) &= \bar{A}\bar{x}(t) + \bar{B}u(t) + \bar{L}f_u(t) \\ y(t) &= \bar{C}x(t) \end{aligned} \tag{11}$$

where,

$$x = T\bar{x} = T\begin{bmatrix} \bar{x}_1 \\ \bar{x}_2 \end{bmatrix}, \tag{12}$$

$$\bar{A} = T^{-1}AT = \begin{bmatrix} \bar{A}_{11} & \bar{A}_{12} \\ \bar{A}_{21} & \bar{A}_{22} \end{bmatrix}, \tag{13}$$

$$\bar{B} = T^{-1}B = \begin{bmatrix} \bar{B}_1 \\ \bar{B}_2 \end{bmatrix} \tag{14}$$

$$\bar{F}_u = T^{-1}F_u = \begin{bmatrix} 0 \\ I_q \end{bmatrix},\ \bar{C} = CT = [CN\ CF_u] \tag{15}$$

con $\bar{x}_1 \in \Re^{n-q}$ and $\bar{x}_2 \in \Re^q$.

Notice that, in Eq. (11), $\bar{x}_2$ is directly affected by unknown fault f_u, while $\bar{x}_1$ it is independent of f_u. Then, is possible to rewrite a system (11) without the unknown input as

$$\begin{bmatrix} I_{n-q} & 0 \end{bmatrix}\dot{\bar{x}} = \begin{bmatrix} \bar{A}_{11} & \bar{A}_{12} \end{bmatrix}\bar{x} + \bar{B}_1 u \tag{16}$$

$$y = CT = [CN\ CF_u]\bar{x} \tag{17}$$

[1] Also designated as diagnostic observer, functional observer or generalized Luenberger observer.

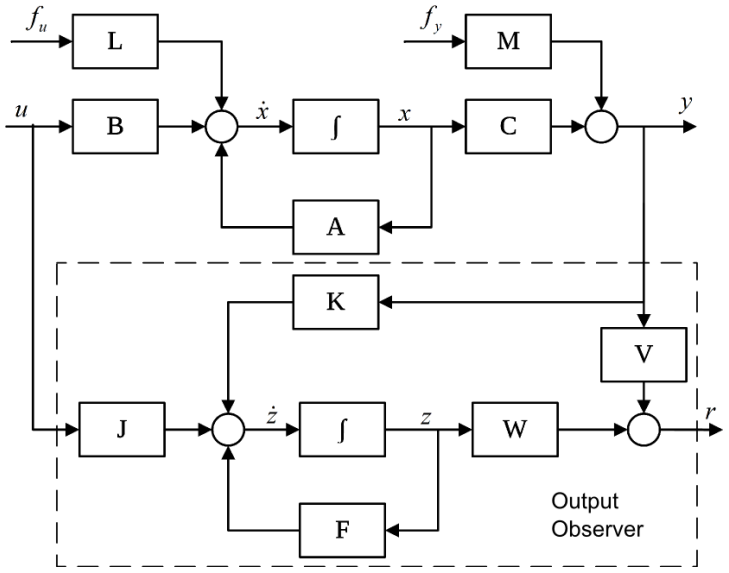

Figure 1: Process and output observer.

Assuming that $\bar{x}_2$ can be obtained from y, the Eq. (16) can be written as a conventional linear system. Indeed, if the matrix $[CF_u]$ is of full column rank, there exist a non-singular matrix

$$U = [CF_u \; Q] \tag{18}$$

Being,

$$U^{-1} = \begin{bmatrix} U_1 \\ U_2 \end{bmatrix} \tag{19}$$

with $U_1 \in \Re^{q\times m}$ y $U_2 \in \Re^{(m-q)\times q}$ and pre-multiplying both sides of Eq. (17) por U^{-1},

$$U_1 y = U_1 CN\bar{x}_1 + \bar{x}_2 x \tag{20}$$
$$U_2 y = U_2 CN\bar{x}_1 \tag{21}$$

and replacing Eq. (20) in Eq. (16) and combining the last equation with Eq. (21) is arrived to

$$\dot{\bar{x}}_1(t) = \bar{A}_1\bar{x}_1 + \bar{B}u(t) + \bar{E}_1 y \tag{22}$$
$$\bar{y} = \bar{C}\bar{x}_1 \tag{23}$$

where

$$\bar{A}_1 = \bar{A}_{11} - \bar{A}_{12}U_1 CN \qquad E_1 = \bar{A}_{12}U_1 \tag{24}$$
$$\bar{C}_1 = U_2 CN \qquad \bar{y} = U_2 y$$

Notice that, it is possible to verify that the $rank(\bar{C}_1) = m - q$.

At this point the pair $\bar{A}_1, \bar{C}_1$ is observable, and following the design procedure of a Luenberger observer, it is possible to design a reduced order observer for the system free of unknown inputs given by Eq. (22) as

$$\dot{w}(t) = \left[\bar{A}_1 - K_e\bar{C}_1\right]w(t) + \bar{B}_1 u(t) - K_e^* y(t),\; w \in \Re^{(n-q)} \tag{25}$$

where $K_e \in \Re^{(n-1)\times(m-q)}$ y $K_e^* = K_e * U_2 + E_1$ and $w \to \bar{\bar{x}}_1$ when $t \to \infty$, and

$$\bar{x} = T\bar{\bar{x}} = T\begin{bmatrix} w \\ U_1 y - U_1 CN w \end{bmatrix} \tag{26}$$

where $\bar{x} \to x$, when $t \to \infty$. Then, the unknown input or disturbance d can be estimated as

$$\bar{f}_u = U_1\dot{y} + G_e w + G_4 y + G_5 u \tag{27}$$

where

$$\begin{aligned} G_3 &= U_1 CNK_e U_2 CN + U_1 CN\bar{A}_{12}U_1 CN - \\ &\quad U1CN\bar{A}_{11} - \bar{A}_{21} + \bar{A}_{22}U_1 CN \\ G_4 &= -U1_C NK_e U_2 - U_1 CN\bar{A}_{12}U_1 - \bar{A}_{22}U_1 \\ G_5 &= -U1CN\bar{B}_1 - \bar{B}_2 \end{aligned} \tag{28}$$

2.3 Observer banks

Figure 2 shows how to implement output and unknown input observer banks to estimate the residues according to the description in the previous two subsections.

3 Fault-tolerant control

The sensor and actuator faults do not impact in a system in the same way. Consequently, the solution for these two types of faults is different.

Fiqure 3 shows the FTC strategy based on [22] and [19] here implemented. Notice that, the detection, isolation and estimation consist in analyzing the results of each residue generator to decide if sensor or actuator is failing.

3.1 Design of FTC system for sensor faults

When a particular sensor fault takes place, a free faults estimation of this particular sensor from observer bank is used, and this signal is feedback. That is, the estimated output variable is considered as good

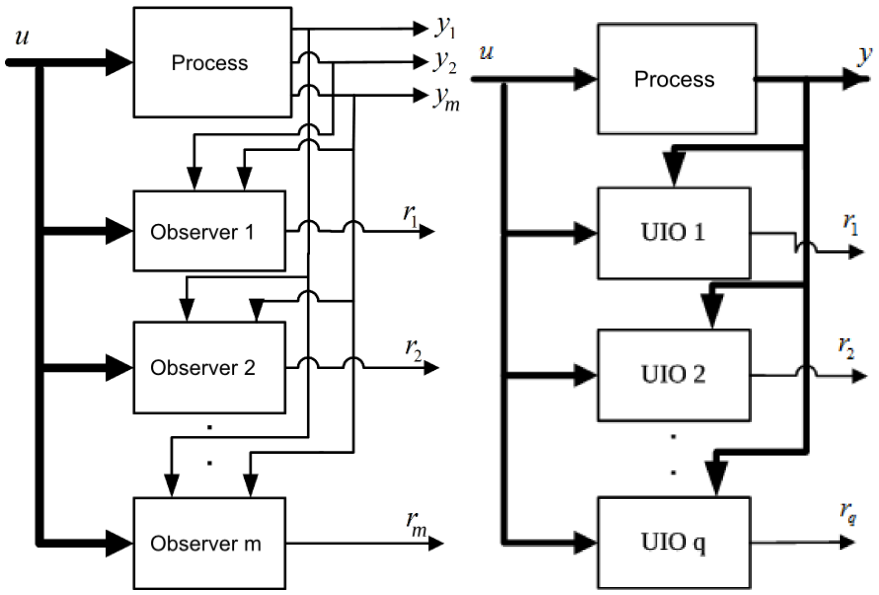

Figure 2: Observer Banks. (a) Output observer (OO) bank for all inputs and outputs except one.(b) Unknown input observer (UIO) bank.

measurement and, the control loop is automatically reconfigured.

The estimation of j-th damaged sensor $\hat{y}_j$ is obtained from an observer which is designed to be insensitive to fault of this j-th sensor. Consequently, the output vector used to implement the control law is

$$y_c(t) = \begin{pmatrix} \check{y}_1(t) \\ \vdots \\ \check{y}_j(t) \\ \vdots \\ \check{y}_m(t) \end{pmatrix} \tag{29}$$

where

$$\check{y}_j(t) = \Big(1 - I(f_j)\Big) y_j + I(f_j)\hat{y}_j(t) \tag{30}$$

with

$$I(f_j) = \begin{cases} 1 \text{ fault in j-th sensor} \\ 0 \text{ sensor without fault} \end{cases} \tag{31}$$

3.2 Design of FTC system for actuator faults

When a fault in an actuator is detected, the control action is compensated by adding to manipulated variable whose value is proportional to the fault in order to minimize the impact.

In this work, a compensation to the control law proposed by [12] is added. Thus, under fault representation presented in Eq. (2), it is propose to add u^{acc} to the nominal control action.

Therefore, when in a particular instant (t_{find}) an actuator fault is detected, the control signal is corrected as follows:

$$u^{FTC}(t) = u(t) + u^{acc} \tag{32}$$

According to this new control law (Eq. (32)), the system described in state space given by Eq. (2) becomes,

$$\dot{x}(t) = Ax(t) + Bu(t) + Bu^{acc} + Lf^u(t) \tag{33}$$

$$y(t) = C_r x(t) \tag{34}$$

where the additional control action must be quickly computed such that the system is recovered as soon as possible. Then, the following condition is requested:

$$Bu^{acc} + Lf^u(t) = 0 \tag{35}$$

The fault estimation ($\widehat{f_u}$) can be obtained by mean of Eq. (35), resulting

$$u^{acc}(t) = -B^{+}L\widehat{f^u}(t) \tag{36}$$

where B^+ is the pseudo-inverse matrix of the matrix B. This compensation control law is represented in Fig. (3) within the module denoted *acomodation and estimation module*.

4 Detecting faults in a CSTR

In order to analyze the system performance with the proposed observer banks above, it is proposed to simulate faults in a CSTR control system. The behavior of the system under actuator and sensor faults was simulated according to the classic non-linear model ([21, 9, 1, among others]) with the parameters suggested by [11].

4.1 CSTR non-linear model

Consider a CSTR represented in Fig. 4, where an irreversible exothermic chemical reaction $A \rightarrow B$ occurs. This reaction takes place in a cylindrical stirred tank

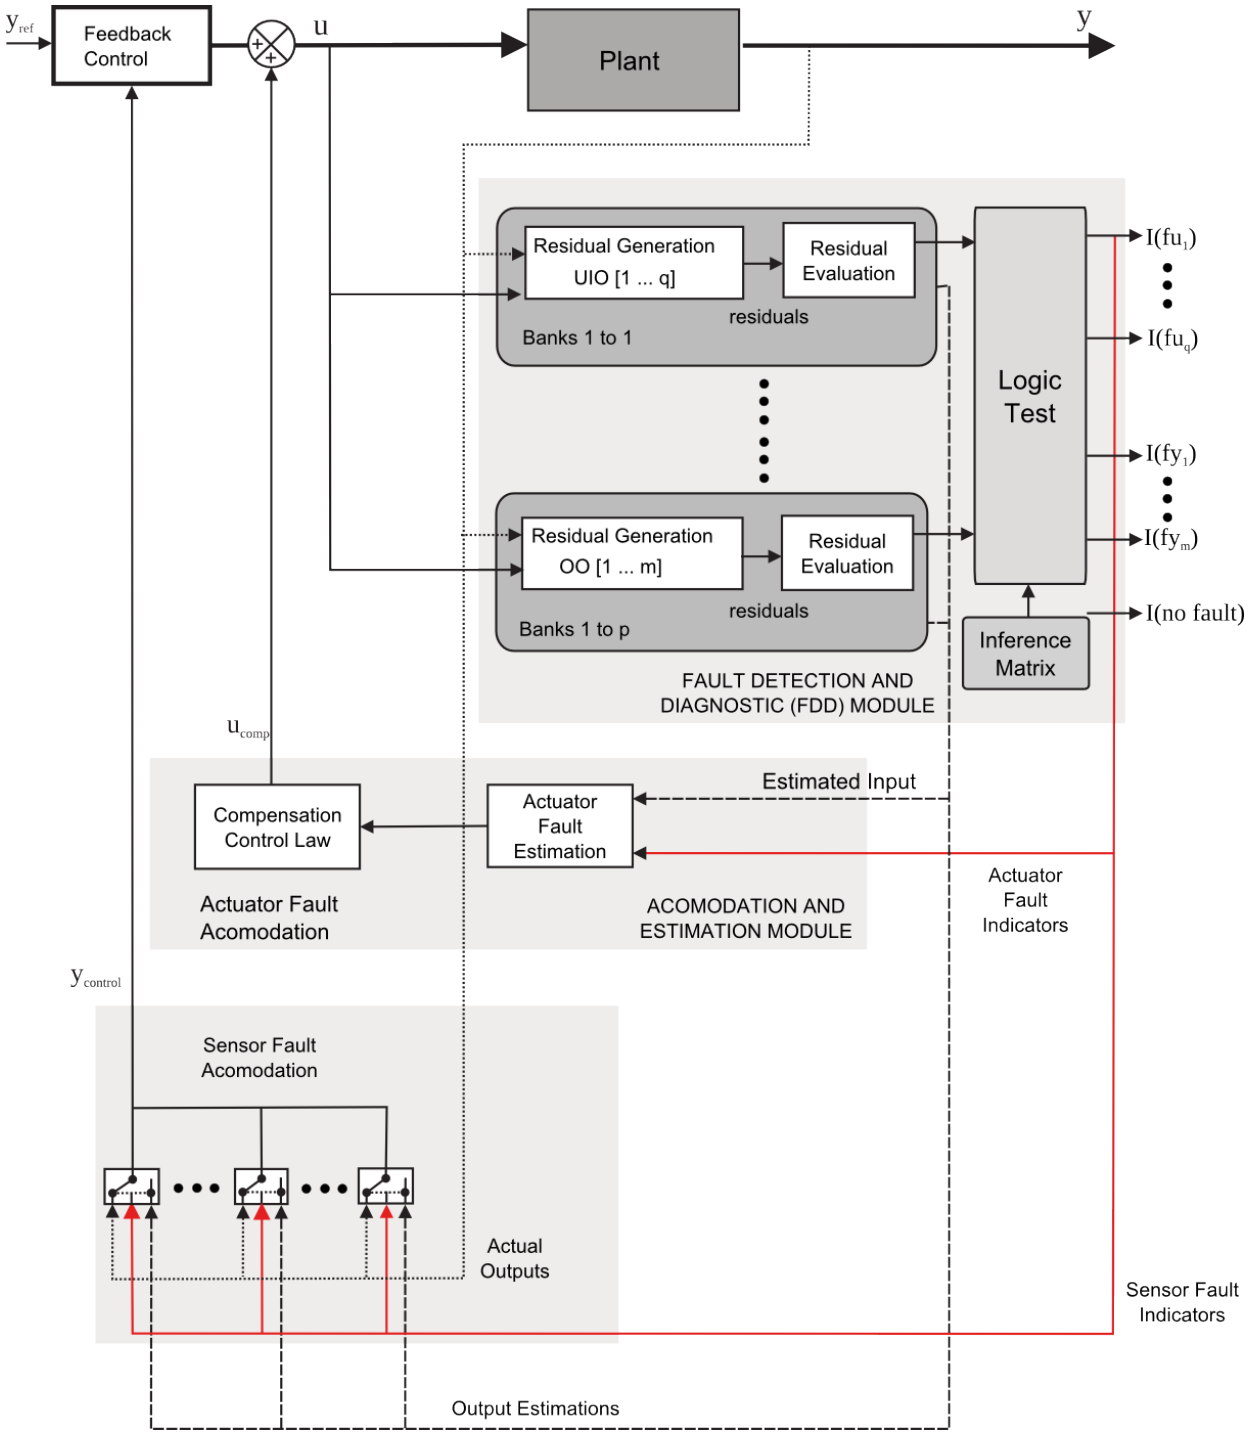

Figure 3: Scheme of a fault tolerant control system including detection and diagnostic module.

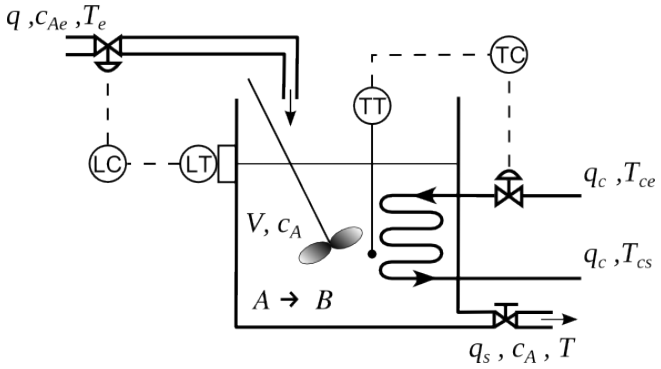

Figure 4: CSTR control schemes.

with a total capacity of $V_{\max} = 120$ l and a transversal section $A = 0.2\text{m}^2$. The principal parameter values are summarized in Table 1.

The complete model (37) can be written according to a non-linear differential and algebraic equation set as follows:

$$\begin{aligned}
\frac{d\,V(t)C_A(t)}{dt} &= q(t)\,(C_{Ae} - C_A(t)) - k_0 Ca(t) e^{-\frac{E}{RT(t)}} \\
\frac{d\,V(t)T(t)}{dt} &= q(t)(T_e - T(t)) - k_1 C_A(t) e^{-\frac{E}{RT(t)}} \\
&\quad + k_2 q_c(t)\left(1 - e^{-\frac{k_3}{q_c(t)}}\right)(T_{ce} - T(t)) \\
\frac{d\,V(t)}{dt} &= q(t) - k_4\sqrt{V(t)} \qquad (37)
\end{aligned}$$

where it is defined the constants,

$$k_1 := \frac{\Delta H k_0}{\rho c_p},\ k_2 := \frac{\rho_c c_{p_c}}{\rho c_p},\ k_3 := \frac{hA}{\rho_c c_{p_c}}, \qquad (38)$$

and the outlet flow rate,

$$q_s(t) = k_v\sqrt{V(t)}. \qquad (39)$$

Using Taylor series expansion around the operation point (C_A^*, T^*, V^*) and, neglecting terms of order two and higher, a matrix-vector equation under state space representation framework can be written. Thus, through this procedure is obtained

$$A = \begin{pmatrix} -\frac{q^*}{V^*} - k_0 e^{-\frac{E}{RT^*}} & A_{12} & -\frac{q^*}{V^{*2}}(C_{Ae} - C_A^*) \\ k_1 e^{-\frac{E}{RT^*}} & A_{22} & A_{23} \\ 0 & 0 & -\frac{k_4}{2\sqrt{V^*}} \end{pmatrix} \qquad (40)$$

where

$$A_{12} = -k_0 {C_A}^* \frac{E}{RT^{*2}} e^{-\frac{E}{RT^*}}$$

$$A_{22} = -\frac{q^*}{V^*} + k_1 {C_A}^* \frac{E}{RT^{*2}} e^{-\frac{E}{RT^*}} - k_2 \frac{q_c^*}{V^*}\left(1 - e^{-\frac{k_3}{q_c^*}}\right)$$

$$A_{23} = -\frac{q^*}{V^{*2}}(T_e - T^*) - k_2 \frac{q_c^*}{V^*}\left(1 - e^{-\frac{k_3}{q_c^*}}\right)(T_{ce} - T^*)$$

By means of parameter values summarized in Table 1 and assuming the operation point suggested by [11],

$$A = \begin{pmatrix} -9.9979 & -0.046787 & -0.009 \\ 1799.6 & 7.3245 & 1.7999 \\ 0 & 0 & -0.5 \end{pmatrix} \qquad (41)$$

$$B = \begin{pmatrix} 0.009 & 0 \\ -0.8854 & -0.8775 \\ 1 & 0 \end{pmatrix} \quad C = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \qquad (42)$$

Finally, according to Fig. 4, the control system has two PI controllers, where the control variables are the temperature T and volume V, which will be controlled by the cooling flow q_c and process flow rate q respectively.

4.2 Design of the observer banks

For this example, two observer bank were developed. One of them consist in three output observer to diagnose faults in the sensors of the volume, temperature and concentration, and the other one include two UIO to diagnose faults in the process and coolant flow rates.

4.3 Output observer design

According to section 2.1, by means of Eqs. (6) the following vectors can be written:

$$\begin{aligned}
J_1 &= (0.1517\ 0.1414)\ F_1 = (-300) \\
K_1 &= (-49.5715\ -0.2975) \\
J_2 &= (38.9958\ -0.8775)\ F_2 = (-200) \\
K_2 &= (8.4374\ -0.0004) \qquad (43) \\
J_3 &= (50.2176\ 48.7760)\ F_3 = (-100) \\
K_3 &= (-1.0005\ -0.0041)
\end{aligned}$$

where the numerical subscript indicates the corresponding OO.

To interpret and isolate faults in the OO bank the isolation patterns are used. For these particular example, is applied a pattern as shown in Table 2.

For example, according to Table 2, if a fault increases the monitored temperature, a decrement of residue related to the reactant concentration (r_{cA}) take place. Furthermore, an increment of temperature residue (r_T) and an invariant residue related to volume (r_v) are observed. As a result of these behaviors, a temperature sensor fault can be inferred.

4.4 Unknown input observer design

According to section 2.2, the following matrices can be written:

$$\begin{aligned}
L_1 &= \begin{pmatrix} 0.009 \\ -0.8854 \\ 1 \end{pmatrix} L_2 = \begin{pmatrix} 0 \\ -0.8775 \\ 0 \end{pmatrix} \\
N_1 &= N_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{pmatrix} \\
K_{e1} &= \begin{pmatrix} 0.0409 \\ 9.7011 \end{pmatrix} K_{e2} = \begin{pmatrix} 0.0385 \\ 8.7476 \end{pmatrix} \qquad (44)
\end{aligned}$$

where L_1 and L_2 are the actuator fault vectors, N_1 and N_2 are proposals to satisfy Eq. (10), and K_{e1} and K_{e2} come from solving the equation of the observer (25).

4.5 Numerical simulation

The performance of FDI procedure here proposed by means of observer banks applied to additive faults are studied by means of numerical simulations.

Table 1: Nominal CSTR parameter values

Parameter	Description	Value
C_A	Meassured product concentration	0.1 mol l^{-1}
T	Reactor Temperature	438.54 K
q_c	Coolant flow rate	103.14 L min^{-1}
q	Process flow rate	100 L min^{-1}
C_{A0}	Feed concentration	1 mol l^{-1}
T_0	Feed temperature	350 K
T_{c0}	Inlet coolant temperature	350 K
V	CSTR volume	100 L
hA	Heat transfer term	7×10^5 cal min^{-1} K^{-1}
k_0	Reaction rate constant	7.2×10^{10} min^{-1}
E/R	Activation energy term	1×10^4 K
ΔH	Heat of reaction	-2×10^5 cal mol^{-1}
ρ, ρ_c	Liquid densities	1×10^3 g l^{-1}
c_p, c_{p_c}	Specific heats	1 cal g^{-1} K^{-1}
k_v	Valve constant	10 $l^{1/2}$ min^{-1}

Table 2: Signs of residues for different types of additive faults in the CSTR.

	r_{C_A}	r_T	r_V
$\pm f_{C_A}$	$\pm$	0	$\pm$
$\pm f_T$	$\mp$	$\pm$	0
$\pm f_V$	0	0	$\pm$

4.6 Temperature sensor fault

Firstly, set-point changes around the reactor operating point are proposed in order to show that the PI controllers allow tracking changes. In particular, the proposed changes are: the volume $V = 110$ L at $t = 5$ min and the temperature $T = 435$ °K at $t = 15$ min.

Figure 5 shows the reactor dynamic response when a 5 % degradation in the temperature sensor at $t = 30$ min takes place. According with Fig.6, without fault tolerant control, the control loop reduces the coolant flow q_c to adjust the temperature of the reactor to the desired value according to an measured incorrect value, assuming that the reactor needs to accumulate more heat. Consequently, the actual temperature of the reactor is much higher at the end of the transient due to this unnecessary adjustment by the controller. However, this behavior does not take place if the FTC is implemented. Notice that, the same figure shows that when the sensor fault adaptation module (Fig. 3) is activated, the right signal is taken, therefore FTC system correction is involved and the reactor temperature value is maintained in $T = 435$ °K when steady state is reached.

Figure 7 shows how the residues (r_T, r_{c_A} and r_V) indicate the presence of a fault in temperature sensor according to Table 2.

4.7 Volumen sensor fault

In this simulation is shown a change in the volume set-point at $t = 5$ min from $V = 100$ L to $V = 110$ L, and then a 5% degradation in the volume sensor at $t = 35$ min.

Figure **??** shows the system dynamic response without fault-tolerant control. The feedback signal from the volume sensor fails abruptly into −5%, monitoring a wrong value ($V = 104.5$ L). As a result of this fault, the control loop corrects the measurement error in order to maintain the level at 110 L. Thus, according to the fault assumed the monitored volume by the sensor suggests to the controller that is correcting properly.

Furthermore, in this figure can also be seen how the FTC reacts an instant later in which it follows that a fault has occurred, the sensor fault adaptation module switches the signal from the observer bank according to Fig. 3. Then, the controlled variable retrieves the set-point value while the measured signal from the sensor continues to the wrong value.

Notice that according to the introduced changes in temperature set-point in $t = 15$ min does not influence the dynamics of the reactor volume, this being consistent with the physics of the problem.

Figure 8 shows how the reactor temperature evolves for both volume set-point change and with volume sensor fault. Notice that when a volume set-point change is introduced, a change in the reactor temperature is observed, forcing the temperature control loop to correct it ($t = 5$ min). Then, in the instant $t = 35$ min, the temperature corrections are made by the control loop. Figure 8 shows this corrections with and without FTC.

Figure 9 shows the dynamic response of temperature and the manipulated coolant flow for the problem with and without FTC, for the time interval between $t = 30$ min and $t = 50$ min. Based on the dynamic response without FTC it is possible to conclude

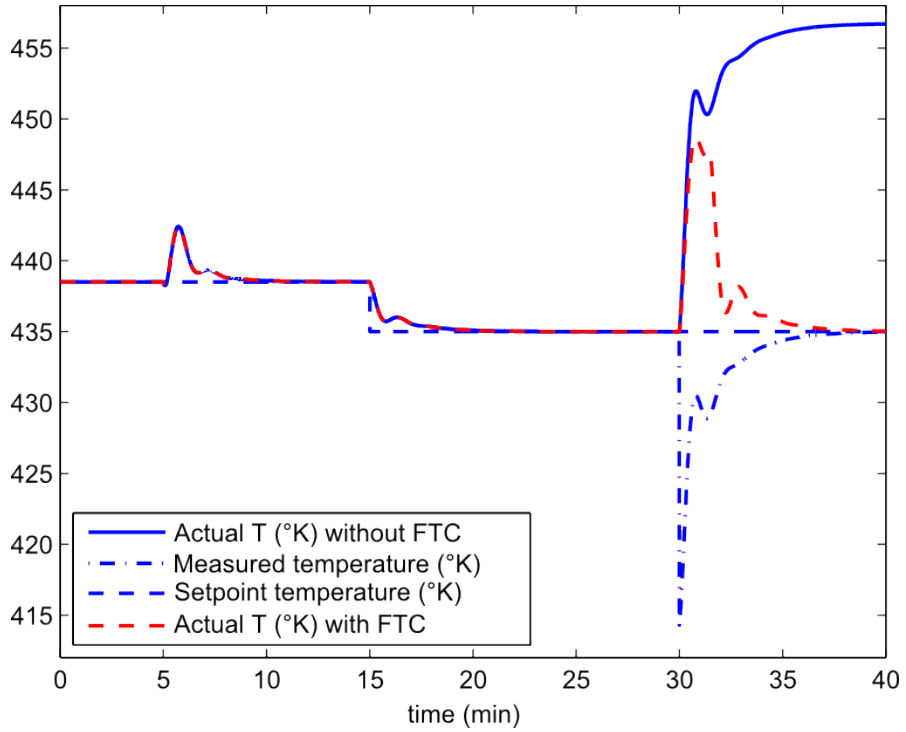

Figure 5: Actual CSTR temperature without FTC, measured temperature in the CSTR, set-point and temperature with FTC. Notice that the following changes was implemented: (1) a set-point change in the reactor volumen at $t = 5$ min, (2) a set-point change in the CSTR temperature at $t = 15$ min and, (3) a 5 % degradation in the temperature measuring element at $t = 30$ min.

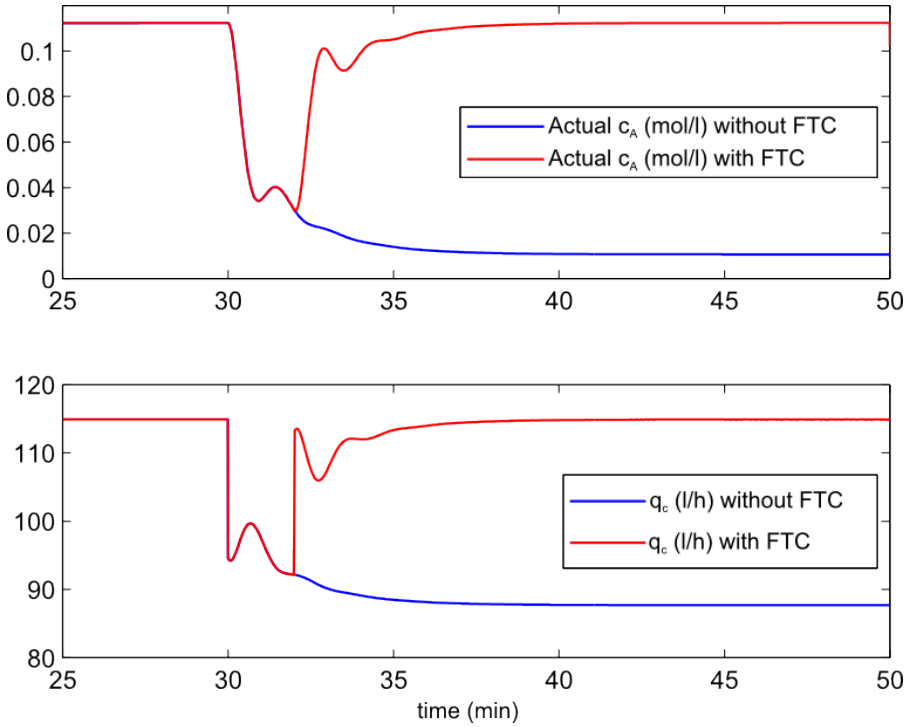

Figure 6: (a) Dynamic response of reactant concentration (c_A) when a degradation of temperature sensor take place with and without FTC. (b) Dynamic response of manipulated variable (q_c) with and without FTC.

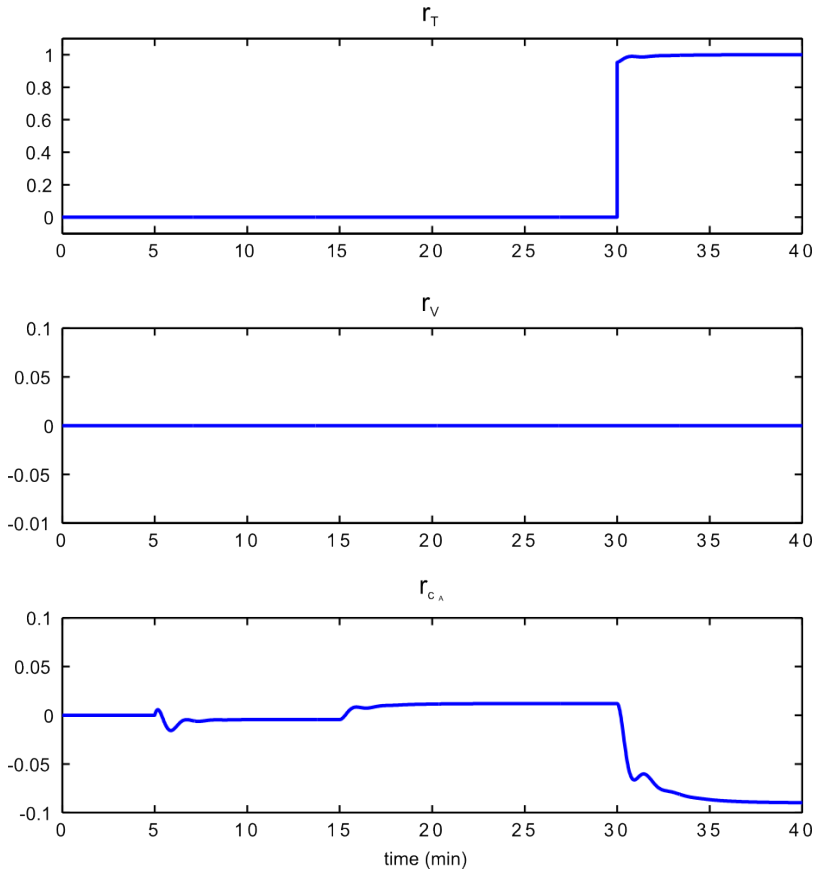

Figure 7: Residues of r_T, r_V and r_{c_A} to a fault in the temperature sensor.

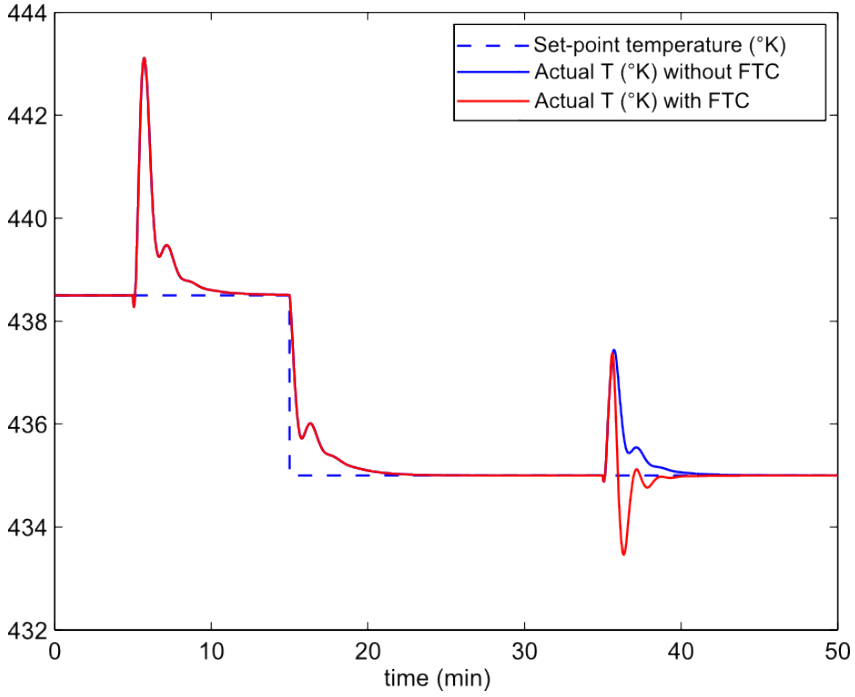

Figure 8: Actual and measured temperature and CSTR set-point. Notice that the following changes: (1) a set-point change in the volume at $t = 5$ min, (2) a set-point change in the CSTR temperature at $t = 15$ min and, (3) a 5 % degradation in the volume measuring element at $t = 35$ min.

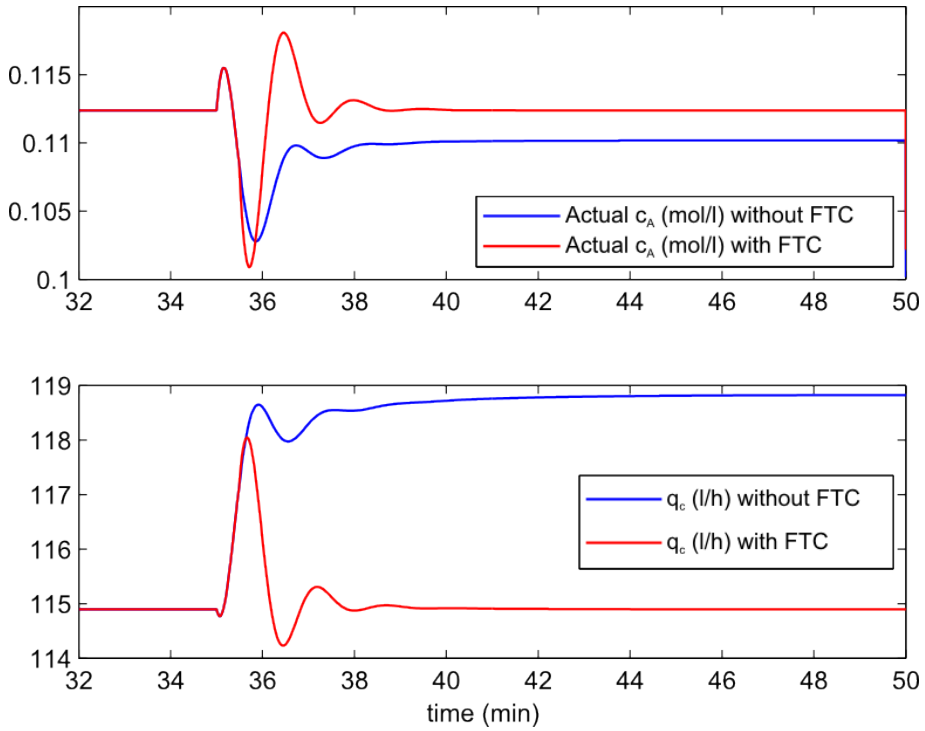

Figure 9: (a) Dynamic response of reactant concentration change (c_A) when a fault in the volume sensor take place with and without FTC. (b) Dynamic response of manipulated variable (q_c) with and without FTC.

that due to the actual volume of the reactor is not in the set-point value, it is necessary to increase the coolant flow to extract the heat required to bring the temperature back to the set-point.

5 Conclusions

In this paper, the design of an active fault tolerant control was presented, showing an adaptation to a fault in both an actuator and a sensor. To achieve this, two schemes that allow to compute residues through analytical redundancy was presented. The main proposal of this work is the use of observer banks to diagnostic sensor and actuator faults. In this context, output observers were used to detect sensor fault while an unknown input observer was used to identify manipulated variable fault.

This fault diagnosis strategy is applied to a CSTR, showing that the methodologies presented lead to satisfactory results. Furthermore, it is emphasized that the chosen example has specially interest in the chemical industry and, although there is many examples in the literature with non-linear systems using this methodology ([13, 8, among others]), but there is few references in FDI applied to CSTR [20, 3].

Finally, this work allows to understand even better the behavior of the CSTR when different faults taken placed.

ABSTRACT

Modeling of direct expansion (DX) air conditioning and heat pump systems can be necessary in developing energy saving methods required to reduce energy consumption in buildings. The artificial neural networks (ANN) can be simple and reliable as compared to traditional methods. A properly trained artificial neural network can provide accurate results, while being relatively straightforward and easy in development. This paper discusses the implementation and validation of an artificial neural network modeling technique to predict the performance of a DX air conditioning and heat pump. The model predicts the compressor power as a function of airflow rate, humidity ratio, ambient and mixed air temperatures. Three different leaning algorithms were compared and validated versus the actual data using statistical indexes to determine the most accurate model structures. Experiments were conducted on a 3-ton DX split-system heat pump fully implemented. The heat pump ran over the course of several months to obtain a wide range of measurements. The results showed that artificial neural network can provide very accurate predictions and this ANN model technique can effectively be used for many energy-efficiency heat pump applications.

1. Introduction

As energy concerns continue to grow, the need for developing more efficient building energy systems has increased. The global contribution from buildings toward energy consumption, both residential and commercial, has steadily increased over the years, with estimates between 20% and 40% in developed countries [1]. Unitary air conditioning and air-source heat pump systems are one of the most common energy systems for both commercial and residential HVAC applications in USA. Those systems can provide the desired thermal comfort for various building types and sizes. Significant advancements have been made in the design of air conditioning and heat pump systems, including advanced cycle components with support for new refrigerants, improved cycle designs, and expanding their range of applications. One study found the potential to reduce energy consumption by up to 80% through the development of better compressor technology [2]. Many of these systems in use today are designed improperly, and with newer systems becoming increasingly complex; more effective modeling methods are required [3].

Modeling of DX air conditioning system that can be integrated into many energy solution tools is necessary to reduce energy operation cost of those systems [4].

This paper proposes the use of data-based model using artificial neural networks to accurately predict the performance of heat pump systems. The artificial neural network capabilities were extended from linear to nonlinear domains in 1974, for developing a method as general as linear regression with nonlinear capability [5]. Artificial neural network modeling has become increasingly popular for a variety of disciplines, including signal processing and character recognition, stock market prediction, logistics, among others. The main advantages of ANN modeling compared to other methods such as expert systems are its simplicity, speed, and ability to handle a multivariable problem to solve complex relationships between variables. Over the last two decades, the use of ANN systems in HVAC system field has been steadily increasing to solve these complicated problems [6-8]. Bachtler and

*Corresponding Author: Nabil Nassif, Civil and Architectural Engineering, North Carolina A&T State University, Greensboro, USA. Email: nnassif@ncat.edu

others used a generalized radial basis function neural network for predicting the steady-state performance of a vapor-compression liquid heat pump [8]. Nassif predicted and optimized various HVAC systems using artificial neural networks and genetic algorithm [4,9].

The proposed modelling technique was tested by performing experiments on a 3-ton DX split-system heat pump. The experiment was prepared utilizing a specially integrated unit in a controlled setting. The heat pump ran under various outside conditions and in heating and cooling modes under. Various ANN model structures and training algorithms were tested and evaluated.

2. Artificial Neural Network

Artificial Neural Networks (ANNs) are non-linear mapping structures that are based on the principle functions of the human brain. They are extremely powerful tools for modeling, especially when the mathematical relationship of a given data is unknown, or not easily discerned. Over the years, they have become the focus of attention, largely due to their wide range of applicability and the ease in which they can work with complicated problems. ANNs are capable of identifying and learning correlated patterns between the input data sets and corresponding target values. After training, ANNs can be used to predict the outcome of new independent input data. They have been used for a large number of applications where statistical methods are traditionally used. Neural Network models are now being employed to solve problems, where in the past was normally solved through logistic regression, multiple regressions, Bayes Analysis and other classical methods. They consist of simple computational units called perceptrons, which are also known as neurons, which are highly interconnected.

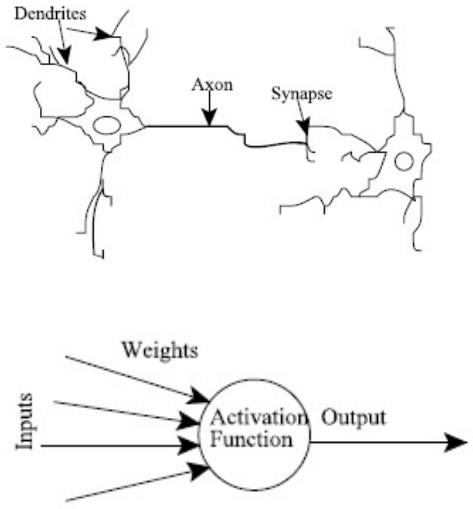

Fig. 1. An artist conception of a natural neuron (top) and an artificial neuron (bottom)

While in actual neurons the dendrite receives electrical signals from the axons of other neurons, with artificial neurons these electrical signals are represented as numerical values. At the synapses between the dendrite and axons, electrical signals are modulated by various quantities. This is also modeled in artificial neurons by multiplying each input by a value called the weight. The higher a weight of an artificial neuron is, the stronger the input which is multiplied by it will be. The calculated weighted sum of the inputs represents the total strength of the input signals. This is then applied to a step function (also known as a Sigmoidal Function) to the sum to determine its output. The weights in most neural networks can be either positive or negative, which have activation or inhibitory influence to each input. Fig. 1 shows an artist conception of a natural neuron (top) and an artificial neuron (bottom). Artificial neural networks need appropriate learning algorithms to be trained. Three learning algorithms were tested: (1) Levenberg Marquardt, (2) Bayesian Regulation, and (3) Conjugate Gradient algorithm. The MATLAB ANN toolbox was used in this study.

3. Experimental Setup

The experimental tests were conducted on a typical heat pump fully instrumented and installed in the HVAC laboratory located at North Carolina A&T State University. This laboratory is equipped with a fully integrated 3-ton DX split-system air conditioning AC as shown in Fig. 2 and controlled by Building Automation and Control network (BACnet) building automation system (BAS). The BAS collects measurement data of nearly all components, including the required measurements such as the outdoor air conditions, temperature and humidity ratio entering and leaving the DX coil, airflow rates, damper positions, and compressor power. Airflow can be changed by varying the position of the return and outside dampers. The airflow through the variable air volume (VAV) box is controlled by two DDC PID cascade control loops; the first control loop determines the set point of airflow rate, and the second controls the VAV damper position. The data collected from BAS can be accessed online, or from a device connected directly to the server's network. The heat pump ran at various intervals covering a wide range of operation conditions. The data collected were the airflow rate, outside, supply, and mixed dry-bulb temperatures, humidity ratio, and compressor power. The ANN developed uses the airflow rate, outside mixed air temperatures and humidity ratio as model inputs. The ANN model outputs were the supply air temperature and compressor power, which were consequently designated as the target variables. In the heating mode, the same input variables applied, except the humidity ratio, as it was not a factor in effecting compressor power or supply air temperature. The artificial neural networks ran multiple times using three different training algorithms, and by varying the number of neurons. These results were then compared against the actual data to determine the most accurate neural networks and model parameters.

The heat pump was first tested to check if its components are all working appropriately. It was found that the mixed air temperature sensor gave readings higher than expected one on the system monitor. This is a common mixed air temperature reading problem in many DX systems. A study conducted by Avery [10] found that mixed air temperature sensors are often unreliable, due to air stratification and the accompanying design documents which rarely detail proper sensor installation. To resolve this problem, the mixed air temperature T_m and humidity ratio W_m are calculated by applying energy conservation equation as function of outdoor air humidity W_0 and temperature T_0 and return air temperature T_r and humidity ratio W_r:

$$W_m = \frac{m_o}{m_a} \cdot W_o + \frac{m_a - m_o}{m_a} \cdot W_r \quad (1)$$

$$T_m \approx \frac{m_o}{m_a} \cdot T_o + \frac{m_a - m_o}{m_a} \cdot T_r \qquad (2)$$

Where the m_a is mass flow rate of the supply air and m_o is mass flow rate of outdoor air. The equations 1 and 2 are applied only when the difference between the return air temperature T_r and outdoor air temperature T_o is relatively large (higher than 5 ºF).

Fig 2. Split System Heat Pump for experimental Studies

To test neural network model, a wide range of operating performance data is needed. Therefore, the system was run at different outside conditions and various times of the year to have more extreme outdoor conditions. At different conditions, the heat pump ran for a few hours, this repeats throughout the months of April through September. The building automation system was set to record the measurements every five-minute interval, and more than 891 performance data points were collected. Approximately 618 data points are used to train the ANN. Roughly 70% of each dataset were designated specifically for training, and the remaining 30% used solely for testing. While there are several different model parameters within an artificial neural network which affects its performance, the most significant factors are number of hidden layer neurons and how the training is performed (training algorithm). In this paper, the neural networks as shown in Fig 3 were configured to run under every permutation between the three different training algorithms and different number of neurons, ranging from 5 to 45. Furthermore, these networks were tested using multiple and single variable outputs.

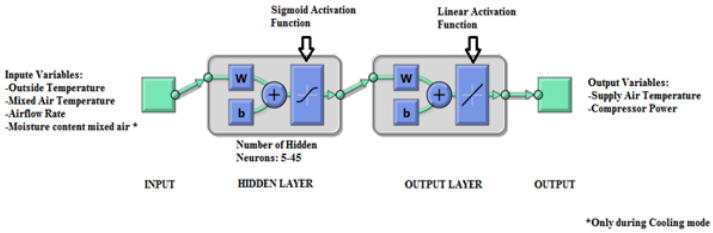

Fig. 3. ANN Model with inputs and outputs

4. Results

As mentioned before, the 891 performance data points were collected and divided into two sets: (1) training data set (618 data points) and (2) testing data points (273). Three learning algorithms Levenberg Marquardt, Bayesian Regulation, and Conjugate Gradient were used to train the neural network model to predict the DX heat pump power. After completing the ANN training, the model was then tested and evaluated. The evaluations were done by comparing the resulted coefficient of variance (COV) for each model options. The COV is calculated by divided the square mean square error to the mean data. The training and testing are done for various number of neurons to find the best or optimal model. The optimal model is determined based on the lowest COV obtained from the testing data set. Fig.4-6 show the COV results for the training and testing data sets and with various training algorithms.

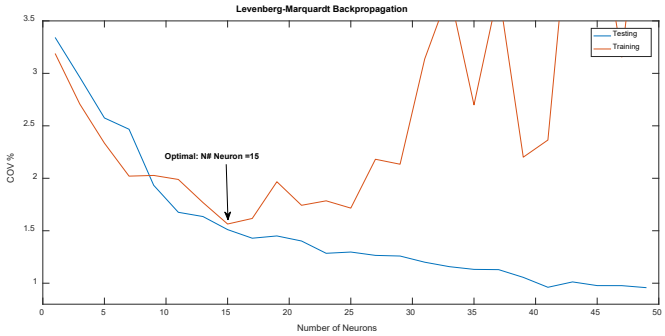

Fig 4. COV results as a function of number of neurons for Levenberg-Marquardt training algorithm

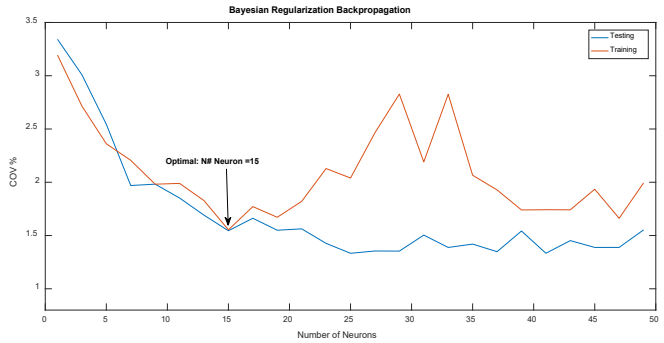

Fig 5. COV results as a function of number of neurons for Bayesian Regularization training algorithm

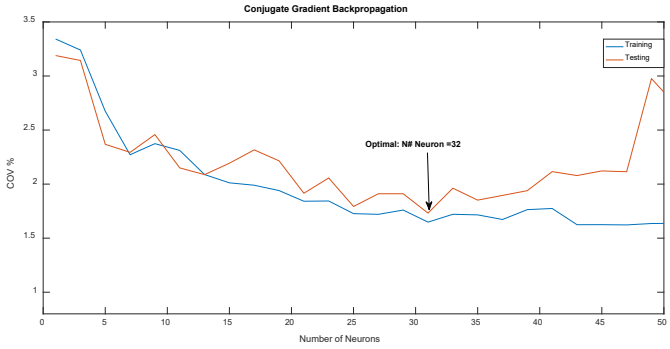

Fig 6. COV results as a function of number of neurons for Conjugate Gradient training algorithm

By increasing the number of neurons, the COV is decreased for training data set. However, for the testing data set, the COV is decreased and then increased. There is an optimal value of number of neurons with the lowest resulted COV that makes the model predict accurately the power for training data set. The optimal number of neurons are 15, 15, and 32, and the lowest COVs are 1.54%, 1.56%, 1.73% for training algorithms Levenberg-Marquardt, Bayesian Regularization, and Conjugate Gradient. Fig. 7 shows the comparison between the simulated and measured heat pump power. The simulation is done by the ANN model with the optimal number of neurons (#15) and training algorithm Levenberg-Marquardt. These results show that the ANN model

can predict accurately heat pump power with COV of 1.54%. The ANN model technique can be used for diffident energy efficiency applications.

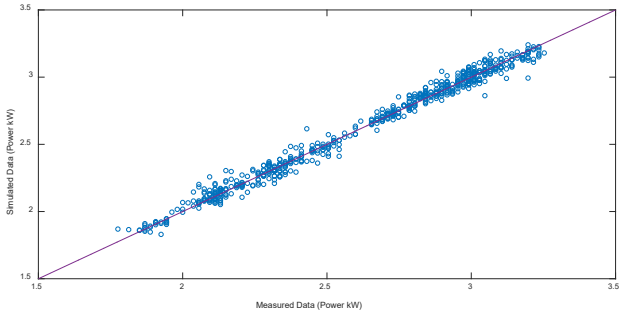

Fig 7. Comparisons between the measured data and simulated data calculated by ANN

5. Conclusion

Various artificial neural network model structure and leaning algorithms were developed and tested. The model predicts the compressor power as a function of airflow rate, humidity ratio, ambient and mixed air temperatures. Experiments were conducted on a 3-ton DX split-system heat pump to collect a wide range of performance measurements. The measurements were divided into training and testing sets. The models were evaluated by comparing the resulted coefficient of variance COV for each model structure and learning algorithm options. The optimal number of neurons are 15, 15, and 32, and the lowest COVs are 1.54%, 1.56%, 1.73% for training algorithms Levenberg-Marquardt, Bayesian Regularization, and Conjugate Gradient. The validation results showed that artificial neural network can provide very accurate predictions and this ANN model technique can effectively be used for many energy-efficiency heat pump applications

ABSTRACT

The present work describes the first serious game designed to reduce the stigma among students towards mental health problems. The game is called Stigma-Stop, and it features characters who suffer from various mental disorders. Players are provided with information about different mental illnesses, and they are presented with several options on how to act when they encounter characters with these problems. In addition, the game questions the participants as to whether they have ever felt like the individuals portrayed in the game, with the goal of fostering empathy for those that suffer from these types of disorders. Stigma-Stop was applied to a sample of second-year university Psychology students to evaluate the game's usefulness and appeal. The results demonstrate the importance of this game and that these students consider it to be highly useful. The most notable characteristics are described in depth in the present paper.

1. Introduction

The present work is an extension of the study presented at the 8th International Conference on Games and Virtual Worlds for Serious Applications (VS-GAMES) called "Stigma-Stop a Serious Game against the Stigma in Mental Disorders" [1]which focused on developing the first serious game designed for the purpose of reducing the stigma towards mental illnesses.

The game features characters with various mental disorders (schizophrenia, agoraphobia, depression, and bipolar disorder). The objective is for the player to convince all the characters to work towards a common goal, which is to form a group to participate in a contest. Over the course of the game, the player is given different options on how to behave when interacting with the characters; the game also provides them with information on which is the most appropriate choice. It gives further details about each of the mental disorders and asks the players questions which seek to foster empathy towards those who suffer from these problems. The video game also features four mini-games, whose ultimate goal is to provide knowledge and dispel traditional myths about mental health [2-5].

In a previous study, the game was successfully used with a sample of 168 secondary school students. In this case, stigma towards mental health disorders was significantly reduced among the students who played the video game, compared to the control group which played other video games and did not display any changes [6].

In this way, Stigma-Stop seeks to familiarize young people with mental disorders, particularly at this age because most of these problems manifest themselves during adolescence. The game intends to increase their knowledge on this subject and strengthen their awareness, while emphasizing the importance of biographical and/or contextual experiences related to these illnesses and that anyone can experience similar problems over the course of their life. The game teaches how to interact with those who suffer from these disorders, fostering interest in helping these individuals. This aspect is of vital importance considering young people are

*Corresponding Author: A.J. Cangas, Departament of Psychology, University of Almeria. Crta Sacramento, s/n CP04120, La Cañada de San Urbano, Almería, Spain. E-mail: ajcangas@ual.es

acquiring and consolidating values they will act on as future citizens.

The present study intends to analyze Psychology students' opinion of Stigma-Stop. Their point of view is quite relevant considering, firstly, they will be future working professionals in the field of mental health, and, secondly, they are at an age (the sample was of second-year Psychology students) when they are very familiar with the use of video games.

The game is optimized to be used in schools and can be applied on an individual basis or in groups. This flexibility makes it possible to initiate discussions in class about these topics, where they can be addressed "naturally" and any misconceptions can be identified and clarified.

2. Method

2.1. Sample

The sample consisted of 26 students in the second year of their Psychology degree at the University of Almería (Spain). Participants were between the ages of 18 and 28 (X=20.12; S.D.=2.85). In this group, 76.92% were female, and the remaining 23.08% were male.

2.2. Tools

Stigma-Stop. This is a serious game designed in a non-immersive virtual reality environment. Stigma-Stop was developed with Unity3D software for three platforms (PC, website and Smartphone application) and it is aimed primarily at young people between the ages of 14 and 21. The player can choose the sex of the avatar they are going to play with. During the game, different characters appear who suffer from various mental disorders (depression, schizophrenia, bipolar disorder and agoraphobia). Figure 1 shows some of the scenes from the program.

Figure 1. Scenes from "Stigma-Stop".

The objective of the player is to interact with each one of the characters and convince them to contribute their knowledge to a project and work towards a common goal: design a video game for a contest. The player does not follow a predefined plot in the game. The player's freedom to choose the character who they visit at any given point in the game was incorporated using a machine of finite states. This machine contains each one of the situations that the user could experience and keeps track of the situations that the user has already completed so each character is visited only once. The user interacts with the characters through dialogs which reveal some of the symptoms of the various disorders. Once the objective of the dialog has finished, the player is presented with three options for solving different dilemmas that arise, only one of which is correct. If one of the less appropriate choices is selected, information is provided explaining why a different option should be chosen and the player is given another opportunity to select a new one. Similarly, a short form will appear with questions about general knowledge concerning each disorder and the user is able access additional information about the current condition of the characters and what circumstances led them to develop these types of problems. Finally, after meeting each character, the player is asked if they think the character is emotionally well, if they themselves have ever felt the same, and if they think they would be able help that person (specifying how). User answers are stored in a database located in an external server. Communication between said database and the serious game is carried out using RESTful Web Services equipped with PHP at the server end. The information transmitted by these Web Services will be in JSON format. When the user chooses the correct option, they will be redirected to the "mini-game" state, where they can play with one of four mini-games included in the program. Each one focuses on a mental illness and provides the user with more relevant information, apart from that already shown throughout the game. The four mini-games are (figure 2):

• Memory: In this mini-game players must match faces of famous people who suffered from different mental disorders to make pairs. These famous individuals include Leonardo da Vinci, Edgar Allan Poe, Vincent van Gogh, John Forbes Nash, Charles Darwin and Robert Schuman. The objective is to complete the game in as few turns as possible. In this way, players will learn that various famous individuals throughout history suffered from some type of disorder. Once they have matched the two cards of the same character, information is displayed about that person (name, profession, mental illness, etc.).

• Trivial: In this mini-game the user will have to answer questions related to mental disorders, specifically whether depression is something that only happens to "weak" people; If we are ever depressed, it means that we will be depressed forever; Whether a depressed person can be helped; If people with mental disorders, especially those diagnosed with schizophrenia, are more dangerous, aggressive and unpredictable than those who do not have a mental disorder; and whether people with mental disorders can work. The questions have been designed in the form of affirmation so that the user answers 'True' or 'False'. In case the person is wrong the program tells then why it is incorrect and they will have to respond again.

• Running with Dali: In this mini-game the user must move through a scene in as little time as possible, while avoiding obstacles and collecting pieces of paintings. If the player hits an obstacle, their time will increase by a specific increment, which depends on the obstacle itself. When they collect one piece of a

painting, the time on the clock will decrease. Once the game finishes, the pieces of the painting collected will be displayed along with a brief biography of the painter Salvador Dali, who also suffered from a mental illness.

• Stigma Shooter: This mini-game contains concepts related to mental illness. The job of the player is to "trap" positive concepts (such as overcoming, improving, independence, acceptance, able to work) and "destroy" negative concepts (unpredictable, dangerous, vague or aggressive) by shooting them.

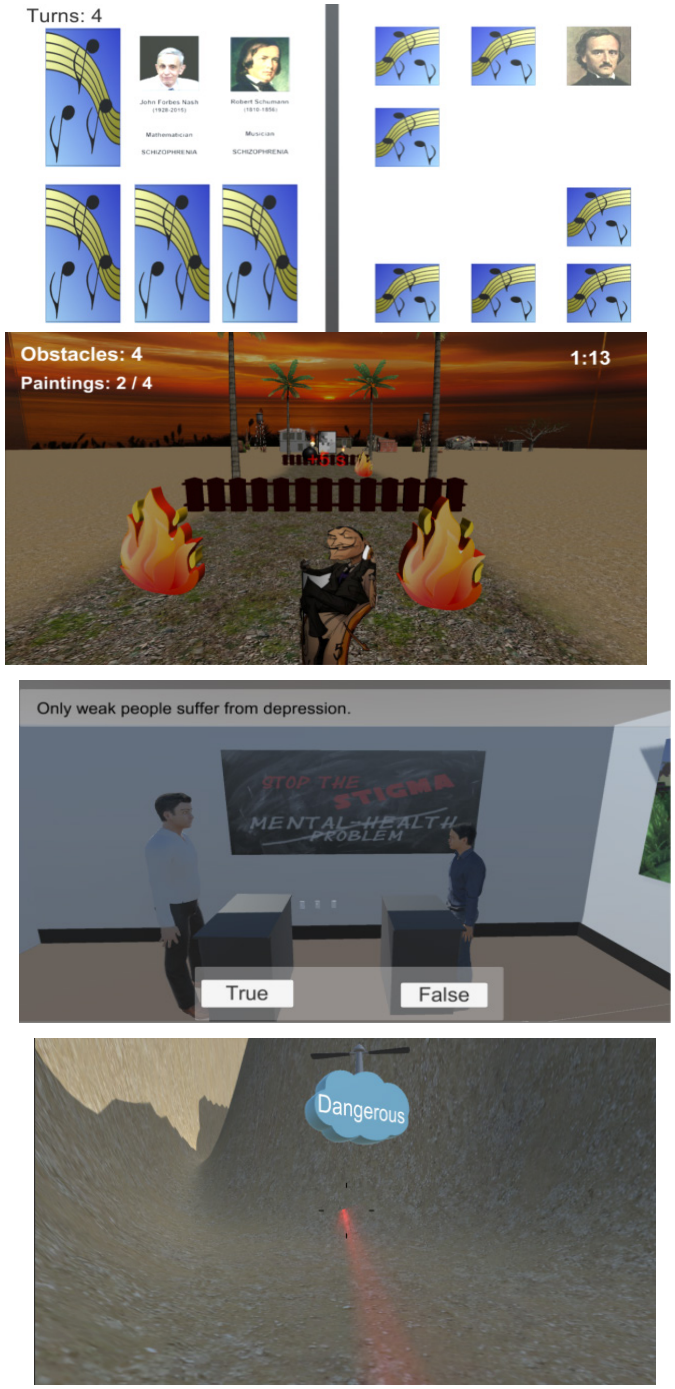

Figure 2. Four mini-games

At the end of each mini-game, the player's results are displayed, and users can see details about their performance. These results will also be stored in the database previously mentioned with the objective of ranking participants and motivating players.

In this serious game artificial intelligence resources have been included to make the game seem more realistic. Routes have been created to simulate the movement of pedestrians and cars through the city, thus giving the sensation of activity. These paths are formed by a set of waypoints [7], which contain the position of the three-dimensional space and are assigned to the position of the 3D model. In addition, each route has a certain speed associated with the movement of the 3D model to ensure that the behavior of pedestrians and cars do not have the same pattern, which would give a feeling that their behavior is predictable and artificial.

The cars, apart from using the waypoints, have an algorithm implemented so that when they detect the presence of a character on the road they do not pass over it and stop until the character is at a safe distance, at which time the vehicle continues its path. The scenes of the city where the user interacts with their character are designed so that the avatar can only cross at the pedestrian crossings and when it is detected that the user wants to pass the road, an invisible wall is created to prevent passage and force them to cross at the crosswalk.

Decision trees [8] is another strategy that has been used in this video game regarding the animation of the characters. As mentioned before the protagonist has to visit his friends to achieve the goal. In each of the visits to his friends, the protagonist will engage in a conversation with his friend. These dialogues are composed of a series of animations that give the 3D models movement. Decision trees determine the animation of the different characters; depending on who the protagonist is talking to, certain actions or others will be shown. The options that the user chooses in response to the situation that arises will be another factor that influences the animations chosen during the dialogue.

Stigma-Stop assessment questionnaire. It evaluates on a scale of 0-10 the degree of attractiveness of the video game and also the interest it arouse. They should also describe what they have learned from the program and whether or not they would recommend its use to a friend. Likewise, for each of the characters that appear in the video game, participants are asked to indicate whether they believe they are psychologically well, if they think they could help the character and if they have ever felt like them.

3. Procedure

The experimental application of the video game took place at the University of Almería in quiet room equipped with tables, chairs and a desktop computer connected to a projector. The activity was conducted in group format in which four participants interacted directly with the video game. Each member of the group visited one character while the others observed on the projector screen. After finishing the program all students completed the Stigma-Stop assessment questionnaire.

4. Results

In terms of the quantitative data, on a scale of 1-10, the participants gave the program an average score of 8.08 (SD=1.35) for its usefulness and 6.58 (SD=1.21) for its entertainment value. In addition, the 26 participants (100%) indicated that they would recommend the game to a friend. As for the question: What do you think you have learned from Stigma Stop? responses were

classified as follows (bearing in mind that some responses may be included in more than only category):

1. Answers that emphasized the educational value of the video game in terms of the information it provides regarding the symptoms of the various disorders in the game, making them easier to recognize. (e.g. answers: "more easily diagnose a mental illness since the symptoms are clearly shown"; "try to diagnose the characters and help them").

2. Answers that specifically highlighted the acquisition of intervention strategies for dealing with the disorders, promoting prosocial and helpful behavior. (e.g. answers: "teaches ways in which you can help people with these disorders"; "how to treat these individuals and how to behave"; "how we should help to improve the situation of the person").

3. Answers that mainly emphasize the usefulness of the game in raising awareness against stigma, dispelling myths, and normalizing the disorders by considering them responses to specific adverse biographical and/or contextual circumstances. (e.g. answers: "end specific stigmas associated with the label of mental disorder"; "the experiences of people are very important for understanding their unusual behavior").

The students' answers were distributed quite evenly among the three categories. 56% of the responses were classified under the second option (teaching intervention strategies) and 52% were categorized under the first and third options (usefulness in providing information on symptoms and capacity to raise awareness against social stigma, respectively).

Table 1. Participant responses regarding characters in percentages

	Panic disorder with agoraphobia (%)		Schizophrenia (%)		Bipolar Disorder (%)		Depression (%)	
	YES	NO	YES	NO	YES	NO	YES	NO
Do you think the character is emotionally well?	4	96	4	96	27	73	0	100
Do you think you could help this person?	100	0	88	12	79	21	92	8
Have you ever felt like this person?	11	89	0	100	31	69	42	58

With respect to the questions where participants indicated whether they thought the character was emotionally well, nearly 100% responded 'no' in every case except for bipolar disorder, which registered at 73 %. These percentages remained similar regarding whether they thought they could help the characters after discovering their problems; virtually all responded 'yes' except in the case of bipolar disorder (79 %). With respect to question as to whether participants had themselves ever felt like one of the characters, 42 % responded 'yes' in the case of depression, less for bipolar disorder (31 %) and considerably less for panic disorder with agoraphobia (11 %). None of the participants identified themselves as having ever experienced schizophrenia (Table 1).

5. Discussion

Serious Games have shown to be highly beneficial in various fields of education [9], problem solving [10], psychological interventions [11] and even job-oriented development of university students [12]. Nevertheless, "Stigma Stop" is the first Serious Game to date that focuses on providing information about mental illnesses and raising awareness among young people about this topic, thereby promoting sensitivity and empathy towards people who suffer from mental health problems.

In the case of the Psychology students in this study, their assessment of the game was highly favorable. This is very significant considering we are dealing with future healthcare professionals, most of whom will work with individuals suffering from mental health disorders. Their evaluations were especially positive in terms of the game's usefulness, yet they were somewhat lower with regard to its entertainment value. In addition, the students highlighted three main benefits of the serious game, namely the fact that it provides intervention strategies, information on symptoms, and raises awareness against social stigma. In regard to this last aspect, although it may have received a lower score than expected, we must bear in mind that many healthcare professionals also display high stigma towards mental disorders and do not recognize them as problems [13-15]. The students similarly scored the other characteristics which they were learning about in their course studies, such as the identification of disorders and intervention and also raising awareness about stigma.

In terms of other issues, most of the students recognized that the characters in the serious game had some psychological problem. However, the percentage for bipolar disorder was much lower (73 %) than for the remaining three (panic disorder with agoraphobia, schizophrenia and depression), which were above 90%. We believe that this aspect is important and reflects the video game's accurate portrayal of the different psychological disorders. Furthermore, it is noteworthy that the psychology students stated they had felt, at some time, similar to the characters with depression and bipolar disorder (42 % and 31 %), something which did not occur in the case of panic disorder with agoraphobia (11 %) or schizophrenia (0%). Finally, as expected, the majority felt capable of helping the people with different disorders.

Ultimately, "Stigma Stop" fulfills three functions: inform on disorder symptoms, provide intervention strategies, and dispel misconceptions and myths; thereby normalizing disorders. Thus, it educates young people about psychological disorders, while always emphasizing the importance of biographical and/or contextual experiences related to these problems. Moreover, it teaches users that we are all susceptible, given specific situations, to experiencing similar problems during our lives. Finally, the game provides players with basic intervention strategies that make them more prone to help individuals with such disorders.

6. Conclusion

Finally, the interest shown by the Psychology students who participated in this study and their favorable assessment of the game's usefulness constitute strong testaments to its effectiveness. It is also especially noteworthy that they unanimously stated that they would recommend using the program to others. As regards the limitations of the present study, we can cite its small sample size, Being necessary to replicate it with a broader sample, as well as to carry out a controlled experimental study, not only descriptive like in this case. Also, the present study did not evaluate the mental

state of students (whether or not they have a mental disorder), an aspect that could also influence the results.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper is an extension of work originally presented and published in IEEE International Multidisciplinary Conference on Engineering Technology (IMCET). This work presents a design and implementation of a moving human tracking system with obstacle avoidance. The system scans the environment by using Kinect, a 3D sensor, and tracks the center of mass of a specific user by using Processing, an open source computer programming language. An Arduino microcontroller is used to drive motors enabling it to move towards the tracked user and avoid obstacles hampering the trajectory. The implemented system is tested under different lighting conditions and the performance is analyzed using several generated depth images.

1. Introduction

For the past years, the development of robot technology has significantly increased due to industrial and military applications. Human tracking robot is one of the applications that could be implemented under robot technology.

Because of its human following capability, human tracking robot can work as solutions for many problems or as assistants for humans in various situations. One of them would be to fight wars in place of humans as tracking and following the enemy to unknown places in order to reduce human casualties. It can also be used to help people with physicals problems to carry their objects [1] , [2].

To achieve this, it is required to use a sensor that measures variables within an environment where these variables can be processed and analyzed to detect a person.

There are several ways to implement computer vision. The first one is to use the 2D scanning like RGB cameras or stereo cameras that have 2 lenses to simulate human binocular Vision [3].

*Corresponding Author: Abdel Mehsen Ahmad, Department of Computer and Communication Engineering, Lebanese International University, Lebanon
Email: abdelmehsen.ahmad@liu.edu.lb

The second way is the 3D scanning like the time of flight that uses both the distance and time to calculate the point in 3D and the structured light that uses a pattern of projected light to calculate the depth image [4].

For example J. Hoang and J. Zhou designed an algorithm based on a color light sensor to model a person after a color histogram for person segmentation [5].

Another example was when a group of researchers created a person following robot using a light sensor capable to detect a person based on the color within a certain region of their clothing [3].

Some researchers have utilized an omnidirectional camera in conjunction with a laser based distance sensor to track a person. Those sensors are capable to detect light outside the visible spectrum [6].

This paper has involved the integration of Kinect sensor that beats any other camera by its ability to capture a direct depth image with high accuracy rate. This small, portable device provided developers with the foundation needed to create and deploy interactive applications that respond to people's natural movement, gestures and voice commands [7].

One of the most amazing capabilities of the Kinect used is the skeleton tracking. This concept is used in this paper to map depth image to make a robot able to track human movements [8].

Another important part of this paper is the obstacle avoidance. The robot may face obstacles while tracking human, these obstacles must be observed and detected by the Kinect so that it would be able to move to the right direction without collide with them.

Robots have proven to be more useful for a wide range of industrial and commercial applications, principally in indoor environments since the outdoor environment brings more challenges and complications. In an indoor environment, the small size of rooms restricts the visual perception where tables, chairs and even walls are encountered as occlusions but it still more beneficial and robustness compared to the outdoor environment where the occlusions there: plants, bushes, etc. are more shaped complexly. In addition, when operating in an outdoor environment, lighting intensity is more dynamic, reducing the robustness of visual perception. So the third part of the paper is to study the flexibility of the Kinect while operating under various lighting conditions [9].

This paper is an extension of work originally presented and published in IMCET conference [1]. In this extended work, we first present the proposed system design, and then we show the evaluation of the Kinect performance in different lighting conditions.

2. Proposed System

2.1. System Design

The project deals with making a robot that will move towards a specific user and avoid obstacles encountered in its path.

The proposed system as shown in Figure 1consists of three main parts: Kinect sensor, Arduino and Processing.

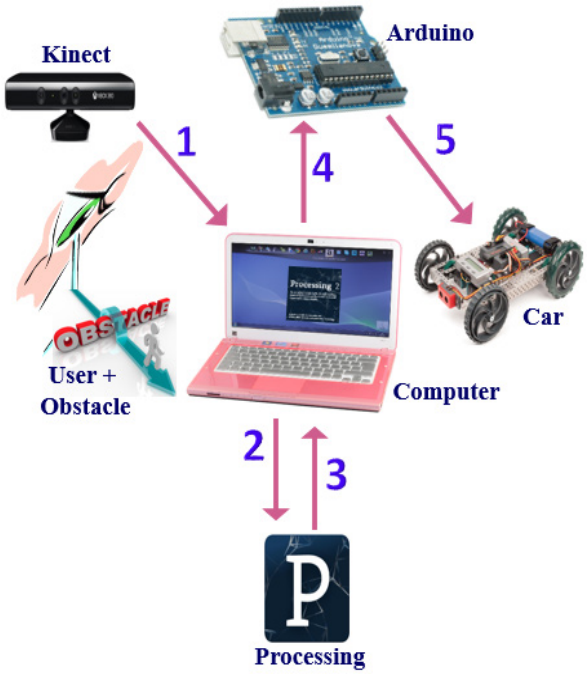

Figure 1: System Design

The Kinect is a motion sensing input device by Microsoft that consists of object detection, object tracking and reorganization. It enables users to control and interact with the applications using full skeleton tracking, gesture recognition and facial recognition and it can also be used to detect and distinguish between different kinds of objects. It has three eyes; 2 cameras and an infrared projector. The IR projector shines a grid of infrared dots and based on the triangulation between the observed and the reference patterns, the depth will be calculated [10].

Thus, the Kinect is used as an effective tool for discovering the surrounding area, calculating the depth image, detecting and tracking a specific human and locate their individual joints and body parts as illustrated in Figure 2.

The Arduino, which is an open source physical platform or microcontroller board, can take input from a variety of sensors and control a variety of motors, lights and others physical outputs [11]. In this project and in order to achieve the full control over the robot, the Arduino will be connected to the car motors.

The processing is an open source programming language used to access the depth data coming from the Kinect, analyze it and display it on the screen [8].

The robot was decided to be a car since it can serve part of the system's demands in regards to the power, rotation and control. It consists of two motors; one is used for the motion and the other for controlling the motion direction of the car. Concerning the Kinect it is necessary to be located on the front of the car to avoid seeing the car parts as obstacle [1].

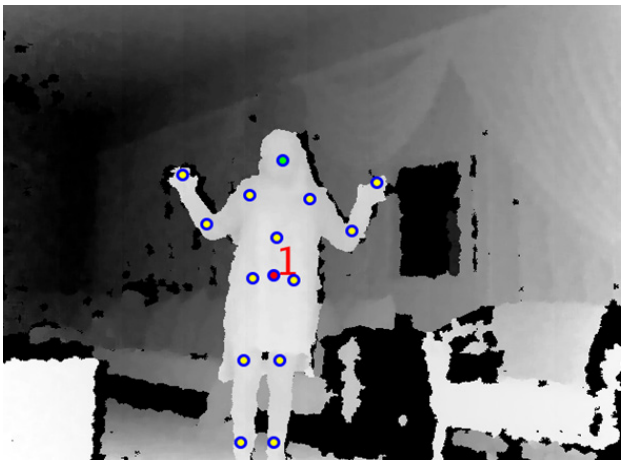

Figure 2: Skeleton Tracking

When turning the system on, the Kinect sensor, which is the main part in the system, starts capturing the depth image of the whole scene in front of it. The information captured by the Kinect must then be transferred to the computer where the processing is running. The processing will analyze the depth image and once it detects a user, it will determine his/ her center of mass which is the main point in tracking him/her and it has also to detect the obstacles between that user and the robot. Based on the analyzed data, the processing will send commands (like: left, right, forward, stop, etc…) to the Arduino serially via the computer, these commands will be already defined between processing and Arduino. Finally, the Arduino which will be connected to the car motors will receive the commands coming from computer, analyze them and order the robot to move in the right way.

Now, the robot can start tracking the user and avoid obstacles according to the information obtained from its "brain", the Arduino, and build on scenes coming from its "eyes", the Kinect [1].

2.2. Sequence Diagram

The sequence diagram in Figure 3shows the interactions between different parts of the system in sequential order.

1- Start with the Kinect that captures depth image at 30 Hz [8].
2- Pass by the processing that will analyze the depth image, detect the center of mass and send commands to the Arduino.
3- Move to the Arduino, serially via the computer, which will receive the commands coming from processing, analyze them and order the Robot to move in the correct direction.
4- End with a robot able to move towards a user and avoid obstacles detected in its path.

2.3. State Diagram

The robot will not move until a user is detected in front of the Kinect. Once this happens, the processing will track his/ her skeleton specifically according to his/her center of mass. If it failed to track the center of mass for a certain period of time, the processing will return back and wait for a new detection. Once the center of mass is determined, the robot should move towards the detected user and processing should maintain the distance between the robot and the user to check if any obstacle exists there. Now, the Robot should avoid obstacles detected and continue moving in the same way the user does. These steps are represented in the state diagram of Figure 4**.**

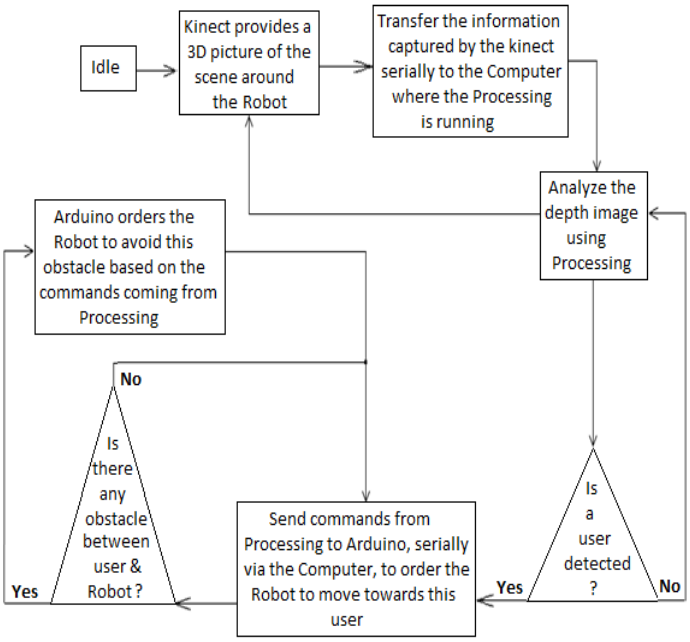

Figure 3: Sequence Diagram.

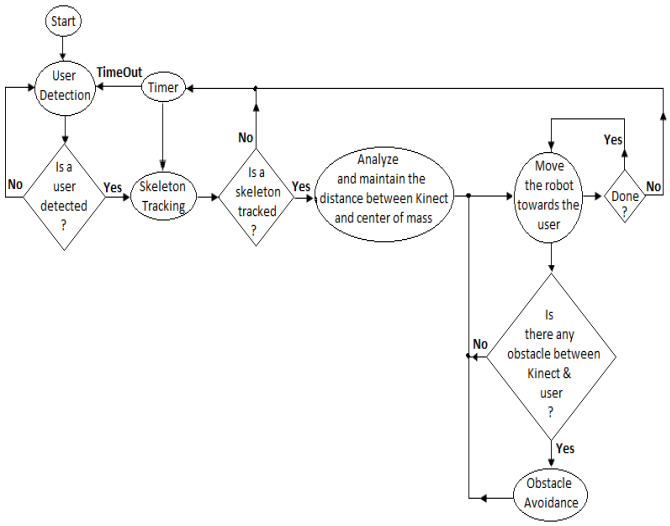

Figure 4: State Diagram.

3. Implementation

The project needs two kinds of software to be implemented, the first one which is the Processing is responsible for analyzing the surrounding information, detecting obstacles, recognizing the user and tracking him/her. The second software is the Arduino Software IDE which is responsible for controlling the robot movement based on commands coming from the Processing.

3.1. Processing

The processing code imports the necessary steps for performing user tracking and obstacle avoidance from the Simple Open NI library.

The first of these steps is to tell the Simple Open NI to turn on user tracking. That happens within the *setup ()* by using *enable User()* function and to access depth data the *enable Depth()* function is used.

The *Depth Map ()*function is used to get the depth array and to save the coordinates of the closest value, each row in the depth image must be checked. In addition, each pixel the row must be observed and the corresponding value must then be pulled out from the depth array.

In skeletal tracking, the body parts of human such as head, neck, hands, legs, shoulders and arms are represented by a number of joints. Each joint is represented by its 3D coordinates [2].Once a user has been detected and successfully calibrated, it uses the joint position data to have circles track the user's joints where the main joint to track him/her is the center of mass (CoM). The real coordinates saved, shall be then translated into projective coordinates to match the 2 dimensional depth images.

As illustrated in Figure 5, the image is divided into three parts in width: left, middle and right where x is the width coordinate. If the closest value saved within 1 meter and the x value of the center of mass are in the same part of the image, then this closest value is an obstacle detected between the user and the robot [1].

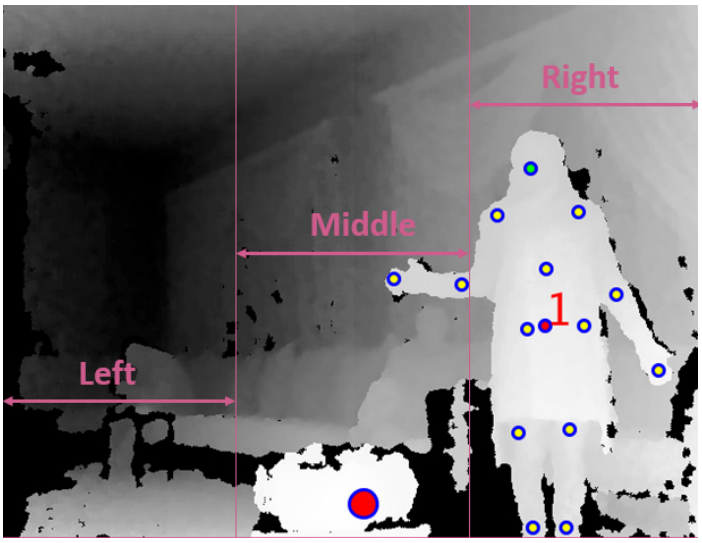

Figure 5: The three parts of the image

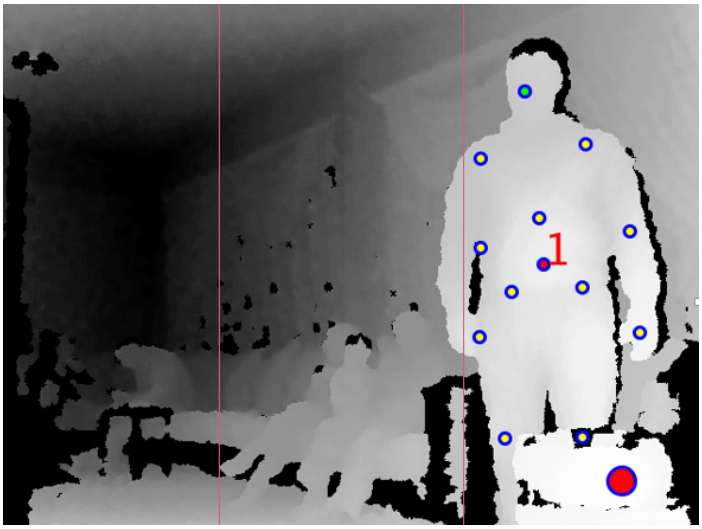

Figure 6: User and Obstacle in the same range (left side)

Depending on the Kinect data, there is an output send to the Arduino to be able to control the robot's movements. For instance, to move: left, forward, right and stop.

The whole process begins when the user enters the view of the Kinect. At this point the *Simple Open NI* detects that the user is present and is a candidate for tracking within the *On New User*() function.

Now, in the case in which the user is located at a distance less than or equal to 1 meter the robot should stop immediately. Otherwise, it checks if the closest value and the center of mass of the user are in the same range; if so, then there is an obstacle that hampering the trajectory of the robot while tracking the user detected as represented in Figure 6. While if no obstacle is detected the robot will continue in its way toward the user as Figure 7 illustrates. This process ends when the user is no longer in the Kinect range by calling the *On Lost User ()* function [8].

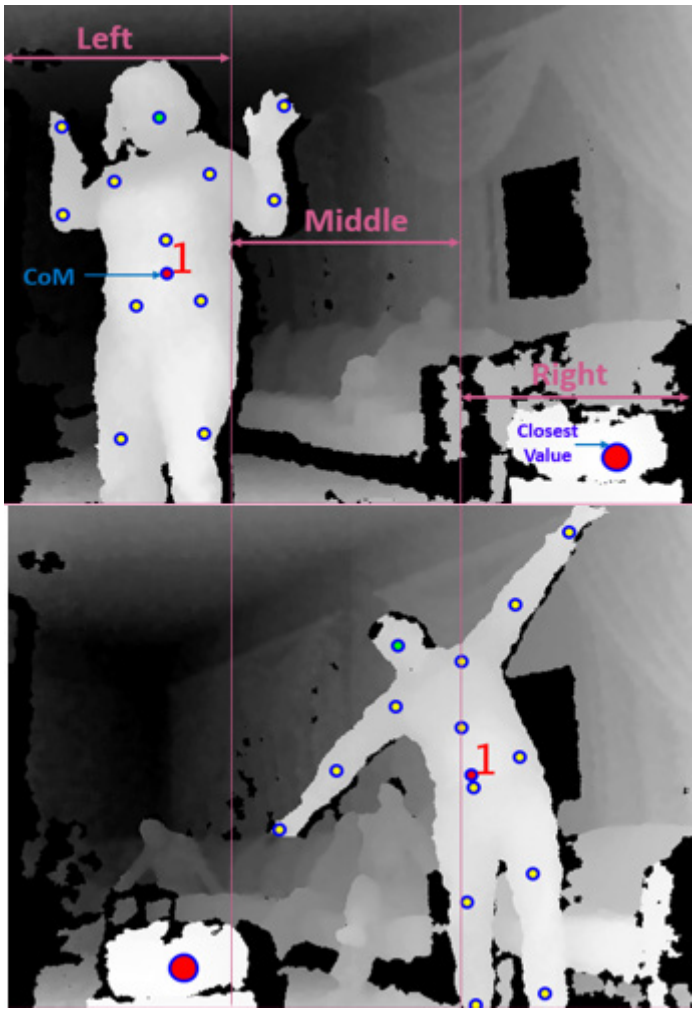

Figure 7: The user and the obstacle are in different range

The final task within processing was to send data from processing to Arduino serially via the computer, by importing the serial library, declaring a serial port and after matching the port on which the Arduino is connected a predefined value is sent on that port to enable the robot to move in the correct direction by using the *write* method. For example, in the case in which the user is in the left range and there is no obstacle in that range, the value '3' is written on the port.

3.2. Arduino Software

The brain of the robot will be an Arduino microcontroller. So, the Arduino Mega 2560 board will be used for its large memory and available ports that make the installation more flexible [12].

To order the robot to move in the correct direction based on the data captured by the Kinect, the processing will communicate with the Arduino serially via the computer. Serial is a simple protocol that allows Processing to send information to the Arduino and vice versa [8].

The basic thing to do is to program the input and output ports, and give the order to apply a specific function at the output once a specific input is received on a specific input port [1].

The Arduino will establish a serial connection to the computer by using the *serial.begin ()* function and then listen for data available on the serial port by using the *serial.available ()* function. This function will return true if any data is available to read and false otherwise. To read the available data the *serial.read ()* function is used [11].

If the received output from the processing is '3', the Arduino should give its command to the system to move left, and thus digital Write function is used to set the pins to the required values. All other directions are defined in the same; by setting the output pins as desired once receiving a specific input.

3.3. Lighting Conditions

The purpose of this part is to analyze the influence of different lighting conditions in the range of Kinect performance.

Six different scenarios, as shown in Table 1, were made under various light conditions producing a set of depth images from the Kinect. For example, scenario 3 is the case in which the Kinect was placed under sunlight while the user was under environmental light [13].

Scenario	Kinect	User	Light Intensity levels
1	Sunlight	Sunlight	High
2	Environmental light	Sunlight	High
3	Sunlight	Environmental light	High
4	Environmental light	Part of the user under sunlight	Medium
5	Environmental light	Environmental light	Medium
6	Artificial light	Artificial light	Low

Table 1: Lighting Conditions Scenarios

4. Simulation Results

The first stage within the processing code was to detect a user, draw his/ her skeleton, detect his/ her center of mass and give him/her a specific ID. This stage was successfully done where the result in Figure 8 shows the skeleton of three different users with their specific IDs.

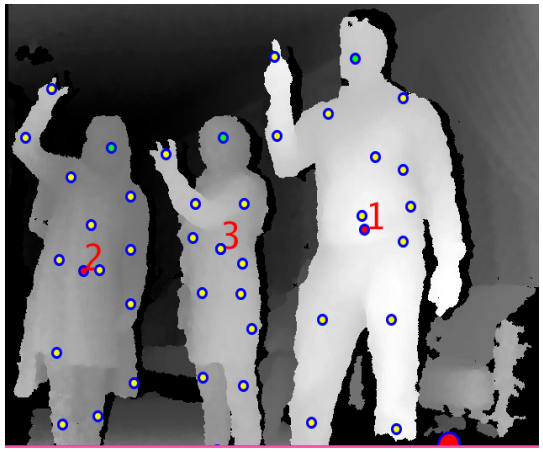

Figure 8: The skeletons of three different users

The next task was to keep track of the first user entering the Kinect range so that the output on the console indicates the movement and position of that user. Figure 9 and Figure 10illustrate the expected results.

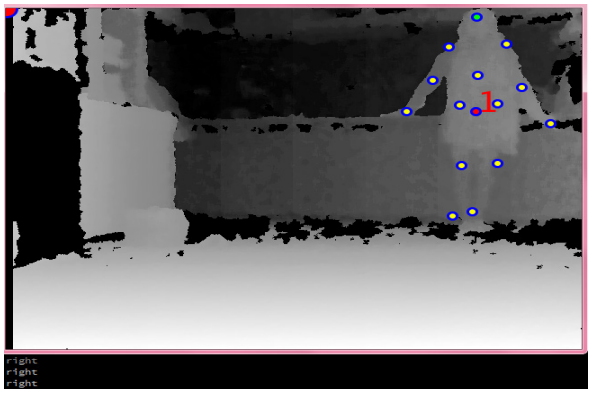

Figure 9: The output is "right"

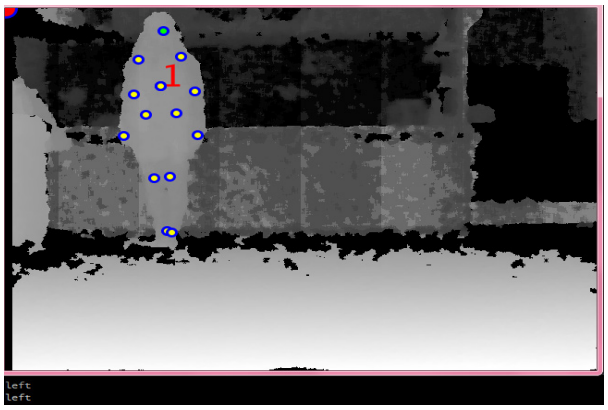

Figure 10: The output is "left".

As displayed in Figure 11, Figure 12 and Figure 13the obstacle detection and avoidance stage was successfully done so that the output on the console indicates where the robot should move to avoid any detected obstacle.

Figure 11: Incoming obstacle, go to the left.

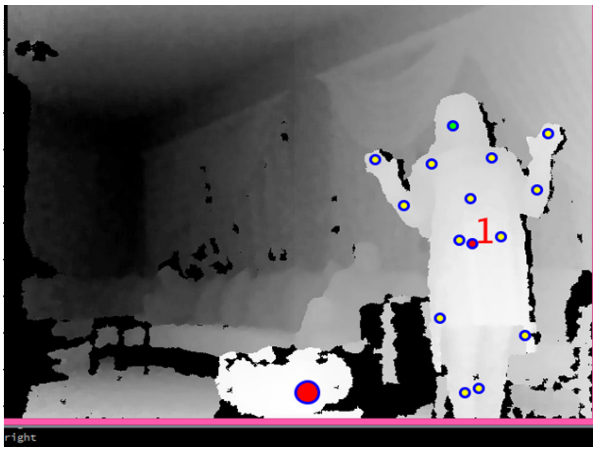

Figure 12: Go right towards the user.

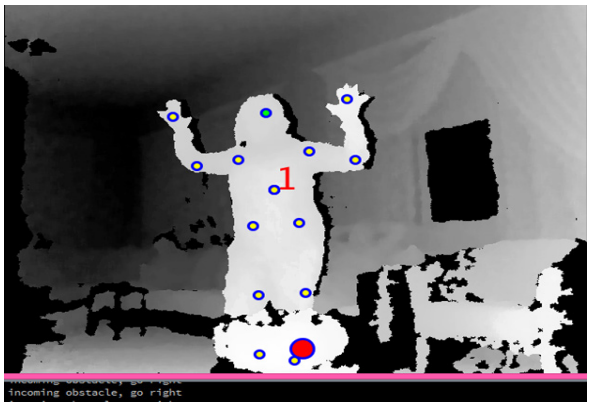

Figure 13: Incoming obstacle, go to the right.

Figure 14: Final prototype of 3D sensor-based Moving Human Tracking Robot with Obstacle Avoidance.

The Arduino was connected to the laptop and the Processing code was run where it started to print the results: Forward, right, stop…etc., according to the state of the user and the allocated obstacles in front of it. The Arduino output is then measured using a multimeter where the measurement ensures the successive work in connecting the Arduino to the Kinect serially.

Finally, all parts were assembled together to get the final system illustrated in Figure 14.

Figure 15 presents the expected results such that tracking the human movement and avoiding the obstacles coming in its way became feasible.

Figure 15: A User followed by the Robot.

5. Lighting Conditions Results

Concerning the lighting conditions, the results of the six scenarios studied, shown in Figure 16, were analyzed.

In scenario 1, in the presence of sunlight over both the Kinect and the user, and in scenario 2, where the Kinect was placed under environmental light and the user still under sunlight the Kinect was not able to obtain the depth information of the user.

Scenario 3 shows a higher intensity over the user with no skeleton joints detected since the Kinect was placed under the sunlight.

While in scenario 4, where only a part of the user was under sunlight, the Kinect was able to capture the depth information of the second part of the user.

For scenarios 5 and 6, where environmental and artificial lights were present, the Kinect performance is acceptable.

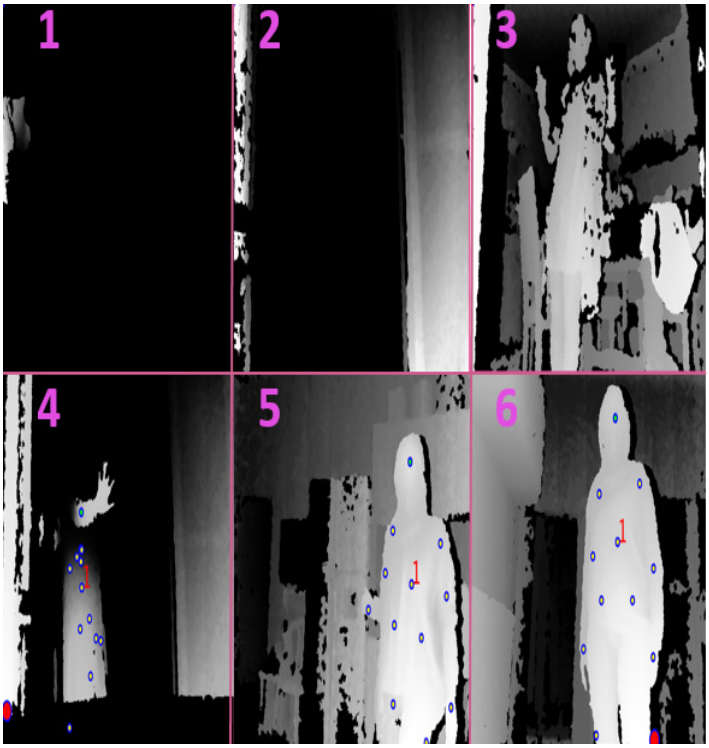

Figure 16: The depth images of the Kinect under various lighting conditions.

It was found that lighting conditions affect Kinect's performance and that the sunlight is the main enemy for the Kinect. So try to avoid having sunlight on the user and don't let the Kinect directly faced it.

6. Conclusion

The paper described the specifications of the Kinect sensor and how it can be integrated as the vision system of the robot. It also presented an experimental study of its performance under various light conditions.

The information of the Kinect were accurate enough to integrate a human tracking robot able to track a specific user in an indoor environment and avoid any obstacle detected in its path.

The project used the Kinect skeleton data to find the location of the user's center of mass. This value is then sent to the Arduino so that it can match the movement of the user with the robot's motor.

Our testing for this platform shows that the Kinect can be used as a powerful and useful device in many fields and that the combination between the Kinect and Arduino is as an advanced step in 3D Kinematics and interactive projects. Many system improvements will come in further works.

ABSTRACT

In the recent years, the fast development and the exponential utilization of social networks have prompted an expansion of social Computing. In social networks users are interconnected by edges or links, where Facebook, twitter, LinkedIn are most popular social networks websites. Due to the growing popularity of these sites they serve as a target for cyber criminality and attacks. It is mostly based on how users are using these sites like Twitter and others. Attackers can easily access and gather personal and sensitive user's information. Users are less aware and least concerned about the security setting. And they easily become victim of identity breach. To detect malicious users or fake profiles different techniques have been proposed like our approach which is based on the use of social honeypots to discover malicious profiles in it. Inspired by security researchers who used honeypots to observe and analyze malicious activity in the networks, this method uses social honeypots to trap malicious users. The two key elements of the approach are: (1) The deployment of social honeypots for harvesting information of malicious profiles. (2) Analysis of the characteristics of these malicious profiles and those of deployed honeypots for creating classifiers that allow to filter the existing profiles and monitor the new profiles.

1. Introduction

Social networks are now part of our daily life, we have certainly several accounts said "social", which are related to our daily lives (Facebook, Twitter), our professional life (Viadeo or LinkedIn), our sporting life or associative (we can cite jogg.in) and why not on sites of meeting (Adopteunmec, Meetic, Lovoo tinder or).

We can divide social networks on those which do not promote the anonymity (Facebook, Viadeo, LinkedIn) or the others which are promoting the anonymity (of general way all the sites of meeting, but also of services of Visio-conference as Skype), we have certainly received requests for connections from persons completely unknown. These applications are, in most of the cases, issued by malicious profiles.

That they emanate from the robots or that they are created to spoof the identity of a user, the malicious profiles are in constant increase on the Internet. On social networks, the malicious profiles can be generated by machines or be the result of identity theft and their motivations are various: Spy a PERSON, Increase the number of fans of a page (Facebook, Twitter…), spammer friends in impunity, fit all types of scams (very often of blackmail), harm the reputation of a person or a company, etc.

In particular, social spammers are increasingly targeting those systems as part of phishing attacks. To disseminate malware, and commercial spam messages, and to promote affiliate websites [1]. In only the past year, more than 80% of social networking users have "received unwanted friend requests, messages, or postings on their social or professional network account". Unlike traditional email based spam, social spam often contains contextual information that can increase the impact of the spam (e.g., by eliciting a user to click on a phishing link sent from a "friend") [1].

Successfully defending against these social spammers is important to improve the quality of experience for community members, to lessen the system load of dealing with unwanted and

*Corresponding Author: Elmendili Fatna, Computer Sciences Systems Engineering Laboratory, National School of Applied Sciences, Ibn Tofail University, Kenitra, Morocco, Email:f.elmendili@gmail.com.

sometimes dangerous content, and to positively impact the overall value of the social system going forward. However, few information is known about these social spammers, their level of sophistication, or their strategies and tactics. Filling this need is challenging, especially in social networks consisting of 100s of millions of user profiles (like Facebook, Myspace, Twitter, YouTube, etc.). Traditional techniques for discovering evidence of spam users often rely on costly human-in the-loop inspection of training data for building spam classifiers; since spammers constantly adapt their strategies and tactics, the learned spam signatures can go stale quickly. An alternative spam discovery technique relies on community-contributed spam referrals (e.g., Users A, B, and C report that User X is a spam user); of course, these kinds of referral systems can be manipulated themselves to yield spam labels on legitimate users, thereby obscuring the labeling effectiveness, and neither spam discovery approach can effectively handle zero-day social spam attacks for which there is no existing signature or wide evidence [1]. With these challenges in mind, we propose and evaluate a novel Honeypot-based approach for uncovering social spammers in online social systems. Concretely, the proposed approach is designed to (1) the deployment of social honeypots for harvesting information of malicious profiles [8, 9]. (2) Analysis of the characteristics of these malicious profiles and those of deployed honeypots for creating classifiers that allow to filter the existing profiles and monitor the new profiles [2]. Drawing inspiration from security researchers who have used honeypots to observe and analyze malicious activity (e.g., for characterizing malicious hacker activity ,generating intrusion detection signatures,),In This extended paper we deploy and maintain social honeypots for trapping evidence of spam profile behavior, so that users who are detected by the honeypot have a high likelihood of being a spammer [1].This paper is an extension of work originally presented in conference 2016 4th IEEE International Colloquium on Information Science and Technology (CIST) in Tangier Morocco, we describe the processes of the proposed approach, starting with the deployment of social honeypots, the use of both feature based strategy and honeypot feature based strategy methods for collecting data, and finally we give the results and the test of this approach by using a dataset of profiles in machine learning based classifiers for identifying malicious profiles [2].These results are quite promising and suggest that our analysis techniques may be used to automatically identify the malicious profiles in social network.

2.1. Overall Framework

Malicious profiles are increasingly targeting Web-based social systems (like Facebook, Myspace, YouTube, etc.) as part of phishing attacks, to disseminate malware and commercial spam messages, and to promote affiliate websites. Successfully defending against these social spammers is important to improve the quality of experience for community members, to lessen the system load of dealing with unwanted and sometimes dangerous content, and to positively impact the overall value of the social system going forward. However, little is known about these social spammers, their level of sophistication, or their strategies and tactics [3].

In our ongoing research, we are developing approach for uncovering and investigating malicious user. Concretely, the Approach for detecting malicious profiles based Social Honeypot to (1) the deployment of social honeypots for harvesting information of malicious profiles. (2) Analysis of the characteristics of these malicious profiles and those of deployed honeypots for creating classifiers that allow to filter the existing profiles and monitor the new profiles [3]. Drawing inspiration from security researchers who have used honeypots to observe and analyze malicious activity. The Approach for detecting malicious profiles based Social Honeypot deploys and maintains social honeypots for trapping evidence of malicious profile behavior. In practice, we deploy a social honeypot consisting of a legitimate profile and an associated bot to detect social spam behavior. If the social honeypot detects suspicious user activity (e.g., the honeypot's profile receiving an unsolicited friend request) then the social honeypot's bot collects evidence of the spam candidate (e.g., by crawling the profile of the user sending the unsolicited friend request plus hyperlinks from the profile to pages on the Web-at-large). What entails suspicious user behavior can be optimized for the particular community and updated based on new observations of spammer activity [3].

While social honeypots alone are a potentially valuable tool for gathering evidence of social spam attacks and supporting a greater understanding of spam strategies, the goal of the Approach for detecting malicious profiles based Social support ongoing and active automatic detection of new Honeypot is to and emerging spammers. As the social honeypots collect spam evidence, we extract observable features from the collected candidate spam profiles (e.g., number of friends, text on the profile, age, etc.). Coupled with a set of known legitimate (non-spam) profiles which are more populous and easy to extract from social networking communities, these spam and legitimate profiles become part of the initial training set of a spam classifier [3].

As the social honeypots collect evidence on the Malicious Behaviors, the characteristics of profiles are extracted from the data of malicious profiles (for example: number of friends, Text, on the Profile, the age, etc.). Coupled to a set of legitimate profiles which are easy to extract the communities of social networks .This is called type of strategy by "Feature based strategy."[2].

A new method used in our approach to improve our classification and increase the ability to detect an attacker on the social networks that is "honeypot feature based strategy", this strategy uses the whole of char-Characteristics of honeypots that interact with users to refine our ranking [2].

The whole of the data collected are becoming an integral part for the training of a classifier of malicious profiles. By iterative refinement of selected characteristics using a set of algorithms for automatic classification which are implement on "Weka Machine Learning Toolkit" we can explore the more wide space of malicious profiles[14]. Fig. 1 present the approach for detecting malicious users.

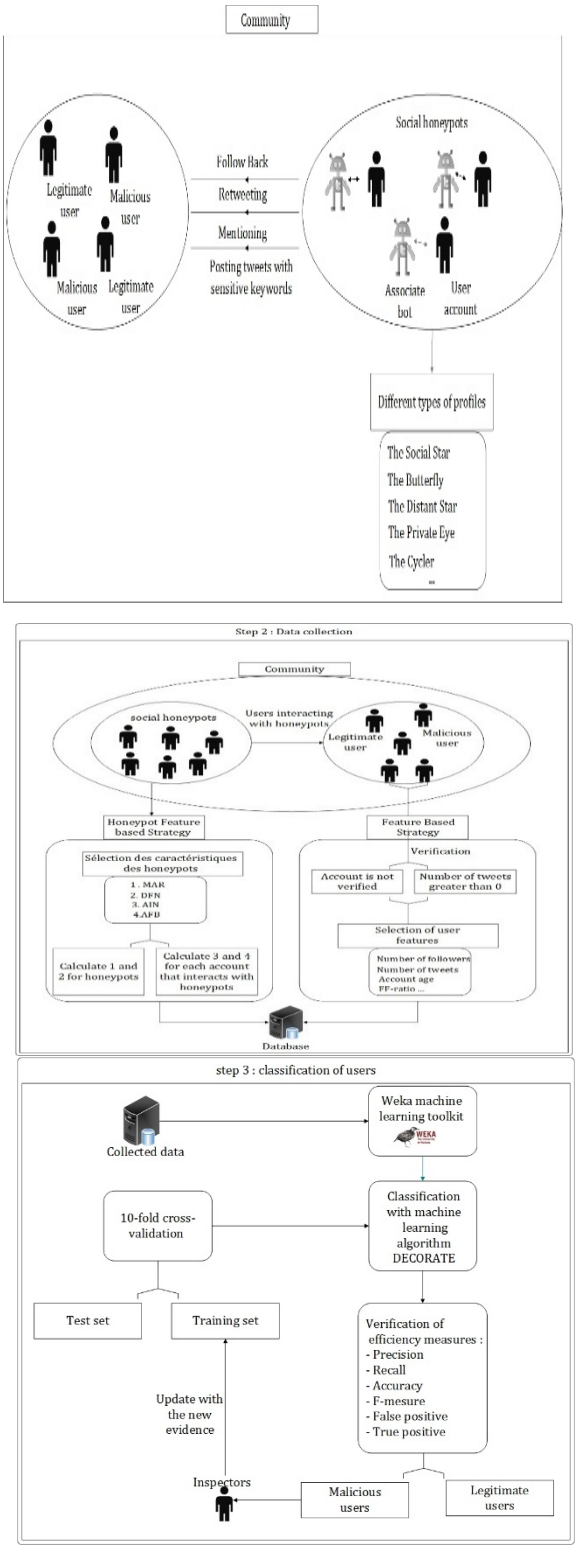

Fig.1 Overall Framework [2].

2. Malicious Profiles Detection Results:

In this section we present the results of our experiment. Creating of social honeypots: To develop our approach, we created 20 honeypots on twitter to trap malicious users and we analyze all the characteristics of users and deployed honeypots using weka that provides a platform algorithms of artificial intelligence and machine learning including Decorate algorithm that we used in our approach. We investigated various characteristics of the 90 friend requests that we collected with our social honeypots.

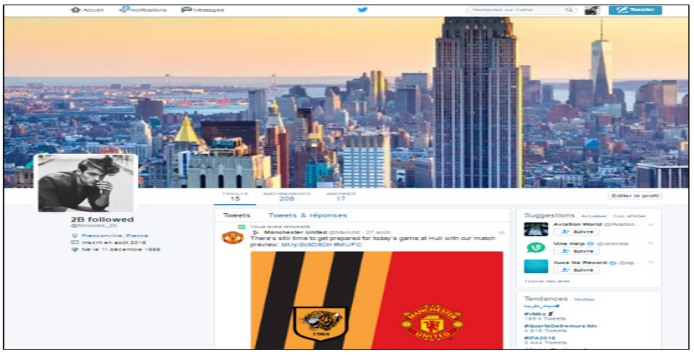

Fig. 2: Example of created honeypots

2.1. Development Tools:

- ***Twitter***

Twitter has become in the space of a few months a media phenomenon on the Internet. Everyone is put to talk in good or bad but without ever remain indifferent to them. Pushed by a few influential on the web, this small service extends more and faster its community.

Twitter has become in the space of a few months a media phenomenon on Internet. Everyone is put to talk in good or bad but without ever remain indifferent to them. Pushed by a few influential on the web, this small service extends more and faster its community.

Twitter is a tool managed by the enterprise Twitter Inc. It allows a user to send free short messages, known as tweets, on the Internet, by instant messaging or by SMS. Those messages are limited to 140 characters. The concept was launched in March 2006 by the company obvious based in San Francisco. The service rapidly became popular, up to bring together more than 500 million users in the world at the end of February 2012. At the 6 May 2016, twitter account 320 million active users per month with 500 million tweets sent by day and is available in more than 35 languages [4].

The first objective of Twitter and the reason of its deployment is to be able to provide a simple answer to the question: what am I doing? The use is very simple and free: We have 140 characters to disseminate our messages to whoever wants to receive if we specify our account in public or to our network only if it is in private. At the same time, we choose the members of Twitter which we want to follow the publications and these Members can we also add in return in their own network.

To publish our messages, several means are available: via the Twitter website, via our mobile phone by SMS, via Instant messaging type Google Talk or via software/third party Web sites based on the api free to twitter [5].

- ***Weka machine learning toolkit:***

Weka (for Waikato environment for knowledge Analysis) is a tool for data search open-source (GNU license) developed in Java. It was created at the University of Waikato New Zealand, by a group

of researchers from the automatic learning, recognition of forms and the search of data. The software allows you to deal with different sources of data: files of various formats, including the format Attribute-Relation File Format (RTTW), developed for Weka; URLs; SQL databases. The analysis can be performed using most of the techniques of existing search.

The bibliographic reference attached to the Software is the book: data mining, practical machine learning tools and techniques with Java implementations, Ian H. Witten & Eibe Frank[6].

2.2. Classification results:

- ***Collection of data:***

After implementing our honeypots and interact with different types of users, we selected 90 profiles among 300 profile strapped by our honeypots and for each profile we selected traditional characteristics «traditional features" such as (Follower number, FF-ratio, Account age, Tweet Number, Mention ratio, ratio URL ...) and features based on honeypots "honeypot based features" such as (the number of honeypots with whom one interacts account, the daily average of new followers fora honeypot ...). The size of the database is 90 profiles.

TABLE 1: Dataset of users

Name	creation date	account age	Followers	followings	Tweets	profile image	average tweets per day	FF ratio followers / following	url ratio (RU)	Mention ratio (MR)	Retweet count (RT)	Tweet similarity (TS)	Number of honeypots a user interact with	class

Further, the data is converted to ARFF (Attribute Relation File Format) format to process in WEKA. An ARFF file is an ASCII text file that describes a list of instances sharing a set of attributes. User Classification with Weka: After preparing our data file, we will use the classification algorithms implemented in Weka for test methods, solve problems, focusing us on the use and the results provided by these implementations without having to rewrite every time algorithms.

The framework within which we will work, and algorithms that we will study and use are based on the following functional diagram:
-There is a set of examples, each example being defined by Description: This is a set of values defining this example. The class that he was associate (with the help of a human expert) [7].

-This set of examples is provided to a program that will generate a classifier. A classifier is a program that, when provided him an example, try to guess its class. In other words, the program tries to guess the class of an instance from its description. After processing the ARFF file in WEKA the list of all attributes, statistics and other parameters can be utilized as shown in Fig. 3.

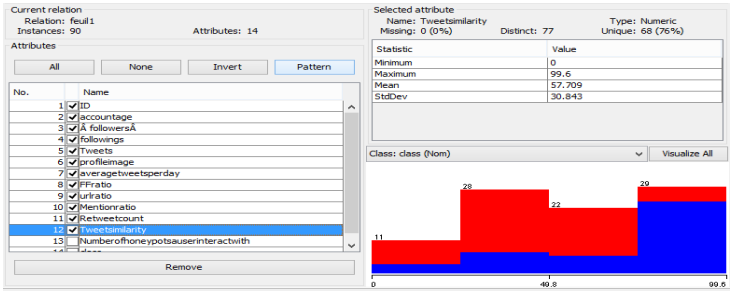

Fig. 3: Processed ARFF file in WEKA

In the above shown file, there are 90 profiles data is processed with different attributes like followers, FF ratio, Retweet-count, Mention-ratio, etc. [10,11,12].

The processed data in Weka can be analyzed using different data mining techniques like, Classification, Clustering, Association rule mining, Visualization, etc. The Fig. 4 shows the few processed attributes which are visualized into a 2 dimensional graphical Representation.

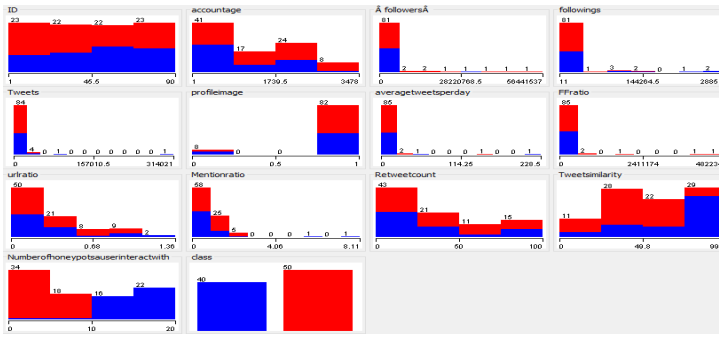

Fig. 4: Graphical visualization of processed attributes

Now that we have loaded our dataset, we used DECORATE machine learning algorithm to model the problem and make predictions and we choose Cross-validation, which lets WEKA build a model based on subsets of the supplied data and then average them out to create a final model[15].

In previous work, generally the métas Classifiers (Decorate, Lo-gitBoost, etc.) Product of Best performance that the classifiers to trees (BFTree and FT) and classifiers based on functions (SimpleLogistic and libsvm) [7]. For our approach we chose decorate as classifier. For different reasons:
-The speed and the execution time;
-Best Performance Compared to Other;
-Of Results approximately correct.

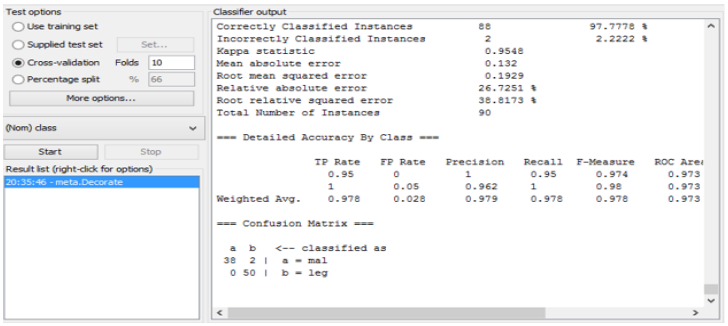

Fig. 5: Classifier output

Fig.5 shows estimates of the trees predictive performance, generated by WEKAs evaluation module [16]. It outputs the list of statistics summarizing how accurately the classifier was able to predict the true class of the instances under the chosen test module. The set of measurements is derived from the training data. In this case 97.7778% of 90 training instances have been classified correctly. This indicates that the results obtained from the training data are optimistic compared with what might be obtained from the independent test set from the same source. In addition to classification error, the evaluation output measurements derived from the class probabilities assigned by the tree. More specifically, it outputs mean output error (0.132) of the probability estimates, the root mean squared error (0.1929) is the square root of the quadratic loss. Theme an absolute error calculated in a similar way by using the absolute instead of squared difference. The reason that the errors are not 1 or 0 is because not all training instances are classified correctly. Kappa statistic is a chance-corrected measure of agreement between the classifications and the true classes. It's calculated by taking the agreement expected by chance away from the observed agreement and dividing by the maximum possible agreement. The Kappa coefficient is calculated as follows:

$$K = \frac{\text{Po}-\text{Pe}}{1-\text{Pe}} \qquad (1)$$

$With\ P_0$: is the proportion of the sample on which the two judges are of the agreement.
(i.e. the main diagonal of the matrix of confusion).
And $p_e = \frac{\sum_i p_i\, p.i}{n^2}$ (2)

Where:

p_i is the sum of the elements of the line i;
p.i is the sum of the elements of the COLUMN I;
n: in a sample size.

The Kappa coefficient takes values between -1 and 1:
- It is maximal when both judgments are the same:

All examples are on the diagonal, and P0 = 1.
- It is 0 when both judgments are independent (P0=Pe).

- It is -1 when the judges disagree. Detailed Accuracy by Class demonstrates a more detailed per class break down of the classifiers prediction accuracy.

- The True Positive (TP) rate is the proportion of examples which were classified as class x, among all examples which truly have class x, i.e. how much part of the class was captured. It is equivalent to Recall. In the confusion matrix, this is the diagonal element divided by the sum over the relevant row, **i.e.** 38/ (38+2) =0.95 for class malicious and 50/ (50+1) =1 for class legitimate in our example.

- The Precision is the proportion of the examples which truly have class x among all those which were classified as class x. In the matrix, this is the diagonal element divided by the sum over the relevant column, **i.e.** 38/ (38+0) =1 for class malicious and 50/ (2+50) =0.962 for class legitimate. From the Confusion matrix in Fig. 6 we can see that two instances of a class "legitimate" have been assigned to a class" malicious", and zero of class "malicious" are assigned to class "legitimate".

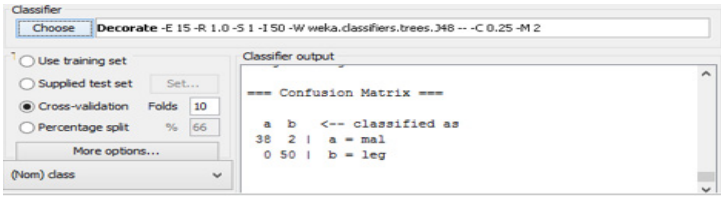

Fig. 6: Confusion matrix

Fig. 7 present the threshold curve for the prediction. This shows a 97.28% predictive accuracy on the malicious class.

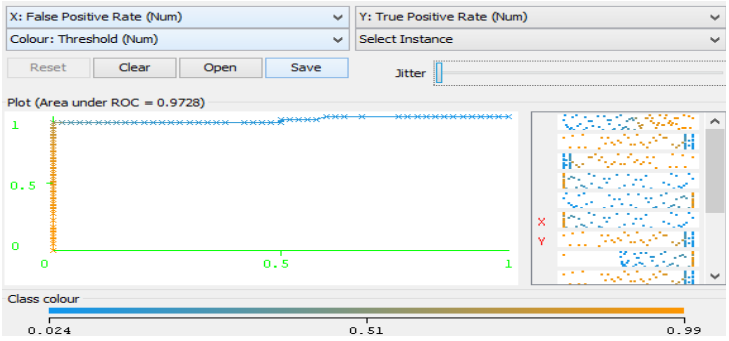

Fig. 7: Threshold curve

In order to find the optimal value of the threshold, we perform the cost/benefit analysis. Consider attentively the window for the Cost/Benefit Analysis. It consists of several panels. The left part of the window contains the Plot: Three should Curve frame with the Threshold Curve (called also the Lift curve).However, the axis X in the Threshold curve corresponds to the part of selected instances (the Sample Size). In other words, the Threshold curve depicts the dependence of the part of active compounds retrieved in the course of virtual screen in gup on the part of compounds selected from the whole data set used for screening. The confusion matrix for the current value of the threshold is shown in the Confusion Matrix frame at the left bottom corner of the window. We observed that the confusion matrix for the current value of the threshold sharply differs from the previously obtained one. In particular, the classification accuracy 74.4444% is considerably less than the previous value 97.7787%, the number of false positives has greatly increased from 0 to 21.

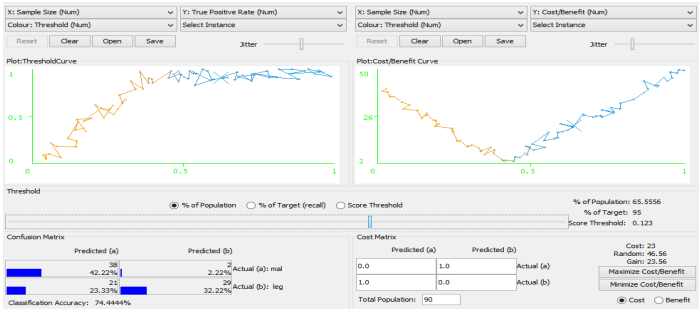

Fig. 8: cost/benefits analysis

In Fig.9, we generated a plot illustrating the prediction margin; the margin is defined as the difference between the probabilities predicted for the actual class and the highest Probability predicted for the other classes.

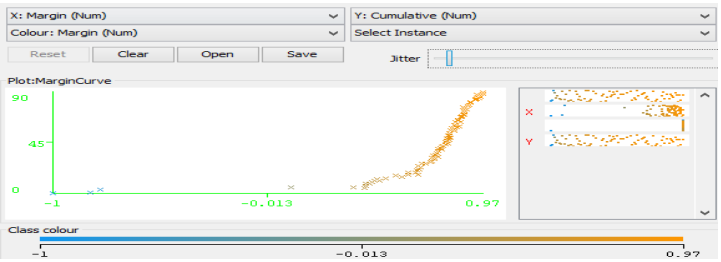

Fig. 9: Margin curve

In Fig.10 we present the performance of our malicious users detector trained with traditional features, honeypot based features and two sets of features together, respectively.

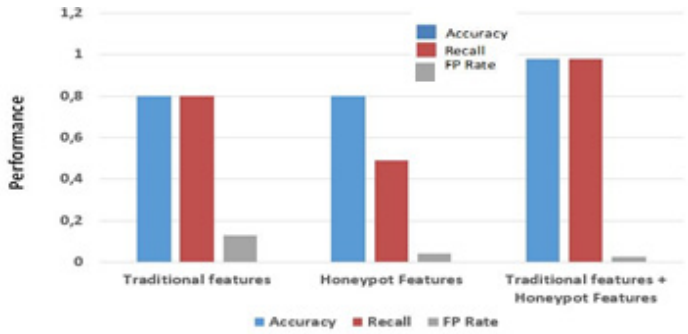

Fig. 10: Malicious user's detector performance with different feature set

We can find that after we combine traditional feature set with honeypot based feature set, we can achieve an accuracy of 0.979, a recall of 0.978 and a false positive rate of 0.028. The accuracy and recall are much better than simply using the other two feature sets independently. Though the FP rate is higher than simply using honeypot based feature set, we can modify the threshold to make a trade-off between FP rates and recall [2].

From the results obtained we can point out that with the hybrid method used (traditional feature set with honeypot based feature), we can detect more wide space of malicious users on social networks and why not apply the same approach to other communities. This hybrid approach gives results relevant to other methods.

3. Conclusion

In this paper, we have presented the results of a novel social honeypot-based approach to detect malicious profiles in social networking communities already published [2]. Our overall research goal is to investigate techniques and develop effective tools for automatically detecting and filtering malicious users who target social systems. Specifically, our approach deploys social honeypot profiles in order to attract malicious accounts. By focusing on twitter community, we use a set of user's characteristics and honeypots deployed characteristics to create a malicious profiles classifier based on machine learning algorithm Decorate for identifying malicious accounts with high precision and allow rate of false positives. In our ongoing work, we are using our analysis results to automatically identify malicious users in twitter social network. We have tried to apply our proposed approach using Weka to classify a set of users caught by our honeypots. From the results obtained we can point out that with the method of classification used, we can detect the more wide space of malicious users on social networks and why not apply the same approach to other communities. We hope this will give us a more macroscopic picture of the privacy awareness of general OSN (Online social network) users [13], and we want to use this to raise the awareness of privacy not only from the user sides but also for the OSN designers. Together with our research on detection malicious profiles in social network, we hope being able to contribute on making OSNs a safer place for the ordinary users [17, 18].

Ultrasonic Pulse generator
PZT and PVDF transducer arrays
Programmable System-on-Chip (PSoC) module

ABSTRACT

This paper describes the design of a pulse generator to excite PZT and PVDF ultrasonic transducer arrays, based on the Programmable System-on-Chip (PSoC) module. In this module, using programmable logic different pulses were implemented; these pulses are required in ultrasonic applications for multiple channels to excite PZT and PVDF transducer arrays. To excite multiple elements, bursts are required which can be generated simultaneously or out of phase, generating dynamic wave fronts. For medical applications where bidirectional blood flow is detected burst and quadrature pulses are used. These pulses can be generated independently or in combinations, as simultaneous pulses, shift pulses or burst. This module can operate with programmable frequencies from 3-74 MHz; its programming may be versatile covering a wide range of ultrasonic applications.

1. Introduction

In ultrasonic applications where it is required to focus the ultrasonic radiation fields, piezoelectric transducer arrays are designed, in order to obtain specific radiation fields. To get a specific response it should be consider the type of piezoelectric material, geometry of the array and the type of excitation for each element [1].

The focusing of the radiation fields depends largely on the form of excitation of the array elements; it is for this reason that the pulse generator for driving ultrasonic transducers arrays plays an important role in ultrasonic systems. The excitation may be in continuous or pulsed mode. The parameters associated with the pulse generator are: the operating frequency of the transducer, the repetition frequency of the pulse burst, the voltage amplitude and the excitation current. The pulsed mode allows determining the distance between the transmitter and receiver transducers, determining the time of flight of the ultrasonic signal, which is affected by the propagation medium. The ultrasonic transducers can be manufactured with PZT (Lead Zirconate Titanate) or PVDF (Polyvinylidene Fluoride) which are piezoelectric materials [1]. The type of transducer depends on the required specific application; PZT transducers can support an excitation of hundreds of volts, whereas PVDF can be driven with maximum voltages of 30 Volts.

Figure 1 shows different types of pulses most commonly used in ultrasonic applications.

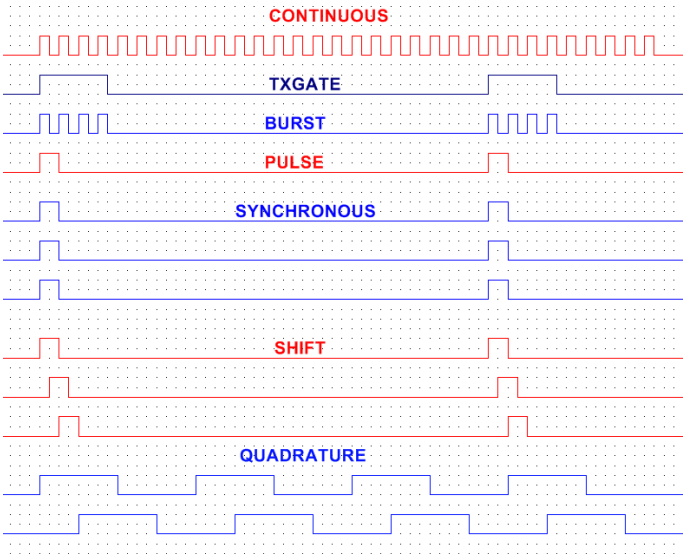

Figure 1 Excitation pulses for an ultrasonic system, a) continuous fix frequency, b) pulse gate, c) burst, d) single pulse, e) synchronous and simultaneous channels, f) shift pulses, g) quadrature pulses.

*Corresponding Author: pedro.acevedo@iimas.unam.mx

Figure 1 shows; a) an excitation signal with fixed frequency and continuous mode, b) gate pulse, c) an excitation signal in pulse burst mode in which the repetition frequency and the number of cycles may be programmable for systems in pulsed mode, d) single pulse, e) several channels with simultaneous excitation pulses for excitation of transducer arrays, f) multiple channels with shift pulse excitation for arrays with focusing applications, g) 2 channels with excitation in quadrature. In medical applications where bidirectional blood flow is detected, signals in quadrature are used for the demodulation of Doppler signals [2-3]. These pulses can be generated independently or in combinations, such as simultaneous pulses and shift or burst.

In applications where it is required to focus dynamically the ultrasonic beam, transducer arrays are used with multiple piezoelectric elements, such as that shown in Figure 2. For excitation of multiple elements pulse bursts are required which can be generated simultaneously or out of phase (with time delays between them) in order to generate dynamic wave fronts.

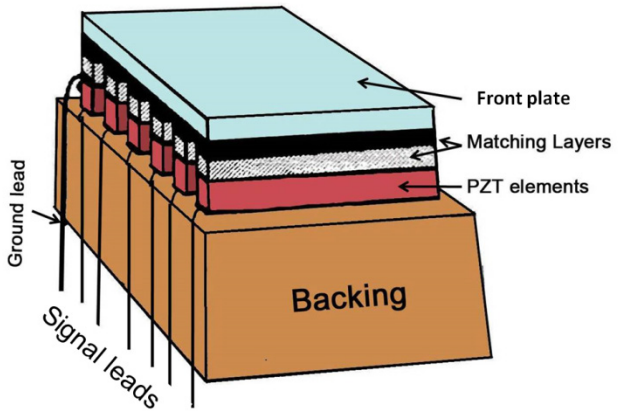

Figure 2. Linear transducer array

The focal depth is determined by the time delay between the electrical pulses. This can be changed electronically to focus pulses to give a good image detail at various depths within the body rather than just one depth with fixed focus transducer. One approach is to create an image by using a sequence of pulses, each one focused to a different depth or zone within the body. The acoustic parameters of the resulting beam, such as incidence angle, focal length and focal point size can be manipulated by the generated front waves in the array, controlling the excitation pulses via software [2].

A pulse generator to excite PZT and PVDF transducer arrays is presented. This pulse generator is based on a PSoC-5LP (Programmable System on Chip) programmable module, which is a USB port programmable development kit, from Cypress Semiconductor PSoC. [2-4]

The PSoC-5LP module has a microcontroller and a set of analog and digital programmable peripherals, all in one integrated circuit along with a 32-bit CPU (ARM Cortex family), The PSoC in the development kit belongs to the 5LP family; this family has an ARM Cortex M3 CPU with a clock rate that can reach up to 80 MHz [4].

The main difference between the PSoC microcontroller and conventional microcontrollers is that in the latter the set of peripherals are defined by the manufacturer, while the PSoC due to its programmable logic composed by Universal Digital Blocks (UDBs) and a set of analog and digital peripherals can be programmed (customize) in order to perform the required functions [5].

The implementation of the design of the programs for PSoC is made using its own IDE (Integrated Design Environment) PSoC Creator 3.2 Service Pack 2[6]. The programming process requires of a schematic diagram design, then an assignment (input/output port), and finally if required to write a C program, this process is integrated in programmable analog logic and digital functions.

2. Methodology

In this work, a programmable CY8CKIT-059, PSoC 5LP module was used.

The PZT transmitter transducer used is a 64 elements linear array (Krautkramer 116-001-264 model) [9], this PZT array has an operating frequency of 3.5 MHz (Figure 3a).

A PVDF Piezoelectric Transducer Sensor (SDT1-28K model) from Shielded Measurement Specialties [7-8] (Figure 3b) and an Ultrasonic Pulser Receiver, Olympus 5072PR (30 dBs amplifier) were used for the reception of the ultrasonic pulses

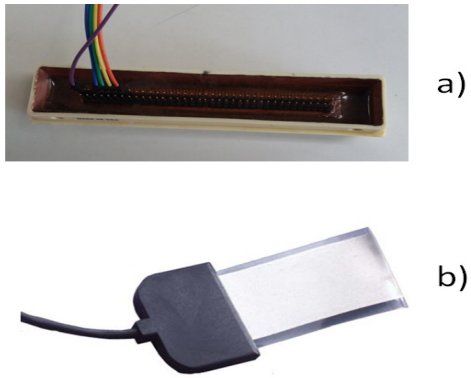

Figura 3: a) Top view of the PZT transmitter array; b) PVDF Piezo transducer Sensor, SDT1-28K model, (16 mm x 30 mm and thickness 75 µm).

To excite the PZT transducer array, it was required to generate 3.5 MHz pulse bursts corresponding to the operating frequency of the array, with a 10 kHz repeating frequency. These pulse bursts are shown in Figure 4.

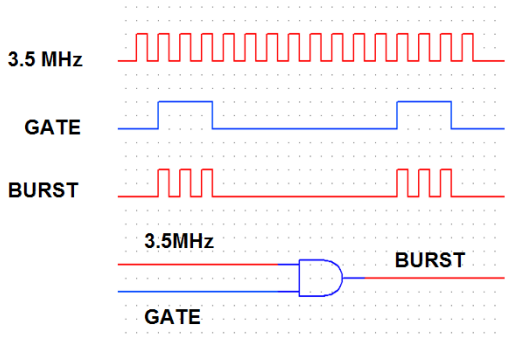

Figure 4. Time diagram of the excitation pulses of the PZT array.

In order to generate the operating frequency of the PZT transducer, the internal PSoC clock was programmed at 40 MHz. An UDB in PWM mode (PWM_35M) was also implemented to obtain a 3.5 MHz frequency, as illustrated in Figures 5 and 6.

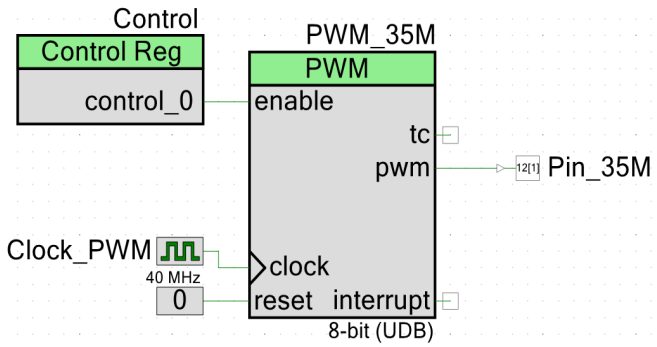

Figure 5: Implementation of the 3.5 MHz clock.

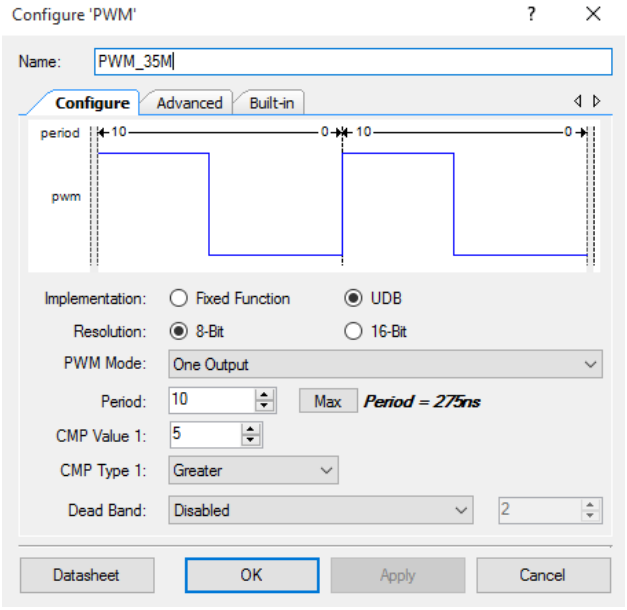

Figure 6. UDB PWM dialog window

In order to generate the 10 kHz repetition frequency a second UDB in PWM mode (PWM-Gate) was used in conjunction with an AND gate to generate the burst pulse, as shown in Figure 7.

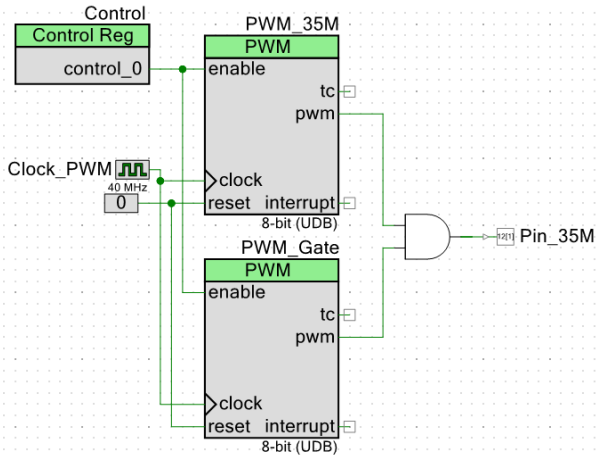

Figure 7 . Implementation of the excitation pulse bursts.

To test the excitation pulse generator, an experimental platform like the one shown in Figures 8 and 9 was implemented. A PSoC CY8CKIT-059-5LP module was used to generate the pulses and excite the PZT transducer elements. A PVDF transducer was used as a receiver, then the signal is amplified 30 dB and acquired with a digital oscilloscope, finally this signal was processed on a personal computer.

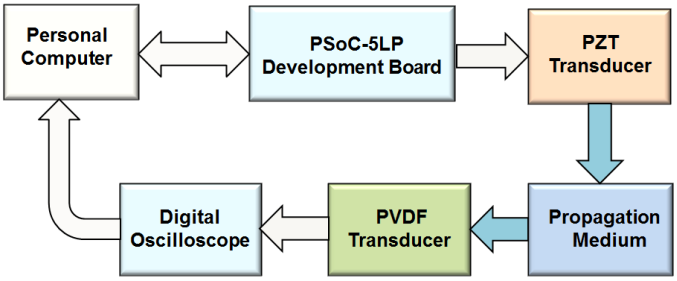

Figure 8: Block diagram of the experimental setup.

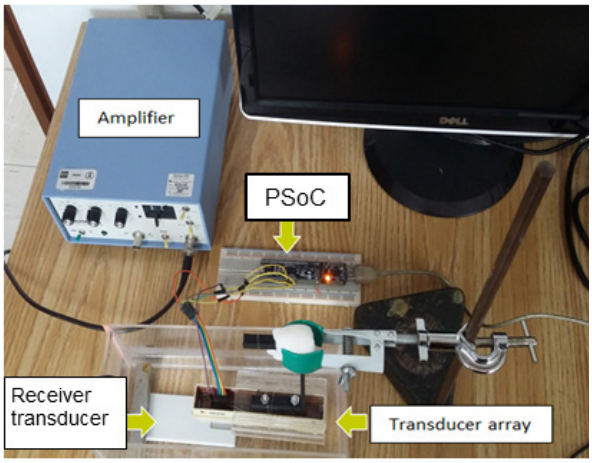

Figure 9: Experimental setup.

3. Results

To test the pulse generator, pulse bursts were programmed in four output ports, which can deliver pulse bursts simultaneously or out of phase as shown in Figures 10 and 11.

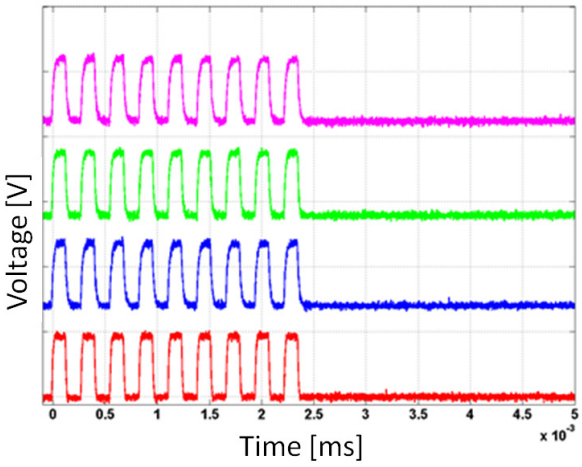

Figure 10. Simultaneous pulse bursts.

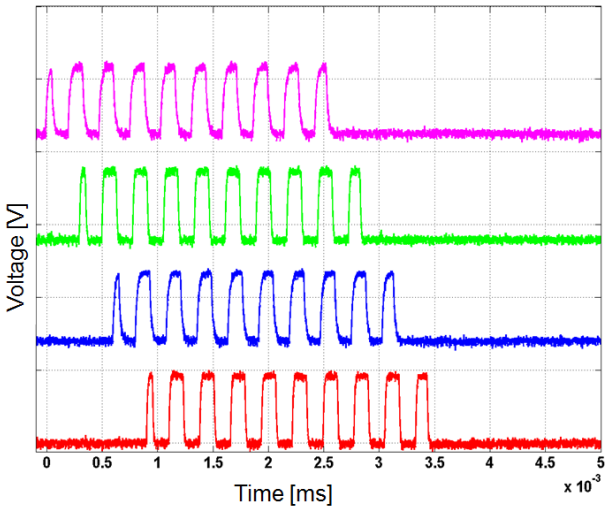

Figure 11. Out of phase pulse bursts.

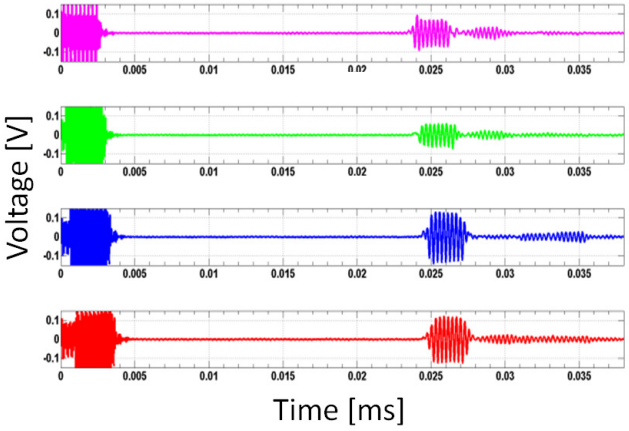
Pulse generation of the four output ports was obtained by repeating the implementation shown in Figure 7 for simultaneous outputs and programming a 25 ns time delay between them for the out of phase outputs.

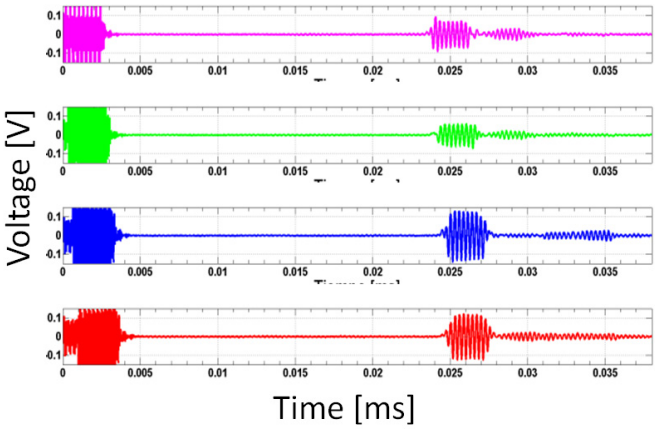
Using an experimental platform like the one shown in Figure 8, two experiments were conducted. The first experiment consisted in generating pulse bursts in four output ports to simultaneously excite four piezoelectric elements of the PZT 64 elements array (Figure 2), then more pulse bursts were generated in four ports to exciting the PZT array but this time with a 25 ns delay between each port. The results of this experiment are shown in Figure 12. Figure 12a shows the acquired signals with simultaneous excitation and Figure 12b shows the acquired signals with phase shifted excitation. The signals were acquired using a linear PVDF transducer array.

The second experiment was similar to the first one, the only difference consisted that in the acquisition of the signals, a single PVDF transducer was used. Figure 12a shows the acquired signals with simultaneous excitation and Figure 12b shows the acquired signals with phase shifted excitation.

The wave fronts generated by the four elements of the linear PZT array are shown in Figure 12, and correspond to a distance of 30 mm between the PZT and PVDF transducers. The signals have a 30 dB gain with a 500 ohms input impedance.



(a)



(b)

Figure 13. PVDF transducer response as a receiver, receiving the signal from four elements of the array at the same time, with amplification of 30 dB (a) Simultaneous and (b) out of phase.

4. Discussion

The precedent of this research work was the implementation of a pulse generator using the Arduino Mega platform [3], in this implementation it was not possible to obtain synchronous pulses in multiple output ports with frequencies above 120 kHz, since its programming does not allow it. Instead the PSoC modules have a

programmable hardware that allows programming the operation clock signal and thus programming output ports with a wide frequency range. It is also possible to program simultaneous output ports and phase shifts between ports, since such delays between signals are implemented with a delay by software of one cycle of the master clock. There is also a previous article in which this subject is presented with less extension [10].

A pulse generator based on a PSoC-5LP to excite PZT and PVDF transducer arrays is presented, it is possible to excite PZT or PVDF elements with 5 volts of amplitude, for applications requiring more power additional voltage power supply and current drivers are required. Figure 14 shows two PZT driver circuits, a) single pulse and b) burst.

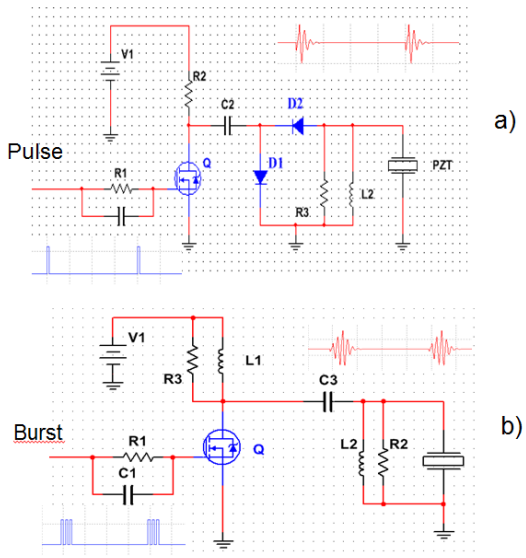

Figure 14. PZT driver circuit, a) driver circuit for single pulse, b) driver circuit for burst pulse.

5. Conclusions

The pulse generation with PSoC-5LP modules is a good alternative because as demonstrated in this work, it is possible to generate different pulses to excite transducers, either in one or multiple output ports, continuous or pulse burst, simultaneously or out of phase.

The advantage of the pulse generator implemented using the PSoC-5LP module with respect to commercial generators is its versatility. It can operate programmable frequencies from 3-74 MHz, which covers a wide range of ultrasonic applications

With the pulse generator implemented in the PSoC-5LP module, it is possible to excite PZT or PVDF elements with 5 volts of amplitude, resulting in an excellent alternative for low power ultrasound applications.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

An effective communication among the road users is crucial for safety precautions. Nowadays, a light emitting diode (LED) are commonly installed on a motor vehicle as the lighting system. The LED lights are more reliable and flexible in terms of the design and power adjustments. To further utilize the LED applications in a vehicular system, a simple data transmission system based on LED lights for short distance is developed. Toy vehicles are used to demonstrate the functionality of the system. This paper explains the components used and the communication protocols of A and B that have been developed and tested. The implementations of a software-based modulation and communication protocols by using a microcontroller can be considered as the initial approach that can be further enhanced for future development. In this paper, the prototype of the system as well as the experimental results are presented. The prototypes are able to send short messages by using the LED and photodetector (PD) which could reach up to 2-meter distance. In addition, it is also believed that this project can be implemented on the real motor vehicles subject to a few improvements.

1. Introduction

This paper is an extension of the work originally presented in 2016 IEEE Student Conference on Research and Development (SCOReD) [1]. The previous work focused on the development of communication protocol and data transmission performance of the toy vehicle VLC system. On the other hand, this work presents the application and prototype of the toy vehicle interaction protocol that have been mentioned in the previous paper.

This work is inspired from one situation that involves a multiple road users. The situation occurs in the middle of the night, on a single lane road, where the driver of a car needs to overtake a slow truck. However, due to the size of the truck, the car's driver is not able to see the traffic from the other side of the road without slightly moving to the opposite lane which is dangerous and might be fatal. Therefore, in order to have a safer driving experience, standard vehicles such as cars and trucks must have several signalling devices such as indicators, brake light, hazard warning lights, headlights and reverse lights [2]. However, the current technology can only provide a limited number of signalling signs such as turning left or right, brake signal, reverse signal, and hazard warning signal.

In the year 2012, the car manufacturer, i.e.: Volvo, started to build a system that enables the communication of a car-to-car and car-to-medium. These types of communication ensures safer driving experience. The technology relies on the GPS system and a dedicated wireless network, in which the car-to-car communication has already acquired a separate range of radio frequency for that purpose. Vehicles within a given radius would be automatically linked together and able to exchange information such as the position, speed, and direction [2,3].

*Corresponding Author: M. A. Ilyas, Universiti Tun Hussein Onn Malaysia, Malaysia | Email: arif.b.ilyas@gmail.com

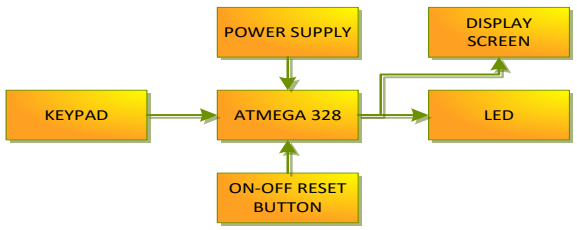
Nowadays, the radio frequency spectrum is highly congested due to the demand for wireless communication applications [3]. As a natural source of energy, a visible light can be thought as an alternative to the RF communication. The visible light communication (VLC) possesses a few key advantages over the wireless RF transmitters. It has a nearly infinite bandwidth, free and unregulated channels, poses no health hazards and concerns, and consumes much less power per given transmission [4,5]. VLC is also a potential low-power and low-cost alternative to the traditional short-range wireless RF communications [6-8].

In this work, a data transmission system for two toy vehicles has been developed by using a light emitting diode (LED) which is highly reliable for short distance communication. It has also been demonstrated that the current LED signalling technology can be further utilized by using the VLC. The LED provides a visual indicator as well as a communication channel for both vehicles to exchange information. Additionally, it provides a medium for the front toy vehicle to convey any information efficiently to the rear toy vehicle.

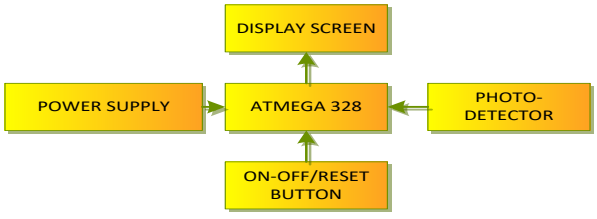
This paper is organized as follows: Section 2 introduces the design method for the VLC system which is followed by Section 3 that discusses the results and discussion. Finally, the paper is concluded in Section 4.

2. Visible Light Communication (VLC) Design

This section focusses on the VLC circuit development starting from the LED selection until the successful implementation of communication between the LED and photodetector (PD). As shown in Fig.1, the transmitter circuit consists of a keypad, LED, and display screen. On the other hand, the receiver circuit only has a PD and display screen. Both circuits have a common microcontroller which is known as Atmega328. It is the brain of the circuit and is responsible for all operations that include the modulation, signal processing and keypad response. When the keypad is pressed, the microcontroller gives an order to the LED to transmit a signal. The data are transmitted using on-off keying modulation (OOK). At the receiver, the PD will detect the signal which will then trigger the microcontroller to demodulate the transmitted signal as well as activating the display screen to show the message.



(a) Transmitter circuit



(b) Receiver circuit

Figure 1: Block diagram of VLC circuit [1]

2.1. Optical hardware selection

In order to establish the VLC communication, an appropriate LED and PD selection must be performed. In this work, the choice of LED must take into account the cost, efficiency, and performance. The LED model chosen in this work is COM-00531. It is classified as a super bright LED and emits white colour. The LED viewing angle is very narrow at 10°, as can be seen from the specification in Table 1 and further illustrates in Fig. 1. The narrow angle will lead to a more focused beam of light that provides better detection. In addition, its emission spectrum is very wide, ranging from 400 nm to 800 nm.

Table 1: Specifications of COM-00531 LED

Material of construction	InGaN/GaN
Emitted colour	White
Lens color	Water clear
Viewing angle	10°
Typical luminous intensity at 20mA	10cd
Typical forward voltage at 20 to 30mA	3.5V
Reverse Current	10 uA

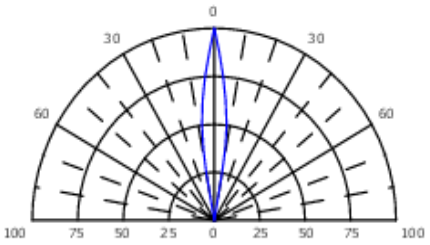


Figure 2: LED viewing angle

As for the PD, a 5-mm PD (flat head) is selected as the light sensor for this work. Table 2 shows the specification of the PD. The justification of this selection is that the PD could detect a light from 400 nm to 1100 nm that covers the visible light range of wavelengths. In addition, it also has a high reverse voltage that could be used to alter the sensitivity of the photo detection for higher detection performance.

Table 2: Specifications of 5-mm PD (flat head)

Reverse voltage	35V
Power dissipation	50mW
The peak wavelength sensor	940nm
Spectral bandwidth	400 - 1100nm
Reverse light current	40uA

A few experimental procedures have been conducted to evaluate the performance of the LED and PD. An oscilloscope is used to observe the behavior and functionality of the LED and PD. The main objective of these experiments is to determine the maximum rate of data transmission for the LED-PD pair. By comparing the signal generated by the PD to the signal provided by the LED, a performance analysis can be examined.

2.2. Electrical Domain

In this section, the VLC design process in an electrical domain is discussed which consists of OOK modulation, communication protocol and system integration.

2.2.1 On-Off Keying (OOK) Modulation

In this work, a non-return-to-zero on-off-keying (NRZ-OOK) with direct detection (DD) is used for modulation as shown in Fig. 3. From the figure, Signal 1 is represented by 5 V and Signal 0 by 0 V, respectively. The PD is continuously detecting the data by using a time delay method that samples the data continuously for every period of time. The modulation is implemented in a software level on the microcontroller as to ease the design process.

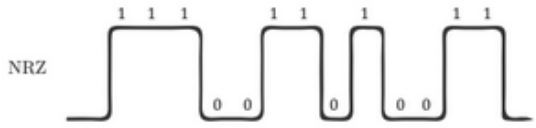

Figure 3: Bit sequence modulation

In this experiment, the possibility of sending signals between the LED and PD is verified. Furthermore, the maximum possible speed of operation for a certain communication distance is investigated. The programming code for this experiment has the following roles:

- To receive the binary input signal from the user's computer (convert the ASCII characters to binary data) – in the transmitter.
- To send data by using an OOK modulation.
- To detect these signals by using a PD.
- To demodulate the message and recover the original binary string.

Once the programming code has been developed and uploaded to each circuit, the experiment is conducted by placing the transmitter and the receiver at a separation distance of 1 cm and 5 cm. Initially, to test the system, a time delay of 1000 milliseconds (ms) is setup for the delay function. Depending of the successful achievement of the experiment, the delay time is then shortened accordingly. For a start, a random binary string is chosen: 01010101 (ASCII: 'U'). If the serial monitor's output produced the same binary string, the experiment can be considered as successful. The experiment setup with the programming code consists of a LED as the transmitter and a PD in the receiver. A binary data sent by the transmitter should be displayed on the receiver.

2.2.2 LED-PD Communication: The Setup of Communication Protocol

This section discusses the setup of communication protocol in the communication system namely, Protocol A and B.

In the previous experiment, the binary string of 01010101 is not the only signal received as the receiver cannot distinguish whether the signal is an actual data or a noise. The serial monitor's output can be viewed Fig. 4. In order to solve this problem, a communication protocol must be established.

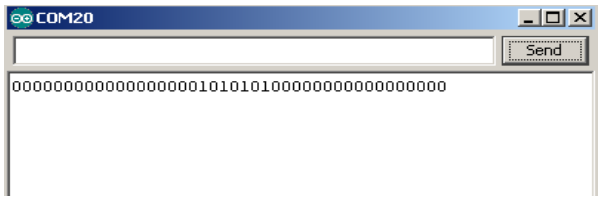

Figure 4: Receiver serial monitor output

Since the objective is to develop a working interactive communication between the two toy vehicles by using a LED signalling, the needs to convert the received binary data to a real and readable information is compulsory. Hence, another programming code is written that would have all the existing features from the previous experiment and also the ability to send an actual text.

In order to get the new code working, two additional features need to be added which are:

- The conversion from text to binary – in the transmitter.
- The conversion from binary to text – in the receiver.

2.2.2.1 The Setup of Communication Protocol A

The best way to address the problem is to add another LED for the transmission to provide a synchronous data transfer for both devices. The communication system would now work with the following procedures:

i. Once the message has been input on the transmitter's serial monitor, the LED begins sending the message through OOK.
ii. If the receiver secondary PD receives any signals from the transmitter secondary LED, it tells the receiver primary PD to start receiving the data sent from the transmitter primary LED.
iii. Once the transmitter primary LED finishes sending the message, the transmitter secondary LED turns off. Thus, the receiver secondary PD will stop receiving any signals and will tell the receiver primary PD to stop receiving data.
iv. After conversion is done, it will then be displayed on the monitor.

The hardware experimental setup consists of two LEDs as the transmitter and two PDs in the receiver circuit. The primary LED is used for data transmission while the secondary LED and PD are used to indicate the start and end of a transmission period.

2.2.2.2 The Setup of Communication Protocol B

Now that the transmitter needs two LEDs to set up a successful communication to the receiver, it is not practical to be implemented in real life situation because the LEDs need to be placed directly at the opposite of the receiver. Therefore, a new protocol is developed so that only one LED is needed for every data transmission. Fig. 5 shows the protocol that has been implemented in the transmitter and receiver system. Every data transmission begins with a start bit, followed by the information on the total bit number and the actual data packet.

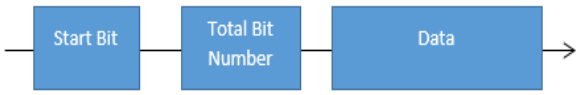

Figure 5: Communication protocol B

Thus, this experimental setup only comprises of one LED as the transmitter and one PD in the receiver circuit. A string data is sent by the transmitter by using a new protocol and will then be displayed on the receiver.

2.3. VLC Complete Circuit Development

This section focuses on the complete VLC circuit development which consists of a 4 × 4 keypad, 5110 LCD, PD, and LED.

2.3.1 Transmitter Circuit with 4 × 4 Keypad and LCD

In this section, a programming code is written to combine the transmitter circuit with a 4 × 4 keypad. Each button has been assigned to a specific string of characters and it is used as a source of information to be transmitted. When a button is pressed, the string will be displayed on the 5110 LCD before being converted to the binary string by using the ASCII codes. The binary data will then be used for OOK modulation. Table 3 shows the characters that has been assigned to each button.

Table 3: String of characters assigned to each keypad button

Fig. 6 shows the hardware setup of the experiment which consists of a LED, 5110 LCD, 4 × 4 keypad and Arduino microcontroller as the programming platform.

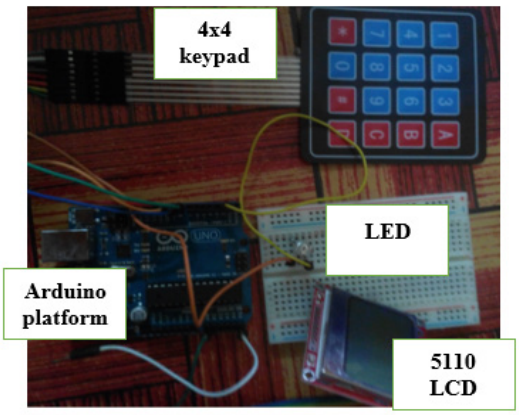

Figure 6: Transmitter circuit with 4 × 4 keypad and LCD

2.3.2 Receiver circuit with LCD

In this section, the receiver is used to display the received characters on a LCD screen. As the receiver received the characters, it is sent to the LCD to be displayed. There is no predetermined character on the LCD. All the received characters are totally based on the received signals.

Fig. 7 shows the hardware setup of the experiments which encompasses of a LED, 5110 LCD and Arduino microcontroller as the programming platform. The performance of the combined receiver circuit is evaluated with the combined transmitter circuit.

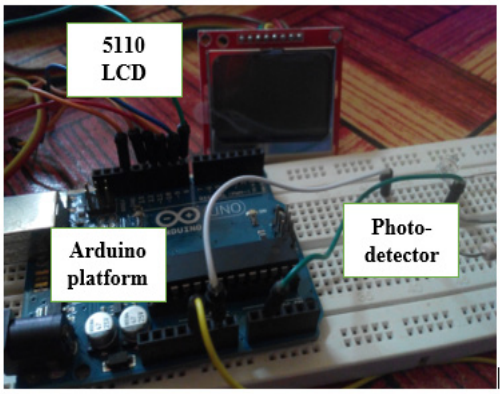

Figure 7: Receiver circuit with LCD

3. Results and Analysis

In this section, the results in optical domain, electrical domain, and circuit integration of each experiment are presented and analysed.

Fig. 8 is the oscilloscope screen that displays the result of the experiment to test the functionality and performance of a PD. Signal 1 is the square signal that is injected into the LED with a function generator. On the other hand, Signal 2 is the behavior of PD in the presence of light from the LED. It is observed that when the LED is having a high voltage that represents bit 1, there is a

voltage rise on the PD. Conversely, when there is no voltage on the LED, the voltage at the receiver decreases. However, the rate of voltage falling on the PD is significantly slower as compared to the rate of voltage rising. This indicates the maximum data rate that the photodiode could handle. In the experiment, the frequency used for injecting the signal to the LED is approximately 300 Hz. In order to have a reliable system, the maximum data rate should be lower than 300 Hz so that the fall time of PD is not an issue during data processing.

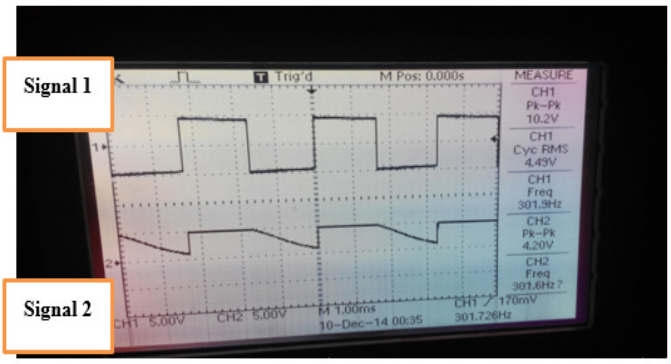

Figure 8: Oscilloscope display

3.1. Electrical Domain

In this section, the results for electrical domain experiments that cover data modulation and communication protocol are presented and analysed.

3.2.1 OOK Modulation Performance

Table 4 and 5 show the experiment results in Section 2.2.1 that compare the delay time and the status of the received string as the distance is increased from 1 cm to 5 cm. The experiment is conducted to find the limit of data transmission rate that could be handled by the system. The results indicate that the maximum time delay that the transmission could handle is 5 milliseconds. This work does not require a fast data transmission rate, but rather a reliable system. However, the distance covered is not long enough due to the limitation of using only one LED. A LED produces a noncoherent and diverging light output pattern. At greater distances, the intensity of the light are becoming much lower and restricts the receiver LED to receive the data.

Table 4: Results for 1 cm distance

Delay time (ms)	*Status of the received string*
1000	Correct
100	Correct
10	Correct
5	Correct
1	Wrong

Table 5: Results for 5 cm distance

Delay time (ms)	*Status of the received string*
1000	Correct
100	Correct
10	Correct
5	Correct
1	Wrong

3.2.2 Communication Protocol A and Protocol B

Fig. 9 and Table 6 show the results of the experiments in Section 2.2.2.1 and 2.2.2.2. The experiments are conducted to determine the performance of the communication protocols when implemented on the actual system. Both protocols are developed to enable the receiver to distinguish between the actual data and unwanted data. Therefore, the receiver will only process the transmitted data and ignore the unwanted data. It also helps in synchronizing the transmitter and receiver transmission timing so that an accurate and reliable data transfer could be established. However, only communication Protocol B is used in the final design since it offers more flexibility as compared to Protocol A. Further explanation can be read in [1].

3.2. VLC Complete Circuit Integration

In this section, a complete circuit of VLC system is presented. The transmitter and receiver circuits have been successfully developed.

3.3.1 Complete Transmitter Circuit

The transmitter circuit has been successfully combined with a 4 × 4 keypad and 5110 LCD. The keypad is used to initiate the data transmission and the characters are displayed on the 5110 LCD. A minor adjustment is made where the user has to press button A to initiate a transmit mode. The changes are made so that the transmitter is compatible with the receiver circuit when they

are combined. The program uses 10,962 bytes (33%) of the program storage space that have a total of 32,256 bytes. On top of that, the global variables use 1,204 bytes (58%) of the dynamic memory, leaving only 844 bytes for local variables. Table 7 shows the results of the transmitter circuit that has been integrated with a 4 × 4 keypad and 5110 LCD.

Table 7: Results for transmitter circuit

Button Pressed	5110 LCD
1	
2	3	
4	
5	6

C	
D	

3.3.2 Complete Receiver Circuit

A combination of the receiver circuit and 5110 LCD has been successfully performed. The receiver circuit will continuously check the condition of PD. If any transmission is detected, the received characters will be displayed on the 5110 LCD. The program uses 10,466 bytes (32%) of the program storage space while the global variables use 1,299 bytes (63%) of the dynamic memory, leaving only 749 bytes for local variables. Notice that the global variable consumes so much dynamic memory which can make the program to be slightly unstable. Some of the original data have to be simplified so that a minimum number of global variables is used. Table 8 shows the results of an integration of the receiver circuit with 5110 LCD.

Table 8: Results of receiver circuit

4. Conclusion and Future Work

In this work, a visible light data communication that can function as a transmitter and receiver has been developed. A LED and PD are used as the light source and light sensor, respectively. In addition, an interactive communication between the two prototype toy vehicles by using a LED signaling has also been constructed in which the transmitter could transmit any characters or information to the receiver by using a single source of light. Currently, the characters that are being assigned to the transmitter are turn left, turn right, U-turn, police indicator, ambulance indicator, and fire truck indicator.

There are, however, a few limitations of this work, which can be attributed from the circuit connections, the written programming code and the platform that is being used. The proposed suggestions are listed below to overcome the limitations which can be considered for future work:

- Faster Processing Platform
  A faster processing platform such as a FPGA can be used to enable data to be processed at a faster speed. In addition, it also helps with the synchronization process between data transmission and enables a large number of bits to be sent correctly.
- Bluetooth Device Enhancement.
  The visible light data communication system can be equipped with other systems such as a Bluetooth to add to the versatility. It will enable the user to change the characters manually for each button by using a smartphone. In other word, it will give the user more freedom to customize the system.
- Brighter LED
  Brighter light source implementation will make the system to be a good candidate to be used in a real motor vehicle. Not only it can increase the distance of transmission, but a brighter LED also provides higher flux density within a certain area. However, a larger power source needs to be used so that it can support the brighter LED

Conflict of Interest

The authors declare no conflicts of interest.

Fractional- order elements

ABSTRACT

In this study, a new method is devised and presented for the dynamic analysis of a 2xn RLC circuit network modeled with the fractional-order circuit elements. The analysis method is based on the principles of dynamic analysis with transfer function approximation. Firstly, the fractional-order 2xn RLC circuit network of interest which is divided into n equal cells connected in cascaded form, then related transmission matrices are individually calculated for each cell correspondingly, Secondly. the transmission matrix of the whole circuit network is calculated based on the properties of the cascaded connection. By means of this transmission matrix and the two-part connection, diagram circuit functions, such as transfer function and the equivalent input impedance of the whole circuit network, are obtained depending on the number of cells (n) and the fractional-order values. Finally, essential dynamic system analysis, such as frequency, step and pulse responses, and the impedance characteristics of the network, are simulated using necessary MATLAB programs depending on cell number n and the fractional-order values.

1. Introduction

Circuit networks have become more attractive in recent years because they can be employed for the modelling of both electrical and non electrical systems, such as biological and chemical ones [1,2]. A study on resistance networks of graphine which indicates the existence of the planar circuit networks in nature won the 2010 Nobel Prize in Physics [3-5]. Over the past few decades, researchers have published some papers on the integer circuits networks. However, the last efforts have been focused mainly on analyzing the resistors or capacitors of the fractional order single component circuit networks [6,7]. Comparatively little attention has been paid to the impedance of the fractional-order multiple-component circuit networks.

Fractional-order mathematical models developed for inductors and capacitors could describe the electrical characteristics more accurately, which allows for higher flexibility, more freedom, best fit and better optimization techniques. In other words, the actual inductors and capacitors are fractional-order in nature [8]. Fractional-order inductors could be designed based on skin effect. Moreover, the fractional order capacitors have been created with different electrolytes recently [9-11].

Nowadays some researchers have been studying to design and realize the fractional elements [12-16]. Furthermore, some researchers have also concentrated on the study of fractional-order circuit theory [17-20]. However, only few researchers are interested in the electrical characteristics of 2xn circuit networks in fractional-order sense. Therefore, we focus on impedances and transfer functions of the network in fractional domain.

The following research contents could make our research more attractive. Firstly, network transfer function and equivalent input impedance formula are obtained depending on cell numbers used in network and fractional-order values. Cascade connection method with the transmission matrices is developed for this derivation. Secondly, the characteristics of circuit network impedance and the transfer function are investigated with respect to cell numbers and fractional-order values by means of MATLAB simulation programs.

2. Analysis of Fractional-Order 2xn RLC Circuit Network

Figure 1 represents the diagram of the fractional-order 2xn RLC circuit network, where z_0 refers to the resistors, z refers to the fractional order capacitors, and z_1 refers to the fractional-order

*Corresponding Author: Mahmut Ün, Biomedical Engineering Department, C İstanbul Yeni Yüzyıl University, 34010 İstanbul, Turkey
Email: mahmut.un@yeniyuzyıl.edu.tr

inductors [17]. The represented network model is planar, and contains only passive circuit elements.

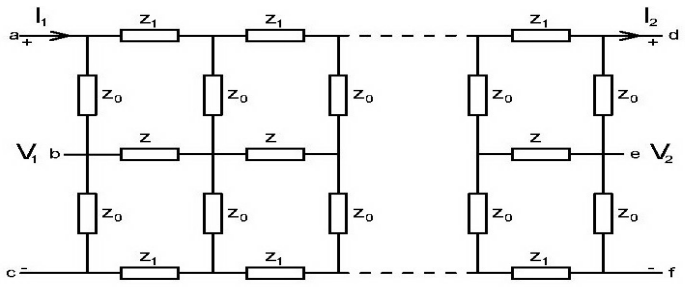

Figure 1: Fractional-order 2xn RLC circuit network model

In order to obtain equivalent impedance and transfer function formula of the fractional-order circuit network, the basic circuit network theory, the two-port transmission matrix, and the matrix tranformation methods are employed. It is clearly seen that the circuit network model shown in Figure 1 includes the network submodel shown in Figure 2a, and the network submodel shown in Figure 2b, which are connected in cascaded form. One can easily verify that the whole circuit network is formed by cascading these submodels. With the help of the calculated transmission matrices for each submodel equivalent transmission matrix, the whole network model can be computed. From the equivalent transmission matrix, the transfer function and the equivalent impedance of the complete network can easily be found.

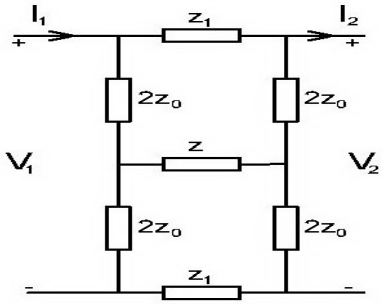

Figure 2a: Two-port subnetwork model for basic unit cell

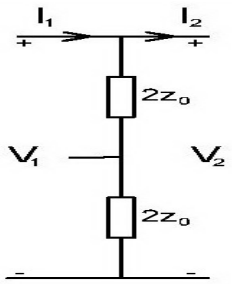

Figure 2b: Two-port subnetwork model used at input and output

Transmission matrice for the two-port network shown in Figure 2a is calculated by

$$T_1 = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \quad (1)$$

Where parameter values of the transmission matrice given by (1) are defined respectively

$$a = \frac{16z_0^2+12zz_0+5zz_1+zz_0}{2z_0\,(4z_0+z+z_1)} \qquad b = 2z_1 \quad (2a)$$

$$c = \frac{16z_0^2+8zz_0+8z_0z_1+2zz_1+zz_0}{2z_0\,(4z_0+z+z_1)} \qquad d = \frac{z_1}{2z_0} \quad (2b)$$

Transmission matrice for the two-port network shown in Figure 2b is computed by the following equation.

$$T_2 = \begin{bmatrix} 1 & 0 \\ \frac{1}{4z_0} & 1 \end{bmatrix} \quad (3)$$

Transmission matrix for the whole network connected in cascaded form becomes

$$T_= T_2 T_1^n T_2 \quad (4)$$

Where ;

$$T_1^n = \begin{bmatrix} a_n & b_n \\ c_n & d_n \end{bmatrix} \quad (5)$$

T_1^n is defined as nth power of T_1 matrice. From Cayley-Hamilton theorem, the following equation can be written as

$$T_1^n = \alpha_0 I + \alpha_1 T_1 \quad (6)$$

Where T_1(2x2) is given by (1) and I(2x2) is unit matrix [21]. Where α_0 and α_1 coefficients are calculated by

$$\begin{bmatrix} \alpha_0 \\ \alpha_1 \end{bmatrix} = \frac{1}{\lambda_2-\lambda_1}\begin{bmatrix} \lambda_2\lambda_1^n - \lambda_1\lambda_2^n \\ \lambda_2^n - \lambda_1^n \end{bmatrix} \quad (7)$$

Where λ_1 ve λ_2 coefficients are non repeated eigen-values of T_1 matrix. If the equations (3) and (5) are substituted in the equation (4), one can easily obtain the following equation.

$$T_= \begin{bmatrix} a_n + \frac{b_n}{4z_0} & b_n \\ \frac{b_n}{16z_0^2} + \frac{a_n+b_n}{4z_0} + c_n & \frac{b_n}{4z_0} + d_n \end{bmatrix} \quad (8)$$

Equivalent input impedance and transfer function can easily be obtained by means of T transmission matrix given by (8). Equivalent input impedance and transfer function are given below, respectively.

$$Z_{in} = \frac{V_1}{I_1} = \frac{4z_0a_n+b_n}{\frac{b_n}{4z_0}+a_n+b_n+4z_0c_n} \quad (9)$$

and

$$H(s) = \frac{V_2}{V_1} = \frac{4z_0}{4z_0a_n+b_n} \quad (10)$$

The derived equivalent input impedance and transfer function equations are employed for the dynamic analysis of fractional-order 2xn circuit network. Finally, the analytical equations for the equivalent impedance and transfer functions are presented in the rational equation form. These equations vary with cell numbers and fractional-order values, thus dynamic characteristics of the network can be investigated with respect to cell numbers and fractional-order values.

3. MATLAB Simulation of Network

The given example of the circuit network shown in Figure 1 with n=10 cell is simulated by using MATLAB program. Firstly, the equivalent input impedance and the transfer function of the circuit network are computed by means of symbolic programming in MATLAB. Then, by using the first order approximations presented in literature for the fractional elements, the transfer function and the equivalent input impedance are correspondingly obtained in the rational function form. Finally, the characteristics of the transfer function and the equivalent input impedance of the 2xn circuit network, such as frequency response, step and impulse responses are investigated with MATLAB simulations.

The parameter values of the proposed network in fractional domain are chosen as $z_0 = 1$, $z_1 = s^{0.5}$, $z = s^{-0.5}$, $n = 10$, $\alpha = \beta = 0.5$. In the simulation, $s^{0.5} = (3s+1)/(s+3)$ the first order approximation are used fort he fractional terms [14]. Firstly, frequency response, step and impulse responses of transfer function given by (10) are obtained by using MATLAB simulations. Graphics of these responses are shown in Figure 3a, 3b, 3c, respectively.

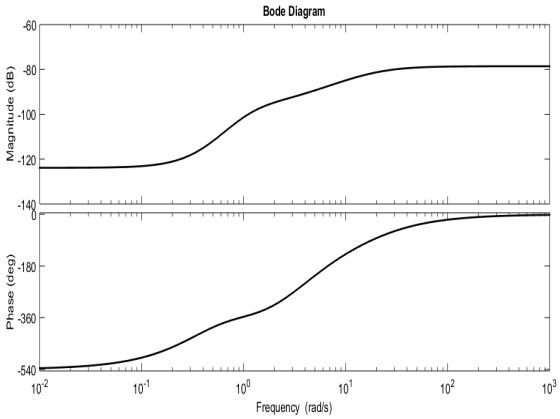

Figure 3a: Frequency responses of the transfer function

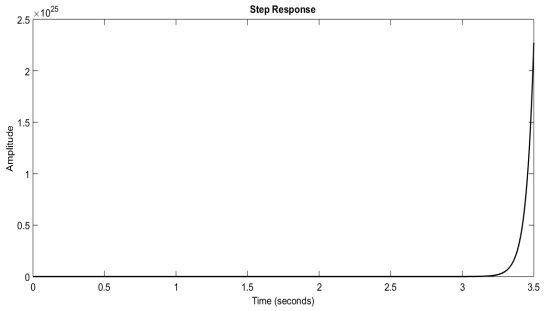

Figure 3b: Step response of the transfer function

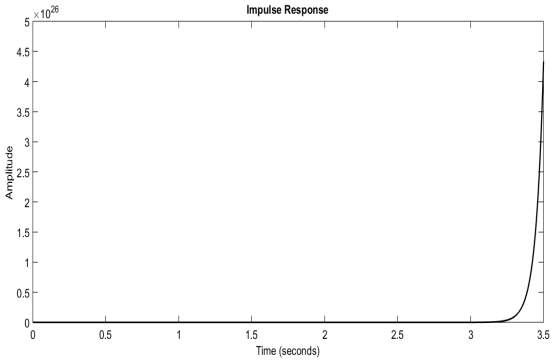

Figure 3c: Impulse response of the transfer function

From the simulation results, we can conclude the following interpretations about transfer function of the network. It is clearly seen that the characteristics of the transfer function has high pass filter characteristic, and the transfer function is stable.

Later, by using the same parameter values and the same approximations for the equivalent input impedance defined in (9), the MATLAB simulations are repeated in fractional domain. Frequency response, step and impulse responses of equivalent input impedance corresponding results are shown in Figure 4a, 4b, 4c., respectively.

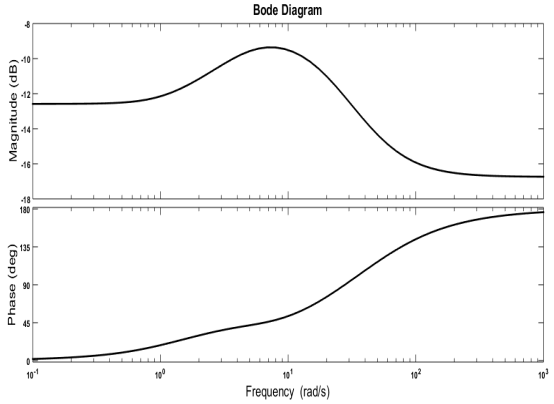

Figure 4a: Frequency responses of the equivalent input impedance

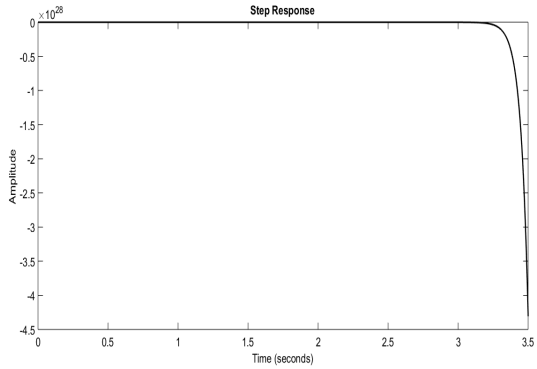

Figure 4b: Step response of the equivalent input impedance

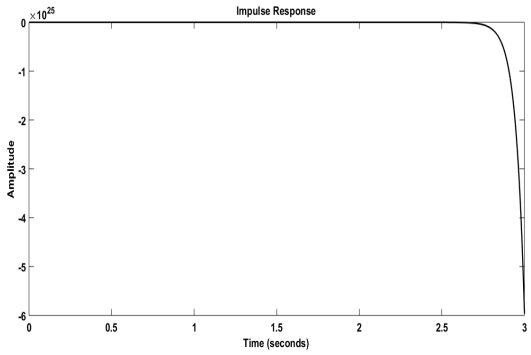

Figure 4c: Impulse response of the equivalent input impedance

From the simulation results, the following interpretions about impedance function can be concluded. It is clearly seen that the characteristics of the equivalent input impedance function has low pass filter characteristic, and the impedance of the network is stable

4. Results and Conclusion

Mathematical model of the fractional- order 2xn RLC circuit network are developed by means of two-port transmission matrices in fractional domain. Mathematical model is in the form of fractional order rational function. By using rational function approximation for the each fractional-order term, the transfer function and the equivalent input impedance of the 2xn circuit network are presented in the form of rational transfer function. Although the fractional- order circuit network contains nonlinear elements, such as fractional- order inductors and capacitors, the transfer function approximation can be employed by using the Laplace transform properties. We have proposed a new method to model and to analyze the fractional- order circuit network in fractional domain.

The characteristics of the equivalent impedance and transfer functions of fractional-order circuit network are investigated by using the MATLAB simulation programming. Network characteristics, such as the frequency, step and impulse responses are obtained graphically for both equivalent impedance ant transfer functions. The dynamic stability and the characteristics of the fractional- order 2xn circuit network are also investigated with respect to the model parameters, such as cell numbers and fractional –order values.

Fire in garages

ABSTRACT

In the work is considered an acceptable constructive scheme from a practical point of view at fire extinguishing in underground garages. The garage space is divided into quadrants which covering, for example, 2 cars. In case of ignition on one of them, a sprinkler nozzle system is triggered by the effect of the vertical convective jet. A protective curtain preventing the spread of fire to adjacent vehicles is realized. The solution is based on an integrated method which allows the calculation from hydrodynamic point of view on extinguishing time of the fire extinguishing system.

1. Introduction

Fire safety in garages for cars is essential and requires taking into account such actions to ensure it. The complexity of the problem requires a development of methods for numerical simulation of heat conduction and mass processes which are solved with the modern methods of CFD.

In the present work a simple method (from a technologically point of view) is offered for solution of the complex problem. It is suggested to isolate the parked in the garage cars in pairs by operating a thick curtain of water at arisen burning. The necessary insulation for solid non-combustible barriers are replaced at this way.

2. Principal of action

Referring to Fig. 1 cars are placed to ensure the possibility between the pairs to have enough distance for the implementation of water curtains. In case of burning over the car is formed upward convective flow, due to differences of the density of the products of combustion and the environment. This stream is proportional to the lift force:

$$dF_A = -\left[\int_f (\rho - \rho_{ok})\, g df\right] dx \ , \quad (1)$$

where f is the area of fire ignition, dx elementary stretch at vertical direction.

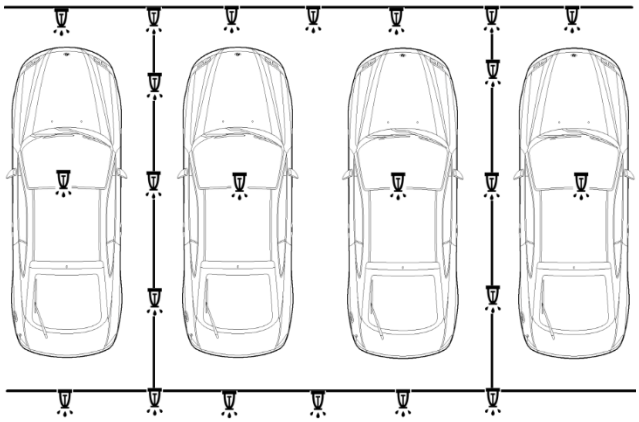

Fig.1 – Distribution of cars in the garages

The power of convective updraft is determined by the number of Archimedes

*Corresponding Author: Rositsa Velichkova, Technical university of Sofia, Bulgaria | Email: rositsavelichkova@abv.bg

$$Ar = \left(\frac{\rho_{ok}}{\rho} - 1 \right) \frac{g d_h}{u_0^2}, \qquad (2)$$

where d_h is the hydraulic diameter of the outbreak of fire; u_0 - initial value of the velocity of the upward flow. The velocity is determined according to Drayzdeyl [6]:

$$u_0^2 = 1{,}9 Q^{1/5}, \qquad (3)$$

where Q, kW is the power of the fire.

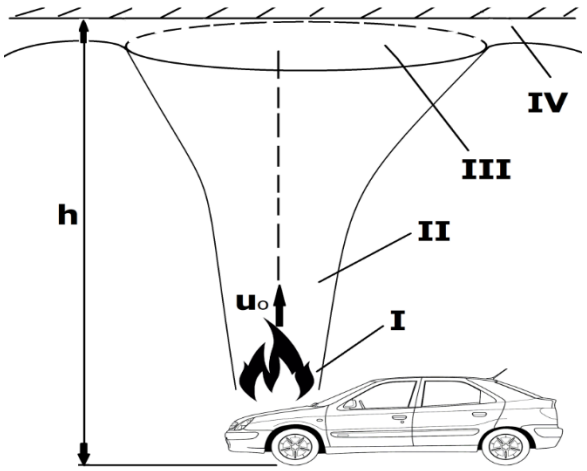

Fig.2 – Distribution of the fire

The formed convective flow is shown in Fig. 2. The conditional arisen stream can be divided into the following areas:

In zone I is formed a convective flow (Fig. 3). In the zone of fire enters from all directions ambient air which is heated and reverses direction in a vertical direction. The second zone is a free convective flow, which continues until it reach the ceiling of the room where the flow changes its character (zone III). In this area the jet is transformed into radial semi-confined stream and spreads along the ceiling of the garage (zone IV).

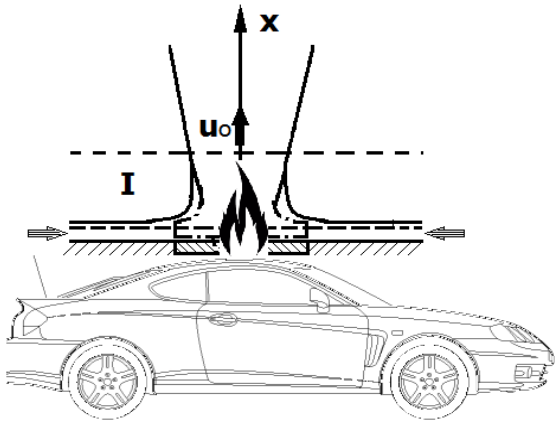

Fig.3 – Sketch of the convective flow

The system includes fire sprinklers- fast response and standard response sprinklers. Reaching the ceiling of the garage under the influence of its temperature convective flow turns on the sprinkler for rapid response and the burning car is flushed with water spray. This is how the process of fire fighting starts in the initial stages Further, spreading out as a radial semi-confined jet reaches the "standard response sprinklers which turns on the water curtain.

This stage is defined as isolating the burning cars from the surrounding area and no affected other pairs.

3. Mathematical model of convective non-isothermal jet

For the purpose of solving the task is used an integral method according to [1] [4]. The used equations are as:

-for amount of movement

$$\frac{d}{dx} \int_0^b \rho u^2 \left(\pi y^j \right) dy = -g \int_0^b \left(\rho - \rho_{ok} \right) \left(\pi y \right)^j dy \qquad (4)$$

-to preserve enthalpy flow

$$\frac{d}{dx} \int_0^b \rho \Delta h u y^j dy = 0 \qquad (5)$$

-for export vertical upward mass flow

$$\frac{d}{dx} \int_0^b u \left(\rho - \rho_{ok} \right) \left(\pi y \right)^j dy = 0 \qquad (6)$$

A simple decision can be made as (5) of enthalpy is replaced by a linear dependence on the widening of the jet

$$b = cx \qquad (7)$$

In (4) on the right side is written the Archimedes buoyancy. The included symbols are as follows: u - jet velocity; y - transverse coordinate, ρ - current density, ρ_{ok} - density of the environment, Δh - enthalpy of the stream. The exponent j marks: at j = 0 -flat stream; j = 1 - axis jet. The coordinate x is directed vertically upwards.

There is a correlation between density and temperature:

$$\rho = \frac{p}{RT}, \qquad (8)$$

where p - pressure of the environment, R - gas constant, T - absolute temperature. Similarity to transverse distribution of the velocity and the density (temperature) are initiated [4] [13], where solving (4) and (6) leads to the parameters of the upward convective stream:

- the velocity of the upward stream

$$u_m = B_u^{"} D_0^{1/3} \Delta T_{пл}^{4/9} x^{-1/3} \qquad (9)$$

- the temperature difference

$$\Delta T_m = T_m - T_{env} = B_{\Delta T}^{"} D_0^{1/3} \Delta T^{8/9} x^{-5/3}, \qquad (10)$$

where D_0 - initial diameter of the heat source of fire (the burning car); $\Delta T_1 = T_{fl} - T_{env}$; $\bar{x} = \frac{x}{D_0}$; the constants B_u^* and $B_{\Delta T}^*$ have values $B_u^* = 0,222\left[m^3 K^{9/4}\right]$, $B_{\Delta T}^* = 0,71\left[m^{1/3} K^{9/8}\right]$.

These values correspond to the case at $\bar{x} = \frac{x}{D_0} \geq 3 \div 3,5$. When adopted fire size created from a burning car $D_0 = 0,5m$ and height $H = 3 \div 4,5m$, $\bar{x}$ of the garage will be always greater than the above values.

At the relatively short distance to the ceiling, the high power of fire (the accepted conditions are $Q = 1500W$ and $T = 600K$), the velocity and the temperature and the rising convective stream doesn't change significantly.

The initial velocity calculated by (3) is $u_0 = 8,2m/s$ and the time when the convective stream will reach the ceiling at different heights of the garage is given in Table 1.

Table 1

h, m	3	3,5	4	4,5
Δt	0,36	0,43	0,49	0,55

This means that less than $1s$ sprinklers over the burning car will be activated and extinguishing stream will flow over the burning car.

The expansion (increasing of thickness) of the jet in height can be determined by the expression:

$$\frac{db}{dx} = 0,22\frac{\rho_0 + \rho_{ок}}{2\rho_{ок}} \quad , \qquad (11)$$

respectively

$$b = \left[0,22\frac{\rho_0 + \rho_{ок}}{2\rho_{ок}}\right] \quad . \qquad (12)$$

The density of the jet in the opening section is defined by (8): at $R = 287J/kgK$, $T_0 = 600K$, $p = 10^5 Pa$ in which for ρ_0 is recived $\rho = 0,58kg/m^3$. The density of the environment is $\rho_{env} = 11,2kg/m^3$ at the same pressure and temperature $T_{env} = 293K$. At this density the widening of the jet in the present case is:

$$b = 0,163x \qquad (13)$$

For the different height in the garage the parameter b is given in Table 2.

Table 2

h, m	3	3,5	4	4,5
b_1, m	0,501	0,507	0,652	0,73
$b_{изт}$, m	0,651	0,77	7,74	1,98

The last row in Table 2 is given the extension of the isothermal jet $(T_0 \approx T_{env})$. Obviously a slight extension of non-isothermal convective flow comparing with the isothermal.

Reaching the ceiling vertical convective stream is transformed into radial jet (Fig. 4).

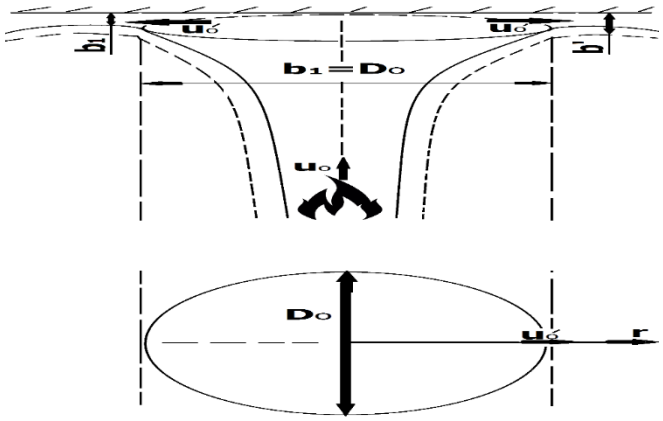

Fig. 4 – Sketch of radial jet

Due to the weak widening of the jet and the short distance to the ceiling the mass flow is not increased significantly because the temperature, density and relatively low mileage ceiling have not changed. The jet has retained its temperature, density and velocity accordig to Abramovich [1] may be determinated:

$$u_{\max} = 0,88u_0 \quad , \qquad (14)$$

where for $u_0 = 8,2m/s$ results as $u_{\max} = 7,2m/s$.

It is assumed that the starting size of the radial jet is equal to the obtained in Table 2- b_1, i.e. $D_0 = b_1$.

Width of the radial jet b_0 is determined by the flow rate Q at the intersection of the reverse flow. This flow rate is amount of initial flow rates Q_0 and increase its height due to suction of air from the environment. Ejecting fluid is considered proportional to the square of the relative increase in the width of the jet $\left(\frac{b_1 - b_0}{b_0}\right)^2$ and the distance x divided by the duration of the process Δt.

$$Q_{ej} \approx \left(\frac{b_1 - b_0}{b_0}\right)^2 \frac{x}{\Delta t}, m^3/s \qquad (15)$$

In this total flow rate is obtained as the sum of normal and ejecting flow rate:

$$Q = Q_0 + Q_{ej}, m^3/s \quad , \qquad (16)$$

where $Q_0 = u_0\frac{\pi d_n^2}{4}$, when $d_n = 0,5m$ and $u_0 = 8,m/s$ we have:

$$Q = Q_0 + Q_{ej} = u_0\frac{\pi d_n^2}{4} + \left(\frac{b_1 - b_0}{b_0}\right)^2 \frac{x}{\Delta t} \qquad (17)$$

The flow rate of the respective heights $x = 3;3,5;4;4,5m$ of the garage is shown in Fig. 5 where is defined by the relationship (12), respectively in case of a leak (13).

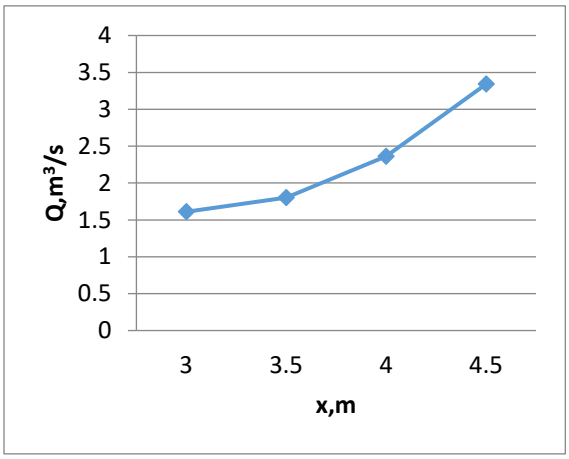

Fig. 5 – Change of the flow rate at different height of the garage

According to Figure 4 is assumed $D_0 = b_1$ that in already known flow rate (16) original width of the radial jet $b_0^{'}$ is calculated:

$$b_0^{'} = \frac{Q}{\pi D_0} \quad . \qquad (18)$$

The relationship $b_0(x) = f(x)$ is given in Figure 6.

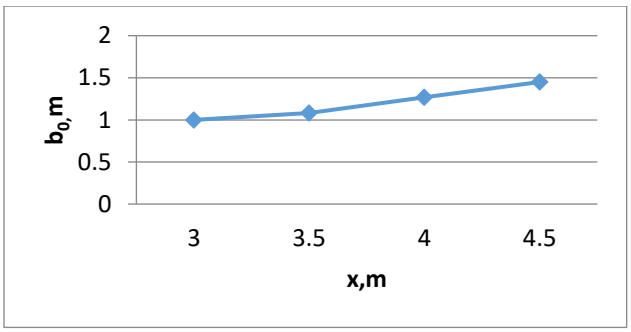

Fig. 6 – Change of the initial weight at different height of the garage

The cross-section of the radial jet, as a function of r is determined by the expression:

$$S = 2\pi r b^{'} \quad , \qquad (19)$$

where r is the current radius, $b^{'}$ is the width of the jet to the corresponding r.

Since the resulting stream is parietal and has parietal boundary layer which thickness is approximately $0,1b^{'}$, than (19) can be recast in the form:

$$S = 2,2rb^{'} \qquad (20)$$

The width $b^{'}$ is calculated by (12) and for the case (13) by replacing x with r then we have:

$$b^{'} = \left[0,22\frac{\rho_0 + \rho_{ok}}{2\rho_{ok}}\right] r = c^{'} r; c^{'} = 0,22\frac{\rho_o + \rho_{ok}}{2\rho_{ok}}, \qquad (21)$$

respectively $b^{'} = 0,163r$.

Substituted in (19) follows:

$$S = 2,2\pi c^{'} r^2 \quad . \qquad (22)$$

The average velocity of the ceiling of the room depending on r is obtained by:

$$u_m = \frac{Q}{S} \quad , \qquad (23)$$

respectively:

$$u_m = \frac{Q}{2,2\pi c^{'} r^2}, m/s \qquad (24)$$

Parking average velocity depending on r about the four heights is shown at Fig. 7. Fig. 8 shows the time to reach the appropriate distance.

$$\Delta t = \frac{r}{u_m}, s \qquad (25)$$

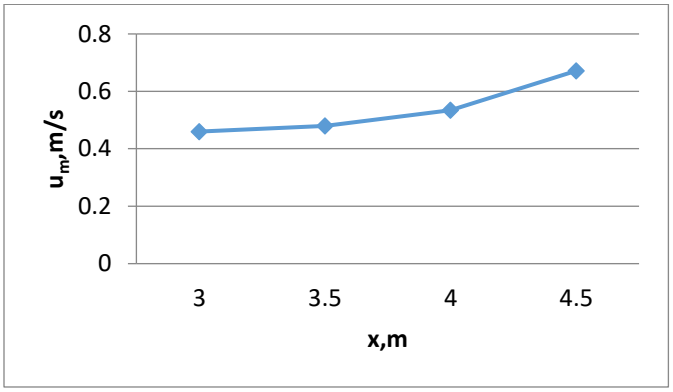

Fig. 7 - Average velocity at different height of garage

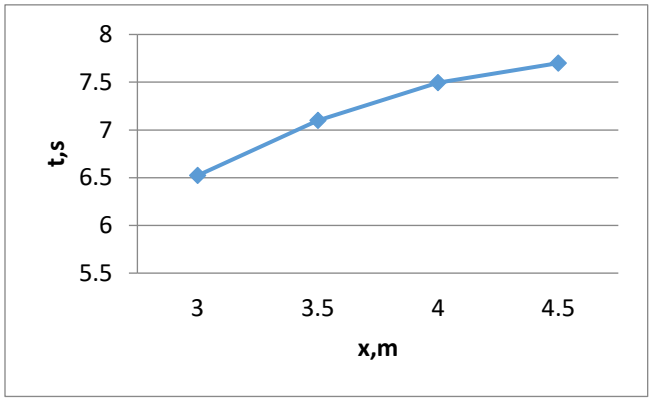

Fig. 8 Time to reach the sprinklers at different height of garage

This means that in the first two seconds all sprinklers at distance of 2 m away from the burning car will be triggered. For longer distances the remote sprinklers will act at a condition if the temperature of the burning car doesn't decrease too quickly. For maximum calculated time of 7,7 seconds could not be expected too much decrease of the temperature, which leads to the conclusion that the ceiling temperature will be much greater than the starting temperature of "fast" sprinklers so that at $t_p = 57^0 C$

or T = 330K will always remain less than the temperature of the wall jet which initial temperature is 600 K.

With the removal from the water curtain it is possible to turn on the other ceiling sprinklers which are in the range.

In the vicinity of the burning car to sprinkler curtain $l \le 2m$ will trigger 3 (to 5) fast sprinklers. At a longer distance it will trigger maximum of three quick sprinklers of water curtain plus the main ones over the burning car and eventually these which are lying in the range of $l = 4m$ ceiling sprinklers so that the number of activated sprinklers will increase [5].

To create a smokeless zone under a layer of smoke floating [6] it is designed and installed air exhaust systems for smoke and hot gases. An exhaust ventilation system for smoke and hot gases is a scheme of safety equipment designed to perform a positive role in spin fire. The smoke is drawn in the direction of the non carrier partition EI from of 2 m / s to 5 m / s velocity. Quoted above standard allowed velocity of 5 m / s, but it should be taken into consideration that this velocity would affect negatively and lead to the merging of streams of pure air.

From [6] the density of the thermal load in the premises for the storage of combustible materials according to their purpose, is determined the heat capacity of the prevailing materials. Ventilation systems to remove smoke and heat (VSRSH) have to reach its designed performance level within 60 seconds of receiving the command signal. Each VSRSH systems has to ensure receipt of sufficient fresh air that enters the room for the expense of the flue products.

4. Thermal impact

Heat transfer by convection and radiation is defined according to [5]. Thermal effects are expressed by the intensity of the heat flow $h_{nbt}, W/m^2$ to the surface of the element is determined taking into account the heat transfer by convection and radiation, such as:

$$h_{nbt} = h_{nbt,c} + h_{nbt,r}, W/m^2 \quad , \qquad (26)$$

where: heat transfer by convection $h_{nbt,c}$ is given by the relationship

$$h_{nbt,c} = \alpha_c \left(\theta_g - \theta_m\right), W/m^2 \qquad (27)$$

radiation heat transfer $h_{nbt,r}$ is given by the dependence:

$$h_{nbt,r} = \Phi \varepsilon_m \varepsilon_f \sigma \left[\left(\theta_1 r + 273\right)^2 - \left(\theta_m + 273\right)^4 \right], W/m^2 \quad (28)$$

Convection component of the intensity of the heat flow is determined by:

$$h_{nbt,t} = \alpha_c \left(\theta_g - \theta_m\right), W/m^2 \qquad (29)$$

where: α_c is the heat transfer coefficient by convection $\left[\frac{W}{m^2}K\right]$; θ_g is the gas temperature near the exposed fire element [^{0}C], θ_m is the surface temperature of the element [^{0}C]

The coefficient of heat transfer by convection α_c is determined by the nominal curves corresponding to "temperature-time". On indirectly heated surface elements the intensity of heat flow h_{nbt} is determined by the relationship (16) where $\alpha_c = 4\left[\frac{W}{m^2}K\right]$. The coefficient of heat transfer by convection has value $\alpha_c = 9\left[\frac{W}{m^2}K\right]$, considering that the effects of heat transfer by radiation are included. Radiating components of net heat flux per unit surface area is defined as:

$$h_{nbt,r} = \Phi \varepsilon_m \varepsilon_f \sigma \left[\left(\theta_1 r + 273\right)^2 - \left(\theta_m + 273\right)^4 \right], W/m^2 \quad (17)$$

where: Φ factor of configuration, ε_m emitting surface element, ε_f transmission of fire, $\sigma = 5,67.10^8\left[\frac{WK^4}{m^2}\right]$ constant of Stefan - Boltzmann, θ_r is the effective temperature of the radiation environment [^{0}C], θ_m is the surface temperature of the element [^{0}C]. Transmission of fire is taking equals $\varepsilon_f = 1$

5. Determination of the intensity of water curtain

Because of the difficulties associated with the construction of fire walls, experiments are conducted so that these areas to be reduced to such proportions that the primarily split up do not disturb of the process. In many cases, such as in buildings of first degree of fire resistance, as already noted, firewalls did not provide the detriment of fire safety. In connection with this arises a need of using such fire barriers that could effectively limit the spread of fire and at the same time would give some freedom for internal layout of buildings with different functions which is the case of the water curtain.

When calculating the water curtains, the assumption of the simultaneous satisfacties the following conditions:

Structural parts of the building to withstand the effects of fire on one side and the passage of flames or hot gases to be prevented by the transfer of heat to the unexposed side. The ability of the structural parts of the building to withstand the effects of fire on one side and prevent the transfer of heat from the exposed to the unexposed side. The transfer is limited so that it does not ignite neither unexposed surface, nor any other material in the immediate vicinity. The structural element is designed to serve as a barrier against the heat and to ensure the protection of people who are close to it.

The effectiveness of water curtains is assessed according to the amount absorbed heat.

It is known that the dependence of the growth temperature of the source of radiation of maximum energy is moving to the side of the shorter waves. This follows from the law of Vin:

$$\lambda_{\max,T} T = 0,29 = const \qquad (30)$$

where: λ is the wavelength in m, T - temperature at the surface of water curtain, ^{0}K.

Good enough inter-phase and heat absorbing surface has a water drops at size 200.10^{-6}. It is considered that in the best case, sprinklers spray water less then $1000\mu m$.

6. Required flow rate for air curtain

The current aim is decide on the following characteristics - density of the radiation heat flux is 1500 W/m^2; density of the irradiation protected material is 900 W/m^2; height of the hole -4 m; length of the hole - 6 m; pressure of water in sprinkler - 0.6 MPa (6 atm) and the radius of the water drops -0,0006 m ($600\mu m$).

Opacity density of the curtain:

$$\delta = \frac{2,303 \log q_{изл}}{q_{кр}} = 0,51 \quad (31)$$

Thickness of the curtain:

$$R = \frac{\delta}{c} = \frac{0,51}{2,8} = 0,182m \quad (32)$$

Flow rate of the water curtain for 1 m^2 of lateral surface is defined by:

$$Q = 0,666\mu\rho\frac{rR}{H}\sqrt{2gh} = 0,467\frac{l}{s}m^2 \quad (33)$$

For the whole surface of the water curtain:

$$Q^H = 11,2l/s \quad (34)$$

Water curtains are constructed so that the entire hole is irrigated with finely dispersed water. For this purpose sprinklers are placed over the hole and next to it. When they are placed at the top of the hole it is possible to remain unprotected areas through which is possible a penetration of hot gases to occur.

Sprinkler heads which are used to spray jets are spaced 0.5 m in protecting small holes and 1.25 - 1.5 m in protecting large holes. For sprinkler heads water curtains which are situated at a distance greater than 3 m, it is required head pressure of the water 4-6 mH_2O.

7. Conclusion

It is made an approximate fast and easy to implement analysis and calculation of water curtain, which replacing the fire walls with water curtains**.**

It is advisable that nozzles for spraying the water to be directed vertically upward to cover the entire space of the garage ceiling to the floor, thus help to keep heat away from the curtain.

These minimum values of pressure in their heads provided sufficiently stable curtain of water flows under the pressure of combustion products.

Water extinguishing systems can completely extinguish a fire or to locate it only on condition that they provide the necessary delivery rate extinguishing substances over the area of the fire.

The proposed firefighting system has some limitations in technical field: secure enough water for the sprinkler system; the entering into the garage cars must be with no Liquefied Petroleum Gas fuel (this condition is not easy to control); the fire extinguishing and prevention of the thermal radiation diffusion system ensure state of safety in the first 10 – 15 minutes from the occurrence beginning- after that time the firefighting department must act in this zone.

8. Additional contributions

It is developed a new fire extinguishing system for configuration and the fire spread to neighboring cars in the garage.

On the basis of an integral method it is made a mathematical model for calculating the extinguishing system and it is given also the respective fire extinguishing times.

It is developed a system for fire extinguished in one of the largest underground garages in Sofia using this conseptual design. The fire extinguishing system described in this article is implemented in fire extinguishing practice after its adoption by specialized scientific councils by authorized institutions (institutions).

ABSTRACT

Direction dependent antenna modulation (DAM), as a potential physical-layer security technique, is able to enhance the security of wireless communication systems by virtue of the capability of its direction-dependent signal modulation format transmission. In this paper, DAM using frequency diverse array (FDA) to produce the modulation is presented. By phase shifting each element, the desired amplitude and phase of each symbol can be produced during a particular transmission in a given range and angle position determined by the switching speed of the phase shifters. Accordingly, the proposed method offers a robust security for wireless transmission, as the transmitted signal can be purposely distorted in undesired positions, while preserving a clear constellation along pre-specified position(s). Numerical examples are given to illustrate the effectiveness of the proposed method.

1 Introduction

Directional antenna modulation (DAM) transmitter has been recently proposed [1, 2, 3] which has the capability of projecting deliberately distorted signals in all directions in free space other than the pre-specified secure communication directions. In doing so, only intended receivers located along this the secure communication direction are able to capture the signal leading to successful demodulation, while distorted signal emitted along undesired directions make signal demodulation by an eavesdropper a difficult task. Unlike classical cryptographic technique adopted at higher protocol layers to provide encryption, DAM technology does not share any keys, and secures data transmission directly at physical-layer which enables information theoretical security [4].

The basic concept of DAM is that it transmits a signal with a known modulation format to the desired receiver. The transmitted signal can be successfully recovered and demodulated by a receiver with a-prior modulation scheme [3]. For any directions distinct from the desired direction(s), the modulation format imposed on the transmitted signal will change. Thus making it difficult for the eavesdroppers to demodulate. In [2] a similar concept directional modulation (DM) was proposed which employs phased-array antenna. Other researches has proposed different DM transmitters such [5, 6, 7, 8]. Nevertheless, up to now, all published DAM transmitters employs phased-array. Although the DAM techniques using phased-array can steer the beam to an arbitrary direction, but the steering is independent of the range. This is because phased-array produces fixed steering direction at an angle for all the ranges [9].

In fact, the ability to control range dependent transmit energy distribution becomes an important requirement in many applications, for instance, range-dependent interference suppression [10, 11, 12] and directional communications [2]. To address the current needs,frequency diverse array (FDA) provides new opportunities to realize DAM. The FDA concepts was initially introduced in 2006 [13, 14]. They reported that the range-angle-time dependent far-field array pattern formation are the core attributes of the concept. FDA has been defined by [15] as an antenna aperture where the frequency of each antenna element is controlled independently to steer the main beam, depending on the time domain of each frequency component in the far-field. The most significant feature of FDA is that, it employs a small frequency increment across its antenna array elements. This frequency increment makes the array beam-pattern to change as a function of the range, angle and time [9, 13, 14].

In this contribution FDA elements is configured using DAM technique to achieve physical-layer security in range-angle dependent. The range and angle dependent DAM is achieved with 2-bit phase controls across the array elements for secure point-to-point communications. The main contributions can be summarized as: 2-bit phase shifters combi-

*Shaddrack Yaw Nusenu, Koforidua Technical University, Ghana, Email: nusenu2012gh@yahoo.com

https://dx.doi.org/10.25046/aj020331

nations is formulated for the FDA-based DAM to achieve directional range-angle dependent M-ary signal constellations. Compared with conventional phased-array based method, our proposed system achieves narrower demodulation beamwidth for the desired receiver.

In Section II of this paper, FDA DAM for secure point-to-point communications is presented. Numerical results are provided in Section III. Finally, this paper is concluded in Section IV.

2 FDA DAM for Secure Point-To-Point Communications

The FDA elements can be excited by either the same waveform or different waveforms. Here, the waveform radiated from each array element is assumed to be identical with a frequency offset of Δf Hz. Consider a uniform linear array (ULA) FDA composed of identical transmit elements with element spacing d. The radiated frequency of a standard FDA from the mth element is given as

$$f_m = f_0 + m\Delta f,\ m = 0, 1, \ldots, M-1 \tag{1}$$

where f_0 and Δf are the carrier frequency and frequency offset, respectively, and M is the number of array elements. The transmit beampattern can be represented by (2), [16] with the common phase Φ_0 given in (3), where c_0 denotes the speed of light and $r_m \approx r - md\sin\theta$, is the target slant range for the mth element and $d = \frac{c_0}{2f_0}$ denotes the element spacing. Equation (2) implies that FDA has range, angle and time dependent transmit beampattern.

To describe directional antenna modulation for M-ary transmission, a two-element FDA antenna with 2-bit phase control which provides four state units $\alpha_A = \alpha_B = [\alpha_1, \alpha_2, \alpha_3, \alpha_4]$ is configured for each FDA array element as shown in Figure 2. Each FDA element is controlled by the RF switch embedded to specifically select one of four possible phase state units. The four phase state units $[\alpha_1, \alpha_2, \alpha_3, \alpha_4]$ herein represents $\left[0^0, 90^0, 180^0, 270^0\right]$ phase shifters, respectively. The signals are modulated individually by controlling the element phase shifters with the RF switchers. In doing so, the array radiation pattern will change at each symbol in the digital modulation scheme. A desired constellation pattern can be produced along pre-specified range-angle positions. At the same time, constellation patterns generated for other positions will be distorted.

The array factor for this FDA based DAM transmitter configuration can be expressed as

$$AF(\theta, r) = \sum_{m=1}^{M} e^{j\alpha_{AB}(t)} \times e^{-j\left[(m-1)\frac{2\pi}{\lambda}d\sin\theta - \frac{2\pi\cdot\Delta f\cdot r}{c_0}\right]} \tag{4}$$

where $e^{j\alpha_{AB}(t)}$ is a time dependent phase shifters. From Figure 2, the directional modulated range and angle dependent signals of two-element configuration can be written as

$$AF(\theta, r) = e^{j\alpha_A(t)} + e^{j\left(\alpha_B(t) + \phi - \pi\sin\theta - \frac{2\pi\cdot\Delta f\cdot r}{c_0}\right)} \tag{5}$$

where e^{jA} and e^{jB}, denotes the phase shifters for each element A and B, respectively. The frequency offset Δf and phase offset ϕ are used here as a fixed value in a particular signal transmission. The Δf and ϕ can be adjusted when considering different signal transmissions. The phase shifter produce by the ϕ is assumed to be chosen between $-80°$ and $80°$. It is important to note that, the phase shifters provided for FDA elements are based on assumption and their corresponding values are shown in Table I.

It is worth noting that, because the FDA DAM technique depends on switching the antenna elements at each symbol rate, a series of high frequency single-pole multi-throw (SPMT) or single-pole-4-throw (SP4T) switches with nanosecond or sub-nanosecond speeds is required [17, 18].

3 Simulation Results and Analysis

3.1 Directional Modulated 16-ary Transmission Analysis

Analogous to [3], sixteen data points was calculated for the desired receiver at the range-angle position $(R, \theta) = (90\ km, 60°)$. The proposed transmitter system can modulates up to 16-ary unique signal constellation at the far field. When 16-ary transmission is considered, Figure 3 shows the 16-ary unique signal constellation at the intended receiver position $(R, \theta) = (90\ km, 60°)$. The modulated signal can be successfully decoded easily by the receiver. Note that in Figure 3, Δf = 70Hz and $\phi = 45°$ was adopted. These arbitrary values of both frequency offset Δf and phase offset ϕ was chosen to generate 16 unique points at the desired position.

Next, the effect of changing the arbitrary values of both frequency offset Δf and phase offset ϕ are examined. As shown in Figure 4, it can be noticed that for distinct values of frequency offset Δf and phase offset ϕ, such as Δf = 70Hz, $\phi = 45°$; Δf = 120Hz, $\phi = 65°$; Δf = 300Hz, $\phi = -75°$; respectively, generate different distributions of constellation points. It is important to note that Δf and ϕ may be considered as transmission signatures and can provide a series of different modulation format.

Figure 5 demonstrate how the proposed system provides additional level of security. As shown in Figure 5, the 16 unique data point generated corresponds to Δf = 70Hz, $\phi = 45°$ and range R = 90 km for distinct observation angles of $\theta = 60°$ (desired angle direction), $\theta = 40°$ and $\theta = 80°$, respectively. It can be observed that at angles distinct from the desired angle direction, new distributions of modulation format are achieved. This implies that apart from the desired angle direction, all other angle directions received signal constellation changes locations making demodulation by an eavesdropper very difficult.

Similarly, Figure 6 illustrate 16 unique constellations for distinct ranges such as R = 90 km (desired range position), R = 110 km and R = 150 km which corresponds to Δf = 70Hz, $\phi = 45°$ and $\theta = 60°$. It is noticed that at other range positions apart from the desired range position, the signal constellation have different distributions making it difficult for the eavesdroppers to intercept information.

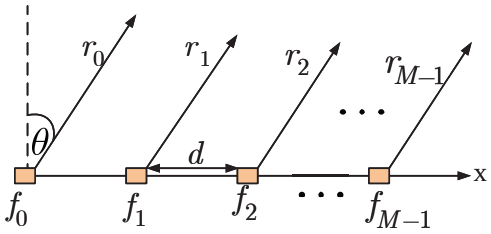

Figure 1: ULA FDA elements with frequency offset Δf.

$$AF(t;r,\theta)=\sum_{m=0}^{M-1}\exp\left\{-j2\pi f_m\left(t-\frac{r_m}{c_0}\right)\right\}\approx e^{-j\Phi_0\frac{\sin\left[M\pi\left(\Delta f t-\frac{\Delta f r}{c_0}+\frac{d f_0\sin\theta}{c_0}+\frac{\Delta f d\sin\theta}{c_0}\right)\right]}{\sin\left[\pi\left(\Delta f t-\frac{\Delta f r}{c_0}+\frac{d f_0\sin\theta}{c_0}+\frac{\Delta f d\sin\theta}{c_0}\right)\right]}} \tag{2}$$

$$\Phi_0=2\pi f_0(t-r/c_0)-\pi(M-1)\Delta f r/c_0+\pi(M-1)f_0 d\sin\theta/c_0+\pi(M-1)\Delta f d\sin\theta/c_0 \tag{3}$$

Table 1: Possible phase shifters combinations for FDA DAM using two-element configuration.

Number	FDA element $[\alpha_A \quad \alpha_B+\phi]$	Number	FDA element $[\alpha_A \quad \alpha_B+\phi]$
1	$[0^0 \quad 0^0]$	9	$[180^0 \quad 0^0]$
2	$[0^0 \quad 90^0]$	10	$[180^0 \quad 90^0]$
3	$[0^0 \quad 180^0]$	11	$[180^0 \quad 180^0]$
4	$[0^0 \quad 270^0]$	12	$[180^0 \quad 270^0]$
5	$[90^0 \quad 0^0]$	13	$[270^0 \quad 0^0]$
6	$[90^0 \quad 90^0]$	14	$[270^0 \quad 90^0]$
7	$[90^0 \quad 180^0]$	15	$[270^0 \quad 180^0]$
8	$[90^0 \quad 270^0]$	16	$[270^0 \quad 270^0]$

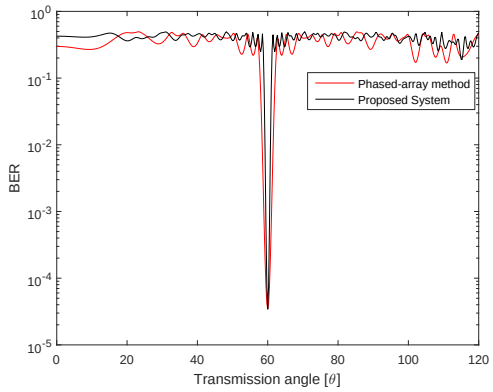

Figure 7: BER performance in angle dimension.

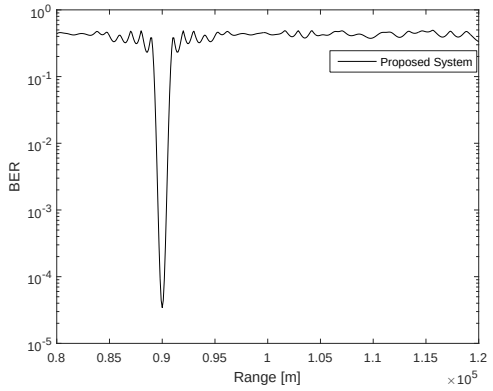

Figure 8: BER performance in range dimension.

3.2 Bit error rate (BER) Analysis

To demonstrate how the proposed system can be applied to a secure communication system, the simulated bit error rate (BER) of the system is calculated in angle and range dimensions using an algorithm based on minimum distance decoding [2].

The essence of Directional modulation technique is to achieve low BER in a narrow beamwidth toward the intended receiver and still enforce a high BER in other undesired directions. The resulting BERs are shown in Figure 7 and Figure 8 . It is fair to ensure that, all BERs are normalized until they are the same at the desired position. In this fashion, the security in undesired directions can be compared while they have the same performance in the intended direction.

In angle dimension, the proposed system achieves a lower BER in a narrow beamwidth with a relatively constant high BER in other directions than phased-array based method. In range dimension as shown in Figure 8, the phased-array-based method has no range resolution capability. In contrast, the proposed system still has good BER performance in the range dimension due to the frequency offsets Δf. These results confirm that, the proposed method achieves good security performance in both range and angle dimensions, not just in the angle dimension as the phased-array-based method and thus yields the worst security performance.

4 Conclusion

This paper has presented a directional antenna modulation scheme using a two-element FDA antenna. The directional manipulation of the constellation points is possible because the signals are modulated at antenna-level with phase shifters changing in each symbol transmission. The proposed system achieves both range and angle dependent DAM for secure 16-ary transmitted symbols for wireless communications. The effectiveness of the proposed system is validated with the aid of constellation diagrams and BER performances. Compared with the phased-array-based DAM method, which scrambles the signal constellations only in undesired angles, the proposed scheme scrambles the signal constellation in both range and angle dimensions. Future work will includes the design of genetic algorithm for phase shifters to improve the security performance.

Conflict of Interest The author declare no conflict of interest.

Acknowledgment The author would like to thank Respected Professor Wen-Qin Wang (Senior Member - IEEE) of UESTC for his great contributions, support and encouragement.

ABSTRACT

Breast cancer is one of the most common cancers among female diseases all over the world. Early diagnosis and treatment is particularly important in reducing the mortality rate. This research is focused on the prevention of breast cancer, therefore it is important to detect micro-calcifications (MCs) which are a sign of early stage breast cancer. Micro-calcifications are tiny deposits of calcium which are visible on mammograms as they present as tiny white spots. A computer-aided diagnosis system (CAD) is created with the development of computer technology that way radiologists are aided improving their diagnostics while using CAD as a second reader. We are aiming to classify into BIRADS 2, 3 and 4 which are the stages when the cancer can be prevented and a fourth category called No lesion which are veins and tissue that our high pass Gaussian filter detects. This research focuses on classification using ANN (Artificial Neural Network). Experimenting with the categories to classify into using ANN, the results were the following: into the four mentioned before an overall accuracy of 71% was obtained, then joining categories BIRADS 2 and 3 into one and classifying into 3 categories gave an 80% of accuracy. Joining this two categories was the result of analizing the ROC curve and observation of the ROI images of the MCs as the regions measured are very alike in this two categories and variation is that MCs are more present in BIRADS 3 than in BIRADS 2. Data matrix was reduced using PCA (Principal Component Analysis) but it did not gave better results so it was discarded as the ANN accuracy to classify was reduced to a 69.8%.

1. Introduction

This paper is an extension of work originally presented in *IEEE CACIDI 2016 - IEEE Conference on Computer Sciences* [1]. Breast cancer is one of the most common cancers among female diseases all over the world. Early diagnosis and treatment is particularly important in reducing the mortality rate. Currently, the most effective method for early detection of breast cancer is mammography [2]. This research is focused on the prevention of breast cancer, therefore it is important to detect micro-calcifications which are a sign of early stage breast cancer. Micro-calcifications are tiny deposits of calcium which are visible on mammograms as they present as tiny white spots [3]. As micro-calcifications are barely visible in a mammogram it is frequent radiologists missing them in an evaluating screening [2]. A computer-aided diagnosis system (CAD) is created with the development of computer technology, the advances of digital image processing, pattern recognition and artificial intelligence, radiologists are aided improving their diagnostics and using CAD as a second reader [2][3].

The interpretation of micro-calcifications is very difficult due to their fuzzy nature, low contrast and low distinguishability from their surroundings. They are very small with various sizes, shapes, and distributions. To deal with said problems, it is very important to suppress the noise, to enhance the contrast between the region of interest (ROI) and background in the image [2]. Particularly in this research the image database used is of a good quality and high resolution so the finding of micro-calcification clusters (MCCs) it is not as problematic as in previous works that had worked with for example a low quality image free database as the MIAS (Mammographic Image Analysis Society) [4,5,6,7,8,9].

Image database used in this research is acquired from the Medical Specialized Unit on Detection and Diagnosis of Breast Cancer (UNEME DEDICAM) in Querétaro, Mexico. This dataset includes its diagnosis into the BIRADS system (Breast Imaging Reporting and Data System) which was published by the American College of Radiology in an effort to standardize mammography reports [10]. This classification system aims to have a standard way of communicating the results of a mammogram, because it allows radiologists to use the same words and terms. In this research we classify into categories in which the advance of cancer can be prevented, that is BIRADS 2, 3 and 4, we added a fourth category called *No Lesion*, which includes false positives like veins, tissue, and what is detected by the filter that is not a MCC.

Although the images worked with are of good image resolution there was the need to enhance the MCCs so we could threshold the ROI images with accuracy and use those to measure the pixels with morphological descriptors. The approaches for enhancement of MCCs, including various filtering methods, global and local thresholding methods, histogram equalization, mathematical morphology transformations, statistic methods, wavelet transformations, neural networks, stochastic models, fractal models, high-order statistic methods, fuzzy logic approaches, etc. [2], but as the Autonomous University of Querétaro has been researching on detection of MCCs as in [11, 8], this research was improved thanks to [8] because from that a filter bank was made in which a ROI was given many filters were applied to it, and the script gave many enhanced images of the ROI, those images were analyzed and the proper filter for our image database was found, which is a High Pass Gaussian Filter.

Once images were binarized the MCCs and the lesions in ROIs were a region of pixels that were measured by morphological descriptors which are a set of numbers that describe a given shape. The regions may be described based on the boundaries of an object or be described based on regions properties [12]. The descriptors used in this study to quantify the binarized images obtained from the ROIs were *area, perimeter, centroid, Euler number, major axis length, minor axis length* and *orientation*. A data matrix was constructed of the measurements of the regions of the ROIs selected from the mammograms. This matrix was used to feed an Artificial Neural Network (ANN) for training, testing and validation of ROIs with anomalies.

In this research a feed forward neural network (FFNN) was used as ANN is a machine learning technique that has been widely used in different fields as they are good at recognizing patterns. It has been used in [4,13,14,15] to classify MCCs into benign and malign but not to classify into BIRADS categories.

2. Previous researches

In this section, we review some researches that have been done on CAD in recent years, main focus in the classification stage. Our direct previous research is [4] in 2014, thesis that classify into Le Gal using ANN as classifier. In this the categories were benign or malignant classification according to Le Gal with a sensitivity greater than 93.26%, the disadvantage of having a high sensitivity in this classification has an impact on the specificity. While many researches regarding classification of MCCs have been done, using BIRADS to classify is not very common, most common is being or malignant.

Few times classification into BIRADS was done, most recent research about classifying into BIRADS is [16], using Fuzzy Logic they introduced morphological descriptors as linguistic variables, the images were analyzed by a group of doctors and those evaluations were introduced to the fuzzy algorithm, an accuracy of 76.67% to 83.34%, said accuracy was affected by discrepancies of radiologists in evaluating the MCCs.

In 2005 a study [15] comparing several machine learning methods —support vector machine (SVM), kernel Fisher discriminant (KFD), relevance vector machine (RVM)— for classification was conducted, demonstrated that the kernel based methods (i.e., SVM, KFD, and RVM) yielded the best performance, outperforming that of Feed Forward Neural Network (FFNN), again this time the classification was into Malignant and Benign, and SVM was used as a binary classifier, outperforming FFNN, it is not useful for our objective of classifying into more that those two categories.

Another CAD system achieving a really good 91.4% and 90.1% classification accuracy using SVM as classifier was Görgel, Sertbas, and Uçan [6] classifying again into benign and malignant.

Most recent research [7] from 2015 that used an ANN as classifier where a ROI image is classified as normal or abnormal (benign or malignant) using a Probabilistic neural network (PNN) shows that their proposed model performance is good at achieving high sensitivity of 97.27% and specificity of 94.38%.

[9] classifies detected MCCs into benign and malignant cases, eight features such as fractal dimension variations, entropy and wavelet coefficients were proposed to classify both malignant and benign cancerous zones, those are identified and utilized in radial basis function neural network.

FFNN is able to classify into more than 2 categories and even if fuzzy can classify into many categories it fails in accuracy because of subjective diagnosis. In the option of using SVM we have not found the use of it to classify into more than two categories, it is an area we want to experiment but SVM as multiclass classifier.

3. Methodology

3.1. BIRADS

The BIRADS is a quality control system, its daily use implies an evaluation in numerical categories of a mammogram, assigned by the radiologist after interpreting the mammography consists [17]. This allows for a consistent and concise radiographic report and can be understood by multiple doctors or hospital centers. It consists of 7 different classes according to their staging, category 6 was added in the 4th edition of the mammography atlas [18].

Category 0: Insufficient X-ray, need an additional evaluation with another study, it is not possible to determine some pathology.

Category 1: Negative mammography to malignancy, no lymph nodes or calcifications. 0% chance of cancer.

Category 2: Mammography negative to malignancy, but with benign findings (intramammary ganglia, benign calcifications, etc). 0% chance of cancer.

Category 3: Result with probable benignity, but that requires control to 6 months. It may have circumscribed nodules or a small group of rounded and punctate calcifications. 2.24% chance of cancer.

Category 4: Doubtful result of malignancy. It requires histopathological confirmation. It consists of 3 degrees according to its percentage of malignancy ranging from 3 to 94%

A. Low suspicion of malignancy. 3 to 49%

B. Intermediate suspicion of malignancy. 50 to 89%

C. Moderate suspicion of malignancy. 90 to 94%

Category 5: High suspicion of malignancy. Requires biopsy to confirm diagnosis. > 95% chance of malignancy.

Category 6: Malignancy ascertained by biopsy.

In this research, we focus to classify into categories were cancer can be prevented, so the categories to classify our findings are BIRADS 2, 3 and 4 and an extra category called *No Lesion,* which is of veins and tissue that the high pass Gaussian filter detects of the ROIs.

Figure 1 shows examples of samples ROIs used for each category. ROIs were manually obtained from the mammograms.

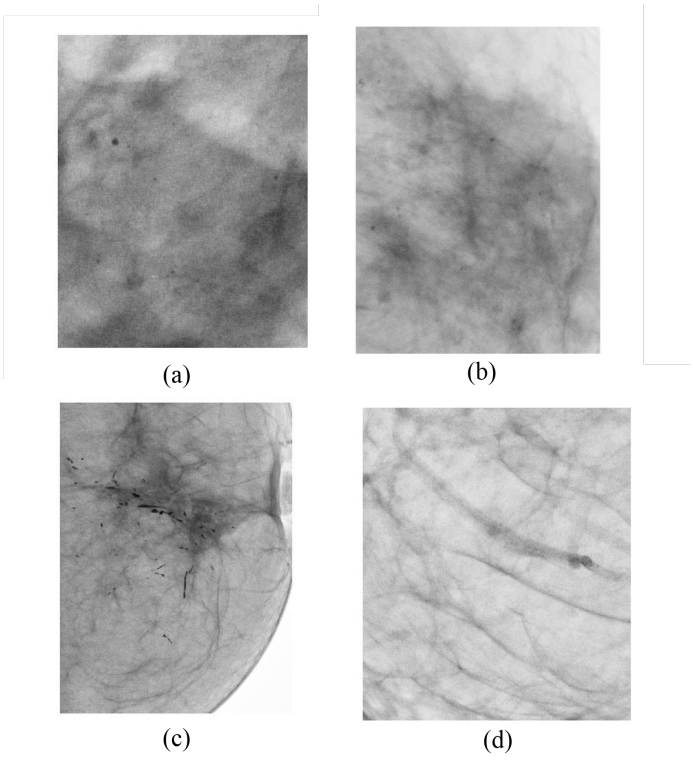

Figure 1. Samples of ROIs of each category taken from the image database from UNEME-DEDICAM: a. BIRADS 2 b. BIRADS 3 c. BIRADS 4 d. No Lesion

3.2. Image Database

Image dataset consists of mammograms of 10 patients for each BIRADS category, 2, 3 and 4. Each patient has 4 mammograms of respective cranial–caudal (CC) view and medio lateral oblique view (MLO) for each breast. For each category 70% of the mammograms were taken for the training stage of the ANN that is mammograms of 7 patients for each category were going to be used to obtain ROIs.

Images format is DICOM (Digital Imaging and Communications in Medicine). DICOM is a standard used worldwide to store, exchange, and transmit medical images. Incorporates standards for imaging modalities such as radiography, ultrasonography, computed tomography, magnetic resonance imaging, and radiation therapy. It also includes protocols for image exchange (e.g., via portable media such as DVDs), image compression, 3-D visualization, image presentation, and results reporting [19].

From the selected mammograms ROIs were manually selected, as seen in Figure 2 meaning areas where MCCs were found in the image according to the respective diagnosis given from UNEME-DEDICAM for each patient study. Display resolution of the images is 3540×4740 pixels.

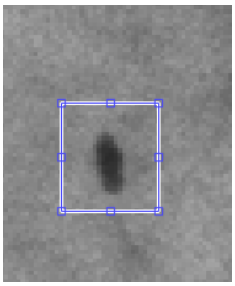

Figure 2. Selecting a micro calcification manually.

3.3. Image Enhancement

First a complement of the grayscale ROI image is applied so that black and white pixels are reversed, and MCCs that were originally black pixels are now white pixels, this done in MATLAB. A filter bank script made using MATLAB environment is used to enhance the ROIs previously extracted, said script is a modified version of what research [8] did to detect MCCs. Script consist of applying three filters to the ROI images, Ideal and Gaussian.

The script uses the High Pass Filters which attenuates low frequencies while keeping high frequencies unchanged. Since the high frequencies correspond in the images to sudden changes of density, this type of filters is used, because among other advantages, it offers improvements in the detection of borders in the space domain, since these contain many of these frequencies. It reinforces the contrasts found in the image. This is important as it is possible to detect by sharpening those areas where MCCs are.

Mathematical description of what the high pass Ideal filter does in the script is described by the following transfer function

$$H(u,v) = \begin{cases} 0 \; if \; D(u,v) \leq D_0 \\ 1 \; if \; D(u,v) > D_0 \end{cases} \quad (1)$$

High pass Gaussian filter transfer function is

$$H(u,v) = e^{-D^2(u,v)/2{D_0}^2} \quad (2)$$

Where D_0 is a specific non negative number which represents the frequency cut-off of the filter and $D(u, v)$ is the distance from point (u, v) to the center of the filter. The script test with different values of D_0.

The script gives ROI images in a loop so it is stopped manually to the point where there are around 1000 images and visually select the best ROI image with the MCCs highlighted the best so when the threshold is to be applied the binary mask obtained reflects accurate the region. In this case the configuration to enhance the

MCCs was a high pass Gaussian filter with a D_0 value of 0.0021 as seen in Figure 3 for each category.

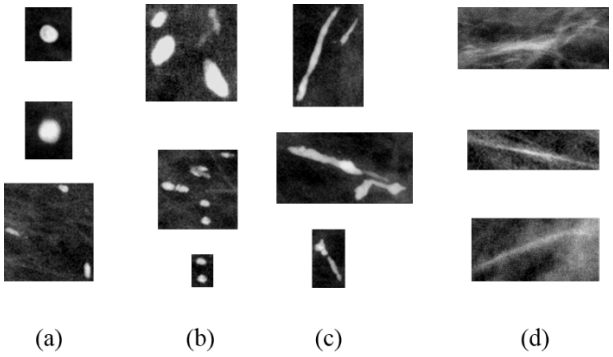

Figure 3. Samples of ROIs with a high pass Gaussian filter with a D0 value of 0.0021 of each category taken from the image database from UNEME-DEDICAM: a. BIRADS 2 b. BIRADS 3 c. BIRADS 4 d. No Lesion

Once the ROI images are enhanced a threshold is applied and a binary mask is obtained with the region of the MCCs ready to be measured. In Figure 4 there a binary mask of a micro calcification (MC).

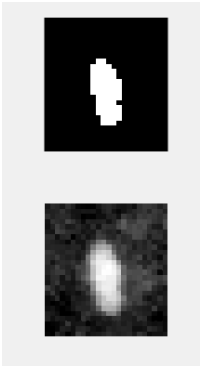

Figure 4. Above, binary image of the ROI. Below ROI with the Gaussian filter applied to the ROI of the BIRADS 4 image.

3.4. Data Matrix

To construct a data matrix it is necessary to measure the ROI images that is to measure the region of white pixels in the binary mask, which will give measurements of the MC region. To measure it, it is used *regionprops* from MATLAB. Region properties selected in this research are:

Area: is the actual scalar number of pixels in the region.

Perimeter: is a scalar that specifies the distance around the boundary of the region.

Centroid: is the center of mass region, in this there are two values, centroid in x and centroid in y.

Equivalent diameter: is the diameter of a circle having the same area with the region.

Euler number: is the number of objects in the region minus the number of holes in those objects.

Major axis length: is the length (in pixels) of the major axis of the ellipse that has the same second moments as the region

Minor axis length: is the length (in pixels) of the minor axis of the ellipse that has the same second moments as the region.

Eccentricity: belongs to the ellipse that has the same second moments as the region, and it is the ratio of the distance between the foci of the ellipse and its major axis length.

Orientation: means the angle (in degrees) between the x-axis and the major axis of the ellipse that has the same second moments as the region [12].

In total 10 features are used to measure MCCs and create a data matrix. Gathering measurements from all the mammograms a 1736 × 10 data matrix. This matrix is standardized, that is take all of the columns of the matrix and standardize / normalize the data so that each data sample exhibits zero mean and unit variance. This means that after this transform, the mean value of any column in this matrix would be 0 and the variance would be 1. This is a very standard method for normalizing values in statistical analysis, machine learning, and computer vision. Following formula describes the calculation of a raw data *x* into a standard data:

$$z = \frac{x - \mu}{\sigma} \tag{3}$$

Where μ is the mean of the population and σ is the standard deviation of the population [20].

Another property used is *Bounding box* that returns the smallest rectangle containing the region and it is used to mark the MCs. Figure 5 shows red boxes marking the MCs it is done using the bounding box property.

Figure 5. Bounding box marking MCs found in the binary mask of a ROI image from a BIRADS 4 mammogram.

3.5. Classification

An ANN is created with the MATLAB toolbox for neural networks to classify the findings in the ROIs in categories BIRADS 2, 3, 4 and *No lesion*, using the pattern recognition tool.

Neural Network Toolbox™ provides algorithms, functions, and apps to create, train, visualize, and simulate neural networks. You can perform classification, regression, clustering, dimensionality reduction, time-series forecasting, and dynamic system modeling and control [12].

In the Neural Pattern Recognition app data to classify is selected, then a network is created. The network created is a two-layer feed-forward with sigmoid hidden and softmax output neurons, can classify vectors arbitrarily well, given enough neurons in its hidden layer. The network will be trained with

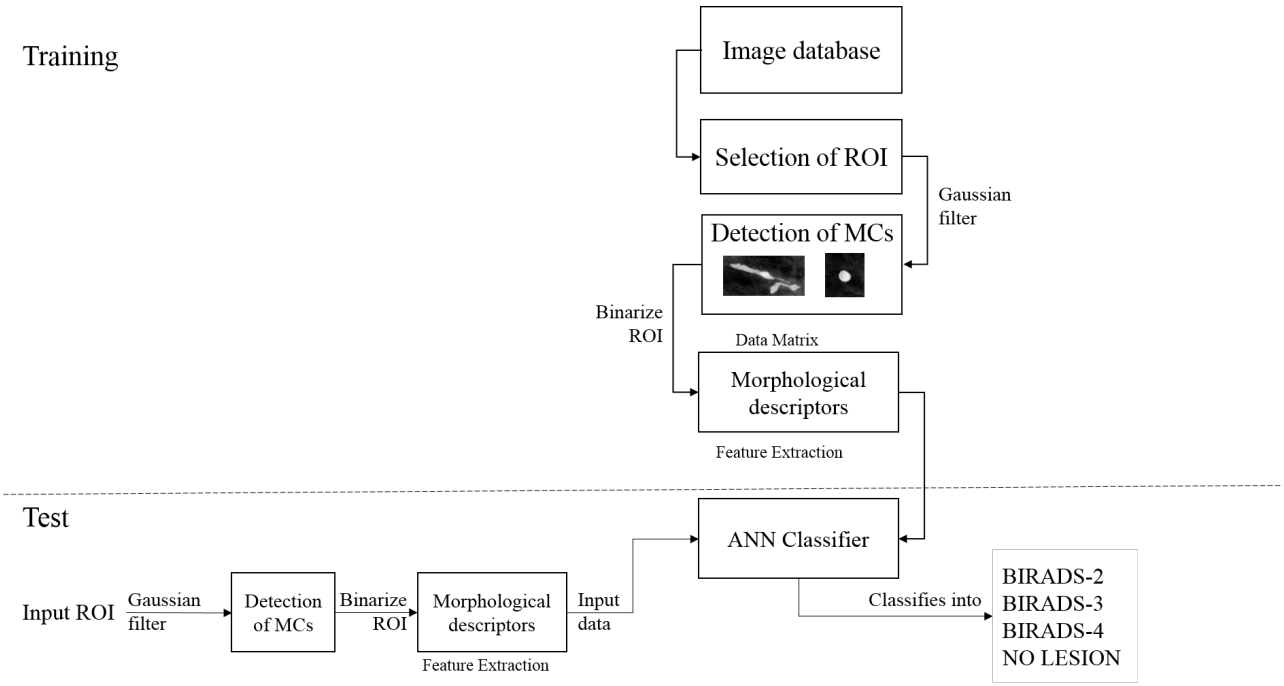

Figure 6. Methodology followed in this research.

scaled conjugate gradient back propagation, in this research it is used ten neurons in its hidden layers.

Next step is to select the data that is the matrix of 1736 × 10 as input data and as output data is a 1736 × 4 matrix with 1's indicating to which category the vector belongs. Each column represents a category, being first column the BIRADS 2 and last column No lesion category. If the data vector belongs to category BIRADS 2 then 1 is in that cell in column 1 and the rest is a zero.

In the next stage the Validation and test data, is where data is distributed into Training, Validation and Testing. In here our 1736 sample are randomly divided. For training 70% of the samples, these are presented to the network during training and the network is adjusted to its error. For validation 15% these samples are used to measure network generalization and to halt training when generalization stops improving. And last 15% for testing, these samples have no effect on training and so provide an independent measure of network performance during and after training. Finally our ANN looks as seen in Figure 7.

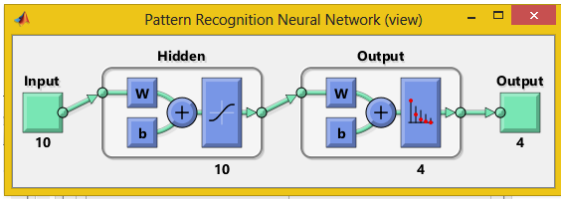

Figure 7. ANN used of 10 input of each morphological descriptor and 4 outputs for each category to classify into. 10 hidden neurons.

Last part is to measure the performance of the ANN. Tools given are the confusion matrices for training, testing and validation and the plot of the Receiver Operating Characteristic (ROC) curve.

The overall methodology used in this research is shown in the diagram in Figure 6. In Figure 8 it is shown the main flow chart of the code used.

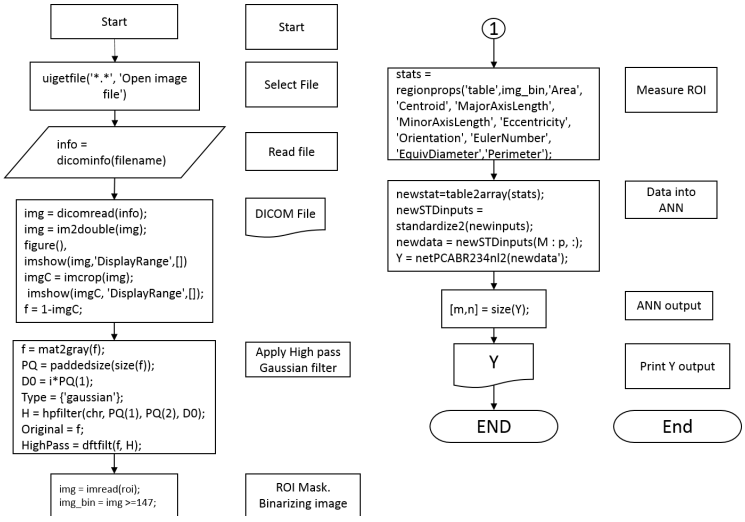

Figure 8. Main flow chart of the code used.

4. Experimental results

In the confusion matrices the green squares are the correct responses and in the red squares are the incorrect responses. The lower right blue squares illustrate the overall accuracies. In this case a 71% of accuracy in general was obtained, but the Test confusion matrix is the most important as the ANN is classifying samples it didn't know and a 75.8% was obtained, see Figure 9.

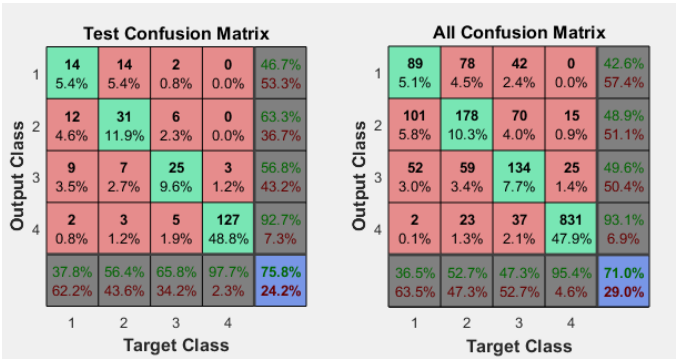

Figure 9. Confusion matrices obtaining a 75.8% in testing and an overall 71%

In the plot of the ROC curve the colored lines in each axis represent the ROC curves. The ROC curve is a plot of the true positive rate (sensitivity) versus the false positive rate (1 - specificity) as the threshold is varied. Sensitivity measures the proportion of positives that are correctly identified as such [21] and the false positive rate is the proportion of all negatives that still yield positive test outcomes, i.e., the conditional probability of a positive test result given an event that was not present. A perfect test would show points in the upper-left corner, with 100% sensitivity and 100% specificity [12]. ROC obtained are seen in Figure 10.

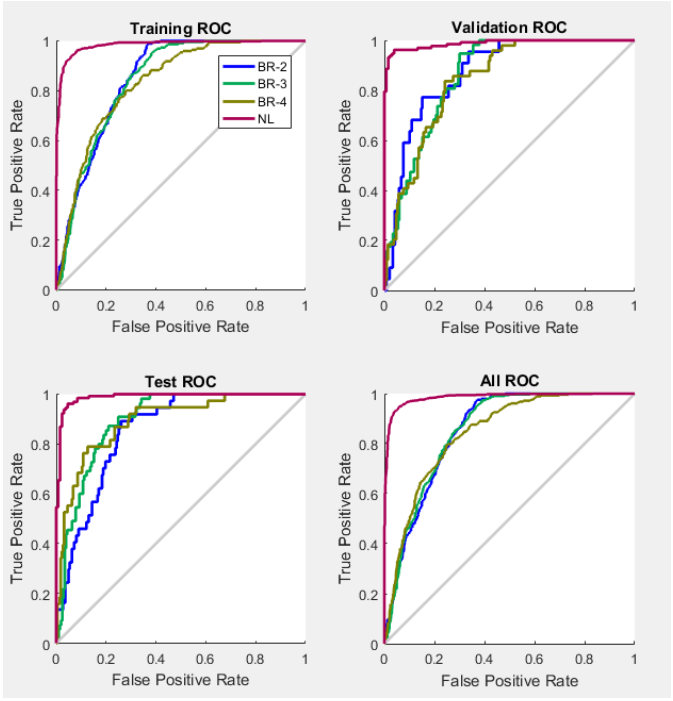

Figure 10. In the ROC plots it is observed that the No lesion category has the best performance, BIRADS 2 and 3 are having trouble to differentiate from each other.

To obtain a better performance of the ANN, it is proposed to apply Principal Component Analysis (PCA) to the data matrix. PCA is a variable reduction technique. It is used when variables are highly correlated. It reduces the number of observed variables to a smaller number of principal components which account for most of the variance of the observed variables. It is a large sample procedure [22]. So this way we expected to discard a region property of the original 10 selected. PCA is applied to the data matrix and outputs 6 descriptors as principal components, those 6 descriptors are area, centroid in x, centroid in y, major axis length, minor axis length and eccentricity. A second network is generated but the overall accuracy gets reduced to a 69.8%, as seen in Figure 11, so using less than the 10 initial descriptors is reducing accuracy so using PCA is discarded.

While experimenting it is notable that the network is having trouble to differentiate the categories BIRADS 2 and 3, as the MCCs in those are very alike in shape, but the difference between them is that the presence of MCCs increases in BIRADS 3. So it is proposed to join this two categories into one and then a new network is generated to train into 3 categories but using the 10 initial descriptors.

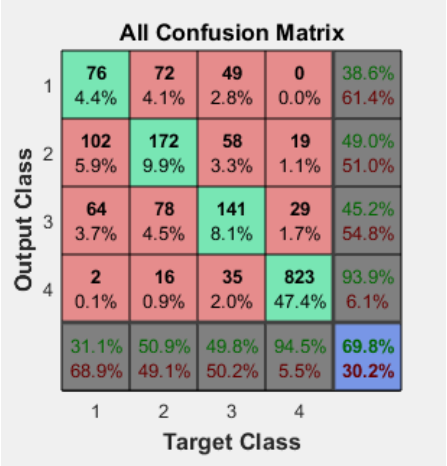

Figure 11. ANN performances gets reduced when only using the first 6 descriptors.

Following the last proposal now the ANN is classifying into 3 categories instead of 4, the overall accuracy is 80% meaning that our previous observation of BIRADS 2 and 3 being alike is correct. In Figure 12 it is observed that the ANN performance improved.

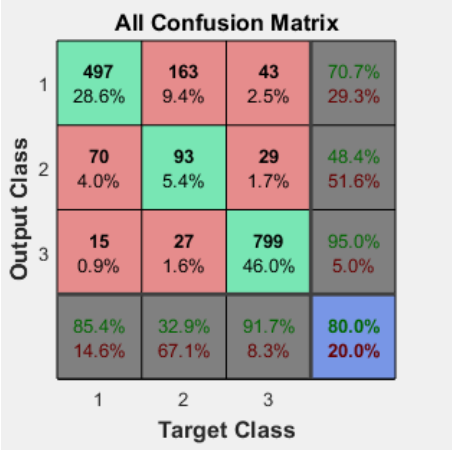

Figure 12. Joining alike categories BIRADS 2 and 3 gave an improvement.

In the experimentation stage the hidden neurons were added up to 15 but it did not improved the performance of the ANN, reducing the hidden neurons reduced the percentage of the overall accuracy of the ANN for a very tiny 1%. So modifying the default 10 hidden neurons is discarded.

5. Comparison with state-of-art

As we discussed in the section *Previous researches,* most of the related researches focus in classifying into two categories, malignant and benignant. As this research focus in the classification method and the system to classify the cancerous findings into BIRADS, our research will be compared against [16] from 2015 and [23] from 2000 which are the more alike as they classify into BIRADS.

First the research conducted by [23] presented an automatic detection and classification of MCCs. A block region growing and K-means clustering-based thresholding is employed to extract the breast region. Then, a blanket method finds and locates the suspicious areas of possible MCCs clusters. The MCCs detection module is developed to automatically extract the MCCs from the ROIs. Among the image processing that are involved in this module are gradient enhancement, contrast enhancement and Gaussian filters. The segmentation of MCCs from the background is done using entropy-based thresholding. Shape cognitron which is based on a neural network-like shape recognition systems is introduced as a classification technique of MCCs. The system achieved as high as 95% classification rate with 93% detection rate [24]. It is important to mention that this particular research has a processing time of 72 seconds as it is completely automatic and it is a more complex methodology, our research is simple, once a ROI is manually selected, goes into a Gaussian filter for denoise, then a binary threshold is applied, regions are measured and finally the data gets classified with a FFNN, all this takes 0.77 seconds of CPU processing time. We obtained an 80% of accuracy, lower against the 95% of [23], it is important to mention they used, 104 cases while we used 120 mammograms. Another difference in methods are that we measure ROIs using morphological descriptors. About the classification technique used they obtained a better accuracy percentage using a neural network-like classifier in our case we are using a more intelligent machine learning technique that is a FFNN that can be tuned every time it is trained and it can learn to be effective. Our research is at disadvantage as it is less accurate, but our methodology is not as complex, and therefore it is faster and barely consume CPU resources.

Next comparing against [16] a computer-aided diagnosis tool for automatic BI-RADS categorization of breast lesions is developed. The user provides parameters such as contour, shape and density and the system gives a suggestion about the BI-RADS classification. Initially, values of malignancy were defined for each image descriptor, according to the BI- RADS standard. When analyzing contour, for example, this method considers the matching of features and linguistic variables. Next, it is created the fuzzy inference system. The generation of membership functions was carried out by the Fuzzy Omega algorithm, which is based on the statistical analysis of the dataset. This algorithm maps the distribution of different classes in a set. Images were analyzed by a group of physicians and the resulting evaluations were submitted to the Fuzzy Omega algorithm. The results were compared, achieving an accuracy of 76.67% for nodules and 83.34%. In this case we are having and ambiguous characterization of the MCCs as it depends of what the user considers is seeing in the mammograms as it is relative to what the user defines as very or little malignancy, as it uses linguistic variables. Contrary to our research where we are actually measuring and obtaining data from the region of the MCC. This data feeds the ANN and helps to obtain an automated classifier.

According to [15] were many classifiers were compared the best is SVM, when classifying binary, next step in our research is explore Multiclass SVM. The advantage of using FFNN is the possibility of classify into more than two categories, therefore achieving to classify into BIRADS. Disadvantage is that our approach is too simple and fails in accuracy, implementing the mesuremnt of MCCs as a cluster could be an improvement for our method as in [23] this approach gave better results than our measuring single MCCs.

6. Conclusions

With the ROC plot it is observed that the best category to classify was the No lesion, from the other 3, meaning that our ANN is accurately discerning from a non-lesion and a lesion or MC. Also the initial 10 descriptors are the better choice and reducing them did not gave a better performance so in future works more descriptors will be added. We are already experimenting with Multiclass SVM as seen in surveys that SVM is better than ANN but as a binary classifier, in our case we'll classify into more categories.

stator, translator

ABSTRACT

The paper describes the fundamentals of magnetic levitation technology. A general background of the magnetic levitation is given in this article, including applications of this technology, several comparisons with other types of technologies, the real stage of its development, etc. Further in the paper, the two main types of magnetically levitated systems are compared within their subgroups, on characteristics and specifications basis. A comparison between the AC and DC power supplies for these systems, including the pros and cons of each type, is also provided in the paper.

1. Introduction

The up and coming era of lithography requires a high exactness organize, which is perfect with a high vacuum condition and for this, a magnetic levitation stage with two or more degrees-of-freedom is considered state-of-the-art technology innovation. Nowadays the size of wafer is moving up to 12 inch to enhance the efficiency of a batch process. Thusly, a high-resolution process and a large operating range simultaneously with the application into a super-clean condition are the prerequisites for the related smaller scale actuators. The non-contact characteristic of magnetic levitation technology (MAGLEV) empowers high accuracy positioning as well as no particle generation. The assembling procedure of a current semiconductor IC, forces exceptionally extreme requirements on the preparing exactness as well as the workplace. However, the heat is inevitably generated, while using electromagnetic actuators for levitation, which deforms the structures and degrades accuracy of the stage, and though a gravity compensator is required.

Between the parts with relative motion of the new sort of wafer transporters, spoke to for instance by belt transporters or articulated robots, there are mechanical contacts. For the most part, to limit and diminish the friction and enhance smooth operation, lubricants (oils) are used in the contact regions. In any case, because of the rubbing activity, there are constantly created a lot of tiny solid particles which are mainly absorbed by the lubricant. During the production process, it can happen that some particles can still flee the wafer transporter. Eventually, a portion of the particles will drop back onto the surface of wafers, damaging the fragile and newly manufactured integrated circuit (IC) device.

A fully operational system with magnetic levitation technology is strongly required to have the following characteristics:

- Gravity compensation with no power consumption
- Large and homogenous force density
- Zero stiffness between the translator and stator part
- Position-independent dynamic force
- Enough workspace for operation in all directions

In the nowadays microelectronic industry, the wafer transporter is ranked the number one in the list of particle source extrinsic to the fabrication process. The presence of lubricant in the contact regions has a negative impact to the process cleanness and this results from the volatility of lubricant. The surface properties are strongly affected by the migration and the diffusion of the gaseous elements into the surface of wafers.

An answer can be that the rate of evaporation is enhanced by the application of a vacuum environment, since the undesirable gaseous elements are evaporated to the processing environment.

[*]Corresponding Author: Florian Puci, Department of Microelectronics, FEE CTU in Prague, 166 27, Czech Republic, Contact No: +420734235015 | Email: puciflor@fel.cvut.cz

Obviously, reduction or if possible total elimination of the contact between relatively moving components, is the most ideal approach to eliminate wafer transport contamination. In this way, a particle-free and oil-free environment can be obtained and consequently both particle generation and lubricant evaporation will disappear simultaneously. For instance, in a wafer transporter, mechanical contacts typically happen and are persistently present in the area between the part that conveys the wafer, so the wafer carrier, and the transporter base that supports the carrier. By isolating the wafer carrier from the transporter base, these mechanical contacts can be dispensed with. This can be accomplished by means of levitation, where non-contact physical forces are applied between the carrier and the base, so the carrier is separated from the transporter base. In the known physical world, there exist three principle strategies that the free-floating levitation can be accomplished:

a) air-bearing b) electrostatic levitation c) maglev

To determine the most suitable and effective technique for our application, is required a general physical understanding of each method's working theory including some fundamental information of incorporated circuit manufacture innovation. An air-bearing system essentially requires two very important components: a special filter used to exclude particles generated by the air pump from entering the transporter and an additional circulation system used to enclose the air. In comparison, with the air-bearing system, in the electrostatic levitation one, the particle residues which are generated in the first installation or accidentally generated during wafer loading and unloading process will be pulled by the electrostatic field. Consequently, this can cause possible particle contamination, with the particles being stick to the transporter due to the electrostatic field.

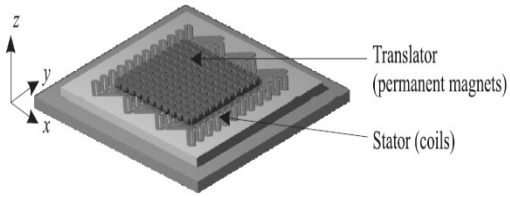
Given the above contentions and to achieve various performance targets, the precision stage using a novel contact-free planar actuator with magnetic levitation is highly recommended and this paper consider it the best solution for IC manufacture. Generally, as MAGLEV eliminates the friction due to a mechanical contact, it has a variety of applications requiring super-cleanness environment, including here the semiconductor wafer transfer. The way of usefulness and functionality of MAGLEV eliminates the problems caused by using the above technologies. It makes a steady state with no mechanical contact when the gravitational force is solely counterbalanced by magnetic forces. This system incorporates levitating tracks, stabilizing tracks, and propulsion coils [2].

2. Magnetically levitated planar actuators

Different types of conventional transportation systems such belt-type conveyors or articulated robots generate dusts and pollution due to the mechanical friction or lubrication. These systems are inadequate and improper to satisfy the environmental demands. The MAGLEV technology has the advantages of being contact free, eliminates the mechanical components e.g., gears, guide etc., reduces the mechanical alignment and maintenance cost, hence it satisfies the environmental demands. In this manner, research on contact-free type transportation system and actuator has been actively performed by worldwide researchers. Present day applications of this technology in equipment like magnetic bearings and magnetically levitated vehicles have given renewed impetus to research efforts in the direction of electromagnetic levitation [3-4].

There exist two main categories of planar actuators, referred as either with moving coils or moving magnets. The actuators from the first type consist of moving air-core coils and stationary magnets. The main advantage of such system is the usage of a small number of coils and their amplifiers, as the stroke force can be easily increased by adding a few more magnets in the magnet array. Additionally, the simple design of these actuators allows torque control on the translator part by using different coil topologies. A major disadvantage for this configuration is the presence of a cable connecting the translator and the stator part, as the coils require power and cooling. The following Figure 1 shows an example of these planar actuators.

a)



b)

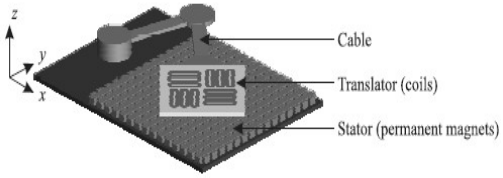


Figure. 1. Planar actuators: a) moving magnets, b) moving coils

The other category is represented by actuators with moving magnets and stationary air-core coils. In opposite with the other class of actuators, it doesn't require a cable for connecting the translator and stator part, which is a big advantage from the design point of view. With the coils located and powered in the stator platform, the amount of disturbances delivered to the levitated translator is then reduced significantly. On the other hand, the torque decoupling as a function of position is more complex than in the moving-coils planar actuators. During manufacturing process, working environment affects the quality of the precision products [3].

3. Designed planar actuator with moving magnets

The moving coil principle in microstructure designs requires powering and cooling of the coils. Additionally, including here the guidance of the current lines on the thin etched silicon beams. The springs which are driven by the Lorentz force, are moving in the magnetic field generated by an external magnet. Strong currents are required to produce large deflections, though this can cause thermally induced bending or buckling of the thin microstructures. Hence, the principle with a moving magnet is more effective, including less complex circuit design.

The carrier consists of several permanent magnets and essentially its stabilization is required. Ideal case is a uniform object with the center of mass coincident with the center of geometry. In numerical analysis, the magnetic flux is firmly related with the levitation distance between the levitated magnet and the cylindrical solenoid underneath. If such distance is very small, then the magnetic flux approaches a constant value. The aim of the stator configuration is the arrangement of the cylindrical solenoids and their floating currents in such a way, so together would form a uniform magnetic field over a planar surface slightly above the coil array. The high-precision positioning performance requires proper setup of carrier control and levitation height. The Figure 2 shows an example of a planar actuator with moving magnets.

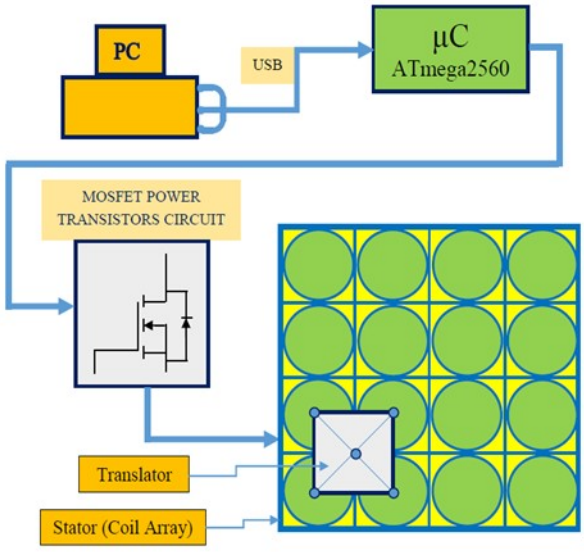

Figure 2. Block diagram of the planar actuator with moving magnets

Referring to the type of planar actuator described here, the translator is represented by a uniform shaped object with specific characteristics. This is embedded with one stabilizing permanent magnet on each corner so it can give sufficient control force against the lateral forces, and with one permanent magnet on the bottom of the carrier to counteract the weight of the carrier. For achieving a high-precision positioning performance, it is required to set up properly the control and the height of the carrier. Coils are supplied by the current flowing through Arduino board pins which are connected to the circuits consisting of MOSFET power transistors. In order to increase the output current from the board pins and strengthen the magnetic field around the coil, 4 such circuits with power MOSFET transistors were designed. For full control of the floating current of the coils, four such circuits are needed. In the stator platform, there are located 16 identical coils, forming together a 4x4 array. The current flowing through a relevant coil is controlled from the output Pulse-Width-Modulation (PWM) signal of one of the board pins of Arduino Mega 2560 [5].

The table below shows the accomplished parameters of the designed microactuator with moving magnets.

Table. Microactuator overall parameters

Parameter	Value			Unit
	min	typical	max	
Supply voltage range	12	-	20	V
Height of magnetically levitated translator	-	5	-	mm
Coil's current	-	0.5	-	A
Electromagnetic field strength	-	62	-	µT
Coil's resistance	-	4.9	-	Ω

4. Supply sources for MAGLEV systems

There exist two main approaches for designing a controlled force magnetic levitation system: the first one uses the attractive forces between an electromagnet and a magnetic flux closure, and the other is based on repulsive forces in interaction between electromagnets and permanent magnets.

Electromagnetic levitation technology uses either an Alternative Current (AC) or Direct Current (DC) source to drive the electromagnets. Despite the fact that there have been manufactured and tested several experimental frameworks which use as the supply an AC source, this method for adjustment is fitting for applications where mass of the levitated object is relatively small. The AC method of stabilization is inappropriate for heavy payloads due to the losses caused by the effect of the eddy currents, the complex circuit design and control of power modulation.

Conversely with the above AC method, the DC method, known also as the electromagnetic levitation system (EMLS), is characterized by simpler circuit configuration and favorable power requirement. The DC EMLS circuits use a switched mode power amplifier to control and utilize the current as well as the attraction force of the electromagnets. An electromagnetic levitation system consists of four main components: (i) Actuator and Rail, (ii) Position Sensor, (iii) Controller, (iv) Power amplifier [6].

The electrodynamic system utilizes the repulsive forces to levitate the carrier, conversely with the other system which levitates the carrier based on the attractive forces. The gap between the magnet pole-face and the ferromagnetic object is sensed and measured by a position transducer. The output signal from the transducer is fed back to a comparator and the process continues with output signal of the comparator being applied to a position controller, giving in this way the reference current for the current loop. The current sensor compares the actual current supplying the coil with the reference current. The power amplifier, a major component in this configuration, produces necessary currents in the actuator coils after receiving a command from the current controller. Preceding this, the current controller completes the current error process task. The output currents from the power amplifier are used to supply the coils. These generate requisite magnetic forces which are the key for levitating the translator.

Applications of electromagnetic levitated and guided systems, can be found for example, in the field of transportation vehicles, frictionless bearings, conveyor systems and lithography scanners [6].

Conflict of Interest

The authors declare no conflict of interest.

Data Collection

ABSTRACT

In this paper, we exploit an integration between Compressive sensing (CS) and the random mobility of sensors in distributed mobile sensor networks (MSNs). A small number of distributed mobile sensors are deployed randomly in a sensing area to observe a large number of positions. The distributed mobile sensors sparsely sample the sensing area for data collection. At each sampling time, the sensors collect data at their random positions and exchange their readings to the others through their neighbors within the sensor transmission range to form one CS measurement at each sensor. After a certain number of rounds for moving, sensing and sharing data, each mobile sensor creates a sufficient CS measurements to be able to reconstruct all readings from all positions that need to be observed. Network performance is analyzed considering the number of sensors deployed in the networks, the convergence time and the sensor transmission range. Expressions for transmission power consumption are formulated and optimal low power cases are identified.

1 Introduction

1.1 Motivation

Energy efficiency is the most important issue for mobile sensor networks (MSN) that can be useful for measuring data in many applications including environmental monitoring, event detection, intrusion detection, etc. These networks are constructed from sensors, control algorithms and other dynamic factors which depend on specific purposes or application scenarios [1, 2]. We define the vector $\underline{\mathbf{X}} = [x_1\, x_2 \ldots x_N]^T$ to represent all sensor readings from the locations to be observed. These readings are typically highly correlated and compressible and could be an object for energy saving.

Compressive sensing (CS) [3, 4, 5] offers to sample and to reconstruct sparse or compressible signals using fewer samples than the Nyquist-Shannon theorem would suggest. CS can be applied effectively with wireless sensor networks (WSN) and MSNs to reduce the amount of data and power required by the network. The technique can recover all data from $\underline{\mathbf{X}}$ based on a small number of CS measurements ($\underline{\mathbf{Y}} = [y_1\, y_2 \ldots y_M]^T$) compared to the number of nodes or positions ($M \ll N$) as $\hat{\underline{\mathbf{X}}} = arg\,min \parallel \underline{\mathbf{X}} \parallel_1$, $subject\ to\ \underline{\mathbf{Y}} = \Phi\underline{\mathbf{X}}$, where Φ is the measurement matrix, also called routing matrix in wireless networks. Each CS measurement can be collected from all sensing nodes or from some random nodes.

In this paper we propose a novel frame work that exploits CS sampling by mobile sensors deployed randomly in a sensing area. At each sampling time, each sensor samples its own data as x_i which is shared with others L connected sensor nodes in the MSN. We assume the mobile sensors move into random positions in the area. After each round of moving, data sampling, and sharing, a linear combination of readings is computed as $y_i = \sum_{j=1}^{L} x_j$. To achieve a desired error-target, each mobile sensor needs to move M times and share data to obtain M CS measurements ($\underline{\mathbf{Y}} \in \mathbf{R}^M$). A CS recovery algorithm can be applied to reconstruct all readings from positions in the sensing area ($\hat{\underline{\mathbf{X}}} \in \mathbf{R}^N$).

With a set transmission range, R, mobile sensors may move out of range and become disconnected from the group. With the proposed method the unequal CS measurements do not negatively impact CS performance due to a sparse binary measurement matrix.

1.2 Related work

The integration between CS and data collection methods in WSNs is being exploited effectively [6, 7]. It offers to reconstruct all readings from the networks based on a small number of CS measurements. Each CS measurement is collected from some random sensors. Some data collection methods utilizing CS are proposed as energy efficient algorithms to reduce power consumption for sensors. In [8, 9, 10] random walks with CS provide distributed routing methods for WSNs. Cluster based [11, 12] and tree based [13, 14] data collection methods significantly show the power reduced based on the combination with CS.

Recent research studies have exploited the mobility of sensors and CS. Wang [15] applied CS to monitoring vehicle networks. Mostofi built maps in mobile networks [16] and robot networks [17] while the mobile sensors and robots were deployed outside the sensing areas. Huang [18] reconstructed a scalar field using MSNs and information fusion. Nguyen [19, 20] used flocking control to lead a group of distributed robots to sample data and applied CS to recover data from the field based on a certain number of CS measurements.

The previous work has not focused on the integration between the random mobility of sensors and CS. In this paper, we complete our previous work [21]. The mobile sensors move only a certain number of times and share data among them to generate a desired number of CS measurements. Each sensor can reconstruct all raw data based on the measurements. The important results in this paper include:

1. A proposed new distributed compressive mobile sensing data collection method.
2. Formulations and analysis for estimating network transmission power consumption.
3. Analysis and simulation of factors such as the number of mobile sensors, the convergence time and the sensor transmission range leading to choices of minimizing power consumption.

2 Problem Formulation

2.1 Network Model

We assume an area to be observed with N unknown positions corresponding to N readings for collection. There are L mobile sensors randomly distributed in the sensing area to sense data. They are allowed to move with random direction and random velocities. The connections between sensors are created by radio links having a maximum sensor transmission range denoted as R. An appropriate value of R is chosen for all sensors. As shown in Figure 1, all mobile sensors are connected as an undirected graph $G(L, E)$, where L is the set of vertices representing the mobile sensors and E is the set of edges representing the connections between sensors.

We further assume that the distributed sensors move randomly in the area. Each mobile sensor shares data to the others through its neighbors within the transmission range R.

2.2 Compressive Sensing (CS)

Compressed Sensing techniques [3, 4, 5] bring us amazing work to recover a compressible signal from undersampled random projections. They are also called measurements. A compressible vector signal $\underline{\mathbf{X}} \in R^N$ ($\underline{\mathbf{X}} = [x_1\, x_2 \ldots x_N]^T$) is k-sparse ($\underline{\mathbf{X}}$ has k non zero elements) or dense but sparse in Ψ domain $\underline{\mathbf{X}} = \Psi\underline{\Theta}$ (where $\underline{\Theta}$ is k-sparse vector) will be sampled and then recovered precisely with CS algorithm. The huge gain when we apply CS is the number of measurements are much less than the number of original vector values. Vector $\underline{\mathbf{Y}}$, called the measurement vector, contains data sampled from N sensor readings; $\underline{\mathbf{Y}} \in R^M$ ($\underline{\mathbf{Y}} = [y_1\, y_2 \ldots y_M]^T$), where $M \ll N$.

Signal Sampling: The random measurements are generated by $\underline{\mathbf{Y}} = \Phi\underline{\mathbf{X}}$ where $\Phi \in R^{M\times N}$ is often full-Gaussian matrices or binary matrices, called projection matrices. $\underline{\mathbf{Y}} \in R^M$ is the measurement vector with $y_i = \sum_{j=1}^{n} \varphi_{i,j} x_j$, where $\varphi_{i,j}$ are all entries on the i^{th} row of our projection matrix Φ.

Signal Recovery: The number of CS measurements required to reconstruct the original signal perfectly with high probability is $M = \mathcal{O}(k\, log\, N/k)$ following the l_1 optimization problem given by [3].

$$\hat{\underline{\mathbf{X}}} = arg\,min \|\underline{\mathbf{X}}\|_1, subject\,to\ \underline{\mathbf{Y}} = \Phi\underline{\mathbf{X}}, \qquad (1)$$

or in case we need sparsifying matrix to have $\underline{\mathbf{X}}$ sparse in Ψ domain (Ψ can be Wavelet or DCT depending on our signal properties) as follows.

$$\hat{\underline{\Theta}} = arg\,min \|\underline{\Theta}\|_1, subject\,to\ \underline{\mathbf{Y}} = \Phi\Psi\underline{\Theta}, \qquad (2)$$

where $\|\Theta\|_1 = \sum_{i=1}^{N} |\Theta_i|$. The l_1 optimization problem can be solved with linear programming techniques such as Basis Pursuit (BP) [3].

In reality, we have to consider the noise while sampling and sending the measurements (in our case we collect measurements and send to the base-station) : $\underline{\mathbf{Y}} = \Phi\underline{\mathbf{X}} + \underline{e}$, with $\|e\|_2 < \epsilon$ and recover

$$\hat{\underline{\mathbf{X}}} = arg\,min \|\underline{\mathbf{X}}'\|_1, subject\,to\ \|\underline{\mathbf{Y}} = \phi\underline{\mathbf{X}}'\|_2 < \epsilon. \qquad (3)$$

2.3 Data Collection in Distributed MSNs utilizing CS

The idea of applying CS into MSNs is that the sensing field can be sampled randomly based on the mobility of mobile sensors randomly deployed in the field. In general, each CS measurement is a collection from some random positions as shown in Figure 2. L mobile sensors are deployed randomly in the sensing area that they can collect sensing data randomly. If these sensors exchange their own data to each other, they can all achieve the data sampled randomly as shown

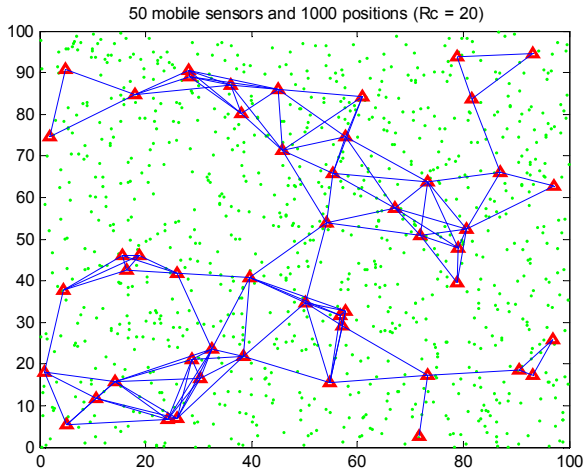

Figure 1: Sparse sampling a square sensing area dimensioned $[0,100]^2$ units: one CS measurement created by a fully connected MSN with 50 distributed mobile sensors.

in Figure 2. At this point, one CS measurement is collected at each distributed mobile sensor. After M moving steps, each sensor has M measurements. This number of measurements defined in CS background in Section 2.2 helps to reconstruct all sensory readings from N positions in the area.

After M periods of time, L distributed mobile sensors visit approximately N unknown positions. The readings are contained in vector $\underline{\mathbf{X}}$ which is compressible or sparse in proper domains as

$$\underline{\mathbf{X}} = \Psi \underline{\mathbf{\Theta}}, \tag{4}$$

where $\underline{\mathbf{\Theta}} = [\theta_1\, \theta_2 \ldots \theta_N]^T$ has k non-zero elements and

$$|\theta_1| \geq |\theta_2| \geq \ldots \geq |\theta_N|. \tag{5}$$

Ψ referred to as the sparsifying matrix, is an orthogonal basis of $\mathbf{R}^N$. If $\underline{\mathbf{X}}$ is a k-sparse vector, Ψ is an identity matrix. Otherwise, Ψ can be chosen from another domain such as wavelet, DCT (discrete cosine transform), etc. In order to verify this problem, Figures 3 and 4 are provided. All raw sensor readings from 1000 points of interest are shown in Figure 3. This real data is not sparse but it is highly correlated due to the positions next to each other. DCT Ψ matrix has been chosen to sparsify the real data. Figure 4 shows all the coefficients in DCT domain. We can see that signal energy would be reduced following Equation 5.

At time instant t, mobile sensor l at position i collects sensory data x_i^l $(i = 1, \ldots N)$. All L mobile sensors share their readings (x_i^l), identified by the corresponding position indices, with the other mobile sensors through their neighbors as shown in the graph $G(L,E)$. After a convergence time [1], denoted as I, each mobile sensor has one CS measurement as a sum of L sensor readings

$$y_t = \sum_{l=1}^{L} \phi_{ti} x_i^l + e_t, \tag{6}$$

where e_t is additive noise dependent on the system. ϕ_{ti} is a binary vector (dimensioned $1 \times N$) that represents which positions are sampled at time instant t. It is also the t^{th} row in the measurement matrix $\Phi_{M\times N}$ after M periods of time. The total measurements collected at each sensor are

$$\underline{\mathbf{Y}} = \Phi \underline{\mathbf{X}} + \underline{\mathbf{e}}. \tag{7}$$

According to [22], the number of measurements required to reconstruct perfectly all the raw reading from the network is

$$M = \mathcal{O}(k \log(N/k)), \tag{8}$$

where $k < M \ll N$. So instead of collecting N readings, one for each sampling position in the sensing area, each mobile sensors needs only M measurements and reconstructs all data from the area. If the network is fully connected all the time, each sensor has the same binary measurement matrix Φ with a constant row weight of L.

$$\Phi = \begin{bmatrix} 1 & 0 & 0 & 1 & 0 & 1 & \ldots & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & \ldots & 1 \\ 0 & 0 & 0 & 1 & 1 & 0 & \ldots & 1 \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ 1 & 0 & 1 & 0 & 0 & 1 & \ldots & 0 \end{bmatrix}_{M\times N} \tag{9}$$

The restricted isometry property (RIP) of the sparse binary matrix has been studied in [23] where it is shown that the matrix can satisfy RIP and therefore can be used as an efficient measurement matrix. This matrix $(\Phi_{M\times N})$ can perform as well as a full Gaussian matrix for the CS recovery process. ϵ is set as $\epsilon < \| \underline{\mathbf{e}} \|_2$. The recovery algorithm is addressed as

$$\hat{\underline{\mathbf{X}}} = arg\,min \| \underline{\mathbf{X}} \|_1, subject\,to \quad \| \underline{\mathbf{Y}} - \Phi \underline{\mathbf{X}} \|_2 < \epsilon. \tag{10}$$

[1] Convergence time is the average number of times each sensor updates data from the neighbors until it achieves a CS measurement collected from all connected sensors. Convergence time is a measure of how fast a group of sensors can create one CS measurement.

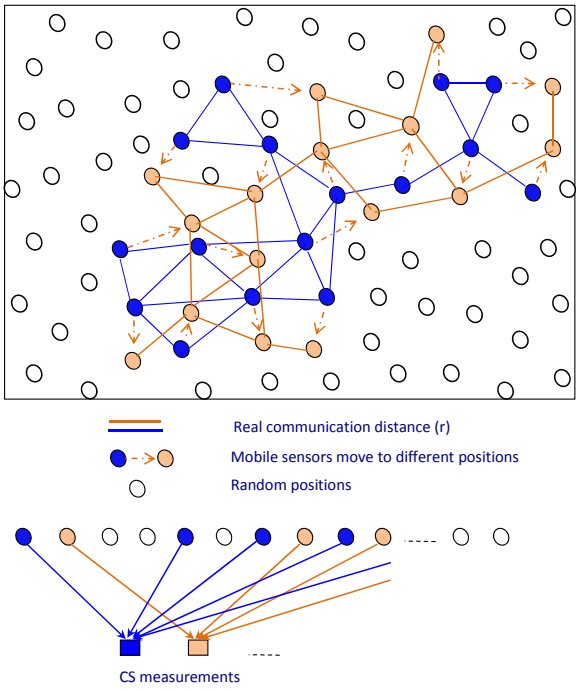

Figure 2: Two CS measurements are created (in blue and yellow) while the mobile sensors are moving in the sensing field.

3 Compressive Mobile Sensing Algorithm (CMS)

for *t = 1 to M* **do**
  L distributed mobile sensors move and sample a sensing area at *M* periods of time, and create 1 CS measurement at each time instant *t*
  while *(Number of times sharing data < I)* **do**
    for *i = 1 to L* **do**
      Each sensor out of *L* mobile sensors has two main activities:
      - send/receive data to/from neighbors
      - add/forward new received data from/to neighbors
    end
    New data is detected by its attached indices
  end
  One CS measurement is created following Eq. 6
end
M CS measurements are created for the CS data reconstruction following Eq. 10

Algorithm 1: CMS Algorithm

As mentioned, each distributed mobile sensor must collect M measurements to be able to reconstruct all readings from N positions in the sensing area. With L distributed mobile sensors fully connected as given by the graph $G(L, E)$ and based on the sensor transmission range R, the proposed algorithm is summarized as Algorithm 1.

Due to the limitation of R and sensor motion, some mobile sensors maybe disconnected from others and separated at time instant $t + k$. This means that the measurements y_{t+k} collected at each sensor are not from all L sensors. This does not affect CS performance when the measurement matrix has different row weights [22]. By applying CS, each mobile sensor only has to visit M positions to collect all data from the sensing area ($M \ll N$). This significantly reduces consumed power not only for communications but also for sensor movements.

4 Analysis of Power Consumption for Communications

The total consumed power for communications in the network consists of three main elements: the intra-neighborhood consumed power denoted as P_{nei}, the convergence time I and the number of measurements required (M). The total power consumption can be calculated as follows

$$P_{total} = P_{nei} \times I \times M. \tag{11}$$

P_{nei} represents the communication cost associated with L mobile sensors transmitting data to their neighbors and can be calculated as

$$P_{nei} = \omega \times R^{\alpha} \times L, \tag{12}$$

where ω is the average number of neighbors of each sensor corresponding to the available communication links, and α is the path loss exponent. It is shown in [24] that $\alpha = 2$ and $\alpha = 4$ for free space and multi-path fading channels, respectively. We choose $\alpha = 2$ throughout this paper. In the following sections both circular and square sensing areas are examined and analyzed.

4.1 Circular Sensing Area

If sensors are randomly distributed in a circular sensing area with radius R_0, the average number of sensors deployed in the area covered by each sensor transmission range R can be found as

$$\beta = \frac{L}{\pi R_0^2} \times \pi R^2, \tag{13}$$

where $\frac{L}{\pi R_0^2}$ is the sensor density. We can calculate approximately the mean value of ω as

$$\omega = (\beta - 1) = (L\frac{R^2}{R_0^2} - 1). \tag{14}$$

Hence, the total consumed power for sharing data between L sensors is calculated as

$$P_{total} = (L\frac{R^2}{R_0^2} - 1)R^2 LIM. \tag{15}$$

4.2 Square Sensing Area

We assume a square sensing area with dimensions $H \times H$. From Equation (13), the average number of sensors deployed in the area covered by each sensor transmission range R is $\beta = \frac{L}{H^2} \times \pi R^2$. Hence

$$\omega = (\frac{\pi L R^2}{H^2} - 1). \tag{16}$$

In Figure 6, both the true and the reconstructed data are shown together to illustrate the accuracy of the CS recovery algorithm with the number of CS measurements given by $M = 300$ stored at each sensor. The larger the number of measurements, the better the accuracy of the reconstruction.

The total consumed power for sharing data for L sensors to achieve M converged CS measurements in the square sensing area can be written as

$$P_{total} = (\frac{\pi L R^2}{H^2} - 1)R^2 LIM. \tag{17}$$

The convergence time I depends on both the sensor density ($\frac{L}{\pi R_0^2}$ or $\frac{L}{H^2}$) and the connections between the sensors. The smaller the number of mobile sensors, the smaller the convergence time. However, since the transmission range R determines the connections, increasing the transmission range R to maintain the connections increases the transmission power consumption. This means that increasing or reducing R may

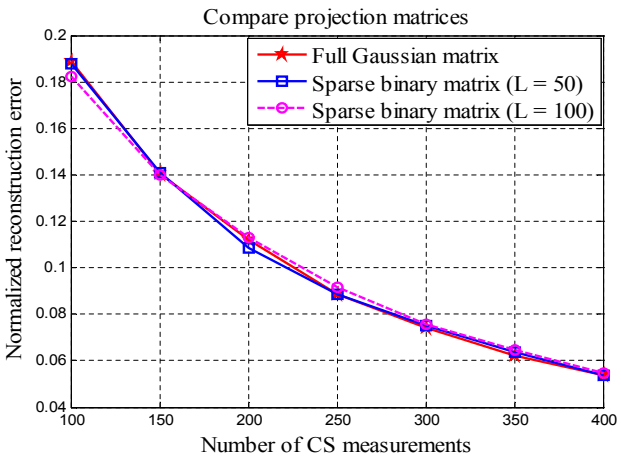

Figure 5: Comparison of three measurement matrices created through the sampling process based on signal reconstruction error.

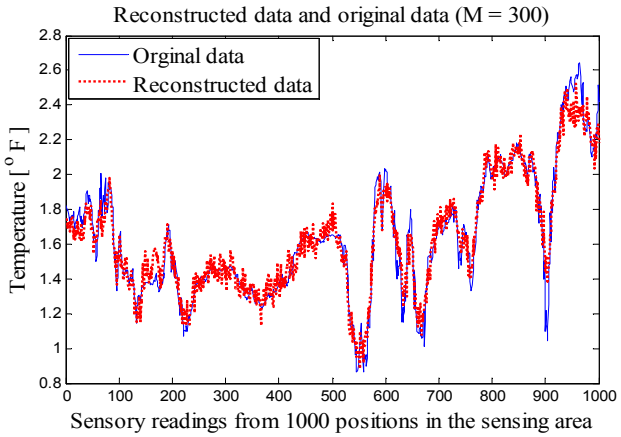

Figure 6: Comparison of reconstructed data and the original data when each sensor stores $M = 300$ CS measurements.

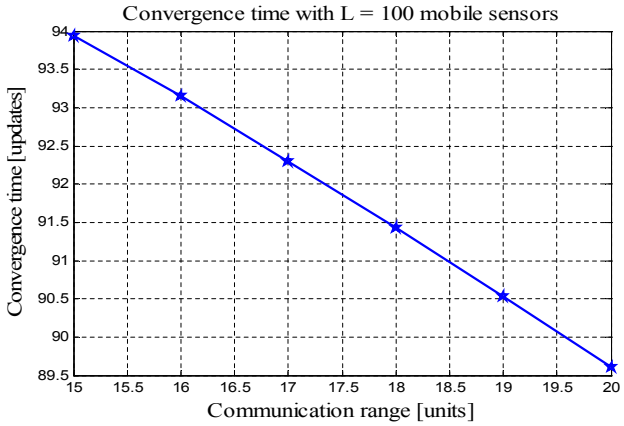

Figure 7: The average convergence time versus different transmission ranges with 100 mobile sensors deployed in a square sensing area.

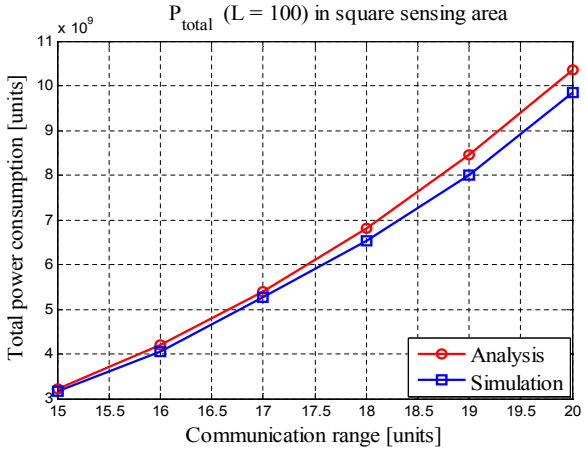

Figure 8: Total power consumption for communications versus different transmission ranges in the square sensing area.

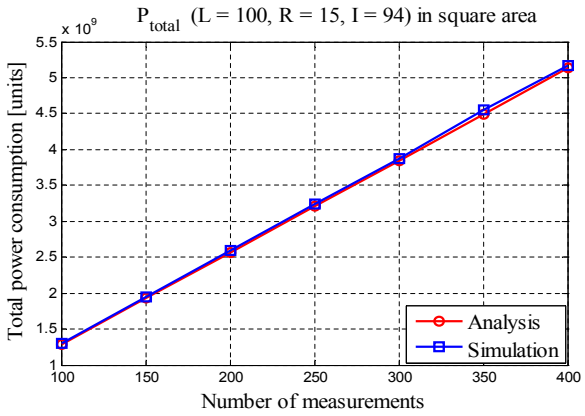

Figure 9: Total communication power consumption with $L = 100$ mobile sensors deployed in the square sensing area and transmission range $R^* = 15$.

increase or reduce the number of connections between the sensors in each neighborhood. Increasing the connections between sensors reduces the convergence time I. Thus a trade-off exists between these various parameters.

5 Simulation Results

We assume a fixed number of 50 or 100 mobile sensors deployed in a square sensing area of 100 square units ($H = 100$). We also assume that there are approximately 1000 positions where temperature needs to be observed. We consider the transmission range of $15 \leq R \leq 20$ units in which the network is always connected. Without loss of generality, it is assumed that the power for transmitting 1 unit of data is 1 unit of power. The simulations were performed using real temperature sensor data from Sensorscope [25]. The reconstruction error related to CS signal recovery is the normalized reconstruction error given as $\frac{\|\mathbf{X}-\hat{\mathbf{X}}\|_2}{\|\mathbf{X}\|_2}$.

Figure 5 compares the ability to reconstruct data in the CS recovery process between three measurement matrices. Both sparse binary matrices with row weight $L = 50$ and 100 are shown to perform as well as the full Gaussian matrix which corresponds to full sampling.

Figure 7 illustrates that as R is increased, the convergence time I is reduced as discussed in Section 4. Figure 8 depicts the corresponding total power consumption in the network, and we see the power consumption is reduced as R is decreased. R cannot be reduced without limit as at some point the L sensors will become disconnected and fragmented resulting in an excessively sparse measurement matrix.

We chose the smallest transmission range $R^* = 15$ and the corresponding convergence time $I^* = 94$ for the optimal total power consumption for sensor communications in the network in both analysis and simulation which are shown in Figure 9.

Finally, in Figure 6, both the true and the reconstructed data are shown together to the show the accuracy of the CS recovery algorithm at the number of CS measurements as $M = 300$ stored at each sensor. The more number of measurements, the better accuracy of the reconstruction.

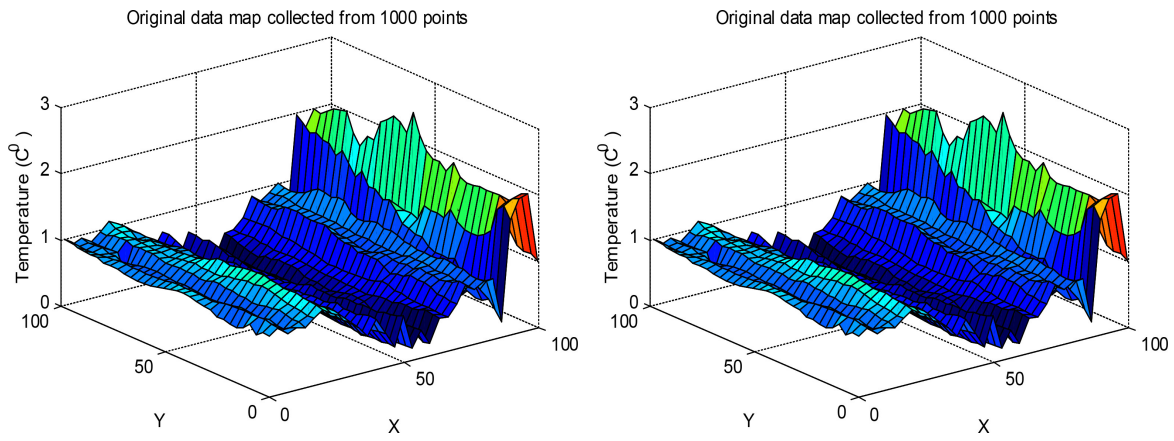

Figure 10: Final result of recovering data in a 3-D map compared to the true map; $M = 300$ CS measurements are collected.

6 Conclusions and Future Work

This paper proposed a framework for distributed MSNs utilizing CS for efficient data sensing and recovery and investigated the dependence of power consumption on various MSN parameters. The algorithm exploits the random mobility of sensors for sparse sampling the sensing area. CS based sampling and reconstruction of the sensory data with a sparse binary measurement matrix were compared with dense Gaussian and shown to be equal under the simulation conditions, illustrating that CS may be used to advantage in MSNs. Expressions for transmission power consumption in the MSN were developed, simulated, and analyzed. The results show the trade-off between the number of sensors, the transmission range, and the convergence time that can further reduce the power consumption for data transmission in the networks.

In future work, we consider the correlation of sensing data in the field. This could help to improve the performance of CS in signal recovery.

ABSTRACT

Conformal Prediction is a recently developed framework for reliable confident predictions. In this work we discuss its possible application to big data coming from different, possibly heterogeneous data sources. On example of anomaly detection problem, we study the question of saving validity of Conformal Prediction in this case. We show that the straight forward averaging approach is invalid, while its easy alternative of maximizing is not very efficient because of its conservativeness. We propose the third compromised approach that is valid, but much less conservative. It is supported by both theoretical justification and experimental results in the area of energy engineering.

1 Introduction

1.1 Topic of the work

This paper is an extension of [1]. The topic of this work is application of **Conformal Prediction** (CP) framework of reliable machine learning to big data. Conformal Prediction was developed in such works as [2, 3]. Its main advantage is producing prediction sets that are valid in weak (i.i.d./exchangeability) assumptions. In the case of supervised learning (classification or regression) the idea of CP is in checking each hypothesis about the new example's label on exchangeability. This means that the exchangeability of the whole data sequence extended by this example is checked.

This has an interpretation in terms of **anomaly detection**: whether the example (supplied with a hypothetical label) is an anomaly with respect to the training ones, or not. As we will discuss, the most questions related to CP can be modelled for the task of anomaly detection first, and then they will be naturally extended to supervised learning or clustering. Therefore in this work we concentrate on unsupervised task of anomaly detection of unlabelled instances. Amongst the previous works on conformal anomaly detection we have to mention[4, 5, 6, 7, 8, 9].

These works did not specifically study the problem of **big data**. Here we model the situation when the data set is so big that CP algorithm can not be calculated directly, the data set has to split into parts. Furthermore, we assume that different parts of the data are collected in different places ('sources'), and these sources are in general case heterogeneous (different in their distribution), and only the mixture of all these distributions is the 'true' distribution that might generate a testing example. Extending Conformal Prediction for this task is not straightforward because of the risks to lose the validity and to informative efficiency of the predictions.

1.2 Application area

Anomaly detection problem can be applied in may areas. In the context of conformal framework the areas mostly considered earlier were vessel trajectories [4, 6, 7] and traces of bots [9].

As a model example, we use a question form the area of energy engineering. Energy Demand Research Project (EDRP) provides the data on customer behaviour (energy consumption) of gas/electricity using households. A data instance here is a summary (profile) of behaviour consumption during a large observation time for an individual household.

This is a kind of a more general problem where the detection of anomalies is understood as an unusual or suspicious behaviour of a complex system or its human users.

https://dx.doi.org/10.25046/aj020335

1.3 Plan of the paper

In the background Section 2 we remind the basic notions of Conformal Prediction, with concentration on validity properties. We discuss both supervised learning and unsupervised learning (anomaly detection) tasks and their connection to each other in more details than in our previous work [1].

In particular, we pay special attention to the choice of Conformity Measure (CM) that is the core element of a CP algorithm. It may be based on any machine learning algorithm, and our preference is k Nearest Neighbours (kNN) approach.

In Section 3 we address the challenge caused by big data split to validity and informative efficiency of Conformal Prediction. Theoretical justification of the suggested solution is extended from [1] with an informal motivating example showing its principal idea.

Sections 4 describes organisation of experiments, which aim to check how the idea works on a set of real data. Here we mostly deal with the questions of computational efficiency of experiments.

Section 5 includes brief description of the data set and its splits, experimental output and its analysis. There are three principal ways of data splits, different in the level of modelled homogeneity/heterogeneity. The part related to the analysis is expanded compared to [1], including more complete series of experiments (using versions of kNN CM with several values of k) and their analysis in several aspects, including influence of different factors.

The paper is concluded with a discussion section including plans for the future work. The most interesting of them is related to potential supervised learning applications.

2 Machine learning background

2.1 Some machine learning problems

In general, the task of machine learning is to say (predict some property) of a new instance z_{l+1} based on existing information about the previous (training) instances $z_1,\dots,z_l$ of the same nature. Learning means that the quality (efficiency) of the predictions grows as the experience (the number of examples analysed during the training) grows. Usually an instance is represented as a vector of features and/or labels.

The most popular machine learning problem is *supervised classification*. Assume that each instance $z_i = (x_i, y_i)$ consists of an object (feature vector) x and a label (usually a scalar) y_i. Everything is known except the label of a new example. So the task is to predict a label for a example x_{l+1} from a given training set of object $x_1, x_2, \dots, x_l \in X$ supplied with labels $y_1, y_2, \dots, y_l \in Y$.

Another large area is unsupervised learning without any labels when there are no labels and $z_i = x_i$. This includes such task as clustering and anomaly detection. The clustering question is to assign some labels to all the objects, based on their similarity to each other. For a new example this will also give a classification, which of the clusters it is likely to belong to. The question of anomaly detection is to detect whether the example is similar to any group of training examples at all or it is a sort of abnormal one. Anomaly detection and clustering tasks together or independently on each other. It can be said that the anomalies are object that remain after clustering of the typical objects while anomaly is a thing such that excluding it from the data set cleans the data makes the clustering task easier. See [9] for more discussion of their connection.

Classification an instance as an anomaly may have several meanings according to the nature of a problem: new tendency in a data stream, some mistakes in data collection, suspicious behaviour of an object or human, reflected in the data. If a normal instance is classified as anomaly, this is a sort of 'false alarm' although may reflect some unusual property of it. Another kind of error is missing a true anomaly (classifying it as a normal instance).

Normally it is better to keep false alarm rate on a decided significance level, and to try decrease the number of second type error, making the method as sensitive for real anomalies as possible. Limitation on the false alarm level allows to talk about reliability of the anomaly detection because otherwise classifying an instance as an anomaly is not a responsible claim.

A reason why we focus our interest in this work on anomaly detection is that the problem of anomaly detection covers the problem of supervised learning in the following sense. If we try to predict a label y_{l+1} for a new example x_{l+1}, this also means that we would like to fill a gap in the data not in an abnormal way. If $(x_{l+1}, \hat{y})$ looks like an anomaly compared to the training examples $(x_1, y_1), \dots, (x_l, y_l)$, then it is unlikely that $y_{l+1} = \hat{y}$ where y_{l+1} is the true label. In the context of supervised learning, the usual understanding of anomaly is the following. A labelled example (a pair (x_i, y_i)) is anomalous as far as y_i is different from the label predicted for x_i by an (underlying) machine learning algorithm.

2.2 Conformal Prediction framework

Conformal Prediction [2] is a framework that can convert practically any machine learning algorithm for classification or regression into a reliable multi-prediction algorithm that produces prediction sets valid in weak (i.i.d.(power) or exchangeability) assumptions about the data generation mechanism.

Conformal anomaly detection was introduced in [4]. Its principal scheme is given by the equations:

$$\alpha_i = A(z_i, \{z_1, \dots, z_{i-1}, z_{i+1}, \dots, z_{l+1}\}). \tag{1}$$

$$p(z_{l+1}) = p(z_1, \dots, z_{l+1}) = \frac{card\{i = 1, \dots, l+1 : \alpha_i \le \alpha_{l+1}\}}{l+1} \tag{2}$$

The principal parameter of the algorithm is a *Conformity Measure (CM) A* that is a measure of information distance of an object z and a set U. Its choice

affects the efficiency of the algorithm which we will discuss further. Then, p-values measures applicability of i.i.d. assumption to the data by testing whether $z_1,\dots,z_l,z_{l+1}$ are likely to be generated by the same distribution, or this is discarded by the last example z_{l+1} being an anomaly.

In other literature such as [2, 6] there is also used the term *Non-Conformity Measure (NCM)* which differs from Conformity Measure in the sign, and correspondingly $\leq$ is replaced by $\geq$ in the equation 2. Usually the CM connects Conformal Prediction framework to one of standard machine learning algorithms such as Support Vector Machines (SVM), Neural Nets, Nearest Neighbours, that is called the *underlying algorithm*.

In the case of supervised learning, p-value is assigned to each possible hypothesis $y \in Y$ about the label of the new object

$$p(y) = p(z_1,\dots,z_l,(x_{l+1},y)).$$

In particular, p-value assigned to the true label y_{l+1} measures exactly the abnormality of the example

$$z_{l+1} = (x_{l+1},y_{l+1}).$$

The main advantage of Conformal Prediction is ability to produce *prediction sets* with guaranteed properties of validity in i.i.d. assumption.

For supervised learning, the prediction set is the set of y such that $p(y)$ is larger than a selected significance level ε. It is proven [2] to cover the true label y_{l+1} with probability at least $1-\varepsilon$.

In anomaly detection, it is possible to talk about prediction set of all z such that $p(z) = p(z_1,\dots,z_l) > \varepsilon$. It is also guaranteed to cover true z_{l+1} in case when it is generated by the same distribution, i.e. it is not an anomaly.

The size of the prediction set is the measure of efficiency: the smaller is the set the more informative is the prediction. It is practically useful that these predictions are individual, so for some examples they may be small (more informative) even if for the majority of testing examples the predictions are not so definite.

Below we will consider these notions in a more formal way.

2.3 Validity

The validity property states the following. If the sequence of examples $z_1,\dots,z_l,z_{l+1}$ is generated by an exchangeable distribution then the probability that $p = p(z_{l+1}) < \varepsilon$ is at most ε. for any significance level ε. An exchangeable distribution means invariance on the permutation of the order of examples. This includes the important case of i.i.d. (power) distribution meaning that the data examples were generated independently by an identical mechanism.

The standard output of Conformal Prediction is in the form of prediction set, where the validity has the meaning that the prediction set is 'large enough' in a statistical sense.

The prediction set in unsupervised task is defined as:

$$R^\varepsilon = \{z \in Z : p(z) = p(z_1,\dots,z_l,z) > \varepsilon\}$$

Validity implies that R^ε covers z_{l+1} with probability at least $1-\varepsilon$. So z_{l+1} can be reported as an anomaly if $p(z_{l+1}) < \varepsilon$ because the probability of this event is below the selected significance level ε. So the validity property actually allows to set a desired bound on the false alarm rate (number of mistakes within normal examples).

In supervised task, the sequence $z_{l+1} = (x_{l+1},y_{l+1})$ is known partially, the task is to predict y_{l+1} by x_{l+1}. The prediction set

$$R^\varepsilon = \{y \in Y : p(y) = p\,(z_1,\dots,z_l,(x_{l+1},y)) > \varepsilon\}.$$

Validity implies that this R^ε covers the true label y_{l+1} with probability at least $1-\varepsilon$. This makes the prediction set reliable: probability of error is limited by ε, if error is understood as a true label left outside the prediction set.

2.4 Informative efficiency

In both supervised and unsupervised tasks informative efficiency is related to size of a prediction set. The smaller it is, the more informative is the prediction.

In supervised case, it means that more hypotheses about the label of a new data instance are rejected, therefore the prediction is more definite. In particular, the prediction of size 1 is called *certain*, and the complement to 1 of the smallest significance level for which this is true is called *individual confidence* of the prediction. This notion is applicable directly to conformal anomaly detection because the predictions test are usually infinite.

In unsupervised case, informativeness means higher sensitivity to abnormality, i.e. classifying more examples as anomalies, (remind that the prediction set includes the instances classified as normals).

In more details, efficiency of supervised learning were discussed in [3] while efficiency of conformal anomaly detection is discussed in detail in [6, 8]. Some ways to measure efficiency numerically were presented in these works.

It this paper we will concentrate just on one aspect: harm to efficiency caused by parallelisation of the framework for big data.

2.5 Deviations from validity

If the formula 2 of p-value calculation is modified or generalised, the first challenge is to keep its validity property, otherwise the outputs of Conformal Prediction would not be reliable.

To measure validity empirically, one has to see how much the empirical distribution of p-values deviates from the uniform distribution on [0,1]. A martingale on-line approach to such testing was presented

in [10] but its focus was on checking exchangeability of data sets.

Now we are focusing on testing the algorithms instead of data sets. The difference form martingale is that for us two kinds of deviations are principally different for us now: if p-values are smaller than expected this leads to invalidity while having too large p-values is a less harmful case of low efficiency.

We consider the probability that $p \le \varepsilon$. Ideally, it should be very close to ε, and this is reached in online smooth version of the standard Conformal Prediction [2].

In general, for a fixed significance level ε there are three practical possibilities:

- Invalidity: $Prob\{p \le \varepsilon\} > \varepsilon$, p-value is not a correct measure of significance.
- Exact validity: $Prob\{p \le \varepsilon\} = \varepsilon$, an ideal situation;
- Conservative validity: $Prob\{p \le \varepsilon\} < \varepsilon$, a cause of undesirable damage to efficiency.

If probability of this event is significantly larger than ε, this means that there is no actual reliability of the results. If this probability is essentially smaller than ε this means the results are reliable but conservative.

Conservativeness is an indirect but important indicator that prediction sets (of non-anomalous objects) are unnecessarily large. If the allowed level ε of normal examples classified as anomalies is not reached, this decreases false alarm level somewhere below the allowed threshold, but it is very possible that some true anomalies are also left undetected.

2.6 Conservativeness as lack of informative efficiency

Note that conservativeness is just one of the possible causes of low information efficiency (too large prediction sets). Another source of damage to informative efficiency than a weak choice of the Conformity Measure (CM) mentioned before.

Studying influence of CM on the efficiency of the prediction is a more complex question. There are no definite answer in the case of anomaly detection, which CM is better, without taking into account the nature of the problem. It may be reflected in another testing set consisting specially of anomalies, or in defining a measure on the object space. See [6] for an example of such comparison.

Another reasons to choice one or another CM may be related to cluster structure of the prediction set (number, purity of clusters), see [9] for details.

Therefore we concentrate on conservativeness now leaving these questions aside this work.

2.7 Assessment of validity and conservativeness

Above we discussed validity and efficiency related to a specific significance level ε. It is more convenient to have a joint parameterless (ε-independent) measure of validity and conservativeness, aggregating information about different levels.

Let us observe the distribution of p-values assigned to testing examples. Ideally (in the case of exact validity) it should be uniform. It was formally proven to be for smoothed version of non-parallelised Conformal Prediction [2]. Smoothing here means assigning a random weight to the cases $\alpha_i = \alpha_{l+1}$ instead of 1. In this work we do not do special smoothing. For the big data size there is usually no practical difference between smoothed and non-smoothed versions, so it is convenient to get rid of this non-deterministic element.

We would like here to assess practically how well this closeness to uniformity is achieved by empirical distribution of p-values of testing examples.

As the first criterion, we measure Average p-Value (APV). Averaging of p-value can be understood as a well as a form of mixing prediction set sizes over different significance levels. It was suggested in [6] as an efficiency measure on a testing set or a measurable space of testing feature vectors. We put it now in a different context: in our check, the testing examples come from the same distribution as the training ones (unlike [6] with a testing set intentionally generated another way). Therefore we know that valid p-values are distributed uniformly, the expected average value of APV is $\frac{1}{2}$.

APV criterion may be considered as a uniform averaging of ε-dependent validity checks by ε. This may be not the best way because in practice only its small values are usually important. Significance levels typically used in statistics are no larger than 0.05, sometimes reaching 10^{-2} or 10^{-4}. Therefore we also consider a modified criterion that is Average Logarithm p-Value (ALPV). It was suggested in [8] as an alternative to APV, applicable in same circumstances. This criterion gives larger weight to small significance levels.For example, if the p-values tend to concentrate around $\frac{1}{2}$ this is not reflected in APV but considered conservative by ALPV. Its expected value of -1 for uniform distribution.

2.8 Selection of Conformity Measure

In general, it is expected that CM approximates the density function of the data distribution. In [3] this principle was justified for supervised classification but can be easily adopted to anomaly detection as well. Further in Sec. 3.8 we will need this property as well.

The problem of CM selection in the context of conformal anomaly detection (not classification) was studied in the paper [6]. In [6] two families of the density approximating functions were compared by their

efficiency.

- A Conformity Measure can be based on kernel density estimation (KDE) by creating a continuous function from the empirical data distribution; a kernel function has to be chosen for smoothing it. Typically the kernel function is the density function of a normal distribution.

- Alternatively, local density at a point can be approximated by nearest neighbours method that shows how close a point is in average to some amount of its nearest neighbours in the data set. Conformity of an example is calculated as the inverse value of the average distance to k nearest neighbours (kNN).

Both methods are actually parametric: either the kernel function needs to be supplied with variance ('degree of smoothing') , or the number of neighbours has to be selected. Experimental comparison in [6] have shown that with the best parameters both methods give the results of similar quality.

However, in the case of k nearest neighbours the method is more robust: the damage to efficiency caused by its imprecise selection is smaller. Therefore we consider nearest neighbours method as the preferable one.

Another intuitive reason is that in context of comparing conformities kNN $k = 1$ may be considered as a 'limit' case of density estimation as the variance parameter of the kernel fucntion tends to 0. At the same time, kNN with $k > 1$ can not be easily explained in terms of kernel density estimation. So this family is in some sense a 'richer' one.

3 Aggregating data sources

3.1 Big data challenges

Processing big data set a limitation caused by limited memory or time does usually appear. This happens because the required time/memory increases in a non-linear way, therefore splitting the data into some parts is the only way to fit it. Also there may be physical or technical reasons requiring parallelisation such as impossibility to collect all the data in the same place simultaneously. Usually we can just assume that, for a concrete algorithm, an upper limit on the data set size processable at once, is somehow determined by the power of one processor/storage, and can not be enlarged.

Parallelising of an algorithm may be exact (producing the same result) or approximate, which happens usually. Some algorithms of machine learning do have special modifications applicable to big data. such as Cascade version of Support Vector Machines [11] which is approximate as well. The principal challenge is that underlying SVM is using a matrix of inter-example similarities, so the load of memory is proportional to the square of the number of training examples, which puts an essential limit on the number of examples which may be processed together.

In our work we also model a situation when only approximate calculation is possible. In the context of conformal framework, the principal challenge is caused by its core detail, calculation of Conformity Measure function A. One of its two arguments is a whole set which may make calculations much complex. In the example which we prefer to consider, CM is based on k Nearest Neighbour algorithm, which also requires a storage of the distance matrix.

In the case of Conformal Prediction, we also wish to see that reliability of results, guaranteed by validity properties, is not affected by parallelisation of the algorithms.

3.2 Modelling of the challenge

In this consideration we try taking into account both causes for data split. The number of data examples processed at once is limited by a number h, and we also assume that data collection was done independently by different groups, and it even may be never stored together. Each of the collecting group may have its own specialising collecting data of a concrete subtype, or related to the collection place.

This means that:

1. in general case it is impossible to make a completely random split;

2. it would be unfair to restrict us just to one of these sources, even as an approximation.

The second note is important. In our modelling we assume that there is no possibility to avoid parallelisation challenge just by using one source of information and expectation that it is not a bad approximation (which in many cases happens in reality).

Formally, we assume that:

- the training set $U = \{z_1, \ldots, z_l\}$ is split into two parts of equal size called U_1 and U_2; this in general case is not always a random split;

- the true data distribution P is a mixture of P_1 and P_2,
$$P = \frac{P_1 + P_2}{2};$$

- the data source U_1 is randomly generated by P_1;

- the data source U_2 is randomly generated by P_2.

- the testing example z_{l+1} is generated by the mixed distribution P;

- simultaneous access to the sources U_1 and U_2 is impossible.

The task is to estimate the $p(z_{l+1})$ with respect to the union of U_1 and U_2 as the training example.

3.3 Averaging Tests for randomness (AT)

Assume that p_1 and p_2 are calculated for the same testing example but for different training sets. So Equation 2 is replaced by two:

$$p_1 = \frac{card\left\{i = 1,\dots,\frac{l}{2}, l+1 : A(z_i, U_1) \le A(z_{l+1}, U_1)\right\}}{\frac{l}{2}+1} \tag{3}$$

$$p_2 = \frac{card\left\{i = \frac{l}{2}+1,\dots,l, l+1 : A(z_i, U_2) \le A(z_{l+1}, U_2)\right\}}{\frac{l}{2}+1} \tag{4}$$

The straightforward way is to approximate p-value by the average of two:

$$p^{AT} = \frac{p_1 + p_2}{2}. \tag{5}$$

This method seems to be a natural way of distributed calculation of p-value but it has no guarantees of validity.

If the split is heterogeneous, then the problem of invalidity can appear as well. This can be shown on the following example. Assume that the sources are completely heterogeneous: P_1 and P_2 distributions having non-overlapping support sets. We can also imagine that they are so disjointed that each example generated by P_1 has the minimal possible p-value $\frac{1}{l+1}$ with respect to the training set generated by P_2 and vice versa. This will lead to averaged p-value of a new P-generated example being approximately uniformly distributed on $\left(0, \frac{1}{2}\right)$ instead of $(0,1)$ that is a strong form of invalidity[1].

3.4 Maximizing Tests for randomness (MT)

The easy way to achieve guaranteed validity is to take the maximum of 'partial' p-value instead of the average:

$$p^{MT} = \max\{p_1, p_2\} \tag{6}$$

It also has a natural meaning: a new example z is typical with respect to the union of two sources if is typical with respect to at least one of them.

However, it such approach is rough and p-values produced this way are likely to be very conservative, especially if the distributions are close to each other. For example, in completely homogeneous case, when each of p_1 and p_2 is lucky to be valid itself as an approximation of p, $\max\{p_1, p_2\}$ will be just larger than p_1 or p_2 of without any use for validity.

3.5 Maximizing Conformities (MC)

The suggested solution is to correct the maximising approach by moving the maximization procedure one step back. Instead of maximizing the p-values themselves, let us maximize the estimates of new example's conformity.

The aggregated p-value is defined by the following equations

$$p^{MC} = \tilde{p} = (\tilde{p}_1 + \tilde{p}_2)/2 \tag{7}$$

$$\tilde{p}_1 = \frac{card\left\{i = 1,\dots,\frac{l}{2}+1 : A(z_i, U_1\}) \le A(z, U_1, U_2)\right\}}{\frac{l}{2}+1} \tag{8}$$

$$\tilde{p}_2 = \frac{card\left\{i = 1,\dots,\frac{l}{2}+1 : A(z_i, U_2\}) \le A(z, U_1, U_2)\right\}}{\frac{l}{2}+1} \tag{9}$$

where

$$A(z, U_1, U_2) = \max\{A(z, U_1), A(z, U_2)\}.$$

A theoretical justification of this approach and is presented further, including a more general from of several sources.

For practical applications, we have to not that this method is not memory-consuming, because it is enough to store conformity scores, not the whole data examples. Also, there is no need to keep them in the original order, this can be replaced by storage of their overall distribution.

3.6 Motivating example

Consider now the following space:

$$X = \{1, 2, 3, 4, 5, 6\}$$

There are two big data sources U_1 and U_2 of equal weight with the following data distributions:

$$P_1 = (0.2, 0.6, 0.2, 0.0, 0.0, 0.0)$$

$$P_2 = (0.0, 0.0, 0.0, 0.2, 0.4, 0.4)$$

The whole distribution is:

$$P = (0.1, 0.3, 0.1, 0.1, 0.2, 0.2)$$

Assume that the new example is $x_{n+1} = z = 3$. If the Conformity Measure corresponds to the local density, the p-values with respect to U_1 and U_2 are

$$p_1 = P_1\{x : A(x, U_1) \le A(z, U_1)\} = P_1\{x : P_1(x) \le P_1(z)\}$$

$$= 0.2 + 0.2 = 0.4$$

$$p_2 = P_2\{x : A(x, U_2) \le A(z, U_2)\} = P_2\{x : P_1(x) \le P_2(z)\} = 0$$

and the true p-value with respect to the whole data set is

$$p = P\{x : P(x) \le P(z)\} = 0.1 + 0.1 + 0.1 = 0.3$$

while its straightforward approximation is

$$\hat{p} = (p_1 + p_2)/2 = 0.2$$

which may lead to a falsely confident rejection of the hypothesis that the new example is not an anomaly.

[1] In particular, it is limited from above by

$$\frac{1 + \frac{1}{l+1}}{2} = \frac{1}{2} + \frac{1}{2l+2}$$

which definitely contradicts the validity for any $\epsilon > \frac{1}{2} + \frac{1}{2l+2}$

3.7 Idea of Correction

How to correct this? The idea is to replace the way of approximation as follows:

$$\tilde{p} = (\tilde{p}_1 + \tilde{p}_2)/2$$

where

$$\tilde{p}_1 = P_1\{x : A(x, U_1) \le A(z, U_1, U_2)\}$$

$$\tilde{p}_2 = P_2\{x : A(x, U_2) \le A(z, U_1, U_2)\}$$

and $A(z, U_1, U_2)$ means the largest of $A(z, U_1)$ and $A(z, U_2)$.

In the example above it would work as follows:

$$A(z, U_1, U_2) = \max\{0.2, 0.0\} = 0.2$$

$$\tilde{p}_1 = 0.2 + 0.2 = 0.4$$

$$\tilde{p}_2 = 0 + 0 + 0 + 0.2 = 0.2$$

$$\tilde{p} = (0.4 + 0.2)/2 = 0.3$$

which is a correct approximation.

3.8 Justification of MC approach

In this section we assume that data U comes from sources $U_1, \dots, U_k$ with weights (contribution percentages) $w_1, \dots, w_k$.

Inspired by the logic of the work [3], we consider true data distribution as a limit (asymptotical) case of the empirical distribution, and the local density as a limit case of (the optimal) conformal density. We are analysing some asymptotical tendency, assuming that the amount of data in each of the sources is representative enough, so the difference between true and empirical distribution is low enough.

We assume that the 'full' distribution is split into sources by weighted formula:

$$P = \frac{w_1 P_1 + \dots + w_k P_k}{w_1 + \dots + w_k}$$

The data in a source U_i is generated by an i.i.d. distribution P_i^* (the star means a power distribution here), while testing examples are generated by P.

We also assume that conformity score $A(x, U_i)$ is an 'optimal' one (in the sense of [3]) i.e. it is an equivalent of the density function $P_i(x)$. Note that CM are equivalent if they are reducible to each other by monotonic transformation. Therefore such methods as k Nearest Neighbours and Kernel Density Estimation are asymptotically suiTable because they are originally created in order to approximate a monotonic transformation of the local density function.

Proposition 1. Assume that the space X is discrete (finite). Each bag U_i is big and representative for P_i and the Conformity Measure $A(x, U)$ is equivalent to the local density so the difference between P_i and the uniform distribution on U_i is negligible. Then a valid p-value is

$$\tilde{p}(z) = \sum_{j=1}^{k} w_j \tilde{p}_j(z)$$

where

$$\tilde{p}_j(z) = P_j\left\{x : w_j P_j(x) \le \max_{i=1}^{k}\{w_i P_i(z)\}\right\}.$$

3.9 Proof of Proposition 1

We will show that this $\tilde{p}(z)$ can be obtained as the resulting p-value of another Conformal Predictor.

We can sssume that an example x is generated in two steps: first, $i(x) \in \{1, \dots, k\}$ is generated according to the distribution $W = (w_1, \dots, w_k)$, then x itself is generated by $P_{i(x)}$.

Set the Conformity Measure to

$$A((i, x), U) = w_i P_i(x)$$

(using our assumption that P_i is recoverable from U_i with required precision). In this case the corresponding conformal p-value is calculated as:

$$p((i, z)) = \sum_{j=1}^{k} w_j P_j\left\{x : w_j P_j(x) \le w_i P_i(z))\right\}$$

$$\le \sum_{j=1}^{k} w_j P_j\left\{x : w_j P_j(x) \le \max_{i=1}^{k}\{w_i P_i(z)\}\right\} = \tilde{p}(z)$$

The last estimate does not depend on i and can be used as a valid p-value for z.

4 Experimental settings

4.1 Data collection

The data are taken from Energy Demand Research Project (EDRP)[2]

representing behaviour (energy consumption) by the customers (households).

We use data for 8,703 households using electricity and gas. For each of the household some social parameters (such as number of rooms, tenants, level of income) are provided. They are summarized by including each of the households into one of 6 Acorn categories. In a part of our experiments we will use these Acorn categories as a way of data split, modelling coming the data from heterogeneous sources.

[2] The data were provided by: AECOM Building Engineering, Energy Demand Research Project: Early Smart Meter Trials, 2007-2010. Colchester, Essex: UK Data Archive [distributor], November 2014. SN: 7591.
Energy Demand Research Project: Early Smart Meter Trials, 2007-2010, UKDA study number:7591.

Table 1: Results: random (homogeneous) split

The data set provides the consumption data in two forms: detailed information about energy usage in each half-hour during several months, and a brief summary (so called metadata). For the aims of this work, we use only the second representation. 8 numerical features were taken from the metadata summary. They are listed below:

1. Inclusive number of days between first and last advances
2. Lowest advance value
3. Highest advance value
4. Average advance value
5. Number of advances expected based on feature 1
6. Number of available advances
7. Ratio of features 5 and 6
8. Time of use identifier

We will use these features for learning, and in some experiments for data splitting as well.

These features are preprocessed by converting into logarithmic scale and standalising (linear rescaling to equal average and variance).

4.2 Data split

We consider three ways of splitting the data, wish the level of heterogeneity step wisely increasing:

1. Random (or homogeneous) split (Table 1).
2. Split by Acorn category (Table 2).
3. Split by one of the features, using its median value as a threshold (Table 3). [3]

The last way of splitting definitely introduces heterogeneity by splitting the object vector space into two parts. As for Acorn categories, they are expected to have different distributions, but the level of their overlapping is not known initially.

The original sizes of Acorn categories are: 1)2982 2)370 3)2855 4)1162 5)1316 6)18. Therefore some of them are not used, others taken together to have enough number of examples.

4.3 Inductive mode

To make calculations more efficient for big data, we apply so called *Inductive Conformal Predictor* (ICP) [2]. Its scheme is given in Table 4. A part of data called *proper training set* is left aside the learning. It is used only in calculation conformities of the remaining *calibration* examples. In an equivalent interpretation, inductive mode may be considered as a sort of the standard (Transductive) CP where proper training set is a sort of algorithm parameter, while the Conformity Measure depends only on the example itself. However we still may need the limitation of its size. In this version, the most time-consuming set is calculation of the distance matrix, all the others are relatively small.

4.4 Distributed computing details

In our experiments we assume that the data set is split into two sources of equal size. Each of them may have its own distribution, however we assume within one source the order of examples is random. A number h is the limit on the training set size. For convenience, we assume that this number is the limitation both for the proper training set size, for the calibration set size, and for the number of testing examples taken from each of the sources. This setting is summarised in Table 5.

We compare three approaches of aggregation:

1. Averaging Tests (AT), Sec. 3.3;
2. Maximizing Tests (MT), Sec. 3.4;
3. Maximizing Conformities (MC), Sec. 3.5.

In each of them, Inductive Confidence Machine (as presented in Table 4) has to be run twice for each of the testing examples.

[3] Splits by features 2 and 8 are not included because of impossibility of doing split the same way. This is due to their distribution (too many equal values).

Size	Split	CM		AT	MT	MC
500	Acorn category 1	$k = 300$	APV	0.494	0.524	0.525

4.5 Conformity Measure

For calculation of conformities we use k Nearest Neighbours method (with a large number of neighbours). This choice was discussed earlier in Sections 2.8,3.8.

We try the following values of the parameter k: $10, 30, 100, 300$. As mentioned before, the parameter may reflect natural specific of the problem or an aim of anomaly detection, therefore we consider all of them as equally reasonable. Usually larger k in nearest neighbours anomaly detections reflects more 'centralised' understanding of what is normal (not anomalous) data behaviour, expectation to have only few typical patterns (clusters).

4.6 Measuring deviations from validity

For measuring deviations we use ϵ-free criteria earlier presented in Section 2.5. Table 6 gives a short summary of how they should be interpreted.

Note that validity in sense of this Table does not imply validity for any ε. It just means that invalidity is invisible with this way of its measurement. Therefore, if invalidity is shown just by one of two criteria (APV, ALPV), it is still detected. However, one may consider in this situation APV-invalidity more tolerable, expecting that it is related to rarely used significance levels ε.

Remind also that keeping validity is strictly the first priority. Conservativeness is undesirable but it does not affect the validity, so the goal is only in its minimisation where possible.

5 Experimental results

5.1 Output

The data was selected according to Table 5. All the subsets mentioned above are selected randomly, and the results are averaged over 50 random seeds.

If the 'size' is set to h (1000 or 500) this means that:

- the first ICP learns on h proper training and h calibration examples form the first source;
- the second ICP learns on h proper training and h calibration examples form the second source;
- h testing examples are taken from the first source, and h testing examples are taken from the second source;
- two ICPs assign p-values (p_1 and p_2 respectively) to each of $2h$ testing examples;
- these p-values are aggregated to p by one of three rules (AT, MT, MC).

The output of experiments is presented in Tables 1,2,3 and in Figure 1 in graphical form.

Below we analyse the experimental results from these Tables.

Size	Split	CM		AT	MT	MC
1000	Low feature 1	$k = 300$	APV	0.378	0.542	0.518

5.2 Effect of data split

For homogeneous split (Table 1) AT approach is (up to the precision) exactly valid in terms of APV. However AT-ALPV in all cases is slightly smaller than -1, this still shows slight conservativeness concentrated for small levels of significance. This may be the topic of a future special study, concentrated on homogeneous case.

In the other experiments (Tables 2 and 3) we have to analyse invalidity effects for AT. Recall that invalidity means that AT-APVs are smaller than $\frac{1}{2}$ or AT-ALPVs are smaller than -1. In Table 3 these deviations are much larger, because these splits was done in a more radically way, forced to be heterogeneous, while in Table 2 there are more natural, practical splits.

Comparing the splits from Table 3 to each other, we can see that for some of the features (1,2,5) the deviations are larger than for the others. This indirectly shows the importance of these features in terms their high influence on the other features. Features (4,7) with relatively small deviation are more random and isolated from the others.

5.3 Effect of merging approach

As it is seen from Table 1, in case of a purely homogeneous (random) split the best way of aggregating p-values is just averaging them (AT), the two others are more conservative.

Two other Tables 2 and 3) contain 36 comparisons of AT, MT and MC approaches. They show is following:

- AT is invalid in all the experiments. This is caught by all 36 AT-APV being smaller than 0.5, and in 31 experiments is also confirmed by AT-ALPV being smaller than -1.
- MT and MC are conservatively valid in all the experiments.
- the conservativeness of MC is smaller than MT in 30 experiments, equal (up to the precision) in 2 experiments, and larger in 4 experiments (by APV); smaller in 34 experiments and larger in 2 (by ALPV).

5.4 APV and ALPV criteria

As discussed above, ALPV criterion gives preference to small values of the significance level, because such values are usually applied in the practice. So deviations according to ALPV are in principle more critical.

Let us summarise the points where the conclusions slightly differ for these two criteria.

- In homogeneous case, ALPV was more sensitive in catching conservativeness, while APV did not catch any deviation from exact validity.
- On the other hand, in catching invalidity (as seen in heterogeneous case) APV is stronger.
- Being more sensitive for conservativeness, ALPV better shows advantages of MC over MT in decreasing its level.

All this reflects that the damage from conservativeness is more concentrated in small significance levels, when CP is distributed for big data.

Average p-Value	Average Logarithm p-Value	Interpretation
$< \frac{1}{2}$	< -1	invalid
$= \frac{1}{2}$	$= -1$	valid and efficient
$> \frac{1}{2}$	> -1	valid but conservative

Table 6: Understanding the results of evaluation

5.5 Effect of CM choice

This work concentrates on the effects of conservativeness and does not aim to answer in general the question which CM is better for the specific problem of anomaly detection. As mentioned above, the full answer actually can be done based either on an additional testing set of known anomalies, or on a measure on the whole objects space, which may depend on the physical meaning of the data.

Here we just make preliminary notes about influence of the parameter k (number of nearest neighbours) on the conclusion. Usually the larger this number is, the more centered/unified is the notion of normal (not abnormal) behaviour, less splitter into separate behaviour types.

- In homogeneous case (Table 1), conservativeness (of AT) increases for the small values of neighbour number k.
- In heterogeneous case (Tables 2-3), validity (of AT) is also a larger problem for small k.
- Conservativeness of MT is larger for small k when the split is moderately heterogeneous (Table 2) and for large k when the split is more heterogeneous (Table 3).
- Advantage of replacing MT by MC is smaller for large k.

6 Discussion

6.1 Conclusion

In this work we suggest a MC way of aggregation of p-values for Conformal Prediction that is the best middle way between invalid averaging and conservative maximization of partial p-value obtained from different data sources. This method is applicable on big and heterogeneously split data.

It advantage was shown in Section 3 theoretically in an asymptotical sense, and confirmed on the experimental part on real data. The validity property is kept, while the conservativeness is essentially smaller than for aggregating p-values by maximizing them in most of the cases.

6.2 Future work

For the future work, we can mention the following points.

First, the general case presented in Proposition 1 (see Section 3.8) is applicable as well to a more general case of several sources of different size, this also is interesting to be checked practically.

Second, the area of application used in this paper was detection of anomalies behaviour of households. An interesting related area where these ideas may be applied in the future is growing area of internet of things such as medical sensors. Anomaly behaviour of users is an actual thing to be detected. The practice shows that the alarm/alert criteria have to be based on the analysis of essential data collections, otherwise they may be too approximate in a specific patient's situation.

Third, it was discussed in the work that this framework is transferrable from anomaly detection to supervised learning where validity of prediction sets is important as well. This opens many more applications. But there is a challenge of the following type. In a supervised learning task, the validity and conservativeness is determined by p-values assigned to *true* hypotheses about the labels of new data examples. It can be measure by analogy to this paper, but what about hypotheses assigned to *wrong* hypotheses? The conformal supervised learning is the more efficient the smaller are these p-values. The best situation is when p-values for all hypotheses except the true one are small (close to 0). This property may be also affected on the aggregated stage, where the p-values tend to increase, so theoretical and/or experimental validation has to ensure that it is not lost.

Conflict of Interest Authors declare no conflict of interest.

Acknowledgments This work was supported by Technology Integrated Health Management (TIHM) project awarded to the School of Mathematics and Information Security at Royal Holloway as part of an initiative by NHS England supported by InnovateUK. It was also supported by European Union grant 671555 ("ExCAPE"), EPSRC grant EP/K033344/1 ("Mining the Network Behaviour of Bots"), Thales grant ("Development of automated methods for detection of anomalous behaviour"), and by the National Natural Science Foundation of China (No.61128003) grant.

The large help for this work was done to Lars Carlsson. He gave us the initial motivation for the work, stating the problem of conservativeness in the case of homogeneous split. Another motivation came from the area of aggregating results of different pre-

diction algorithms. In particular it was inspired by recent works [12] with application of CP to big data. and [13] covering the theme of merging data splits as well as merging prediction algorithms. We are grateful to Paolo Toccaceli, Vladimir Vovk, Alex Gammerman and Zhiyuan Luo for useful discussions in this area.

TIHM project directed our attention to anomalies in behaviour-related practical problems as an area of application. We are especially grateful to Energy Demand Research Project for providing the data.

ABSTRACT

Segmented and unsegmented 3D insulated copper through silicon vias (TSVs) of diameter 10 micro-meter, height 100 micro-meter and silicon of sizes 100 micro-meter by 100 micro-meter by 100 micro-meter are modeled using analysis system (ANSYS), equivalent circuit using advanced design system (ADS) at frequency ranges between 100MHz and 40GHz and 10MHz step size. The segmented via is divided into three parts.Each part modeled separately. Scattering parameters are found. The outputs are optimized to give accurate results. The results show that the outputs reflect the transmission characteristics of an ideal TSV.

1 Introduction

S-Parameters Optimization in both Segmented and Unsegmented Insulated TSV was featured in [1]. This paper advances the work done in [1] by optimizing the S-Parameters but to a higher frequency of 40GHz. S parameters have been given much considerations since they allow a device to be treated as a black box with inputs and resulting outputs, making it possible to model a system without having to deal with the complex details of its actual structure.

However, the bandwidth of todays Integrated Circuits (IC's) keeps increasing. This paper has found it important to characterize their performance over wide frequency ranges up-to a maximum of 40GHz. This is because the traditional low-frequency parameters such as resistance, capacitance, and gain can be frequency dependent and therefore may not fully describe the performance of the IC at the desired frequency. Moreover, it may not be possible to characterize every parameter of a complex IC over frequency therefore system-level characterization using S-parameters may provide better and more reliable data [2, 3, 4].

In the previous paper [1], the scattering parameters especially the S21 which defines power loss in TSVs was given much attention. Here we consider other parameters such as S11 too.

2 S-Parameters

A simple RF relay is used to demonstrate the techniques of high-frequency model verification.It is considered a three-port device with an input, output and a control to switch the circuit on and off. However, since the device performance is independent of the control terminal it is simplified to a two-port device. Therefore, it is characterized by observing the behavior at its input and output terminals. This is elaborated in figure 1.

Where,
a_1 = incident wave on port 1
b_1 = reflected wave from port 1
a_2 = incident wave on port 2 (reflected from the load)
b_2 = reflected wave from port 2
Z_S= source impedance
Z_L= load impedance

From figure 2 notations, S-parameters defined the reflected waves b_1 and b_2 as shown in equation (1) and (2)
.

$$b_1 = S_{11}a_1 + S_{12}a_2 \quad (1)$$

$$b_2 = S_{21}a_1 + S_{22}a_2 \quad (2)$$

*Juma Mary Atieno, UESTC, No.2006, Xiyuan Ave, West Hi-Tech Zone, 611731, Chengdu, Sichuan, P.R.China , majuma84@yahoo.com

https://dx.doi.org/10.25046/aj020336

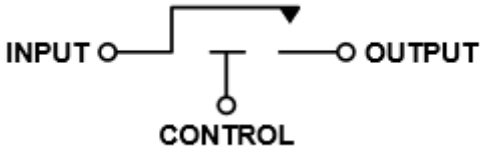

Figure 1: RF relay model [2]

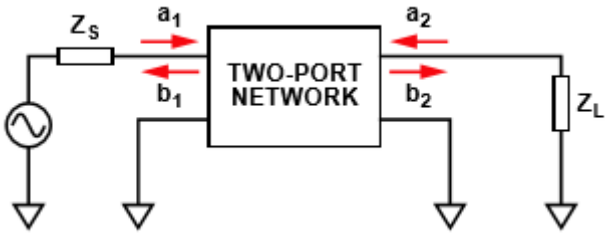

Figure 2: S-parameter model [2]

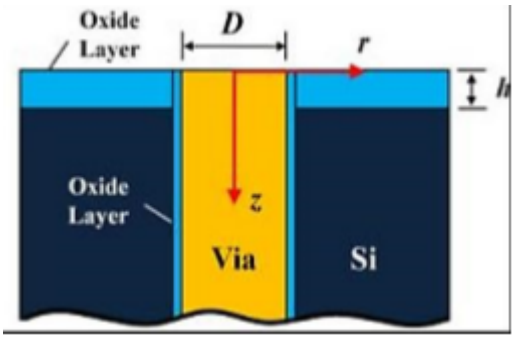

Figure 3: TSV structure [7]

If $Z_S = Z_0$, that is; impedance of two-port input, no reflections occur and $a_1 = 0$. If $Z_L = Z_0$ that is; the impedance of two-port output, no reflections occur and $a_2 = 0$. Therefore we can define the S-parameters, based on the matched condition as follows:

$$S_{11} = \frac{b_1}{a_1} \tag{3}$$

$$S_{22} = \frac{b_2}{a_2} \tag{4}$$

$$S_{21} = \frac{b_2}{a_1} \tag{5}$$

$$S_{12} = \frac{b_1}{a_2} \tag{6}$$

To realize the above parameters in a physical system, Z_S, Z_0, and Z_L must be matched. For most systems this is easily implemented over a wide frequency range [2]. The authors implemented up to a maximum frequency of 40GHz.

3 Through Silicon Via (TSV) Technology

This study contributes to knowledge about parameter distribution, transmission properties, electrical effects and so on. This is the basic foundation of 3D IC [5, 6].

Figure 3 shows a structure of a TSV. It's made up of key areas such as via where the filler material is put. The filler material is copper in most cases since it's a good conductor. The letter z defines the via depth direction, D is the via diameter while r is the via radius direction. The TSV is surrounded by an oxide layer which is silicon dioxide and h defines its height or thickness. The whole model is done in silicon which is a substrate material. Increasing power, performance and financial bottle-necks beyond 3222 nm industry has led to development of TSV [8]. TSVs can be processed in different ways. For instance; Front

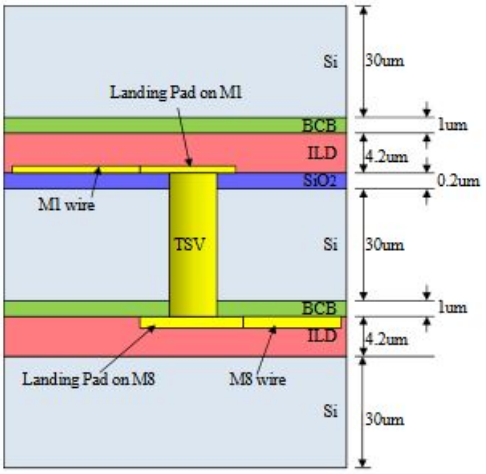

Figure 4: Via First TSV [9]

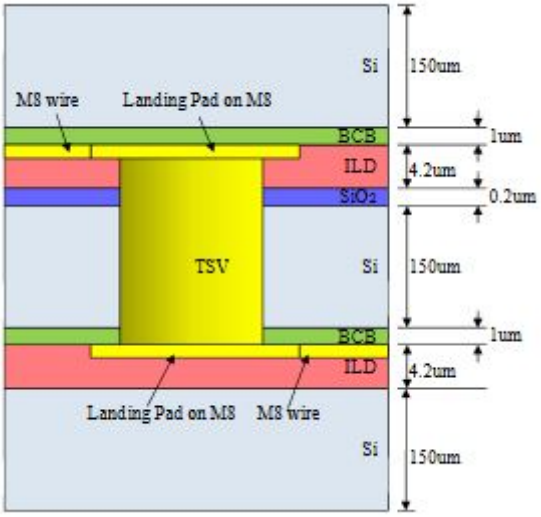

Figure 5: Via Last TSV [9]

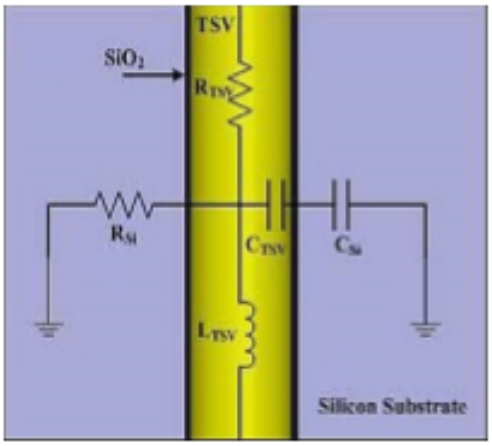

Figure 6: Unsegmented TSV model [6]

End Of Line (FEOL), Back End Of Line (BEOL), Via First (poly-silicon filled via) whereby TSVs are fabricated before transistors. Via Middle (copper filled via) whereby TSVs are fabricated before the copper interconnects and Via Last (copper liner) where TSVs are fabricated after bonding the stack. Figures 4 and

5 show the differences between via first and via last technologies. Potential reliability issues can arise due to during or after these processes. During the via design the stress management can be a problem. This is experienced through via fabrication which may induce tensile stresses in silicon, via may also experience compressive hoop stresses which could lead to via buckling, the quantity and spacing of via may also result in undesirable stress fields and finally the most common thermally induced stresses due to coefficient of Thermal Expansion (CTE) mismatch which may lead to cracking of the silicon wafer. Thermal management is another design problem. This is due to large and non-uniform heat flow within the package. There also exists redundancy in the design used.

Apart from the problems experienced during design of TSVs, some problems are experienced during processing. These include; metal voiding which happens during material filling, uniform via wall material deposition, active Integrated Circuit (IC) surface connectivity and wafer handling problem. Other challenges are experienced during the performance of the TSVs. For instance; limited reliability, thermal cycling, electro migration, silicon depletion at or around the via and also shock and vibration. Noise coupling, fabrication process limits and failure issues have been discussed in [10]. However TSV has several advantages such as reducing the delay, power and area. It also promotes the integration of heterogeneous devices.

4 TSV Liner

Although the TSV has several advantages, these would not be viable unless the TSV is well protected. This is enhanced by TSV liner. In our paper we propose the use of silicon dioxide material as a liner due to its many advantages. Dielectric liner functions as electrical isolation between the TSV metal fill and silicon substrate; therefore it should have zero leakage, high breakdown voltage, low stress, process temperature compatibility, good step coverage and uniformity. Silicon dioxide has these properties. However, other materials such as nitride and polymers are also used as liners for TSV applications [11,12, 13].

5 Methodology

There are several ways of characterizing the ports behavior. One is by admittance matrix Y or impedance matrix Z which defines the relationship between voltages and currents at the ports [14]. Various ways are available and are used to calculate functions that can accurately produce port characteristics within a desired frequency at the same time meet the physical requirements such as symmetry, causality, stability and passivity [15,16, 17 and 18]. The second way of characterizing the port behavior is by use of the incident and reflected waves that are related through the scattering parameter matrix [14], [19], [20]. This second way is often applicable in high speed electronics modeling over the admittance formulation because it gives more accurate results at very high frequencies; it is also useful in applying pure transfer functions models in a simulation. These transfer function capability provides an easy way of observing internal voltages and currents in a subnetwork represented by a Y-, Z- or S-parameter-based port equivalent, and it reduces the computational burden of the model identification process as the number of ports is reduced [14].

As discussed in, [14], Y parameter models can be interfaced with electromagnetic transients program tools through equivalent circuits [21], [22]. However, the circuit experiences inaccuracy hence should be avoided and instead the model can be represented using convolutions [23], [24] which are considered a little bit standard as per [25, 26]. This paper is accessing the variation of S-parameters on a single insulated unsegmented TSV and segmented TSV over a frequency range of 40GHz. The S21 parameter which represents the insertion loss is the key area of research. Insertion loss is expected to be as low as possible on the graphs. The equivalent circuits of the unsegmented and segmented vias are simulated and the results represent the TSV characteristics. The segmented TSV gave a much lower insertion loss as compared to the unsegmented one. This shows that its more reliable and can be used to alleviate the insertion loss problem mainly experienced in the TSV thereby alleviating that reliability problem in 3D packages. The S parameters are converted to Z parameters, Z21 which gave much lower values than the S21 but still maintained the TSV characteristics. S11 characteristics are also listed.

5.1 Unsegmented TSV

Figure 6 represents a vertical TSV model. The R_{TSV}, C_{TSV} and L_{TSV} represent resistance, capacitance and inductance respectively along the TSV. R_{Si} and C_{Si} are the resistance and capacitance respectively in the silicon substrate.

The Advanced Design System (ADS) simulator developed the schematic in figure 7 from the model in figure 6. LTSV, RTSV and C4 are inductance, resistance and capacitance respectively along the TSV. The C1 and C2 are capacitances in the TSV liner, RSi and CSi are the resistance and capacitance respectively along the silicon substrate, S parameter with the terms give the insertion and other loses experienced in TSV while the yield ensures accurate results are obtained. The schematic is an improvement of the work done in [1, 6]. In [6], silicon dioxide layer which act as a TSV liner was not included in the circuit. Moreover, optimization was not done to enhance accurate results. This has been done in this paper by including the yield in the system the frequency has been extended to 40GHz too. A total of 250 trials were made to finally end up with 100 percent yield. The trials were done within the frequency ranges specified in the S-parameter icon. S11 parameters have also been discussed.

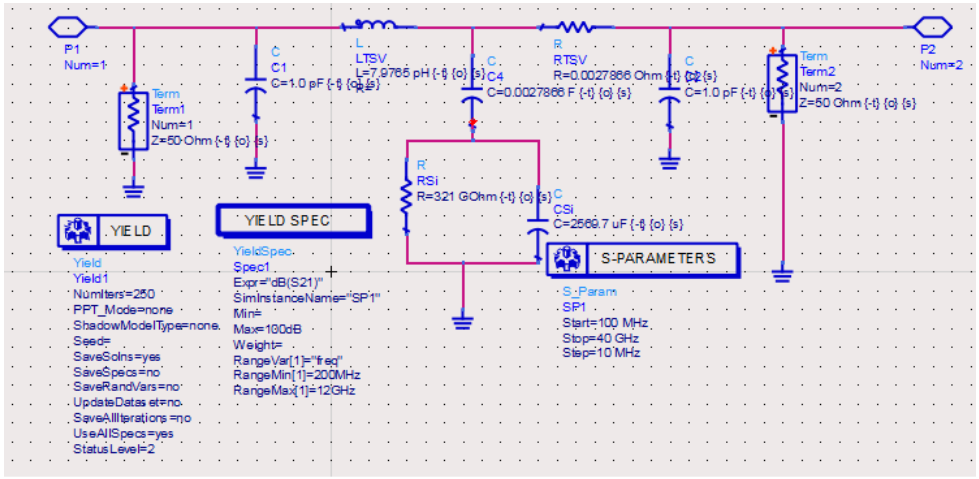

Figure 7: Unsegmented TSV equivalent circuit

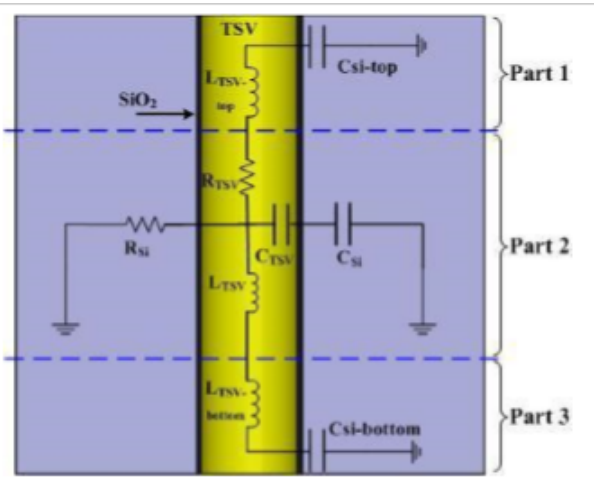

Figure 8: Segmented TSV model

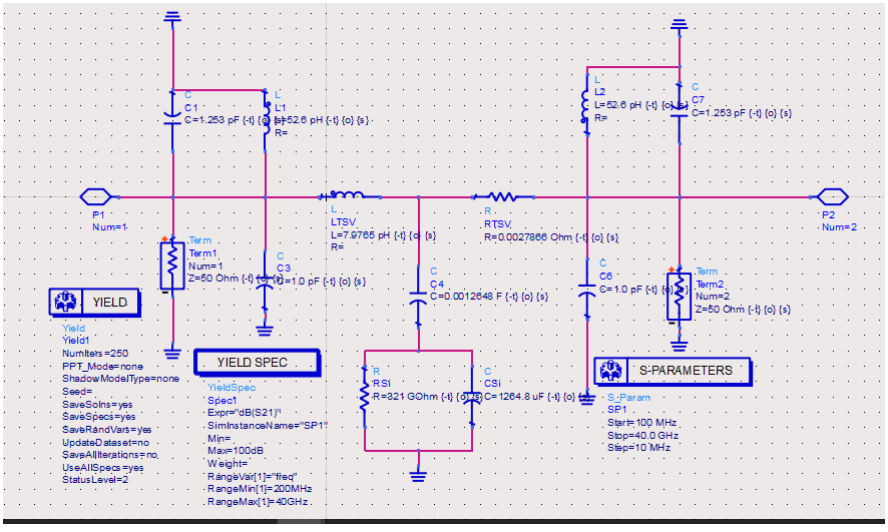

Figure 9: Segmented TSV equivalent circuit

5.2 Segmented TSV

Figure 8 represents a partitioned vertical TSV. It is divided into three main parts namely; Part 1, Part 2 and Part 3. The partitioning of the TSV reduces the insertion loss which is a reliability problem in TSVs. Parasitic resistance, inductance and capacitance exists just like in figure 6.

Figure 8 developed figure 9 whereby; C1 and C7 represent the capacitance developed across the insu-

lator layer silicon dioxide. The LTSV, RTSV and C4 are the inductance, resistance and capacitance respectively along the TSV. RSi and CSi are the resistance and capacitance respectively along the silicon substrate. The S-parameter and the yield simulators play the same role as in figure 7.

6 Results and Discussions

6.1 Unsegmented TSV

Figure 10 looks exactly as what was done in [1] but the difference is that the frequency range has been stretched to 40GHz. The dB values are decreasing with the increased frequency. The markers, m3 and m4 define the dB values at those particular frequencies.

Figure 11 is a list of S11 parameters with varying frequencies. As the frequency increases the S11 value decreased as evident in the list.

6.2 Segmented TSV

Figure 12 describes the dB(S(2,1)) with variation in frequency up to 40GHz. The m3 and m4 in this figure defined the parameter at those frequencies. However, the maximum power on the 'YIELD SPEC' was varied to enhance smooth curve; dB(Z(2,1)) was not plotted too, although the graph gave exactly the variations discussed in [1].

330.0 MHz	1.000 / 179.967	1.000 / 179.966
340.0 MHz	1.000 / 179.966	1.000 / 179.965
350.0 MHz	1.000 / 179.965	1.000 / 179.964

Figure 13: S11 list of values in Segmented TSV

Figure 13 on the other hand described S11 parameter with varying frequencies. It was noted that just like in the unsegmented TSV, the S11 values decreased with increased frequencies, the differences in S11 are however slight. However, The S11 in the segmented TSV is slightly higher than that in unsegmented one at the same frequency.

7 Conclusions and Recommendations

Both segmented and unsegmented TSV were modeled using ADS software. This work was an improvement of work done by [1 and 6]. In the previous work [1], the maximum frequency range considered was 20GHZ but in this paper, it has been stretched to 40GHz. We recommend extension of the frequency range because by doing so, its application will be possible on more electronic devices made. Optimization of the values also promotes more accurate results. Just like in the previous work we intend to do the modeling of TSV in more portions rather than three parts in future. We will also include the effects of changes in length and thickness of the TSV alongside use of other TSV liner materials such as polymers on the power losses. With more factors put into consideration, we hope to reduce the insertion losses in TSV even further. There has been increasing need of cheaper and high performance devices in the world today. These have made researches seek for solutions to these problems. Figure 14 describes the future of TSVs. Varia-

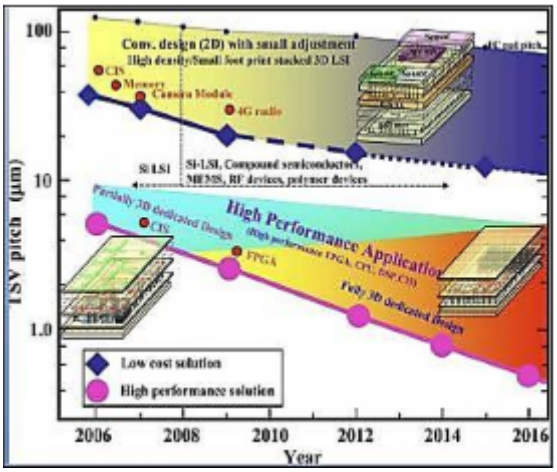

Figure 14: The future of TSV

tion of TSV pitch have greatly influenced the cost and performance of TSV which later influence the devices made between the year 2006 and the current 2017. In the year 2006, the cost of manufacturing TSVs was too high yet the performance of the devices made from the technology was poor due to high TSV pitch. This reduced the reliability of the electronic devices made [1].

Just like in [1],as years went by, research was done and the researchers realized that the TSV pitch size greatly influenced the cost and performance of the TSV modeled devices. They therefore proposed the reduction of the TSV pitch from 100 micro-meters in the year 2006 to less than 1 micro-meter now; 2017. Through the gradual reduction in the TSV pitch size, the cost of production has gone down and the performance of the electronic devices made from the TSV technology has increased. High costs and low performance was evident in 2D conventional designs. However, the use of semiconductors, MEMS, RF devices and polymer devices enhanced development of partially 3D dedicated design to fully 3D dedicated designs which experience low costs and high performance.

Acknowledgment The first author would like to acknowledge the enthusiastic supervision of Prof. HE Song Bai and Zhang Xuliang for their great guidance and advice throughout this paper; they truly inspired me. Their will to motivate me played a major role in this paper. I would also like to thank them for giving me some good examples of some published papers which are related to this work. I would not forget to thank University of Electronic Science and Technology of China (UESTC) for providing a conducive environment and materials to work with on our paper. Our appreciations also go to the laboratory technicians and members who were patient with us all the time. They also contributed to some great ideas in this paper. Finally, we would not like to forget our families and friends for their understanding and support in our work without which this work would not be possible.

Vehicle electric system design

ABSTRACT

In this article, we give a brief overview of future trends and corresponding stakeholder requests regarding the design of automotive electric and electronic (e/e)-architectures. While today's optimization is mainly based on the static design criteria of unit costs and weight, three dynamic design criteria are considered decisive factors in the future: voltage stability, vehicle energy consumption and total cost of ownership. It is shown, how quantitative values for each criterion can be derived, on basis of which different designs of a potential future power supply system could be evaluated. Subsequently, their potential influences on the future system design is discussed.

1 Introduction

This paper is an extension of work originally presented in the 4th International Conference on Electrical Systems for Aircraft, Railway, Ship propulsion and Road Vehicles and International Transportation Electrification Conference [1]. The focus of [1] is to summarize the results of guided expert interviews on future trends, associated hurdles and requirements of the electric and electronic (e/e)-architecture.

The design of the e/e-architecture of vehicles faces many challenges. The information and communication system has to manage and distribute an amount of data that is rapidly growing due to digitization and new functionalities, while the energy distribution system has to provide sufficient energy to securely supply the growing number of electrical components. This growing number of components, functions and connections makes system complexity ever-increasing [1]. This also means that development expenditures are growing significantly. Over 40% of the development expenses of a luxury vehicle is related to e/e [2].

The expert interviews were designed to find out which trends the e/e-architecture will shape in the future, and whether and how the design criteria for development will change. Considering these results, we are expanding our work by synthesizing design criteria that will be important in the future, focusing on the power supply system as part of the e/e-architecture. These criteria are based on the trends and the overview given in [1]. We also discuss the effects of such a change in design criteria on the development of vehicles, and in particular the design of the energy distribution system in the future.

This paper is organized as follows: section two discusses current trends concerning the e/e architecture. Section three summarizes important stakeholder requests on the design of e/e-architectures. While design criteria that are considered important for future power supply systems are synthesised in section four. Examples show their possible impact on design. Subsequently section 5 discusses their influence on future system design. The final section shows conclusions and future works.

2 Trends Concerning the Vehicle Electric System

Today, autonomous driving is one of the most important trends in the automotive industry. Last year, the number of companies testing autonomous vehicles in California doubled. By March 2017, 27 companies received Autonomous Vehicle Testing Permits from California Department of Motor Vehicles.

What is more, in recent years, a change in the mobility behaviour can be observed in all the countries of the Triad [3]. In 2015, the number of registered car sharing users in Germany amounted to 1.26 million already, equating to a six-fold increase since 2011

[*]Lisa Braun, lisa.braun@partner.kit.edu

https://dx.doi.org/10.25046/aj020337

[4]. This strong growth might even be reinforced even more by the introduction of autonomous vehicles. A possible combination of apps like SMILE, GoogleNow, and e-hailing with autonomous vehicles promises to create ideal robot taxis as part of a multimodal mobility concept to implement mobility as a service [5].

To allow autonomous manoeuvres, an exact environment model and thus a large number of sensors for environment detection on board the vehicle are necessary. Moreover, networking with other vehicles and the infrastructure is a precondition to avoid dangers on the route [1]. Both lead to yet another significant increase in the amount of data on board [6]. In addition, they must not fail during driving in order to ensure safe operation of the vehicle. Therefore, the power supply needs to provide at least two independent sources, so that the supply of these safety-relevant components is at no time endangered.

To allow for the provision of this growing power demand, a multi voltage power supply is seen as certain. With the 12 V electrical system limited to 3.6 kW maximum power, it became increasingly difficult to provide the growing power demand of new functions such as active roll stabilization (ARS) [7]. The introduction of an additional 48 V level shall solve that problem [8].

Further, it is cheaper as high-voltage systems in hybrid vehicles as it is still below 60 V, which means no additional isolation is necessary. The higher voltage also allows a reduction of cable cross sections while the efficiency of the distribution increases. The weight of the cable harness could be further reduced by using semiconductors instead of fuses and relays [9].

3 Stakeholder Requests

About 90% of the surveyed experts mention costs as an important design feature of the established e/e-architecture, followed by 80% naming weight. Thus, these two criteria are clearly mentioned most frequently, see also Figure 1 [1].

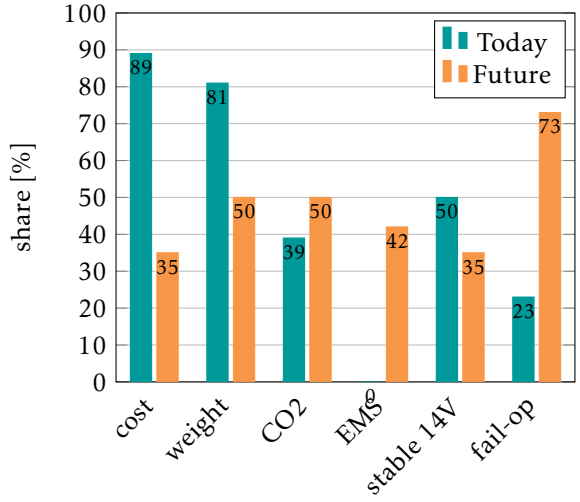

Figure 1 Significance of today's and future requirements concerning the e/e-architecture.

Concerning future design criteria, however, this picture changes. While the importance of cost and weight sink to 35% and 50%, over 73% of the experts think a fail-operational design is important. Another criterion for safe operation, the stability of the voltage, is considered important in future design by at least one third of the experts. The reference to the reduction of carbon emissions increases from 39% to 50%. In addition, about 40% of the experts are asking for an energy management system (EMS) for the future, while it does not seem to matter at all [1].

The focus on fail-operational is due to current developments in driver assistance with the aim of integrating autonomous driving. Failures are not acceptable and must therefore be prevented by a corresponding design of the system, mostly realized by redundancy mechanisms. An example how this could be realized for the information and communication architecture is the developed centralized platform computer of the RACE project [10]. A fail-operational power supply is realized through at least two independent power sources [11]. While this applies to an electric vehicle with DC/DC-converter and one battery in the low-voltage network, sailing with switched off combustion engine or start-stop mode would lead to a system with only one source, if only one battery is installed additionally to the generator [7].

What is more is that voltage stability must be guaranteed even with fast load changes and high power peaks. An EMS could therefore contribute to the stabilization of the voltage as well as the reduction of the consumption and associated emissions.

However, the experts' answers do not allow any conclusion as to whether these changes in the values are due to actual changes in the prioritization or due to the current trends and associated expected future problems. In the case of costs in particular, it seems questionable whether their significance in the future will actually decrease so clearly. Nevertheless, these figures allow conclusions to be drawn on expected changes in the development. In the following, important future design criteria of the power supply system are derived from this selection.

4 Synthesis of Important Design Criteria

Not technical aspects are the main problem for achieving future solutions but legacy restrictions and fixed corporate structures, which go along with the structure of the vehicle's e/e-architecture [1]. Design criteria that consider future changes can help to weigh up possible solutions in the early stages of development. Therefore, the aim of the derived design parameters is to provide the advantages and disadvantages of the various designs of the power supply system even in an early development phase. For this reason, they must provide measurable target variables, with the aid of which different designs can be evaluated and an optimal solution can be derived.

Firstly, to guarantee the safe operation the voltage stability must be guaranteed. This is an essential constraint for the integration of safety-relevant functions. Although fail-operational is of great importance for the design of future e/e-architectures due to the results in [1], no corresponding evaluation criterion is developed in the following. In addition to the requirement of a redundant power source, an isolated view of the power supply system does not seem to make sense. Rather, an intelligent combination of measures in the communication and power supply network can save required redundancy effort, e.g. through a combination of powerline communication and power over dataline for safety-relevant components [12].

Secondly, at the latest since the diesel-gate, vehicle emissions have been the focus of attention. Weight reduction as well as higher efficiency of the power distribution or reduction of the power consumption e.g. through EMS can help to reduce the energy consumption of the vehicle as well as the corresponding emissions. There is a conflict, however, between a light weight wire harness with small cable cross-sections and the achievement of minimal power losses through the distribution, as small cross-sections increase the cable resistance. In order to find an optimum compromise, the vehicle consumption is therefore chosen as a further design criterion.

Finally, today the costs per function must be minimal. We expect this to change in the future due to the growing volume of car sharing and stricter emission limits. Operators of car sharing fleets are less interested in the purchasing prize than in the total cost of ownership. Simultaneously, the operating time and thus the influence of the travel costs on the total cost of ownership increases. For this reason, not only development and production costs but also operating costs must be taken into account in minimizing costs in the future.

4.1 Voltage Stability

For safe operation of e/e-systems, it is important that the voltage limits of 11 V and 16 V are maintained at the sinks, otherwise the functionality is not, or only partially, provided. Via the buffer of the voltage to these limits, for example, in an extreme driving scenario, it is possible to compare different configurations of the power supply system [13].

The disadvantage of this method is that it does not provide any information about the temporal behaviour of the voltage. The minimally determined value could be anything between an outreach and a constant curve or a broadband noise within the determined range.

Conclusions on the scattering can, for example, be drawn with the so-called quantiles. This is a method of statistics in which an ordered data series is split into two equal halves by the median. The box plot can thus be formed over the interquartile distance between the 25% quantile and the 75% quantile. The median indicates which voltage level the curve varies, and the size of the box between the 25% value and the 75% value shows how strong this variation is.

Alternatively, the standard deviation s based on the empirical variance σ can be used as a further method of statistics for evaluation. It indicates the average deviation of the measured values x_i from the mean value $\bar{x}$ of n data points. The smaller the standard deviation, the more stable is the curve of the voltage for the observed time interval. The standard deviation is calculated as follows [14]:

$$s = \sqrt{\sigma(x)} = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{x})^2}{n}} \quad (1)$$

Figure 2 shows voltage curves with varying volatility. The blue curve shows a strong fluctuation around 12V. The green curve fluctuates considerably less by 14V. The orange curve includes a voltage jump after 300s. Before the jump, it is comparatively stable at 11V, then stable at 14V. Figure 3 shows that for the blue and green curves the fluctuation and its corresponding voltage level can be represented well with the box plot. However, the jump of the orange curve is not evaluated correctly. The values before the jump are considered as outreach and therefore this curve appears incorrectly as the most stable.

If the mean value is replaced by the system voltage of 14.3 V the standard deviation in figure 4 can as well consider the voltage level in the evaluation. Figure 4 shows that the standard deviation, in contrast to the box plot, correctly reflects the stability of the voltages in figure 2 and the green voltage curve is correctly recognized as the most stable followed by the orange. Therefore, the standard deviation appears to be a suitable parameter to evaluate voltage stability.

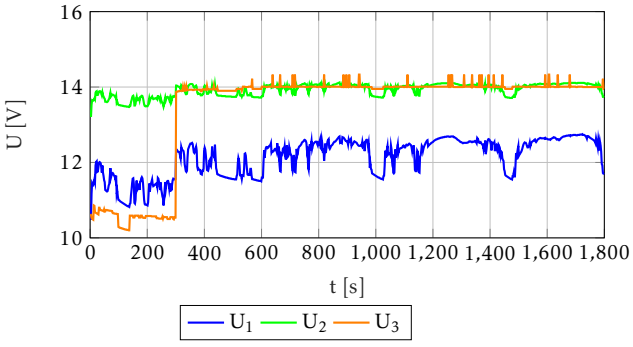

Figure 2 Voltage curves with variing volatility.

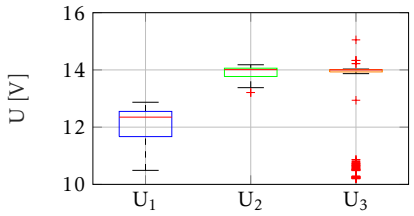

Figure 3 Box plots of shown voltage curves.

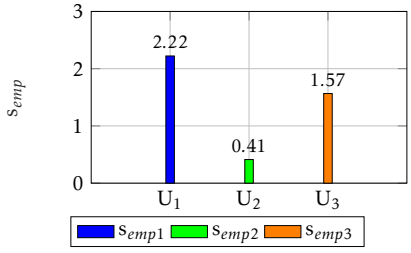

Figure 4 Standard deviation of shown voltage curves.

4.2 Vehicle Energy Consumption

In Europe, the allowed CO_2-emissions will be reduced to 95$\frac{gCO_2}{km}$ by 2020, while the full fines will reach 95$\frac{€}{g}$ from 2019 onward [15]. What makes it even more difficult is the fact that from 2020 onwards a new test method with a realistic driving cycle, the Worldwide harmonized Light duty driving Test Cycle (WLTC), for the determination of the emissions takes effect. It is expected that the discrepancy between the actual consumption and the calculated standard values will drop from an average of about 45% in 2015 to 23% in 2020 [16]. Conversely, this means that if the actual consumption is constant, the measured standard emissions are increased by 22%.

One reason for this is the fact that the consumption optimization of the vehicles to the unrealistic, static speed profile of the previous New European Driving Cycle (NEDC), no longer takes effect. Without the untypically high dead times and frequent stops, the previous high influence of consumption-reducing measures such as start-stop-automatic and downsizing is reduced [17]. Other factors such as weight reduction and the reduction of transmission losses in the power supply network are instead brought into the focus.

The specific vehicle consumption B_{sV} per 100 km can be calculated as a function of the distance travelled s_c and the needed propulsion energy W_{pro} and recuperation energy W_{rek}. If no recuperation is integrated, W_{rek} is zero.

$$B_{sV} = \left(W_{pro} + W_{rek}\right) \cdot \frac{100}{s_c} \tag{2}$$

The energy required by the propulsion or the recuperation energy which may be fed back depends of the energy requirement W_c on the tires. It depends on the total drive resistor F_t and the travelled distance s_c which can be derived from the velocity profile v_c of the drive cycle.

$$W_c = F_t \cdot s_c = F_t \cdot \int_0^t v_c(\tau)\mathrm{d}\tau. \tag{3}$$

In addition to the time profile of the energy requirement on the wheels during the cycle, the energy required by the propulsion or the recuperation energy to be fed back depends on the efficiency η_{dt} of the drive train.

$$W_{pro} = \int_0^t \frac{1}{\eta_{dt}(\tau)} \cdot F_t(\tau) \cdot s_c(\tau)\mathrm{d}\tau \qquad \text{for}(F_a > 0) \tag{4}$$

$$W_{rek} = \int_0^t \eta_{dt}(\tau) \cdot F_t(\tau) \cdot s_c(\tau)\mathrm{d}\tau \qquad \text{for}(F_a < 0). \tag{5}$$

The total drive resistance F_t is composed of several values: the rolling resistance F_r, the slope resistance F_s, the air resistance F_l and the acceleration resistance F_a which are calculated as follows [18]:

$$F_t = F_r(m_{veh}) + F_s(m_{veh}) + F_l(v_c(t)) + F_a(m_{veh}, a(t)) \tag{6}$$

$$F_r = m_{veh} \cdot g \cdot c_r \tag{7}$$

$$F_s = m_{veh} \cdot g \cdot sin(\beta(t)) \tag{8}$$

$$F_l = \frac{1}{2} \cdot \rho_l \cdot c_W \cdot A_{veh} \cdot v_c(t)^2 \tag{9}$$

$$F_a = F_{a.trans} + F_{a,rot} = a(t) \cdot \left(m_{veh} + \frac{J_{Wh} + i^2 \cdot J_{En}}{r_{stat} \cdot r_{dyn}}\right) \tag{10}$$

The rolling resistance F_r and the slope resistance F_s depend on the vehicle weight m_{veh} and the gravity g. The coefficient c_r takes into account the walk losses which occur on the road. β indicates the slope angle of the street. The air resistance F_l is calculated from the front surface A_{veh}, the air density ρ_l, the air drag coefficient c_W, and the air inflow velocity v_c(t) of the vehicle. The resistance F_a, which is dependent on the acceleration a, consists of a weight-dependent translatory part and a rotational part. The latter depends on the moment of inertia of the wheels J_{Wh} and engine J_{En}, the translation i and the static r_{stat} and dynamic r_{dyn} free radius.

The energy consumption of the electrical components and the power distribution W_E can be determined either by measurement in a test stand or, especially in early development phases, by means of a model-based analysis. In both cases, an operating model of the loads $P_i(t)$ is required to determine the energy consumption, as it fixes the current flow and thus the losses $P_{V,dst}(t)$ during transmission. What is more, in a vehicle with an internal combustion engine (ICE), the efficiency of the drive η_d and the efficiency of the generator η_g must be considered. In the case of an electric vehicle, this would instead be the efficiency of the high voltage battery and the DC/DC-converter. In order to determine the specific consumption B_{sE}, the values have to be converted to a distance of 100 km analogous to the driving consumption

$$W_E = \int_0^t \frac{1}{\eta_d(\tau) \cdot \eta_g(\tau)} \cdot \left(\sum_{i=1}^{n} P_i(\tau) + P_{V,dst}(\tau)\right)\mathrm{d}\tau \tag{11}$$

$$B_{sE} = W_E \cdot \frac{100}{s_c} \tag{12}$$

The sum of both specific consumption values provides the total consumption of the vehicle, which is to be optimized.

Table 1 Vehicle data of a small car (A), a SUV (J) and an electric luxury car (F).

Parameter	unit	A	J	F
propulsion		ICE	ICE	electric
weight	[kg]	885	2,435	2,000
standard consumption	$[\frac{kWh}{100km}]$	38.7 (=4.5l)	80.84 (=9.4l)	22.04
standard emission	$[\frac{gCO_2}{km}]$	93	218	0

The given standard values in table 1 are measured with the established New European Driving Cycle (NEDC). Assuming that both ICE-vehicles would be 50 kg lighter, the power consumption per 100 km of the small car could be reduced by 0.89 kWh and the standard emissions by 2.4 g. For the SUV, the consumption would drop by 0.91 kWh which would lead to 2.45 g less emission per km. In comparison, the high efficiency of the electric drive train with 3.71 kWh enables a significantly higher reduction in consumption by weight reduction. These values are calculated in MATLAB with the given equations (2) to (10) and the cycle data of the NEDC.

To calculate the equivalent electrical energy consumption during the NEDC, an average speed of 33.6 $\frac{km}{h}$ is assumed. It is further assumed that the efficiency of the ICE is 35%, the efficiency of the generator is 75%, while the efficiency of the high-voltage battery and the DC/DC-converter is 95%. Under these circumstances a reduced electrical energy consumption of 78 W for the small car, 80 W for the SUV and 1125 W for the electric car would have the same effect.

4.3 Total Cost of Ownership

Since, on the one hand, the permissible emission limit values $G_{CO_2,0}$ fall, and on the other hand, higher standard values are to be expected by the more realistic determination in the future, the deviating development costs of alternative designs are estimated with the help of CO_2-emission penalties.

The allowed emission limit G_{CO_2} of a vehicle is calculated depending on its weight m_{veh} and the weight correction factor m_0 [15]:

$$G_{CO_2} = G_{CO_2,0} + 0.0457 \cdot (m_{veh} - m_0). \qquad (13)$$

For each automobile manufacturer its fleet limit value is calculated with the individual emission limit of their different vehicle models and their sales figures. If the fleet emission exceeds this value, a penalty of €95 will be due for each gram from 2019 onwards.

The production costs can be estimated from the sum of the material costs of the power supply system. Furthermore, the operating costs can be determined from the specific driving consumption and the respective energy costs of the vehicle. Taxes for petrol vehicles in Germany are also dependent on the specific CO_2-emissions and the engine displacement of the vehicle.

Table 2 Emission penalties and annual travel costs of the example vehicles at a running distance of 36,500km a year.

Parameter	unit	A	J	F
propulsion		ICE	ICE	electric
allowed emission limit	$[\frac{gCO_2}{km}]$	72.74	143.58	123.7
emission penalty per car in 2019	[€]	1,735	7,070	0
cost energy	$[\frac{€}{kWh}]$	0.1605	0.1605	0.2869
specific cost	$[\frac{€}{100km}]$	6.21	12.97	6.32
Travel expenses per year	$[\frac{€}{a}]$	2,267	4,736	2,308
taxes (Germany)	$[\frac{€}{a}]$	198	496	0

Table 2 shows the associated costs of the three vehicles given in table 1. First of all, table 2 shows that considering the weight correction factor of 1,372 of the year 2016, the emission limit of 95 gCO_2 per km, and today's standard emission, both vehicles with internal combustion engine are significantly above the emission limit. Considering the new test procedure mentioned above, the high penalty per sold vehicle could rise even further. The annual taxes calculated in Germany are also dependent on CO_2-emissions and therefore are the highest for the SUV.

For the comparison of different alternatives of the power supply network, an additional statistical calculation of the service costs is dispensed with since it is assumed that due to the low failure rates of electrical systems these will be similar for all alternatives.

5 Influence on Future System Design

While existing evaluation criteria such as unit costs and weight are static and can therefore be determined directly from the system design [19], all design criteria defined here depend on the dynamic operation of the vehicle and the electrical loads. Consequently, an operational model is essential for the determination of these criteria.

In order to evaluate the stability of the voltage, a worst-case scenario appears to be fitting, as is currently used when designing the energy source. However, for an accurate determination of the energy consumption and operating costs, the operation has to be taken into account over a longer period of time, as the ambient conditions such as light, weather and temperature change substantially over the course of a year and thus the use of the electrical loads varies. The created operating models of the loads must allow to adjust the environmental conditions, the route, and the driver in order to simulate the energy consumption of

the electrical network in a realistic manner.

In the established determination of the standard consumption, electrical loads are switched off if possible. Thus, they are not considered when measuring the standard consumption and emission.

If for the implementation of safety, critical functions voltage stability is an indispensable constraint, it must be fulfilled at all costs. In particular, in the case of speed-dependent power generation in a combustion vehicle, a minimum battery capacity is required to maintain the voltage limits at all times. The standard deviation allows to evaluate different designs. It can for example be used to define a maximum allowed deviation value for a design to be considered stable. If a stable architecture is to be selected, designs with high storage capacity are preferred. Considering the fail-operational request for a redundant power source for internal combustion vehicles, the power supply network will likely contain at least two batteries independent of the other design criteria. In addition, bus or ring topologies are preferable to the existing star topology since these allow a simple distribution of the energy sources in the network in order, for example, to ensure the supply of the components in the event of a fault in the supply line [20].

The defined cost analysis also shows that the unit costs over the emission penalty as well as the operating costs depend on the consumption and consequently on the energy efficiency of a vehicle. Consequently, future architectures follow a trade-off between an energy-efficient design and small unit cost. A reduction of the consumption of the energy supply system by 200 W of the SUV discussed in the previous section by means of a system more expensive by € 570 would be cost neutral due to the 6 g lower emissions and therefore reduced penalties. But an equivalent reduction of the emission by a weight reduction of 125 kg would only result in a reduction of the penalties by € 50, since the permissible emission limit also drops to 138.1 gCO_2 per km.

This shows that in this combination of evaluation criteria the optimization of the efficiency of the energy distribution is preferred to the optimization of the weight. In contrast, in the case of an electric vehicle, the optimization of the weight has a greater effect on the consumption, because of the high efficiency levels in the supply of the electrical network as well as the drive train. To minimize the operating costs, it does not matter how the reduction of the energy consumption is realized.

In summary, a redesign of the established power supply system to reduce the power consumption would not only lead to lower operating costs, but could also reduce the product price of ICE vehicles. In contrast to of today's cost optimization, higher costs per function through higher development or production costs might be acceptable as long the saved emission penalty costs are even or higher. These assessment criteria therefore call into question the established optimization approaches of the cable harness based on unit costs and weight.

Today, the introduction of a power bus with semiconductor switches instead of existing fuses in established vehicle models seems to be economically unprofitable due to the high development and material costs. If, however, the design criteria determined here are applied, the additional costs associated with the introduction would be acceptable if weight or efficiency savings in the electrical grid lead to equal or higher savings in emission penalties.

6 Conclusion

Electrification and digitalisation combined with new functions challenge the established e/e-architecture. Hence, it must change to meet future requirements. To be able to compare different alternatives of the power supply network, important design criteria are derived from prioritized stakeholder requests, taking into account the trends identified.

The stability of the voltage is an important boundary condition for the increasing integration of safety-relevant components into the vehicle. It is shown that using the standard deviation not only the voltage limits, but the temporal fluctuations in the assessment of the voltage stability of different design alternatives can be considered. This allows to evaluate different designs concerning their expected stability.

Moreover, consideration of the energy consumption of the whole vehicle allows to find an optimum compromise between minimal weight and minimal electrical losses. On the one hand, the energy consumption of the vehicle combined with the usual energy costs of the different drive alternatives determine the specific operating costs. On the other hand, the energy consumption will significantly influence the selling price of a vehicle in the future by means of the emission penalties if the emission limit values are exceeded. This means that higher development or production costs for a redesign of the established power supply system are acceptable as long as they are equal or below the saved penalty costs. An additional bonus is that a higher efficiency lead to lesser operating costs which are of high importance for fleet vehicles e.g. for car sharing especially.

Since a weight reduction also reduces the permissible emission limit values of a vehicle, an equivalent reduction of the emission over a more efficient energy distribution system has a higher effect on the penalty savings. Therefore, the found optimization criteria call into question the established optimization approaches of the cable harness based mostly on unit costs and weight.

In future research, we will investigate the extent to which different freedoms in shaping the energy network can influence and facilitate the fulfillment of these criteria. For this purpose, a modelling environment in MATLAB/SIMULINK is created, which allows to examine alternative designs of the power supply network with regard to the dynamic design criteria defined here and to derive optimal combinations.

ABSTRACT

In virtual environments, virtual hand interactions play a key role in interactivity and realism allowing to perform fine motions. Data glove is widely used in Virtual Reality (VR) and through simulating a human hands natural anatomy (Avatar's hands) in its appearance and motion is possible to interact with the environment and virtual objects. Recently, hand gestures are considered as one of the most meaningful and expressive signals. As consequence, this paper explores the use of hand gestures as a mean of Human-Computer Interaction (HCI) for VR applications through data gloves. Using a hand gesture recognition and tracking method, accurate and real-time interactive performance can be obtained. To verify the effectiveness and usability of the system, an experiment of ease learning based on execution's time was performed. The experimental results demonstrate that this interaction's approach does not present problems for people more experienced in the use of computer applications. While people with basic knowledge has some problems the system becomes easy to use with practice.

1 Introduction

As a result of technological transition, VR has allowed to get over physical tools' limitations by triggering the evolution of traditional devices into new more simple and intuitive ones, thus fostering the emergence to *Natural User Interfaces* (NUI). These enhance the natural impression of living in a simulated reality by improving the interaction between users & VR environments.

NUI set a new HCI paradigm exploiting the skills that human being has developed throughout his life for social interaction. Though most social interaction among humans takes the form of conversation, there is a large sub-text to any interaction that is not captured by a literal transcription of the words that are said. All of the factors going beyond the verbal aspects of speech are called *Non-Verbal Communication* (NVC) and takes many forms, or modalities like: *facial expression*; *gaze* (eye movements and pupil dilation); *gestures*, *bodily movements*; *body posture*; *bodily contact*; *spatial behaviour gesture*; *non-verbal vocalizations*, among others.

Social interaction is a key element of modern virtual environments. VR systems that enhance the presence in social interactions must collect gestural, positional, sound and biometric user information. As a solution, most VR developers propose a NUI with virtual characters simulating real human social interactions (personifying user and computer). Additionally, as a result of a physical and mental need in user's interaction with computer games/applications, many games are designed to test the physical skills of its users setting gestures as the most common means to establish communication. In particular, studies on cognitive science state that hand gestures are which best express key information.

When developing a NUI, two different approaches are usually addressed: based on *tracking devices* or based on *vision*. In robotics, research focus on controlling a war robot or drones in high-risk areas or in remote-control surgery by tracking a robot hand. In medicine, virtual environments allow objectively quantify surgical performance, and accelerate the acquisition of baseline surgical skills without risk to real patients based on motion capture. These approaches have also greatly aided in sign language recognition research, to training of children to write, play instruments, to control objects, 3D modelling, among others. This paper's work presents a VR system built on NUI principles, allowing the simulation of gestures and animations of human hands based on the recogni-

tion of their movements using a data glove as an input device.

2 Related Work

From bibliography, most of VR and NUI related works try to increment the immersion level by replacing classical devices (such as mouse, keyboard, joysticks) for new technological device tracking or image processing [1, 2]. From these works, it has been identified the following specified shortcomings [3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]:

- Study of manipulation in VR environments results in a gap for vision-based works.
- Related research to gesture recognition are mostly vision-based.
- Vision-based systems that perform gesture recognition are usually limited to a tracking zone, in addition to noise and high processing requests.
- Regarding gestures recognition, the combination of two or more gestures to get a new complex gesture for a complex task has not yet been achieved.
- Works based on data gloves are scarce where the main VR primitives are only studied and those existing works only emphasize in some of them.
- In many of mentioned works the *User Experience* has not been analyzed.

The present work is an extension of a previous work originally presented in [16] covering the following topics:

First of all, there is a virtual character that exhibits a correlational behaviour with a user (*Avatar*). It is explicitly controlled by commands specified by the user through a device as an external animator. This is the most common option while considering that VR applications based on NUI concepts and Gesture Interaction should provide certain facilities to the user for a more bearable interaction [17].

Secondly, during the interaction through the avatar each gesture is a control command associated to a process. The involved process tries to match incoming data from data glove with the modelled avatar [18, 19]. The avatar's virtual behaviour is controlled by the following standard primitives [20, 21]:

- **Navigation**, the displacement of the user in the virtual space and the "cognitive map" he/she builds on it.
- **Selection**, the action of user pointing to an object.
- **Manipulation**, the user modification of an object's state; and
- **System control**, the dialogue between the user and the application.

In this context, this work tries to meet the provided demands by mentioned gaps. Therefore, in addition to developing an HCI environment, the system provides a natural way to interact freely on a scenario through a data glove. Mainly, the system focus on the use of natural movements and gestural protocols (in HCI, set of gestures to establish communication between human and system) performed by hand [22, 23]. As an effective way to prove how positive can be this kind of interaction, it is worth to perform a user's experiment that shows the richness of the virtual experience. The next section show the offered features by system.

2.1 Natural User Interface based on Data Glove

The system uses a data glove (integrated sensor textile glove) as a gestural interface that allows a real-time interaction where the user communicates through an *avatar*. In consequence, according to the mentioned multi-dimensional control tools, excepting the selection tool, it has been developed the next basic features:

- **Navigation**. Most of the known and implemented navigation options used by game and VR applications developers are: "walk", "stop", "run", "jump", change different views of the scenario, among others. Particularly, this system has implemented the "walk", "stop" and change of view of the scenario (As shown in Figure 1 (a)). All of them are associated with a set of gestures (protocol) that performs each action. As an extra functionality of the system, it is possible to remotely control an air-plane toy included in the scenario (As shown in Figure 1 (b)). As it is possible to do two different types of navigation (avatar navigation and air-plane navigation), it is necessary to perform a gestural protocol to swap between them.
- **Manipulation**. While a user interacts naturally on the scenario, also has the need to perform handling actions in it. Basically, these actions are to be able to touch the virtual elements and grab them (As shown in Figure 1 (c)). Some involved factors for implementing this functionality are: physics treatment, proximity to objects (to grab) and avatar hand position.
- **System Control**. This control tool relates to the user-application dialogue. In this approach, user-application dialogue implies to control the system by using simple and natural gestures. This feature is achieved through navigation and manipulation tools.

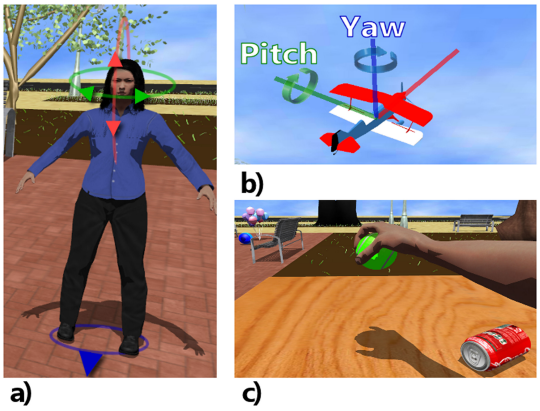

Figure 1: System's Features: a) Change of View Avatar, b) Airplane Navigation, c) Grasping in a work's table.

As a consequence of the correlational behaviour between user and avatar it would be nice to be able to visualise user hands and avatar hands as synchronised as possible. Thus, this system implements the next feature:

Real-time Imitation. This involves that avatar's hands can mimic user's hands through a refined model management, physics treatment and rendering tuning (frame rates). Realistic visualisation of the replicated gestures needs the model representation of hands and mapping of human hands' motion into the model which is not straight-forward due to different sizes and joint structures of bones for the human hands. It is necessary to consider that some movements are not feasible by the user then the avatar should not be able to do it.

3 System Overview

For a proper and efficient operation of the system is necessary to consider certain particular operating features (As shown in Figure 2). It is worth mentioning that the used input device was an integrated sensor textile glove *DG5 Vhand Data Glove 2.0* distributed by *DGTech Engineering Solutions* [24, 25]. This device has five embedded bend sensors which enables to accurately measure the finger movements, while an embedded 3 axes accelerometer allows for sensing both hand movements and hand orientation (roll and pitch).

The interaction between user and system implies that, at first, the direct **acquisition** must be performed by different sensors capturing performer's actions. So, to use the system, the user should go through an implemented **calibration** process that will allow obtaining greater sensitivity. In order to this, it is necessary to establish the appropriate user maximum and minimum flexion degrees of fingers with the glove. The corresponding values will be provided with gestural protocols that will allow flexion limits to be recorded. These protocols were named "Extended Hand " and "Closed Hand".

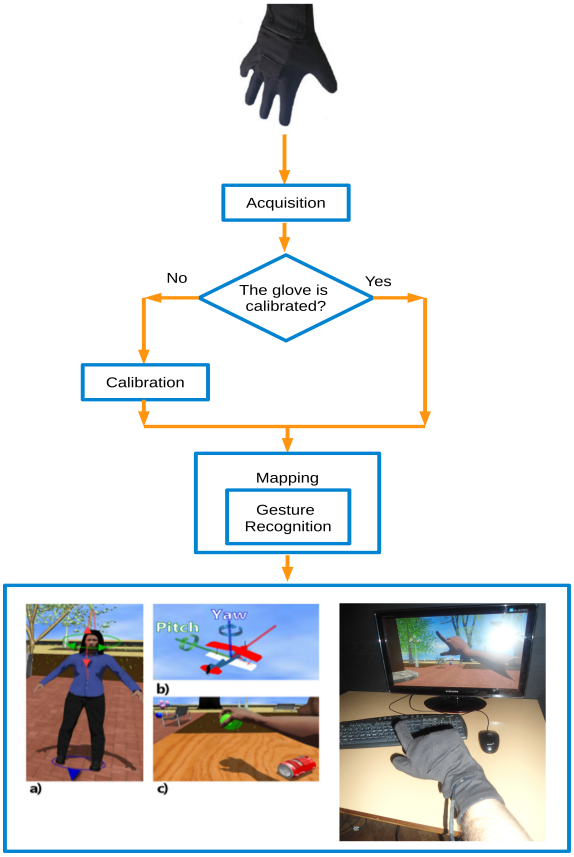

Figure 2: System's Flowchart

Thereafter, the new bending, orientation, and acceleration values after calibration should be mapped to values within the avatar model domain (**mapping**), i.e, are matched to model values getting a transition from physically detected movement (real domain) to avatar model image movement (virtual domain).

In relation to **gesture's recognition**, each gestural protocol was defined by a set of gestures, so each gesture consisted of the degrees, orientation and acceleration values previously stored in a database. The developed gestural protocols are *forward walking*, *backward walking*, *stop walking*, *revolver*, *grasp*, among others. Finally, to generate a particular event such as "walk" on the scenario, user must execute a forward walking or a backward walking. The system is responsible for controlling, monitoring and supervising in real-time all the user's actions/requests.

4 Evaluation and Results

McNamara and Kirakowski proposed a model of factors for understanding the interactions between humans and technology: *User Experience* (UX) and *Usability* [26]. The UX can be academically summarized as every aspect of the interaction between a user and a product. According to the most famous usability expert Jakob Nielsen, usability is a quality attribute that assesses how easy user interfaces are to use [27][28]. Also states that usability has five attributes which are: *ease of learnability*, *ability to remember*, *efficiency*, *error*

rate and *user satisfaction*.

On the other hand, it is known that there are two method types to evaluate an HCI experiment: qualitative and quantitative form.

Thus, knowing that gestures allow executing predefined actions very quickly and naturally, it is interesting to develop a test based on wasted time while executing main actions on the virtual world. On this way, an ease of learnability test was designed and aimed to measure the quality of NUI system. Basically, the test analyzes how well user uses the interface to arrive at a specific scenario's point and how well achieves to manipulate/modify the elements on a virtual work table (see Figure 1(c)).

4.1 Evaluation Test Design

An evaluation test was applied to a thirty participants' group between fifteen and thirty-nine years old. Before test, the system's goal and implemented gestural protocols were explained to each participant. Based on collected answers from a priori questionnaire about user's computer experience, participants were divided into two subgroups: *Basic* and *Intermediate-to-Advanced* users.

There were fifteen participants by subgroup. People that only use cellphone as a communication way and computer for their work were gathered together into *basic* experience group (Group 1). The *intermediate-to-advanced* experience group (Group 2) gathered digital natives (people who have grown up using technology like the Internet, computers and mobile devices). This group included girls and boys that have ever played video games.

During the experiment, each participant must execute two proposed tasks (ten repetitions per task). The main goal is to accomplish an evaluated challenge in time by timing the task. The following tasks were evaluated:

- **Task 1 (Navigation feature)**: Initially, beginning at a specified point on the scenario, user must move to another already specified point through the defined gestural commands.
- **Task 2 (Manipulation feature)**: The goal is to arrive at the virtual work table, to grasp an object and move it to another table's place.

4.2 Tasks Performances

Figure 3 shows the recorded average time from each performed repetition for the execution of task 1 to both evaluated groups. Curves behave similarly but with different initial average time (first repetition). In *basic* group, the average time remained approximately constant for all replicates, showing that the execution's ease was minimal. Particularly in the seventh repetition it arises the maximum local progress. In *intermediate-to-advanced* group, the execution time decreased progressively as increasing the repetitions, but in the sixth, seventh and eighth repetition there were certain regressions that are due to users' attempts to improve their execution times (it might be because Murphy's law).

Similarly, Figure 4 shows the recorded times for the execution of task 2. As long as, in both cases, the average time decreased significantly as repetitions increase, it reveals an implicit incremental curve of ease of learnability. In *basic* group, excepting the first and second repetitions, the execution's time decreased progressively in each repetition. In *intermediate-to-advanced group*, in first repetitions a high progress was gained, whereas in last repetitions the progression was constant.

While considering each step of curve as a line it is possible to obtain a gradient. Table 1 and Table 2 shows all gradients for each group in each task, meaning that when a gradient is zero, there is no variation in wasted execution time, so there is no progress and no regression at ease; when a gradient is under zero, wasted execution time was reduced, so there is a progress at ease; and finally, when a gradient is over zero, wasted time was increased, so there is a regression at ease.

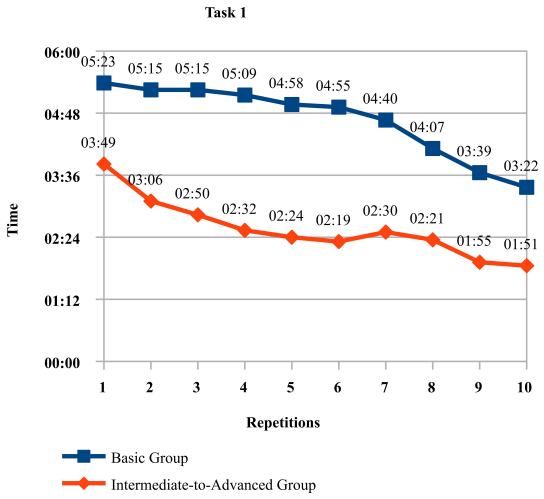

Figure 3: Task 1 Results.

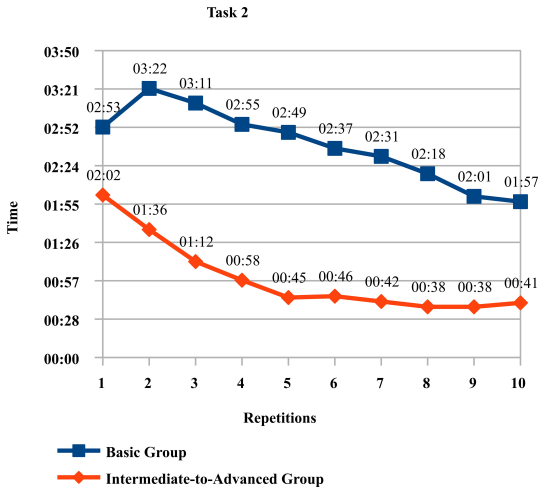

Figure 4: Task 2 Results.

Gradient (seconds) to task 1	
Group 1	Group 2
-00:08	-00:43
-00:00	-00:16
-00:06	-00:18
-00:11	-00:08
-00:03	-00:05
-00:15	00:11
-00:33	-00:09
-00:28	-00:26
-00:17	-00:04

Table 1: Gradient between repetitions for task 1

Gradient (seconds) to task 2	
Group 1	Group 2
00:29	-00:26
-00:11	-00:24
-00:16	-00:14
-00:06	-00:13
-00:12	00:01
-00:06	-00:04
-00:13	-00:04
-00:17	00:00
-00:04	00:03

Table 2: Gradient between repetitions for task 2

Average Time in seconds (standard deviation)	
Group 1	Group 2
-13,4 (11,1)	-13,1 (15,2)

Table 3: Average and Standard Deviation of gradients for task 1

Average Time in seconds (standard deviation)	
Group 1	Group 2
-6,2 (13,9)	-9 (10,7)

Table 4: Average and Standard Deviation of gradients for task 2

According to this established statements, *intermediate-to-advanced* group shows a more accelerating and increasing ease of learnability than *basic* as was expected; the average and standard deviation of the gradient (Tables 3 and 4) clarify this affirmation.

These results show that when user experience is basic, ease of learnability execution time tends to reflect constant values till a specific point of repetitions were gradients decreases exponentially showing mayor ease of learnability execution time.

5 Conclusion and Future works

In HCI, virtual worlds are developed for users to interact with a computer, and a solution to provide this is through of developing of avatars; an efficient, realistic and immersive alternative.

The process of designing 3D human correlated avatars must consider verbal and non-verbal communication. As well as non-verbal behaviour appears to be a primary factor in human-human interaction it is also considered for human-computer interaction.

Particularly, gestures are first tools of human communication. Therefore, with the intention of harnessing and enhancing the natural abilities of the human, at the present time, there exist works involved in adding user technology to implement Natural User Interfaces into multi-RVMedia systems [29].

This work focuses on use of hands as interaction's media. The development is based on the insertion of appealing devices such as data gloves within a virtual world, mostly, the research is addressed to real-time hand movements and gesture recognition providing the following features: hand tracking, navigation on stage and object manipulation, where for each feature, gestures play an important role and should be easy to learn and do not require any special attention from the user.

Presented preliminary user experiments consist in the evaluation of usability, in particular, the *ease of learnability* based on execution time where results are quantitative. From graphics it can be inferred that experienced users have no problems in adapting to new interface paradigms while basic users reflect a notable drawbacks till a threshold (60% repetitions). It will be a challenge to reduce this threshold by reducing system' s shortcomings. Nevertheless, the computer experience and previous practice do not have to determine the system simplicity and comfortability.

Due to some systems aspects are beta version, future works will be oriented to improve the environment issues, such as hardware platform. We consider that the system should provide the necessary multi-VR media and multi-platform structure and optimise the handling of 3D objects in the scenario using new libraries of physics or reprogramming of existing ones.

Gestural communication in virtual environments continues to be a major challenging but we think that are on the path to new and interesting research.

ABSTRACT

In this paper, we propose a two steps-based algorithm to solve the modular link version of the Capacitated Network Design Problem (CNDP) which consists to determine the optimal network that guarantees the routing of a set of commodities. In our proposition, CNDP is divided into two sub-problems: Network Design problem (NDP) and Network Loading Problem (NLP). In the first step, we solved NDP by using the genetic algorithms which select sets of network topologies. In the second step, NLP is solved with the use of Linear programming to evaluate and validate the best network topologies. Simulation results on three real network instances (Atlanta, France and Germany) show that the proposed algorithm is better and more efficient than the Iterative Local Search algorithm.

1 Introduction

To save resources (routers, optical fibers, etc.) networks should be efficiently designed. Diverse networks models were then defined and used to represent a wide range of issues in transportation, telecommunications, logistics, production and distribution networks. All these models consider a graph composed of nodes and edges (optical fibers, cables, etc). For a better use of these resources, networks designers should solve the modular Capacitated Network Design Problem (CNDP) which consists of selecting edges and allocating optimal capacities to route a set of commodities between source and destination pairs. Each edge of the graph has a potential set of module capacities with their associated costs, a fixed cost that is incurred only if the edge is selected, and a routing cost which is proportional to the amount of flows along the edge. Each commodity is defined by origin and destination nodes, and the amount of flow to be routed. The objective is to minimize three criteria: edge cost, modules and routing. These capacitated network design problems are NP-hard and very difficult to solve in practice. The CNDP is a particular case of the well known Multicommodity Network Design problem (MNDP), in which we distinguish an important number of special cases and extensions [1]. The most studied ones are:

- The unsplittable variant where the flow of each commodity is required to follow one route between the origin and the destination. This variant increases the difficulty of the problem [2].
- The expansion variant, where some edges already have an existing capacity.
- The fixed charge MNDP [3][4] in which the link capacities are known. Solving MNDP consists to determine the set of edges that should be opened in the final topology.
- The capacitated MNDP, where the number of modules to install on the edges are modeled by integers [1]
- The Network Loading Problem (NLP), where the number of module types is limited, each one with a given unit cost and capacity.

Various heuristics and exact approaches have been developed for designing capacitated networks. However, the heuristic approaches are more likely to be trapped in local optima, while the exact approaches are applied only to small or medium size problems. Due to the weaknesses of the two approaches and the increasing popularity of metaheuristic approaches, we have witnessed many metaheuristics being applied to network optimization problems. In this paper, we propose a novel metaheuristic that combines linear programming with Genetic Algorithms (GAs) to solve

https://dx.doi.org/10.25046/aj020339

the CNDP problem. We recall that the genetic algorithms were extensively used to solve many difficult combinatorial optimization problems in industrial engineering and operation research. Genetic algorithms are one of the most powerful and broadly applicable stochastic search and optimization technique. They have achieved great advancement in related research fields, such as network optimization, combinatorial optimization, multi-objective optimization, etc. Our contribution consists in an efficient two steps-based heuristic that extends the approach in [5] by combining the GAs and Linear Programming (LP) to solve CNDP.

The remainder of this paper is structured as follows: related work is introduced in section 2, notations and mathematical formulation of the addressed problem are given in section 3. Section 4 describes and explains in details our proposed heuristic. Experimental results are discussed in section 5 where we compare our proposition against Iterative Local Search (ILS) algorithm. Finally, section 6 concludes the paper.

2 Related work

Capacitated Network Design Problem is one of the major research area in network optimization. It is related to two issues: Network Design Problem (NDP) and Network Loading Problem (NLP). In the NDP, the goal is to identify the network topology by selecting routers and links that interconnect them. Thus, the objective function aims to minimize the total constructive cost under some topological constraints. In this class of problems, the flow is not modeled and considered as uncapacitated. In the NLP, it is assumed that the topology is already established. Thus, solving NLP consists to search for the set of resources to allocate for the network components. These problems are complementary. Generally, NDP and NLP are solved separately though they should be combined together to optimize the resources.

One can say that most of network optimization problems can be seen as a kind of (1) NDP, (2) NLP or (3) a combination of both where the objective and the constraints may differ from one problem to another: connectivity [6] [7], limited budget [8], hop limit [2] [9], delay [10] [11], reliability [9] [10], and survivability [11]. The NLP in capacitated or uncapacitated case and with both single or multiple facilities is a special case of the well known Multicommodity Network Design Problem (MCND). Previous works on this problem can be classified as:

- Uncapacitated network design problems where on each network link, it is only possible either to open the link with an infinite capacity and a given fixed cost, or the capacity and cost are nil [12].
- Single facility capacitated network loading problem where, the capacity can be done by installing on each link an integer unit of a given basic facility [13].
- Two facilities capacitated network loading problems where the capacity can be achieved by means of two types of modules, each capacity has a specific cost [14].
- Multi-type facility capacitated network loading problems where various types of capacities can be installed on each link, each facility has a specific cost [8].

The early works on capacitated modular network problems were focused on the approximation methods. These methods define residual capacity and cut-set inequalities for single commodity and multicommodity cases on directed, undirected and bidirected link models [15][16]. Since these works consider that the underling network is established, they focus only on the determination of the facilities allowing the accommodations of flow demand. Their effectiveness depends on the size of the problem instance.
With the appearance of metaheuristics, both the NLP and the NDP have attracted some attention. The authors benefit from their efficiency to deal with more complex variants with real size instances. In [17], the author compared several neighborhood structures to solve the uncapacitated facility location problem. In [11], the authors proposed an evolutionary approach for capacitated network design considering cost, performances and survivability. The objective is to minimize network cost and packet delay. Kleeman et al. [10] used an evolutionary algorithm to solve multicommodity capacitated network design problem with an objective function optimizing costs, delay, robustness, invulnerability and reliability. A tabu search heuristic algorithm with real costs on facilities is developed in [18]. A firefly algorithm is proposed by Ragheb et al [8], they combined facility location and network design problem with multi-type of capacitated link and limited budget on facilities. Contreras et al. [19] presented a unified framework of general network design problems which combine location decision and network design decision.

3 Mathematical Formulation

Let $G = (V, E)$ be an undirected network where V is the set of vertices and E is the set of undirected edges. Let K be the set of commodities. Each one $k \in K$ is associated with a flow demand d_k and has a source denoted by the function $s(k)$ and a target $t(k)$. Let f_{ij} be the fixed cost of including edge (i, j) in the network, r_{ij} the unit variable flow cost on (i, j), and p_{ij} the pre-installed capacity on the edge (i, j).
The formulation of CNDP is shown below:

$$Min \;\; z(x,y,n) = \sum_{(i,j)\in E} r_{ij} \sum_{k\in K} \sum_{(i,j)\in E} x_{ij}^k + \sum_{(i,j)\in E} f_{ij} y_{ij} + \sum_{(i,j)\in E} \sum_{l\in L} c_{ij}^l n_{ij}^l$$

$$\sum_{(i,j)\in E} x_{ij}^k - \sum_{(j,i)\in E} x_{ji}^k == \begin{cases} 1, & i = s(k) \\ -1, & i = t(k) \\ 0, & \text{otherwise} \end{cases}, \forall k \in K \quad (1a)$$

$$\sum_{k\in K} (x_{ij}^k + x_{ji}^k)\, d^k \le p_{ij} + R_{ij}, \quad \forall (i,j) \in E \quad (1b)$$

$$R_{ij} \le \sum_{k\in K} d^k \, y_{ij}, \quad \forall (i,j) \in E \quad (1c)$$

$$R_{ij} \le \sum_{l\in L} m_l \, n_{ij}^l, \quad \forall (i,j) \in E \quad (1d)$$

$$x_{ij}^k \ge 0, \quad \forall (i,j) \in E, k \in K \quad (1e)$$

$$R_{ij} \ge 0, \quad \forall (i,j) \in E \quad (1f)$$

$$y_{ij} \in \{0,1\}, \quad \forall (i,j) \in E \quad (1g)$$

$$n_{ij}^l \in Z^+, \quad \forall l \in L, \forall (i,j) \in E \quad (1h)$$

This formulation is a mixed integer linear program which uses four types of variables: the first type is a binary design variable y_{ij} which is defined as $y_{ij} = 1$ if (i,j) is included in the network and $y_{ij} = 0$ otherwise. The second type is a continuous path flow variable x_{ij}^k, which represents the amount of flow of commodity k routed on link (i,j). The third type is an integer allocation module variable n_{ij}^l which represents the number of module type $l \in L$ (L is the set of potential modules) that should be allocated on edge (i,j). Each module l is characterized by a capacity m_l and an installation cost c_{ij}^l. The fourth type is a continuous variable R_{ij} representing the required flow capacity on link (i,j). A positive capacity $p_{ij} + R_{ij}$ on edge (i,j) implies that it is used to route demands in the two directions: from i to j or from j to i. This formulation corresponds to a general model that can deal with several variants of capacitated network design problems.

The objective function corresponds to the sum of the flow costs, the fixed costs of edges and the allocated module costs. These costs are relative to the problem that we deal with and are not all aggregated in some cases. For instance, the fixed charge problem MNDP includes only the edge costs. The modules and routing costs on edges are nil. Constraints (1a) consist of flow conservation equations, for each commodity k. Constraints (1b) specifies that the required capacity R_{ij} on each link (i,j) should be greater than the cumulated flows traversing the link minus the pre-installed capacity. Constraints (1c) forces the installation of link (i,j) (i.e, $y_{ij} = 1$) if the required capacity R_{ij} is positive (otherwise, $y_{ij} = 0$). Constraints (1d) specify that the total capacity of the allocated modules should be greater or equal to the required capacity on each link. (1e) and (1f) state out non-negativity constraints for the decision variables X and R. Constraints (1g) express the binary nature of the variables Y whereas constraints (1h) show that the module facility are allocated in discrete amounts.

If we assume that the edge and module vectors (y,n) are fixed and known, the main task in the above formulation becomes the search of a feasible flow that satisfies all the demands with the use of limited and fixed link capacities. Hence, the NP-hard CNDP problem can be reduced to the Capacitated Multicommodity Flow Problem (CMFP) which is solvable in polynomial time and formulated as follows:

$$Min \;\; z(x(\bar{y},\bar{n})) = \sum_{(i,j)\in E(\bar{y})} r_{ij} \sum_{k\in K} \sum_{(i,j)\in E(\bar{y})} x_{ij}^k$$

$$\sum_{(i,j)\in E(\bar{y})} x_{ij}^k - \sum_{(j,i)\in E(\bar{y})} x_{ji}^k == \begin{cases} 1, & i = s(k) \\ -1, & i = t(k) \\ 0, & \text{otherwise} \end{cases}, \forall k \in K \quad (2a)$$

$$\sum_{k\in K} (x_{ij}^k + x_{ji}^k)\, d^k \le p_{ij} + R_{ij}, \quad \forall (i,j) \in E(\bar{y}) \quad (2b)$$

$$R_{ij} \le \sum_{k\in K} d^k \, \bar{y}_{ij}, \quad \forall (i,j) \in E(\bar{y}) \quad (2c)$$

$$R_{ij} \le \sum_{l\in L} m_l \, \bar{n}_{ij}^l, \quad \forall (i,j) \in E(\bar{y}) \quad (2d)$$

$$x_{ij}^k \ge 0, \quad \forall (i,j) \in E(\bar{y}), k \in K \quad (2e)$$

$$R_{ij} \ge 0, \quad \forall (i,j) \in E(\bar{y}) \quad (2f)$$

The multicommodity flow problem formulation presented in the linear programming (2) is obtained by replacing the vectors (y,n) in the original CNDP formulation (1) by their fixed values $(\bar{y},\bar{n})$. In this reformulation, the objective function aims to minimise the routing of flows. Constraints (2a) are flow conservation equations. For simplicity and efficiency, we delete the variables R by replacing the constraints (2b), (2c), (2d) and (2f) by the following constraints (3a):

$$\sum_{k\in K} (x_{ij}^k + x_{ji}^k)\, d^k \le p_{ij} + \sum_{l\in L} m_l \, \bar{n}_{ij}^l \, \bar{y}_{ij} \quad \forall (i,j) \in E(\bar{y}) \quad (3a)$$

The previous constraints (3a) force the use of limited capacities by guaranteeing that the flows do not exceed the installed capacity (i.e, sum of the pre-installed capacity and module capacities). Constraints (2e) state out continuity and non-negativity of the decision variables X.

A solution to the CNDP can be viewed as (1) a binary assignment $(\bar{y})$ to each design variable, (2) an integer vector assignment $(\bar{n})$ to the allocation module

design variables and (3) an optimal solution for the multicommodity minimum cost flow problem $x^*(\bar{y}, \bar{n})$. In this way, the CNDP objective function value associated to a solution $(\bar{y}, \bar{n}, x^*(\bar{y}, \bar{n}))$ is the sum of the fixed cost of the open edges in $(\bar{y})$, the cost of the modules allocated $(\bar{n})$ and the objective function value of the CMFP associated to $x(\bar{y}, \bar{n})^*$. Thus, to solve the CNDP problem, we propose here to separate it into two sub-problems:
(1) link and resource selection which consists to choose the links, modules and their numbers by making decision on the vectors y and n,
(2) solve the CMFP problem (formulated in (2)) with respect of decisions made in (1) to determine the optimal routing that flows all the demands.

Note that sub-problem (2) can be solved in polynomial time. Thus, the challenge consists to solve the sub-problem (1) by identifying the best decision vectors (y) and (n) which allow to solve the flow sub-problem in (1). In other words, the decision vectors (y) and (n) should be selected so that the overall routing, link and module costs are optimal.

In the next section, we show how to solve jointly and efficiently sub-problems (1) and (2). In the first step of our proposition, we used the genetic algorithms to explore different potential solution areas for the decision vectors (y, n). Each solution $(\bar{y}, \bar{n})$ is then evaluated in the second step by solving CMFP problem.

4 Genetic Algorithm for CNDP

Genetic algorithms introduced by Goldberg et al. [20], are based on the mechanics of natural selection and genetic. They start with an initial set of random solutions, called a population. Each individual in the population, called a chromosome, represents a solution to the problem. The initial population evolves through successive iterations, called generations. A measure of fitness defines the quality of an individual chromosome. In each generation, chromosomes are evaluated by a fitness function, also called an evaluation function. After a number of generations, highly fit individuals, which are analogous to good solutions to a given problem, will emerge. Genetic algorithms consist of five components:

1. A method for encoding potential solutions into chromosomes;
2. A means of creating the initial population;
3. An evaluation function that can measure the fitness of chromosomes;
4. Genetic operators that can create the next generation population;
5. A way to set up control parameters; e.g., population size, the probability of applying a genetic operator, etc.

4.1 Individual representation

In the design of genetic algorithms, the encoding is the most important task. There are some methods to encode each individual in a population, such as binary encoding, integer encoding, etc. In this paper, we define a new encoding method called IME (Implicit Modular Encoding) that is relative to our modular case. An individual built by IME is shown in Figure 1. Each individual I is a matrix $I_{n,m}$, where n and m corresponds to the number of modules and to the number of edges respectively. Hence, $I[l_i][e_j]$ gives the number of module types l_i allocated on edge e_j.

Our encoding represents the decision vector n and implicitly the decision vector y. For example, $T[l_1][e_4] = 2$ (see Figure 1) means that we should allocate two modules on the edge e_4. Thus, we implicitly deduce that edge e_4 exists in the final topology.
When multiple types of modules are allowed, the edge exists if at least one module is allocated on it, i.e:

$$\begin{cases} x_e = 1 & if \ \sum_{l_{i=1}}^{n} T[l_i][e] > 0 \\ x_e = 0 & otherwise \end{cases}$$

In our example in Figure 1, edge e_1 will not be opened in the final network since $\forall i : T[l_i][e_1] = 0$.

4.2 Initial population

The choice of the initial population is a very important aspect of the whole search procedure. If it is too specific, then the search will be limited to a small region of the solution space leading to a local optimum. On the other hand, if the initial population is very

diverse then the algorithm will spend valuable computational resources exploring a variety of promising areas of the search space.

There are two ways to generate an initial population: random initialization and heuristic initialization. Here, we applied the Iterative Local Search (ILS) heuristic [21] that provides one approximated solution for the CNDP problem.

To create a diverse initial population (c.f. algorithm depicted in Figure 2), we applied various perturbations on the individuals. After encoding the solution given by ILS heuristic according to IME, we obtain the first individual I_0. To form the rest of the initial population, we apply some perturbations on I_0. This results in the creation of new individuals, wherein there are some ones corresponding to unfeasible solutions. Obviously, only individuals corresponding to feasible solutions are added to the initial population. We recall that an individual corresponds to a feasible solution to CNDP problem if its decision vectors $\bar{n}$ and $\bar{y}$ allow the flowing of all the demands. Thus, an individual corresponds to a feasible solution $(\bar{n}, \bar{y})$ if the linear program in (2) has solutions. Otherwise, the individual corresponds to an unfeasible solution.

Creation of the initial population's individuals

We recall that our individual representation is based on edges and modules (see Figure (1)), where the

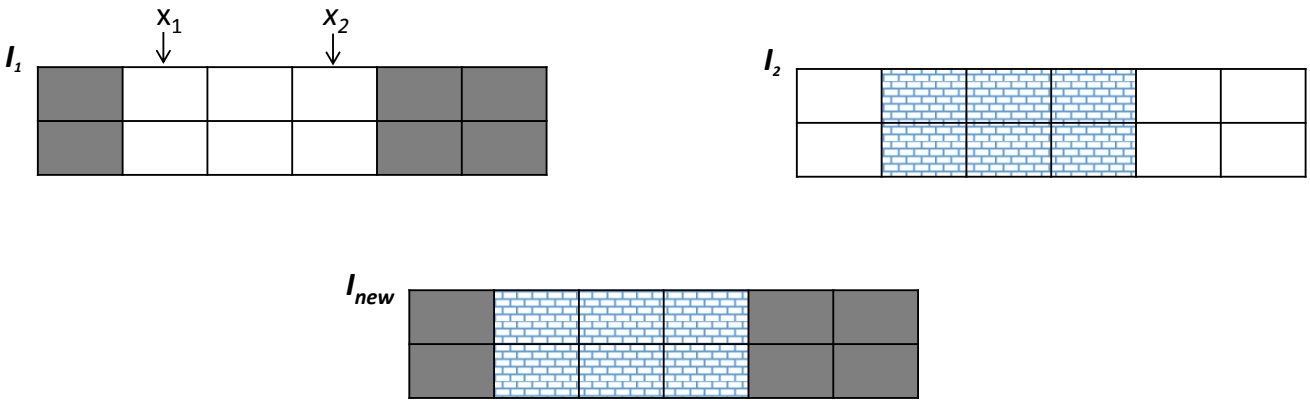

Figure 3: Crossover operator

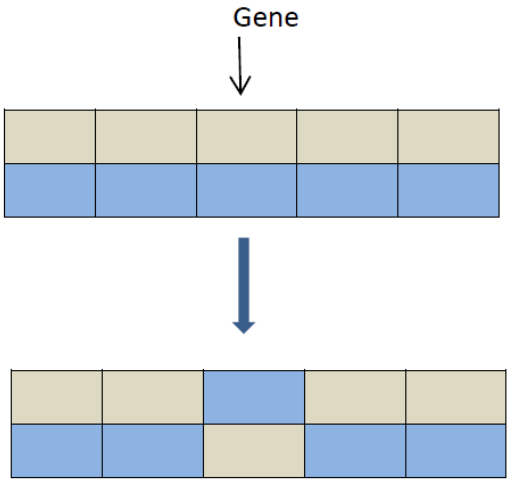

Figure 4: Mutation operator

columns represent the edges, and the rows represent the module types allocated on edges.

At initial stage, our population contains only one individual I_0. The other Individuals in the initial population are determined by applying some perturbations on the individual I_0.
A perturbation consists to delete one module from the I_0's edges. The complete procedure of generating the initial population is described in the following steps:

- for each module type $l_n \in L$,
- for each edge e from the set E

Genetic Algorithm

Table 1: The Instance Setting Parameters

- create a new individual I that corresponds to a copy of I_0,
- decrement the number of modules l_n on the edge e of individual I
- add the new individual to the population if it allows a feasible flow of demands.

4.3 Fitness function

The fitness function corresponds to the objective function of CNDP. It is computed as the sum of the allocated module costs, the fixed edge costs and the routing costs. Note that the first two costs are deduced from the individual representation whereas the routing costs are given by solving the CMFP linear program (2).

4.4 Genetic operators

The next populations are generated by applying the crossover and mutation operators described below.

4.4.1 Crossover

The crossover operator is responsible for combining two chromosomes so that a new offspring chromosome can be generated. In our proposition, we used a two point crossover: we randomly chose two integers in the individual length interval ($0 < x_1 \leq x_2 \leq m$) and two individuals (I_1 and I_2) in the current population, then we apply the two-point crossover operator to generate a new individual as shown in Figure 3. Typically, a new individual I_{new} is generated by selecting the modules of edges in $(e_1, e_{x_1}] \cup [e_{x_2}, e_m)$ from I_1 and (e_{x_1}, e_{x_2}) from I_2.

4.4.2 Mutation

An edge (that corresponds to a gene) and two modules types are randomly chosen in the chromosome. Then, the numbers of modules relating to the selected types of modules are exchanged on the chosen edge (see Figure 4).

4.5 The genetic algorithm

After explaining and detailing the basic components of our proposed genetic algorithm, we describe below its operation (see Figure 5 for instructions). In our algorithm, we first initialize the population through $InitialPopulation()$ procedure (see Figure 2). Then N successive populations are generated by applying the two-point crossover and mutation operators ($Crossover()$ and $Mutation()$).

As said previously, only individuals allowing a feasible multicommodity flow solution are added to the current population. This is verified by the running of $CplexSolver()$ procedure that solves the linear program in (2). The best solution $Gbest$ is updated at each generation and returned when the termination condi-

tion is satisfied.
CleanPop() procedure allows to switch from one population to another by selecting individuals from the first population. It is based on elitist strategy, i.e., better is the fitness of the individual, greater is the probability of keeping that individual in the next population.

The algorithm stops its running after a fixed number of generations or when the result is not improved after a certain number of generations.

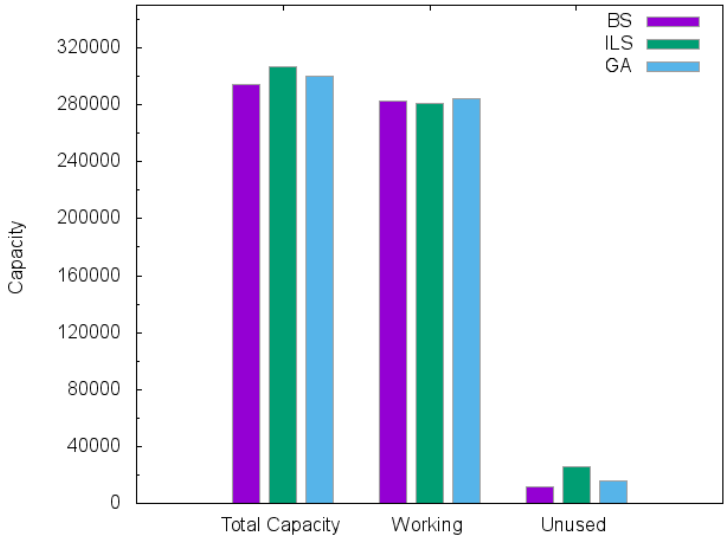

Figure 6: Atlanta network

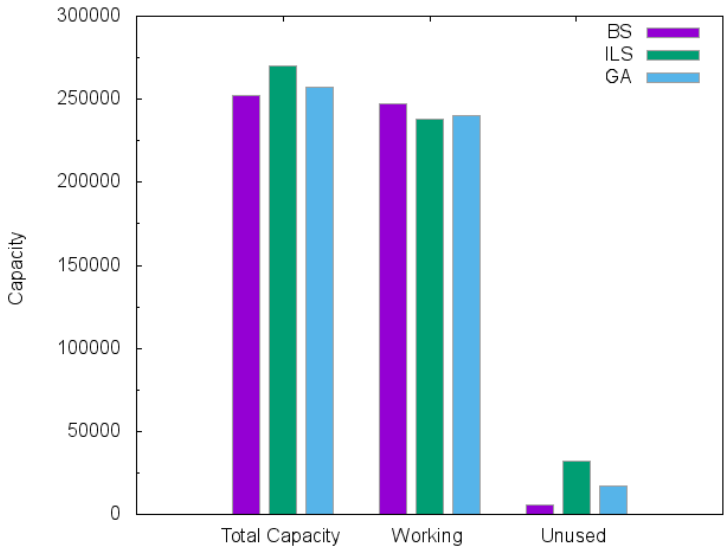

Figure 7: France network

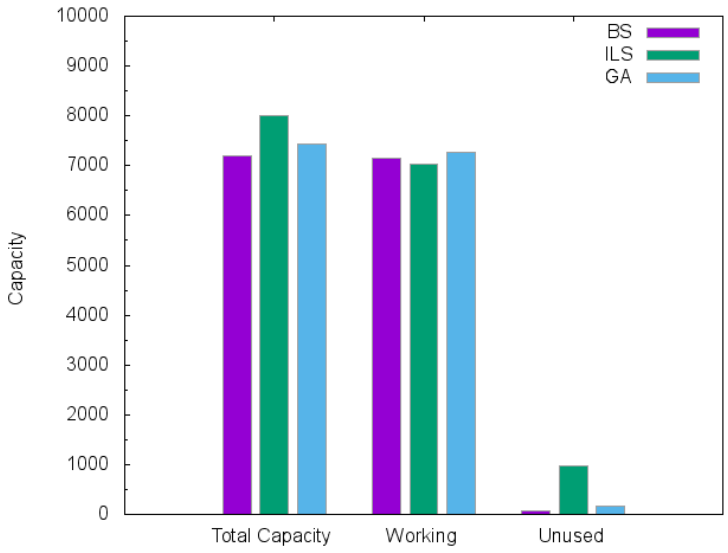

Figure 8: Germany50 network

5 Experiments and Results

In our experiments, we used three real world instances of network topologies including Atlanta, France and Germany50. All can be downloaded from $http://sndlib.zib.de$ [22]. We followed the model filter specified in Table 3. The population size is 50 and the number of generations is 15.
Each instance is characterized by the number of nodes $|V|$, the number of potential links $|E| = m$ and the number of traffic demands $|K|$. Table 1 summarizes the instance specification details. We classify them into two categories; instances with Single Facility allocation (SF) and instances with Two Facilities allocation (TF). The set of capacity modules L differs from one network instance to another. The allocation cost $MCost$ is variant on links except in France instance. Atlanta instance assumes a Pre-installed capacities p_{ij} on their potential links with a unit routing cost r_{ij}. See [22], for more details on the filter model and on the setting parameters.

In Table 2, ILS and GA correspond to the solutions obtained by iterative local search algorithm and our genetic algorithms-based heuristic respectively. We examine the quality of a given algorithm A (A could be GA or ILS) by computing its optimality gap (see equality 10) that is defined as the ratio between the difference of the A's cost and the Best Solution (BS) cost. Note that BS corresponds to the best solutions published in [22].

$$GAP(A) = \{Cost(A) - Cost(BS)\}/Cost(BS) * 100 \quad (4)$$

As depicted in Table 4, GA is better than ILS since it determines solutions more close to the best solutions than those of ILS. Concretely, the mean gap obtained with ILS is 3.5 times higher than the mean gap obtained with GA. This can be explained by the exploration of multiple solution areas with GA while ILS determines only a local optimum.

Figures 6, 7 and 8 show the allocated capacities and their usage for Atlanta, France and Germany50 networks respectively. We compared the total installed link capacities, the total working capacities and the total unused capacities for BS, ILS and GA solutions. We remark that the total installed link capacities in ILS and GA are more larger than the BS ones. This justifies the cost gap. On the other hand, ILS uses fewer working capacities than BS because ILS wastes and over-allocates module resources, leading to efficient routing. Indeed, instead of splitting flows and exploring the small unused capacities on links, ILS routes the majority of demands on shortest paths. With GA, the CPLEX optimizer tries to exploit the residual quantities on the allocated modules to route the flows. This leads to a bifurcation of demands on multiple paths that could be quite long, though routing costs slightly limit the path lengths.

6 Conclusion

In this paper, we proposed a two steps-based algorithm to solve the modular version of the Capacitated Network Design Problem (CNDP). In the first step, we applied genetic algorithms to select sets of promising networks (i.e., links with their modules) which are checked, evaluated and validated in the second step with the use of linear programming.

To explore the promising areas in the solution space, the genetic algorithms we used were adapted to treat and design efficient network topologies by: (1) defining a flexible and meaningful encoding scheme IME (Implicit Modular Encoding), (2) two point crossover and mutation operators and (3) an elitist population strategy. We generated the initial population by combining an iterative local search al-

gorithm with a heuristic procedure that modifies the number of modules on the network links. Successive populations were then generated by applying two point crossover operator which creates a new network from two other ones by selecting some edges from the first network and the rest from the second network. A mutation operator is possibly applied on links to exchange the module types. Finally, a probability-based elitist population strategy chooses promising network topologies that we combine to determine the next population. In our proposition, the networks are associated with probabilities in a way they guarantee an offspring often coming from the best individuals.

To measure the fitness of a solution, polynomial time linear program which determines the routes by searching for feasible flows on the corresponding network is used.

Simulations results confirm that the combination of genetic algorithms and linear programming in two steps is satisfactory and efficient. Indeed, the results show clearly that our proposition outperforms the iterative local search heuristic and determines solutions close to the known best ones.

ABSTRACT

A wormhole attack is one of the most critical and challenging security threats for wireless sensor networks because of its nature and ability to perform concealed malicious activities. This paper proposes an innovative wormhole detection scheme to detect wormhole attacks using computational intelligence and an artificial neural network (ANN). Most wormhole detection schemes reported in the literature assume the sensors are uniformly distributed in a network, and, furthermore, they use statistical and topological information and special hardware for their detection. However, these schemes may perform poorly in non-uniformly distributed networks, and, moreover, they may fail to defend against "out of band" and "in band" wormhole attacks. The aim of the proposed research is to develop a detection scheme that is able to detect all kinds of wormhole attacks in both uniformly and non-uniformly distributed sensor networks. Furthermore, the proposed research does not require any special hardware and causes no significant network overhead throughout the network. Most importantly, the probable location of the malicious nodes can be identified by the proposed ANN based detection scheme. We evaluate the efficacy of the proposed detection scheme in terms of detection accuracy, false positive rate, and false negative rate. The performance of the proposed algorithm is also compared with other machine learning techniques (i.e. SVM and regularized nonlinear logistic regression (LR) based detection models). The simulation results show that proposed ANN based algorithm outperforms the SVM or LR based detection schemes in terms of detection accuracy, false positive rate, and false negative rates.

1. Introduction

Wireless sensor networks (WSNs) consist of self-directed devices (i.e., sensor nodes), which are used in a collective manner to monitor environmental or physical phenomena in a remote and/or hostile environment. Spatially distributed autonomous sensor nodes are capable of communicating amongst themselves in order to transfer sensed data to a base station. The WSN is a type of ad-hoc network that has gained popularity for its versatile application in military and civil domains such as battlefield monitoring, tracking objects, healthcare, and home automation[1].

In WSN, a larger number of sensor nodes perform an assigned task in a hostile environment without any human intervention. Since sensor nodes use a known in-band radio channel for communication and are usually deployed in a hostile or remote environment, therefore, WSNs are prone to various security threats like a Sinkhole attack, Sybil attack, and wormhole attack. WSN has several vulnerabilities that an attacker can exploit to obtain access to the network. Implementing security measures like data encryption is not practical solution for the most WSNs. However, research on security measures has made certain progress in secure localization algorithm, lite weight routing protocols, and secure data aggregation scheme. However, those security mechanisms don't provide any protection against any attack from a legitimate node. If an attacker gains control over a few legitimate nodes, full access would be gained to the data traveling through these compromised nodes. The attacker may achieve the capability to modify the contents of the control

*Corresponding Author: Ken Ferens, University of Manitoba, Electrical and Computer Engineering, R3T2N2, Canada | Email: Ken.Ferens@umanitoba.ca

packets later by extracting the cryptographic contents from the captured data packets.

Wormhole attack is recognized as one of the most detrimental security threats for any routing protocol of WSNs [2-3]. The wormhole attack can be easily launched by taking over at least two legitimate nodes from the two distant parts of the network or deploying two nodes with superior capabilities (e.g. directional antenna, larger radio range) in two distant places of the sensor field. Wormhole nodes are connected through a virtual tunnel which can be implemented in numerous ways (e.g. high-quality channel, packet encapsulation or packet relay and high powered transmission) [4]. This direct low latency tunnel is known as a *wormhole link* [5]. A *wormhole link* creates an illusion in the network that these two colluding nodes are located within their communication range, but, in fact, their physical locations are very far apart.

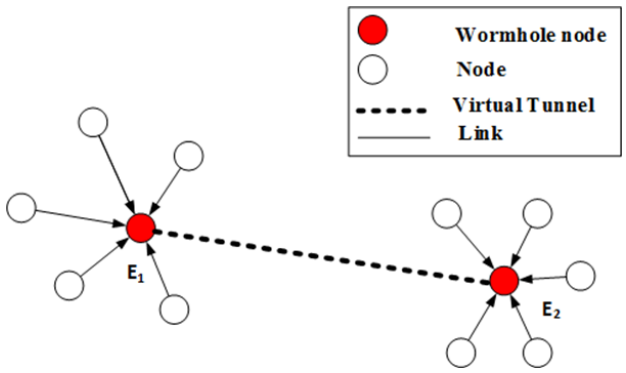

Fig. 1 Depiction of the structure of a wormhole attack.

By creating this unauthorized link, wormhole nodes gain the ability to circulate false route information into the network that they are few hops away from the base stations. This illusion drives other sensor nodes to transmit data packets to the base station through the wormhole nodes. Wormhole attack disrupts the existing network data flow in order to monitor and capture the data packets passing through it. As shown in Fig. 1, the E_1 and E_2 wormhole nodes, connected by a *wormhole link*, capture the data packets from one terminal of the virtual tunnel and retransmit them to another terminal of that link.

Subsequently, this wormhole attack becomes so severe that it might destroy the network or hamper the usual operation of the network by the selective dropping of packets, manipulation of traffic, or modify data packets without revealing their identities.

Therefore, detection of wormhole nodes is an essential task for ensuring the security of wireless sensor networks. It is a very simple task to implement wormhole attack, but a very difficult task to detect an infected network since wormhole nodes retransmit valid packets into the network. Most of the existing countermeasures use the distance bounding technique, direction, and location abnormality among claimed neighbor nodes as detection attributes to fight against wormhole attack. To gain a certain level of accuracy, some existing schemes uses complex and highly advanced devices such as directional antenna[6], GPS[7], or ultrasound for distance measurement [8]. However, those special devices are very costly for practical deployment. A few statistical wormhole detection schemes based on hop count [9], node connectivity [5], or neighborhood count [10-12] are proposed that do not need any special hardware. However, they usually include a hardware supported scheme as a secondary approach. Furthermore, centralized statistical wormhole detection [10] may cause significant network and communication overhead in contrast to a distributed statistical approach [11]. In the network connectivity based wormhole attack detection schemes [5,13-14], the positions of neighboring nodes are estimated from the received signal strength (RSSI) by each node, which sends this information to the base station. By doing this, the network layout is determined by the base station and compared with the given network layout. This approach also causes a significant amount of control packets flow to the base station. Moreover, it is prone to distance estimation errors. Furthermore, neighborhood-based wormhole detection schemes [10,12] may not detect wormhole attack if the wormhole nodes are located in a sparsely populated area and caused the significant flow of packets to the base station. In addition, their performance in non-uniform sensor distribution is in question.

In recent years, network anomaly detection schemes have been increasingly using artificial intelligence to improve detection accuracy. An artificial neural network (ANN) is a very simplified information processing model that aims to grossly imitate the human brain function. An ANN consists of interconnected processing units and works in a parallel fashion to find a solution to a particular non-linear problem. The adaptive and self-learning ability of an ANN help to increase the competence of an anomaly detection model [15]. Moreover, ANNs have been widely deployed to deal with pattern recognition and classification problems [16].

In this paper, we introduce a novel detection scheme based on an ANN using '*neighborhood count*' and '*average residual energy pattern of neighbors (AREPN)*' as detection attributes. The proposed detection scheme is able to detect wormhole attacks in both uniform and non-uniform sensor distributions and does not need any special hardware. Here, we have introduced a mobile node, called as detector node (D_N) that visits randomly chosen locations within the region of interest and collects two featured data samples, along with coordinate for each site visited. When the detector node D_N moves into a wormhole infected zone, this paper *theorizes* that the collected number of neighbors increases *abnormally* (uniform network scenario) or slightly *abnormally* (non-uniform network scenario), compared to a non-infected zone, in which the counts change *normally*. This paper also introduces a new detection attribute, named AREPN that significantly

decreases at the wormhole infected zone compare to non-infected zone. D_N captures these features as evidence of the presence or absence of a wormhole attack. The gathered dataset is used for training in the proposed ANN based detection scheme. After the training phase, the test data samples are fed into the ANN, and the scheme decides if there is any wormhole attack in the network or not.

We have studied in detail and compared the performance of the proposed algorithm with SVM and LR based detection schemes through simulations. Our simulation results confirm that an ANN based wormhole detector can detect wormhole attacks with higher precision and accuracy as compared to the non-linear logistic classification algorithm.

The rest of this paper is arranged as follows: Section 3 presents a detail of wormhole attack and its classification. We discuss literature review, ANN, SVM and LR in Section 3, 4, 5, and 6, respectively. The proposed ANN-based detections scheme described in detail in Section 7. The evaluation results are discussed in Section 8. Section 9 concludes the paper and provide a scope of future work.

2. Wormhole attacks

A wormhole can be a severe attack against any packet routing protocol, especially in ad-hoc and wireless sensor networks. It is very difficult to detect and to take preventive measures against wormhole attack since the malicious nodes behave as legitimate nodes and initially do not perform any illegal activity in the network[2]. The word 'wormhole' means the creation of any shortcut path between two far apart points in the space-time [17]. Thus, the concept of 'wormhole' is used as a tool to launch this attack aiming to spoil the existing routing protocol.

The wormhole attack starts by compromising at least two nodes from the sensor network by hacking or, deploying two nodes with superior capabilities (e.g. directional antenna, larger radio range) in two distant places of the network [18]. This attack would be more devastating if the aggressor launches the attack with multiple nodes. Although, wormhole attack can be launched with the single node by broadcasting received packets with high power level [19-20]. Those malicious nodes are known as '*wormhole node'*. Furthermore, to launch the attack, the wormhole nodes connect themselves through a low latency communication link, which is called the wormhole link. In some literature, this link is also named as wormhole tunnel [11]. The wormhole nodes gain unprecedented access to the network by forming this low latency link. This wormhole link can be formed in numerous ways, such as packet encapsulation, high power transmission, wired link and out of band radio link [4]. Packet encapsulation is the most prominent way to establish wormhole link in the network where smallest hop count is used as metric to select the best route.

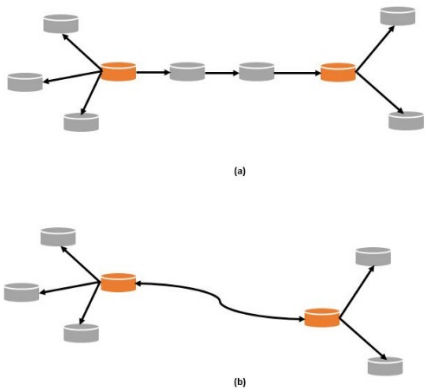

Fig. 2 The depiction of (a) 'in-band' and (b) 'out-band' wormhole attack.

The wormhole attack can be categorized into two classes based on the wormhole link formation. In the '*out band' wormhole* [21], two external nodes are deployed with higher communications and computational power than deployed sensor nodes. This kind of attack is hard to establish due to the requirement of the special hardware. In this case, the adversary connects two separate regions of the network using a directional antenna or wired link. Similarly, in the *'in band'* wormhole, the adversary compromises at least two legitimate nodes from the different zone of the network. One of these is usually located close to the base station so that it could disguise its adjacent nodes by advertising fabricated routing information. In contrast to '*out of band'* wormhole attack, adversary uses packet encapsulation technique to create wormhole node rather than a directional antenna or wired link [9]. In this circumstance, two compromised nodes are connected through several legitimate nodes between them.

Once the wormhole link is functional, one of the colluding nodes transmits the data packets, collected from the one part of the network, towards another malicious node. The other malicious node broadcasts those received packets into its radio range [22]. The wormhole node influences those nodes, who normally multiple hops away from it, to send data packets via wormhole by convincing them that they are few hops away from the base station [23]. In the other words, due to the high-speed wormhole link, the received data packets (by wormhole nodes) would travel faster from one part of the network to another part of the network than a usual multi-hop route. This illusion would disrupt existing packet routing mechanisms.

At the initial stage, wormhole node eavesdrops or captures the packets passing through it for further analysis and retransmits them to another wormhole node. When the wormhole attack begins, malicious nodes do not know about the cryptographic keys are being used in the network. If this malicious node starts dropping the packets without knowing the content of the packets, the target of compromising the integrity and confidentially would not be achieved. On the other hand, the dropping of the packets might rise suspicion of those nodes who have relayed the packet

through wormhole node. Therefore, there is a chance of being detected as a malicious node in the network. In fact, Wormhole node tries to place itself in most of the route without revealing its identity. However, the initial phase of wormhole attack is called *hidden wormhole attack* [20]. In the *hidden mode of attack*, the wormhole does not appear in the routing table. Still, wormhole node is able to establish the denial of service (DOS) [24] attack by dropping packets in the *hidden mode of attack*.

Once the wormhole node breaks the encryption technique by analyzing the recorded packets, then the aggressor takes the attack to the new level. In the *active mode*, the malicious node takes part in the routing mechanism as legitimate node [20] and starts modifying or dropping the packets passing through it [4]. In some cases, wormhole node drops the selected or critical packets to interrupt the usual operation of the network [21].

2.1. The impact of wormhole attack:

Wormhole attack is considered as server threats for routing protocols of WSNs. This attack usually occurs in the network layer and immune to encryption techniques. The wormhole attack is able to degrade the performance of the routing protocol and compromises the integrity and confidentiality of the data packets traveling throughout network [25]. Once wormhole nodes get the access to the network, the adversary can drop the packet selectively or delay the transmission of critical packets for the system in order to destabilize the system performance [21]. The aggressor tries to establish the denial of service attack (DOS) and attempts to compromise the integrity and confidentiality of the network.

During the active mode of this attack, the malicious nodes become the sinkholes [4]. However, other nodes around wormhole send data packets without aware of the fact that they are the victims of the wormhole attack. Hence, a significant amount of data traffic is passing through the malicious node and attacker can control and monitor the packets without having multiple observation points in the network. Some literature also suggests that wormhole node also lessens the throughput of the network by the selective dropping of the packets [4]. Furthermore, wormhole node also can turn on and off the wormhole link randomly [4]. This event creates instability in the routing service and causes a significant amount of control packets flow throughout the network.

In general, the routing protocol of the wireless sensor network can be categorized into two classes, such as 'pro-active' routing protocol and 'on-demand' routing protocol. Routing updates are transmitted periodically in the pro-active routing protocol, whereas on-demand routing protocol searches the route to a specific destination when it is necessary. However, the wormhole attack is successful to invade the network accessibility for the both class of wormhole attack [26]. Some literature on wormhole attack mentions that two wormhole nodes are able to attract more than 50% data traffic towards them directed to the base station[6][27].

3. Related works

As the wormhole attack can be launched from legitimate nodes and relays the valid packets into the network; therefore, it is reasonably difficult to detect it from the infected network. Furthermore, lightweight cryptographic solutions are incorporated into most of the routing protocol to prevent false data packets injection into the network. As the legitimate nodes are compromised by the adversary and the wormhole node doesn't change the packet's content at the initial stage, so the wormhole node easily passes the cryptographic test. The wormhole attack is a simple task to launch, but very difficult to identify. Many researchers have been working on this field to develop efficient wormhole detection schemes based on the geographical locations, transmission time, connectivity graph, neighborhood counts and radio fingerprint.

3.1. Distance consistency based approach:

Most of the researchers in this field try to detect the wormhole attack by distance bounding techniques. In these approaches, two communicating nodes are allowed to determine the distance between them; based on message traveling time information, transmission time information, and geographical information. Sometimes sensor nodes are equipped with specialized hardware like the directional antenna, GPS, ultrasound[8] to measure the distance between two adjacent sensor nodes. However, these schemes are considered impractical due to the addition of the special hardware and their performance in the sparse sensor network. These schemes may not perform well in the presence of *'out of band'* wormhole nodes.

3.2. Time information based solutions:

The most popular detection methods of wormhole attack use the packet traveling time between two consecutive nodes as a detection attribute. Most of the cases, the data packets traveling time is calculated from the measured round trip time (RTT) [28-31], the authors proposed RTT based solutions to confront against wormhole attack. In [32], delay per hop is determined by measured RTT whereas, for each successive hop, RTT is measured to detect wormhole attack [33]. In these schemes, the distance between two adjacent nodes is measured using RTT and determine if the two communicating sensor nodes are apart by the valid possible distance. If the measured RTT is higher than a defined threshold value, the presence of wormhole node will be declared. However, the RTT based solutions require the cooperation of the sensor nodes on the path and don't work properly on the DSR[34] and DSDV routing protocols [35-36]. These RTT based solutions may not perform well if the wormhole is created by protocol deviation. The wormhole nodes forward the packets without waiting for the certain time in order to reach the destination earlier than legitimate multiple hop path. Beside this, in the *'out of band'* wormhole attack, the wormhole nodes use the high-speed low latency link for transferring packets between them. In this type of attack, data packets reach to another wormhole node more quickly than *'In-band'* wormhole attack. In fact, the

time required to forward the packets to another wormhole node is significantly reduced in '*out of band'* wormhole attack. Therefore, the performance of RTT based detection scheme is in question with the presence of *'out of band'* wormhole attack. Some works of literature [37] also suggested that the RTT based detection scheme cannot detect *'active'* mode of wormhole attack and may not detect wormhole attack in the sparse sensor network.

In [38], the authors proposed a detection scheme based on neighborhood count and RTT. The authors considered the two facts. First, as the malicious nodes establish the new link in the network, so the neighbors around the malicious node increases significantly. Second, the measured RTT between two malicious nodes increases significantly in a similar fashion. However, these proposed solutions may not detect *'out of band'* wormhole attack from the infected network.

In [37], the authors proposed a detection scheme based data transmission time of each successive hop in a route assuming that the wormhole nodes are in hidden mode. In this scheme, the data transmission time of each successive hop is calculated from the measured RTT. All sensor nodes in the route transmit the recorded transmission time to the source. The source is solely responsible for checking if there is any wormhole node exist in the route. This scheme may perform poorly in the sparse sensor network. In fact, the performance of this scheme may be degraded when malicious nodes use high-speed communication channel.

3.3. Special Hardware-based scheme:

The directional antennas are incorporated with sensor nodes for adding access restriction [6,39-41] and finding legitimate neighboring nodes in the network. The entire communication region of a sensor node is divided into several zones. Moreover, each zone is defined by a directional antenna. When a sensor node receives the signal first time from its peering sensor node, then the probable location of the sender in terms of the zone is determined by the directional antennas. According to the authors, if a sensor node sends a packet from a particular zone, the recipient will get the signal from the opposite direction (zone). After that, the recipient sensor node verifies the legitimacy of the sender through receiving direction of the packet from unknown sensor nodes. The recipient node also cooperates with its neighbors to find out whether this node is known to other legitimate neighboring nodes or not. The incorporation of directional antennas to each sensor node makes this scheme expensive and inappropriate for practical deployment.

Another protocol named SECTOR was introduced in [29], that mostly depends on special hardware. The main concept of this detection scheme is to measure the distance between two communicating nodes based on the data transmission speed. The proposed model does not need any clock synchronization and geographical information of communicating nodes. In this algorithm, the mutual authentication with distance bounding (MADB) protocol [42] was implemented to measure the distance between nodes at the time of the encounter. According to the authors in [42], the proposed scheme permits one node to measure the mutual distance between two nodes and compares with maximum possible upper bounding distance. In this scheme, each node is incorporated with the special device that can give feedback to the sender without any delay. Initially, a node sends the one-bit challenge to its neighbors before sending any packets. Then recipient node responds back through a special device to the sender at the time it receives the one-bit challenge. When the sender transmits the one-bit challenge to a node, it turns on the clock and measures the time till it gets the response back from that node. After that, the sender estimates the mutual distance based on the measured time assuming that the data transmission speed is as same as the speed of light. However, in the [30], the authors slightly modify the schemes described in [42]. In [30], both parties are allowed to measure the mutual distance and validated the authenticity of the adjacent nodes around their communication range. The addition of the special device to each sensor node makes this scheme expensive and inappropriate for practical deployment.

3.4. Geographical information-based schemes:

In [43] and [7], the author proposed a detection scheme that assigns a maximum traveling distance to each data packet. The authenticity of a data packet is ensured by using the concepts of geographical and temporal packet leashes that would help to minimize the effectiveness of the wormhole nodes in the network. In the geographical leash (GL), when a sender sends packets to any sensor node, the sender node incorporates sending time and its own location information to the packet. When the recipient node receives the packet, it will estimate the approximate distance between the sender and receiver based on the geographical leashes. The temporal leash includes the maximum lifetime to each packet. In temporal leash (TL), a sender adds either transmitting time or expiration time of packet so that the recipient can verify if the packet has made a journey too far based on maximum transmission speed and time. A predetermined time threshold is set between any two neighbors based on their position in the network. For a specific two neighboring nodes, the data packet would be discarded if it violates the time boundary set by these specific nodes. This scheme can perform better if strict time synchronization and the additional device like GPS are provided. Beside this, this proposed scheme may be performed poorly when the wormhole node is in active mode.

3.5. Trust Based Solutions:

Trust information of neighboring nodes is used as an attribute to detect wormhole attack in the WSN. Each sensor node monitors the data packet forwarding pattern of its neighbors and rates them accordingly. In the trust base scheme, a sensor node selects the most trustworthy path to reach the destination based on the trustworthiness of its neighbors. In this scheme, the researchers consider the fact that the wormhole node drops all the received packets coming from its adjacent nodes. It is expected that the system would rate the least trust level to the malicious nodes. By using this trust level scheme, the wormhole node can

be avoided during the selection of a path to the destination. This also helps to reduce the effectiveness of the wormhole nodes in the infected network. The source node would forward the packets to the neighbor which possess maximum trustworthiness.

In [44], a new detection scheme was proposed to detect wormhole attack in the network based on both time and trust. In this scheme, both data travel time and trustworthiness of the sensor are used as potential attributes to detect the malicious nodes from the infected network. These two modules of this proposed scheme run in parallel. Here, the time-based module works in three stages. Firstly, each sensor node identifies its neighbors and update the neighbor list accordingly. Secondly, each node finds the best path toward the base station based on the trustworthiness of neighbors. Finally, the proposed algorithm determines the presence of the wormhole nodes in the selected path. According to the authors, the malicious nodes deceive the time-based solutions in many ways. Hence, the trust-based model is incorporated with the time base scheme. In this scheme, a sensor node monitors the neighboring node continuously and select the best route to the destination based on the rating.

Another trust based wormhole attack detection scheme was proposed in [45].To execute the model, the deployed sensor node must operate in a particular mode, named as 'promiscuous mode'. This trust-based scheme is applied to the DSR protocol and inherent features of DSR routing protocol are used to measure the trust level of the neighboring nodes. Here, the algorithm must be executed in each sensor node and each node must measure the trust level of its neighboring nodes by monitoring the packet transmission pattern stated by the system. The source node verifies in several stages whether the forwarding node passes the IP packets or not through the sequence of integrity check. If the neighboring node for a particular source forwards all the packets, the trust level of the node would be increased. Similarly, if the opposite happens, the trust level of that node would be decremented.

The success of this module lies on the packet dropping criteria of the malicious nodes. However, the wormhole nodes do not drop packets in the hidden mode of this attack. Hence, the trust base detection model is not capable of detecting the hidden wormhole attack. On the other hand, each node monitors the packets forwarding pattern of its neighbors. As we know, sensor nodes have some constrained-on power and energy resources. It would be a burden for the system which leads to excessive energy dissipation of the nodes.

3.6. Graph-based solution:

Multi-dimensional scaling-visualization of the wormhole (MD-VOW) [46], was proposed based on the graph theory. The multi-dimensional scaling analysis of the constructed connectivity graph was used as an analysis tool to detect malicious node in the network. For the static sensor network, the connectivity graph is not supposed to change frequently. Hence, the authors have considered the fact that the presence of malicious nodes introduces the anomalies in the connectivity graph. In the network connectivity based wormhole attack detection schemes, the positions of the neighboring nodes are estimated from the received signal strength (RSSI) by each node and send this information to the base station. By compiling the received information, the base station determines the network layout and compared with the current connectivity graph. Then the presence of the wormhole node can be detected if any forbidden structure is found in the constructed network layout. However, it is prone to the distance estimation errors, especially for the sparse network. The surface smoothing technique is applied to the constructed network layout graph to compensate distance error. This approach also causes a significant amount of control packets flow to the base station. Similarly, if the wormhole node is located in the sparsely populated area, then the wormhole attack may not be identified by this network visualization based algorithm.

3.7. Radio fingerprinting based scheme:

In [47], the authors explored the potentiality of the fingerprinting device as a tool to validate the legitimacy of the node in a wireless sensor network. Most important goal of this research is to extract the features from the radio signals, radiating from the nearby sensor nodes; by which the legitimacy of a node can be evaluated. In this research, each node has to be equipped with the radio fingerprinting device. The radio fingerprinting device captures the radiated radio signal from the nearby sensor nodes. After that, the fingerprinting device converts the radio signals into digital format. The transient part of the signal is located and the important features are extracted. After that, those extracted features are taken into account as fingerprints so that recipient sensor node can identify the neighboring node. The authors also implemented the incorporation of the radio fingerprinting device with a sensor node [47]. In this research, the authors also showed that the fingerprinting approach identified the nearby node while the message contents and the identification of the nearby devices were hidden. There are few issues are required to be investigated in this approach. The radio fingerprinting devices' performance in a noisy environment, and in the mobile platform is in question. By using this detection method, only the 'out of band' wormhole attack can be detected. This proposed algorithm cannot detect 'in-band' wormhole attack as it can be launched from the legitimate node.

3.8. Neighborhood counts based detection scheme

No. of neighbors around a sensor node are used in [10-12,19] as detection attributes in the neighbor based detection scheme. In the centralized method, each sensor node finds the number of neighbors within its communication region and sends this information to the base station. As the distribution of the sensor node is known, the base station computes the hypothetical distribution of the number of neighbors along with the true distribution of the neighborhood counts. This process also creates a significant amount of control data packet flow throughout the network and leads to the unexpected energy dissipation of sensor node. This process is also used as secondary approach with the

distance-based scheme. In another neighborhood count based approach [12], detector node takes the count of neighbors at the each site it visited. In this approach, ANN-based detection scheme may not able to detect the wormhole attack if the wormhole nodes are located in the sparsely populated area. Another important factor is that by this scheme, the probable location of the wormhole node cannot be identified. Some authors also use signal processing tool like Fourier transform, Discrete wavelet transform [48] and, variance fractal dimension [49] on the data series of the neighborhood counts. However, these proposed algorithms only work on the acquired data series while deployed sensors are distributed uniformly. However, these schemes may not able to locate the probable location of the wormhole node.

4. Artificial neural Network (ANN)

The Artificial Neural Network (ANN) is a network based stochastic learning model that has evolved from the study, characteristics, organization, and decision-making ability of the unit cell of a human brain called a neuron [19]. In other words, it aims to imitate the most simplified and basic function of the human brain. Analogous to the unit cell of a human brain, an ANN contains several interconnected information processing units, called a neuron, learning the underlying process of the data samples presented to the network. The significant phenomena of ANN are the ability to estimate the non-linear complex relationship between inputs and outputs without any prior knowledge of dataset like a black box. ANN is usually observed as a model of interconnected neurons that maps the input and outputs through information exchange among neurons[50].

Furthermore, in a multi-layer perceptron (MLP), there is an input layer, followed by one or more hidden layers, and an output layer [51]. In each layer, several neurons are employed, which are fully connected with other neurons of an adjacent layer, and they are connected to different random weight values. In other words, neurons are fully attached to the neurons of the following layer; but in the same layer, neurons are not connected with each other. The number of neurons in the output layer depends on the type of the problem that we want to solve by the ANN.

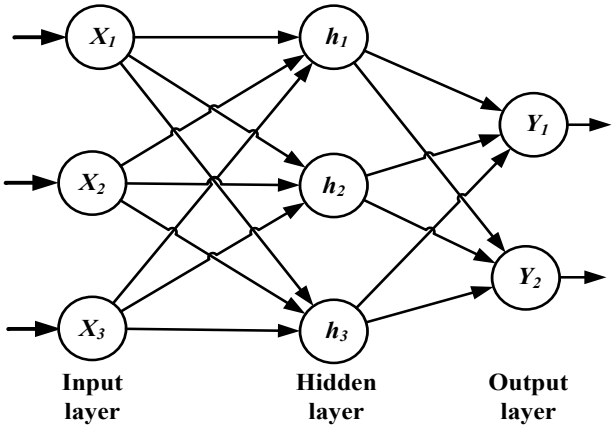

Fig. 3 The structure of an ANN.

4.1. Forward Propagation of the ANN:

Input features from the input layer are shared with an adjacent hidden layer through unidirectional branches[50]. Those input features are multiplied by random weights associated with the unidirectional branches; summed up, and passed through the activation function of the neuron (e.g. sigmoid function). The bias term is also added to each layer except the output layer to activate the artificial neurons. This bias term is also connected to the neurons of the adjacent layer with unidirectional branches associated with the weight values ($b_i^{(l)}$) so that the summed inputs exceed the predefined threshold.

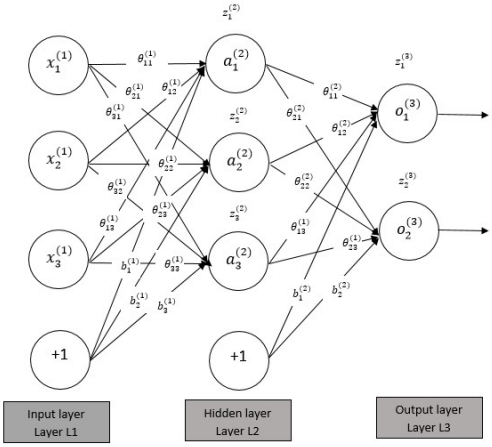

Fig. 4 Forward propagation of ANN

In the forward propagation, the output of each neuron of the prior layer is considered as the input to all neurons of the following layer. As shown in the Fig. 4, the three layers are connected with the weight value $\theta_{ij}^{(l)}$. $\theta_{ij}^{(l)}$ represents the weight value going to the unit i in layer $(l+1)$ and coming from the unit j in layer l. According to the Fig. 4, the net output of i^{th} unit (including bias term) of the hidden layer ($a_i^{(2)}$) is,

$$Z_i^{(2)} = \sum_{j=1}^{n} \theta_{ij}^{(1)} x_j^{(1)} + b_i^{(1)} \quad (1)$$

$$a_i^{(2)} = g(z_i^2) = g(\sum_{j=1}^{n} \theta_{ij}^{(1)} x_j^{(1)} + b_i^{(1)}) \quad (2)$$

In the equation (1) and (2), $Z_i^{(2)}$ represents the total input of the i^{th} unit of layer 2 .Similarly, the net output of k^{th} unit of the output layer can be shown as equation (3),

$$o_k^{(3)} = g(\sum_{j=1}^{n} \theta_{kj}^{(2)} a_j^{(2)} + b_k^{(2)}) \quad (3)$$

The cost function,

$$J(\theta) = \sum_{k=1}^{n} \frac{1}{2m} \sum_{i=1}^{m} (o_k^m - y_k^m)^2 \quad (4)$$

In the equation (4), $J(\theta)$ refers to the average error occurred over m training samples during the training procedure, and k defines the number of neurons in the output layer.

The transfer function of a neuron plays an important role in the training procedure. The purpose of the transfer function is to replicate the activation mechanism of the biological neuron. Usually, the net output of a unit in a layer is calculated from the net received input through the transfer function. The transfer function must be non-linear, continuous and differentiable at any point in order to apply gradient descent learning algorithm. There are several types of transfer function such as sigmoid function, hyperbolic tangent function, and rectified linear function. Some literature also suggests that the rectified linear function was found to accelerate the convergence rate of stochastic gradient descent due to its non-linear and non-saturating form. However, in our research, the sigmoid function was used as the transfer function of each unit in any layer (except input layer).

$$g(z) = \frac{1}{1 + e^{-z}} \quad (5)$$

$$g(z) = \tanh(z) = \frac{e^{z} - e^{-z}}{e^{z} + e^{-z}} \quad (6)$$

$$g(z) = \begin{cases} 0 & if\ z \leq 0 \\ z & if\ z > 0 \end{cases} \quad (7)$$

4.2. Back Propagation of the ANN

In the back propagation, the outcome of the output layer is compared with desired output. The error between the network output and desired output is measured and propagated backward to adjust the branch weights in order to minimize error that would occur due to the estimation of output. In other words, we minimize the cost or energy of the error function, $J(\theta)$ by passing back the error occurred during the training phase. In the back propagation, the gradient descent algorithm is applied to learn the network parameters $(\theta_{ij}^{(l)}, b_{ij}^{(l)})$ from the training set $\{x_i^m, y_i^m\}$.

However, there are many ways to update the weights: batch mode, online mode. In the batch mode, each weight is updated once by the total error occurred in an epoch (i.e. after one training cycle). In contrast, in the online mode, a training sample is drawn randomly from the training set and passes through the network. The network parameters are modified m times per training cycle if there are m training examples in the training set. This online mode of weight updating is also known as stochastic gradient descent[50].

Let's consider the multilayer feed forward network shown in Fig. 4. The impact of the change in the weight $(\theta_{ij}^{(2)})$ on error $(E_k^{(3)})$ occurred in the output layer is,

$$\frac{\partial E_k^{(3)}}{\partial \theta_{ij}^{(2)}} = \left(o_k^{(3)} - y^{(t)}\right).o_k^{(3)}\left(1 - o_k^{(3)}\right).a_j^{(2)} \quad (8)$$

In the equation (8), $o_k^{(3)}$ represents the output of the k^{th} unit of the output layer and $y^{(t)}$ refers to the desired output of a training example. Similarly, the impact of the change in weight $(b_k^{(2)})$, associated with bias and the neurons of the output layer, on error $(E_k^{(3)})$ occurred in output layer is,

$$\frac{\partial E_k^{(3)}}{\partial b_k^{(2)}} = \left(o_k^{(3)} - y^{(t)}\right).o_k^{(3)}\left(1 - o_k^{(3)}\right) \quad (9)$$

According to the above equations (8) and (9), the update formulas for the weights associated with output layer are given below.

$$\theta_{kj}^{(2)} = \theta_{kj}^{(2)} - \alpha\left(o_k^{(3)} - y^{(t)}\right).o_k^{(3)}\left(1 - o_i^{(3)}\right).a_j^{(2)} \quad (10)$$

$$b_k^{(2)} = b_k^{(2)} - \alpha\left(o_k^{(3)} - y^{(t)}\right).o_k^{(3)}\left(1 - o_i^{(3)}\right) \quad (11)$$

In the equations (10) and (11), α refers to the learning rate of the network. Now, we can calculate the rate of the change in the error $(E_k^{(3)})$ over the weight $(\theta_{ij}^{(1)})$, associated with the input layer and the hidden layer shown in the equation (12).

$$\frac{\partial E_k^{(3)}}{\partial \theta_{ij}^{(1)}} = \delta_k^{(3)}.a_i^{(2)}.x_j^{(1)}.\left(1 - a_i^{(2)}\right).\theta_{kj}^{(2)} \quad (12)$$

Considering

$$\delta_k^{(3)} = \left(o_k^{(3)} - y^{(t)}\right).o_k^{(3)}\left(1 - o_k^{(3)}\right) \quad (13)$$

Similarly, impact of the changes in weights $(b_i^{(1)})$, associated with bias and the neurons of the hidden layer, on error $\left(E_k^{(3)}\right)$ occurred in output layer can be calculated as

$$\frac{\partial E_k^{(3)}}{\partial b_i^{(1)}} = \delta_k^{(3)}.a_i^{(2)}\left(1 - a_i^{(2)}\right).\theta_{kj}^{(2)} \quad (14)$$

Therefore, according to the equations (12) and (14), the weights associated with input layer and the hidden layer can be modified by the following equations during the training procedure.

$$\theta_{ij}^{(1)} = \theta_{ij}^{(1)} - \alpha\delta_k^{(3)}.a_i^{(2)}.x_j^{(1)}.\left(1 - a_i^{(2)}\right).\theta_{kj}^{(2)} \quad (15)$$

$$b_i^{(1)} = b_i^{(1)} - \alpha\delta_k^{(3)}.a_i^{(2)}\left(1 - a_i^{(2)}\right).\theta_{kj}^{(2)} \quad (16)$$

These weights adjacent procedure continues recursively until the network reaches either to the minimum tolerance level or maximum epochs at the training.

5. Support Vector Machine

The support vector machine (SVM) is one of the reliable and widely used supervised learning models that analyze the presented data samples to perform classification and regression analysis[50]. The SVM learns the given data samples, each sample marked with a specific class, builds a model that can assign a class to a new data sample. SVM learning model set a hyperplane in an optimum position in the data space so that Euclidian distance from the decision surface for all training data samples would be maximized. SVM has been emerged to provide the generalized performance to solve a wide range of classification and pattern recognition problems such as face detection, pedestrian detection, and text categorization etc.

Let's consider a training data set, $D = \{(x^m, y^m)\}$ contains m training data samples where $x^m \in R^n$ and $y^m \in \{-1, +1\}$, represents the label of the m^{th} data sample. The hyperplane in form of decision surface can be defined as

$$\sum_{i=1}^{m} \boldsymbol{w}^T x^{(i)} + b = 0 \quad (17)$$

In the equation (17) $\boldsymbol{w}$ and b represent a weight vector and a bias term that can be determined through the training process. Through these parameters (w, b), the decision surface places itself in the optimum position in the data space. As we know, the SVM places the decision surfaces in the data space in such way that it maximizes the geometric margin of all training data samples. In this circumstance, the optimization problem is

$$\min_{w,b} \frac{1}{2} \parallel W \parallel^2 \quad (18)$$

Subject to

$$\sum_{i=1}^{m} y^{(i)}(W^T x^{(i)} + b) - 1 \geq 0$$

The concept of the Lagrange multiplier is implemented to solve this optimization problem with constraint boundary stated in the equation (19). Therefore, the Lagrange function is

$$L(w, b, \alpha) = \frac{1}{2} \parallel W \parallel^2 - \sum_{i=1}^{m} \alpha(y^{(i)}(W^T x^{(i)} + b) - 1) \quad (19)$$

In the equation (19) α is the multiplication factor and $\alpha \geq 0$. If we differentiate the Lagrange function with respect to w, b and ; then the optimization problem mention in the equation (18) can be formulated as

$$\max_{\alpha} L(\alpha) = \max_{\alpha} \Big(\sum_{i=1}^{m} \alpha_i - \frac{1}{2} \sum_{i=1}^{m} \sum_{j=1}^{m} \alpha_i \alpha_j y^{(i)} y^{(j)} x^{(i)} x^{(j)} \Big) \quad (20)$$

Subject to

$$\sum_{i=1}^{m} \alpha_i y^{(i)} = 0$$

$$\alpha_i \geq 0, i = 1,2, \ldots\ldots, m$$

The solution of the equation (20) drives to get optimum decision surface that is able to separate the positive and negative training data samples. If the presented data samples are not linearly separable, then the non-linear kernel trick can be implemented to deal with this problem. The Gaussian kernel is widely used as the kernel function. Because this function can increase the dimensionality of the data samples infinitely[52]. The expression of the Gaussian kernel is shown as equation (21).

$$K\left(x^{(i)}, x^{(j)}\right) = \exp\left(\frac{-\parallel x^{(i)} - x^{(j)} \parallel^2}{2\sigma^2}\right) \quad (21)$$

6. Non-linear Logistic regression

Logistic regression is a statistical model in which the category, from a predefined list of categories, of a new observation or data sample, is predicted, by estimating the probability of the class using a logistic function (e.g. email sorting). It is evolved from linear regression and designed to solve classification problems. That's why, in some literature, it is referred as logistic classification[50].

Logistic classification can be shown as a special case of linear regression, but we can draw a distinct line between these two statistical models. In the linear regression, the predictor predicts the continuous value by a fitting curve to the given training input data samples [53]. In contrary, in logistic classification, a predictor learns how to classify the data through a training phase and predicts a discrete value for the corresponding new data sample. Like linear regression, the same decision boundary equation is used for logistic classification.

$$h_\theta(x) = \theta_0 + \theta_1 x_1 + \theta_2 {x_2}^2 + \cdots + \theta_n {x_n}^n = \theta^T \mathbf{x} \quad (22)$$

Here, in the equation (22), $\boldsymbol{x}$ represents a given input vector that contains n input features. The θ refers to the model parameter that is required to be optimized by using the training input data samples. This decision boundary can be either linear or nonlinear that depends on the application of the logistic classification.

$$Z = \theta^T \boldsymbol{x} \quad (23)$$

$$g(z) = \frac{1}{1+e^{-z}} \quad (24)$$

In logistic regression, a sigmoid function is used to measure the certainty level of the class that new observation or data sample belongs to. The main advantage of using sigmoid function is that it is continuous, differentiable at any point and monotonically increasing. The probabilistic interpretation can be done in a simple way; as the value of the $g(z)$ in greater than 0.5, the predictor would be more certain about the class of the given data sample [54]. If the same cost function of linear regression is used, $J(\theta)$ yields non-convex cost function. Consequently, special kind of the cost function is used in logistic classification to learn model from the training data which is convex.

$$J(\theta) = -\left[\frac{1}{m}\sum_{i=1}^{m} y^i \log\left(h_\theta(x^i)\right) + (1-y^i)\log\left(1 - h_\theta(x^i)\right)\right] + \frac{\lambda}{m}\sum_{j=1}^{n}\theta_j^2 \quad (25)$$

$J(\theta)$ denotes the cost function of the logistic classification with regularization term, where m refers to the total training examples of a given training set, λ is the regularization parameter, y^i represents the target output for i^{th} training example, and x^i represents the i^{th} training example. There are two learning methods used in the training procedures: Gradient decent and Newton's method. In this research, the newton's method is applied as the learning model. Because it converges to the optimal solution within few iterations.

7. Propose detection scheme

The proposed algorithm is a network based approach, in which neighborhood counts are used as the detection feature to detect a wormhole attack.

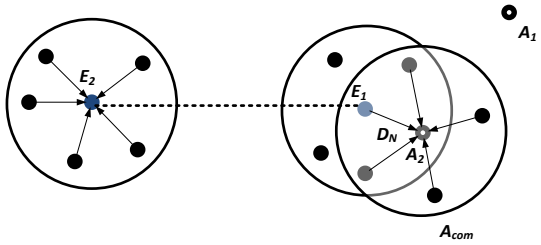

Fig. 5 Impact of wormhole attack on neighborhood count.

A mobile sensor node, known as detector node (D_N), is deployed in an area where sensor nodes could be uniformly or non-uniformly distributed. The detector node D_N moves around this sensor field and collects a neighborhood count and the coordinate at each site it visited. When it reaches to the wormhole infected zone, the neighborhood population would increase abnormally sharply or abnormally lightly, depends on the sensor distribution and the position of the wormhole nodes. For instance, Fig. 5 shows the impact of wormhole nodes on the neighborhood counts. Let's say, the detector node D_N is moving spontaneously around the area where the sensor nodes are deployed. At the time t_1, D_N moves from a location A_1 to another location A_2. Since the detector node collects the neighborhood count at each site, it transmits neighbor discovery message (NDM) to the adjacent sensor nodes within its communication range. According to the Fig. 5, the wormhole node (E_1) also hears the broadcast as it is located in the transmission range of D_N.Since wormhole node doesn't read the content of the packet, it encapsulates and forwards the packets along the virtual tunnel to another malicious node (E_2). Furthermore, E_2 retransmits the received packets towards its neighbors. The neighbors of the distant malicious nodes (E_2) respond back with valid neighbor ID (NID) through the wormhole link. After that, E_1 unicasts the received responses to the originator, D_N. E_1 compels D_N to think that the responses have come from the sensors located within its radio ranges. Though some of those responses have traveled long distant within the network. That's how the neighborhood counts from the infected zone increases sharply due to the wormhole node shown in the Fig. 6. This may be true for uniform sensor distribution.

As we know, the sensor density in the non-uniform sensor distribution is inconsistent over the area. If the wormhole nodes are placed in the sparsely populated area, then the number of neighbors would not increase abruptly or lightly as expected. In this circumstances, it would be difficult for ANN based detection scheme to detect wormhole attack based on the collected neighborhood counts (also true for the sparse network).

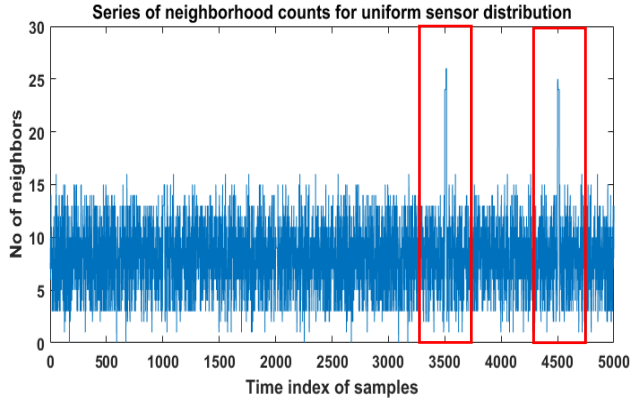

Fig. 6 The series of neighborhood count (Uniform sensor distribution)

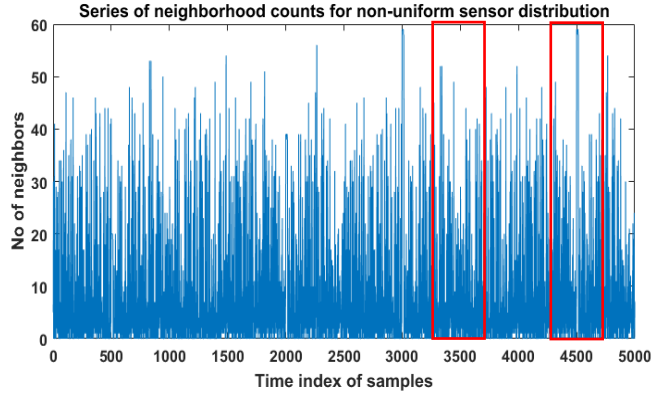

Fig. 7 The series of neighborhood count (Non-uniform sensor distribution)

Sometimes the neighborhood counts taken from the infected zone are same as, or far smaller than the counts taken from the

non-infected zone shown in the Fig. 7. In this case, the ANN-based detector may suffer to distinguish between positive and negative data samples. Therefore, another detection feature along with neighborhood count is required in order to detect wormhole attack from the infected network (either uniform or non-uniform) more precisely and confidently.

In this paper, we introduce a new detection feature called 'average *residual energy pattern of the neighbors (AREPN)'*. As we know, wormhole nodes circulate false route information into the network that the base station is multiple hops away from the wormhole nodes. Therefore adjacent sensor nodes of the wormhole get influenced and transmit their data packets to the base station through wormhole nodes. However, the wormhole nodes force them to hand over the collected data packets to one of the wormhole nodes. That means the wormhole nodes receive more data packets after the base station and its neighbors. Now, the question is how the wormhole nodes get those data packets coming from the adjacent nodes. Apparently, the data packets are coming through its neighbors.

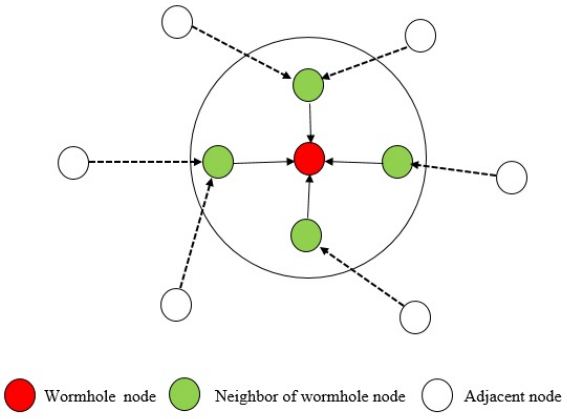

Fig. 8 Impact of wormhole nodes on adjacent nodes.

More packets arrive at the wormhole node means, more packets have been received and transferred by its neighbors. As we know, a node dissipates a significant amount of energy due to the transmission and reception of the data packets. Since the wormhole nodes are getting the numerous data packets from the adjacent nodes, so the neighbors of the wormhole nodes are also losing energy more quickly by retransmitting packets intended for the wormhole node. Now it can be said that the sensors located in the infected zone lose more energy than other nodes located in the non-infected zone.

In our proposed scheme, the detector node broadcasts NDM to the adjacent sensor nodes at each site it visited. The adjacent nodes reply back by transmitting a data packet incorporating valid NID and information of residual energy. By this way, D_N is able to calculate the number of neighbors and average residual energy of the neighbors (AREPN). D_N captures this evidences as a two-featured sample and stores it. It is expected that AREPN taken from the infected zone is much smaller than the AREPN taken from the non-infected zone. As we know, the adjacent nodes of the base station dissipate energy quicker than the normal node. That's why, D_N doesn't cover a certain geographic area based on the location of the base station. Once the mobile node reaches close to the base station, it transfers all the collected samples for further analysis.

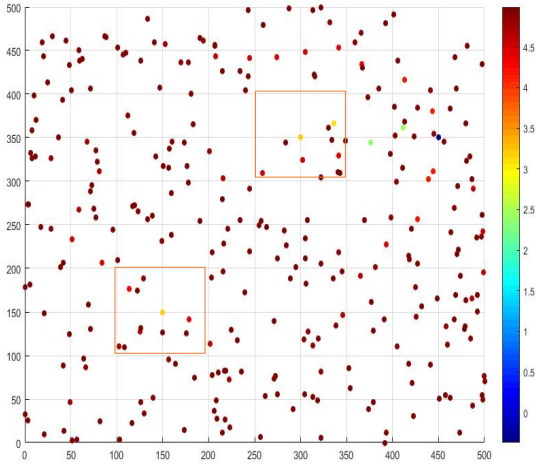

Fig. 9 Wormhole infected network.

As shown in the Fig. 9, the sensors of the wormhole infected zone lose energy (red marked box) more quickly than the non-infected zone. In that case, the initial energy of each sensor node is 5 units.

The performance of an artificial neural network highly depends on the method of training and the dataset containing potential features. The Base station gathers (by the help of the detector node) a data set (D_{set}) consists of N data samples. In this first half, D_N gathers two featured K data samples ($K \in N$) from the non-infected zone which are called negative data samples. Similarly, the same amount of data samples is collected from the wormhole infected zone, known as positive data samples. After that, those two types of data samples are mixed up randomly so that training can be performed without any bias. Then, M data samples ($M \in N$) are drawn from the D_{set} and stores in a training dataset D_{train} ($D_{train} \subset D_{set}$). At the same time, rest of the P data samples ($P \in N$) are stored in D_{test} ($D_{test} \subset D_{set}$) to evaluate the learning performance of the trained neural network.

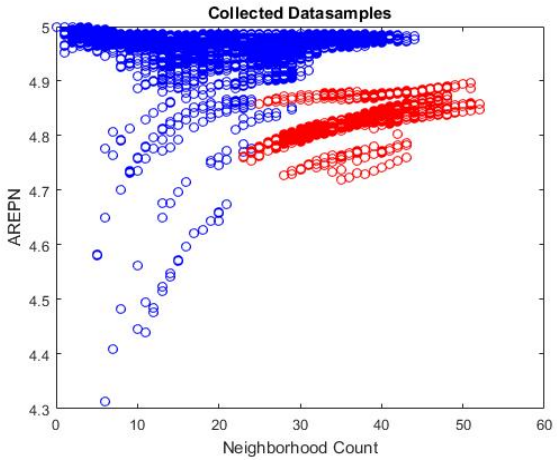

Fig. 10 Collected two featured data samples by D_N (red marked samples are positive data samples) .

Proposed Algorithm:

1. Collect two featured K negative data samples from the non-infected zone
2. Collect two featured K positive data samples from the wormhole infected zone
3. Store the both type of data samples in D_{set} which consists of N data samples
4. Select M data samples from D_{set} and store in D_{train} where $(D_{train} \subset D_{set})$
5. Rest of the P data samples are stored in D_{test} where $(D_{test} \subset D_{set})$
6. Train the neural network with the data set D_{train} and appropriate network parameters up to T epochs
7. Test the neural network by using the samples of D_{test}
8. If output for a specific sample ≥ 0.5 , then this sample represents wormhole attack and probable location of the malicious node are identified.
9. If output for a specific sample < 0.5 then this sample doesn't represent wormhole attack
10. Update D_{train} by D_{test} for further training
11. Reset D_{test} and update with new data samples gathered by D_N

Furthermore, data samples of D_{train} are fed into the input layer of the ANN. The training procedure is performed repeatedly until it reaches a predefined maximum number of training cycles i.e. T epochs. The testing procedure involves checking the learning progress of the ANN-based detector. In the testing part, each data sample passes through the trained neural network. If the output for a specific data sample is greater than 0.5, then this sample represents wormhole attack. Since, D_N stores the coordinate of the locations along with the two featured data samples, so the probable position of the wormhole node can also be identified by the detection scheme.

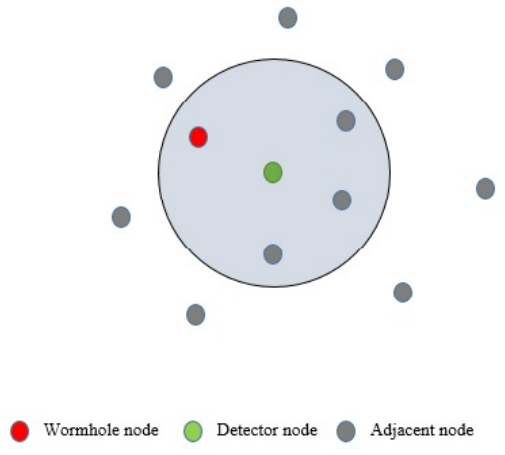

Fig. 11 Probable location of a wormhole node

After that, D_{train} is updated by the D_{test} for further training. This would minimize the error level that has achieved in the training phase. The D_{test} entries are cleared up and updated with new data samples collected by the D_N in real time.

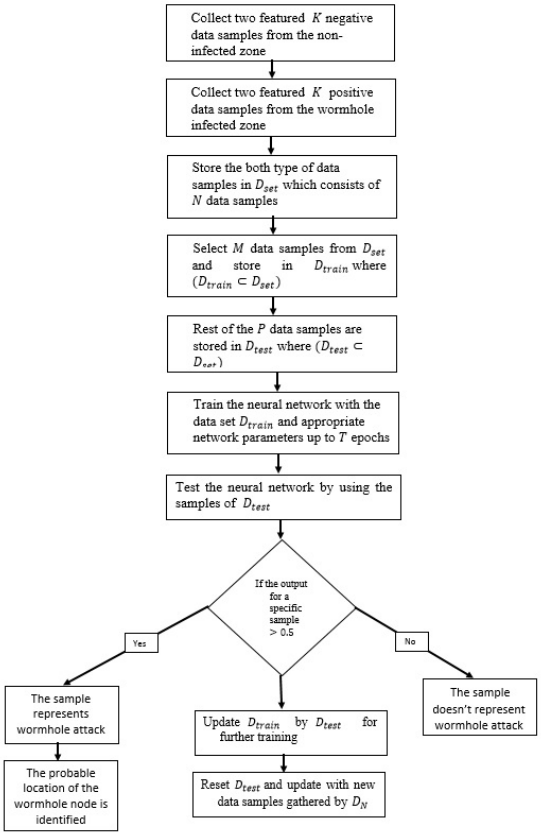

Fig. 12 Flowchart of the ANN-Based proposed algorithm

8. Simulation and results

In this section, extensive research experiments are conducted under various network scenarios to assess the effectiveness of the proposed algorithm in detecting wormhole attack from the affected sensor network. The first phase of the experiments is conducted to see if the proposed scheme is able to classify the malicious data samples that represent wormhole attack. Furthermore, we evaluate the performance of the detection scheme in terms of detection accuracy, false positive rates, and false negative rates. In the second phase, the efficacy of the proposed algorithm is explored considering single featured data samples and two featured (i.e. the number of neighbors and AREPN) data samples. As the energy dissipation of the sensor node depends on the routing protocol; hence, the proposed algorithm is also tested considering 'On demand' based routing protocol (AODV) and cluster based routing protocol (LEACH). Afterward, we record and analyze the efficacy of the proposed algorithm in detecting wormhole attack from different sensor distributions. Finally, the performance of the proposed algorithm is compared with the performance of other machine learning technique based detection schemes like support vector machine (SVM) and regularized non-linear logistic regression (LR). In addition, all experiments have been performed in MATLAB 2015a.

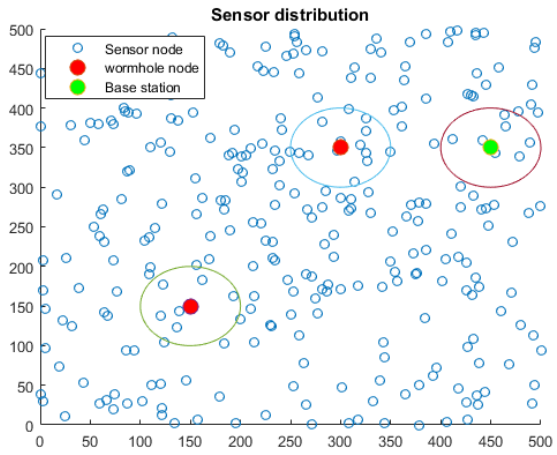

Fig. 13 The depiction of the simulation set up (uniform sensor distribution)

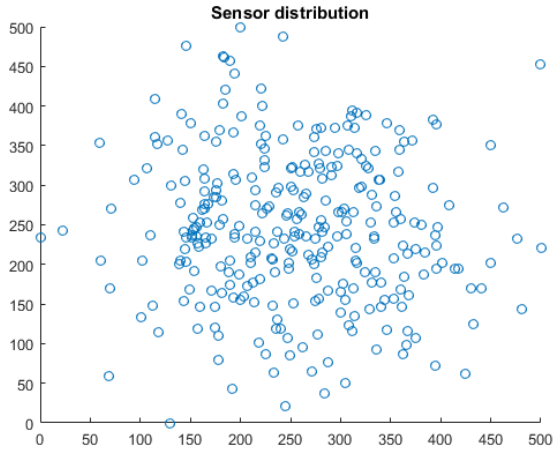

Fig. 14 Non- uniform sensor distribution (Gaussian)

In the simulation, 300 sensor nodes are distributed (uniform or non-uniform) within the square field of $500m \times 500m$. The deployed sensor nodes and the base station are static in nature. Each sensor node has the communication resources of which they use to communicate with the adjacent sensor nodes. Radio range of each sensor node equals to $50\ m$. Initially, each sensor node has five (05) units of energy that would be used in sensing and transferring packets. A detector mobile sensor node, D_N is deployed as a mobile observation point of the network. The basic task of the D_N is to collect neighborhood counts and AREPN of neighboring population at each site it visited within this deployed area. The radio range of the detector node is same as deployed sensor nodes. We assume that the detector node is fully aware of its position, the boundary of the targeted area, and any obstacles in the area that may restrain its movement. A pair of wormholes node is placed at the locations $150m \times 150m$, and $300m \times 350m$. Random waypoint model is implemented in the simulation as the mobility model for the D_N.Similarly, the base station is positioned at a location of$350m \times 450m$ .In these experiments we only consider the data communication between a node to the base station. Moreover, the experiments have been conducted on thirty (30) different instances for each sensor distribution (e.g. uniform sensor distribution) in order to get valid (average) performance matrices of the proposed detection scheme.

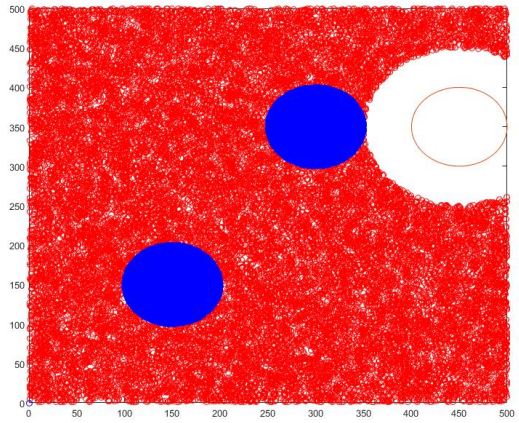

Fig. 15 The location visited by the D_N (red ,blue and white indicate non-infected zone, infected zone and the area not covered by D_N).

In this simulation, the detector node collects two featured data sample (i.e. number of neighbors and AREPN) at each site it visited. For each instance of each sensor distribution (uniform or non-uniform sensor distribution), the detector node,D_N collects 50000 data samples from deployed area in which 25000 samples are negative data samples, and 25000 samples are positive data samples. The collected data samples are stored at the D_{set} in the base station. After that, 49000 randomly selected samples are stored in the D_{train} for the training purpose. Rest of the data samples is used to test the learning performance of the proposed detection scheme.

8.1. The performance of Proposed ANN based detection scheme:

A multi-layer, feed forward network (with back propagation algorithm) is implemented for the experiments. The input layer contains one or two neurons considering the type of data samples (one featured or two featured) used to train the network. Moreover, the hidden layer consists of 100 neurons and the output layer has only one (01) neuron. We used a sub data set, D_{train} comprised of 49000 randomly selected data samples from D_{set} for training collected by D_N.

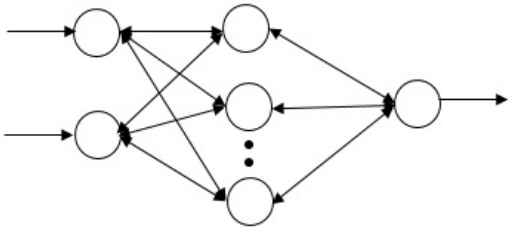

Fig. 16 The structure of the ANN for two featured data samples

At first, the neural network was trained by the single featured the training examples from D_{train} and evaluated learning performance of ANN by the rest of the data samples stored in the D_{test} . After that, two featured training samples are

fed into the neural network and acquired results are compared with the results obtained by using single feature data samples. During the training period, the minimum error tolerance level is set to 10^{-5}. The Table 1 represents the parameters which are used during the training phase.

Table 1 Parameters used for ANN.

Parameter	Value
No of attributes	2
No of Data points (training)	49000
No of Data points (testing)	1000
Architecture (for one feature)	[1,100,1]
Architecture (for two features)	[2,100,1]
Performance	0.00001
Learning rate, α	0.001
Epoch	500
CPU time (for one instance)	2.17 mins

In the testing phase, the test data set, D_{test} is fed into the input layer. Then the output of the ANN based model is observed if it could detect the existence of wormhole attack in the given network. Fig. 17 shows that, the ANN based wormhole attack detection scheme can classify the samples that represent wormhole attack from the both single featured and two featured data samples successfully

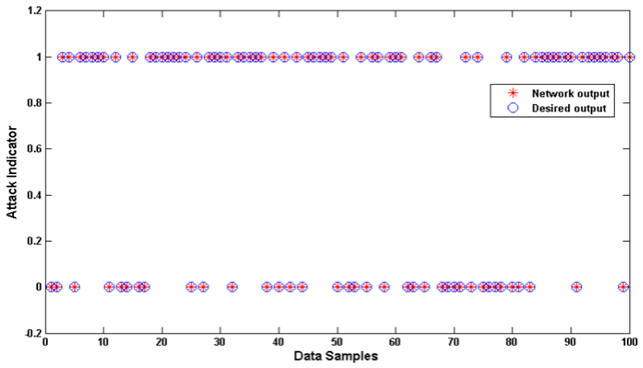

Fig. 17 Classification of wormhole attack

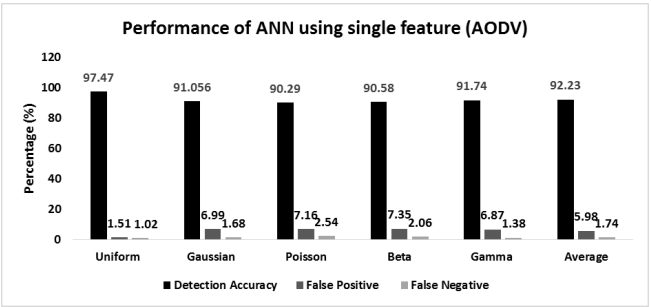

Fig. 18 Performance of the ANN-based detection scheme using single featured data samples (AODV)

Fig. 18 shows the performance of the ANN-based detection model in detecting wormhole attack using single featured data samples (i.e. neighborhood count) when the network uses AODV routing protocol. In this graph, the highest detection accuracy is recorded as 97.47% when sensors are distributed uniformly in the square field, whereas the lowest detection accuracy is measured 90.29% for poisson sensor distribution. Furthermore, detection accuracy for Gaussian distribution is almost same as the gamma distribution. Accordingly, 91.056%, 91.74%, and 97.873% detection rates are measured for Gaussian, Gamma, and Beta sensor distribution. However, the average detection accuracy is calculated as 92.23%. The false positive rate and false negative rate entirely follow the same trend of detection accuracy. The lowest false positive rates and false negative rates are measured for uniform sensor distribution. The average false positive rates and false negative rate are accordingly 5.98% and 1.74%.

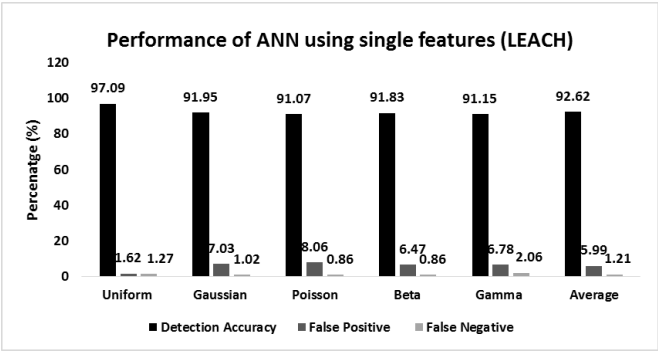

Fig. 19 Performance of the ANN-based detection scheme using single featured data samples (LEACH)

Fig. 19 shows the results obtained by applying single featured data samples on ANN based detection model considering LEACH routing protocol. It is observed that this algorithm performs better for uniform sensor distribution compares to non-uniform sensor distribution. 97.63% detection accuracy, 1.62% false positive rate, and 1.23% false negative rate are achieved for the uniform sensor distribution. After that, it has performed better for Gaussian sensor distribution among all non-uniform sensor distributions. The detection accuracy, false positive rate and false negative rate for Gaussian sensor distribution are 91.95%, 7.03% and 1.02% accordingly. The similar trend in detection accuracy is observed for Poisson, beta, and gamma sensor distribution. However, considering all the sensor distributions, the false negative rates are lower than the false positive rates. The average detection accuracy and false positive rate for all sensor distributions are accordingly 92.62% and 5.99%.

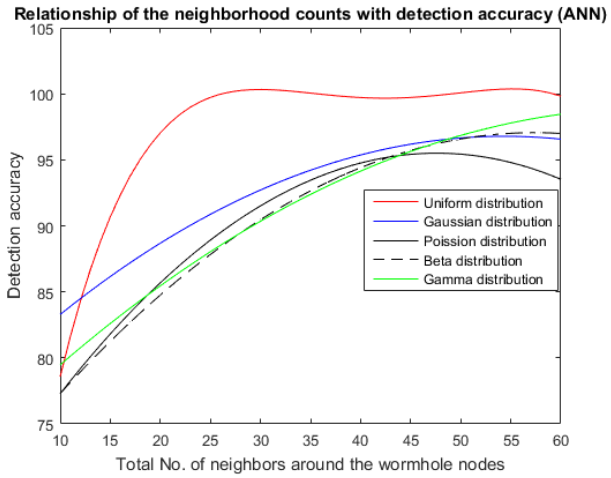

Fig. 20 The relationship between neighborhood count and detection accuracy (ANN)

Fig. 20 represents the relationship between the neighborhood counts and the detection accuracy. Undeniably, the detection accuracy of the proposed algorithm (considering single featured data samples) increases as the total number of neighbors around wormhole nodes increase for all sensor distributions. The detection accuracy of the system has a non-linear relationship with the total number of the neighbors around the wormhole nodes. For the uniform sensor distribution, we can model this relationship as 4^{th} degree polynomial. For the other non-uniform sensor distribution, the relationship can be modelled as 2^{nd} .It means that the proposed scheme may not perform well considering single featured data samples if the wormhole nodes are located in the sparsely populated area in the network.

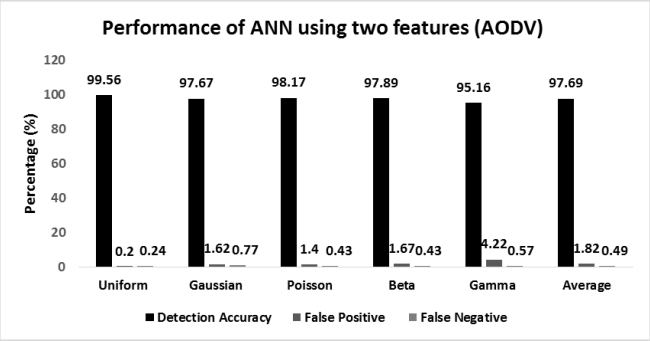

Fig. 21 Performance of the ANN-based detection scheme using two featured data samples (AODV)

The two featured data samples are applied to the ANN-based detection scheme. Like prior, the performance of the ANN is evaluated considering both AODV and LEACH routing protocol. Fig. 21 presents the performance of the ANN-based model considering two featured samples and AODV routing protocol. The proposed algorithm gives a better performance to detect the wormhole attack for the uniform sensor distribution. 99.56% detection accuracy, 0.2% false positive rates, and 0.24 % false negative rate are achieved for the uniform sensor distribution. For all non-uniform sensor distribution, the detection accuracy varies in between 95% to 97%. In this circumstance, the average detection accuracy and false positive rate for all the sensor distributions are 97.69% and 1.82%. Most importantly, the detection accuracy, considering all sensor distribution, is significantly increased for the application of the two featured data samples.

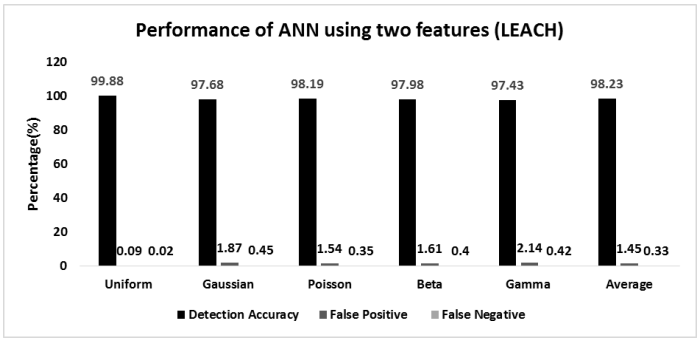

Fig. 22 Performance of the ANN-based detection scheme using two featured data samples (LEACH)

As shown in the Fig. 22, the performance of the ANN-based detection scheme improves significantly considering LEACH routing protocol and the application of two featured data samples on the ANN. Evidently, the ANN-based model performs better for the uniform sensor distribution compares to all non-uniform sensor distribution. The highest achieved detection accuracy for the uniform sensor distribution is 99.88%. The detection accuracy for the non-uniform sensor distributions fluctuates from 97.43% to 97.98%. Furthermore, the lowest false positive rates and false negative rates are achieved for the poisson sensor distribution which is 1.54% and 0.35% respectively. In this circumstance, the average detection accuracy, false positive rate, and the false negative rate for all the sensor distribution are accordingly 98.23%, 0.45%, and 0.33%. In summary, the application of the two featured data samples on the ANN enhances the performance of the proposed scheme for both AODV and LEACH protocol.

A. The performance of the SVM-based detection scheme

For the different sensor distributions, one and two featured training examples are applied to the SVM accordingly. The average result of detection accuracy, false positive rates, and false negative rates are calculated to measure the efficacy of the SVM-based algorithm for all network scenarios. The Table 2 represents the parameters which are used during the training phase.

Table 1 The parameters used for SVM

Parameter	Value
No of attributes	2
No of Data points (training)	49000
No of Data points (testing)	1000
Kernel	Gaussian
Sigma	default
Tool	MATLAB
CPU time (for one instance)	3.17 mins

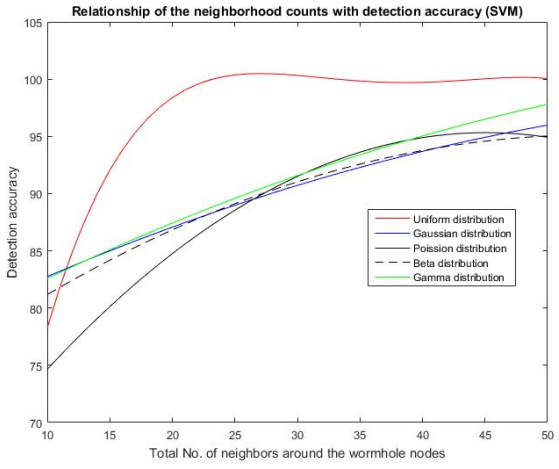

Fig. 23 The relationship between the neighborhood count and the detection accuracy (SVM).

Fig. 23 represents the relationship between the counts of neighbors around wormhole nodes and the detection accuracy considering one featured data samples applied to the SVM-based detection scheme. Like the previous case, the detection accuracy follows the non-linear relationship with the total number of neighbors for all sensor distribution. As the neighborhood count increases, the detection accuracy of the SVM-based algorithm also increases. Similar to the ANN-based detection scheme, it may suffer to detect wormhole attack if the wormhole nodes are placed in the sparsely populated area.

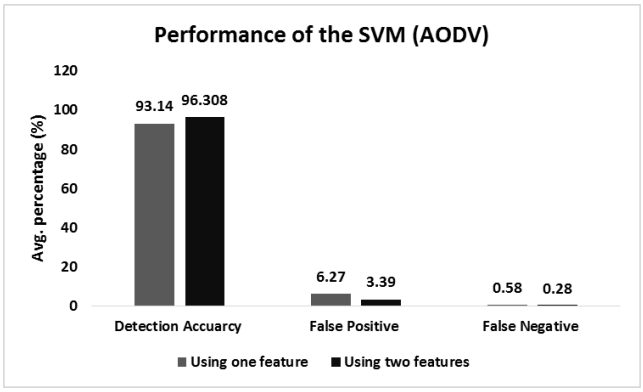

Fig. 24 Performance of the SVM-based detection scheme (AODV).

Fig. 24 shows that the performance of the SVM-based algorithm when the network uses AODV as the routing protocol. According to the Fig. 24, SVM-based detection scheme gives better the performance considering two featured data samples like the ANN-based model. SVM-based algorithm reaches approximately 96.30% on an average for all sensor distribution. Similarly, it achieves lowest false positive and false negative rates for two featured data samples which are 6.27% and 0.58% approximately. Using two featured data samples, the performance of the SVM-based algorithm enhances around 3.39%.

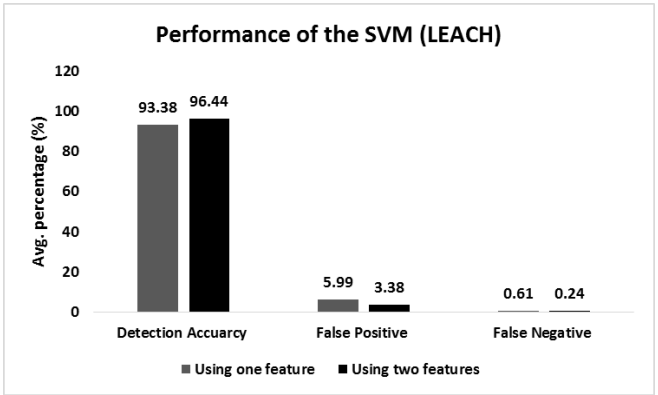

Fig. 25 Performance of the SVM-based detection scheme (LEACH).

Fig. 25 shows the performance of the SVM-based detection scheme considering LEACH protocol. Similar kind of trend in detection accuracy, shown in Fig. 24, is observed for the LEACH protocol. Like Fig. 24, SVM-based detection scheme performs better with the two featured data samples. It achieves averagely 96.44% detection accuracy for all sensor distribution, whereas, 93.38% detection accuracy is measured for the one featured data samples. In this case, the detection accuracy increases approximately 3.27% for the two featured data samples. Inversely, the false positive rates and false negative rates declined significantly for the two featured data samples.

B. The performance of the non-linear logistic regression:

Non-linear logistic regression (LR) algorithm is used to measure the performance on this classification problem and compare its outcomes with the proposed algorithm. Table 3 shows the parameters which are used during the training phase of the non-linear logistic classification algorithm.

Table 2 Parameters used for logistic linear classification

Parameter	Value
No of attributes	2
No of Data points (training)	49000
No of Data points (testing)	1000
Iteration	07
Regularized parameter (λ)	default
Learning method	Newton's methods
CPU time (for one instance)	3.17 mins

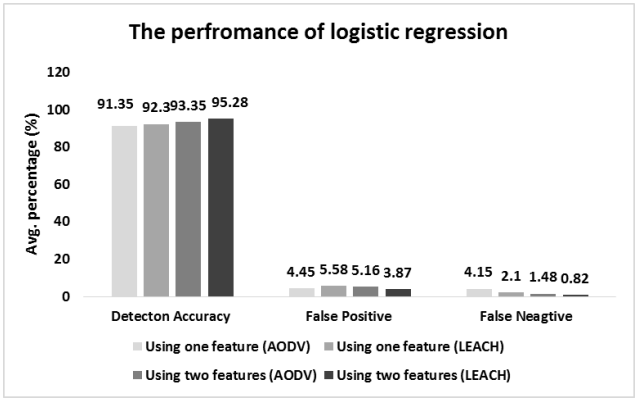

Fig. 26 Performance of the LR.

Fig. 26 represents the overall performance of the LR to detect the wormhole attack considering one featured and two featured data samples. According to the Fig. 26, LR based detection scheme performs better with two featured data samples when the network uses LEACH as the routing protocol. The detection accuracy reaches to 95.28 % considering two featured data samples. In this case, lowest false positive rate and false

negative rate are achieved for the LEACH routing protocol, which is 3.87% and 0.82% respectively. Most importantly, this LR based detection scheme gives better performance with two featured data samples like ANN or SVM based detection scheme.

C. Performance comparison

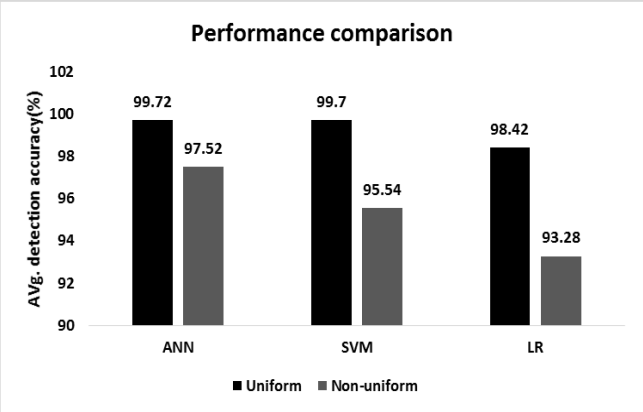

Fig. 27 Performace analysis on the uniform and the non-uniform sensor distribution.

Fig. 27 represents the performance of the detection schemes on the uniform and the non-uniform sensor distributions considering two featured data samples. Clearly, for the uniform sensor distribution, three (03) detection schemes achieve higher detection accuracy in contrast to the non-uniform sensor distributions. As the sensor density of the area is uniform; the neighborhood counts increase significantly with the presence of the wormhole nodes in the network. In contrary to the non-uniform sensor distribution, the neighborhood counts increase slightly or significantly depends on the position of the wormhole nodes in the network. Sometimes the neighborhood counts are smaller than the count taken from the wormhole non-infected zone (wormhole nodes can be placed in the sparsely populated area in the network). Since the uniform sensor distribution has consistency in the node density, the total neighbor population of the wormhole nodes is much smaller than the total neighborhood counts in non-uniform sensor distribution. As the neighbors of the wormhole nodes are the only way to reach the wormhole nodes; therefore, the neighbors of wormhole nodes in uniform distribution dissipate more energy than the neighbors of the malicious node in non-uniform sensor distribution. Hence, positive data samples are easily distinguished from the presented data set. That's why the detection accuracy of these schemes is much better for uniform sensor distribution.

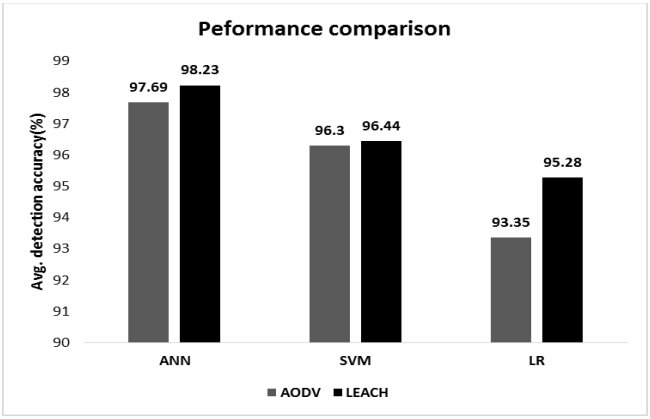

Fig. 28 Performance comparison among ANN, SVM, and LR.

If we analyze the performance of the three detection schemes (shown in the Fig. 28), ANN outperforms SVM and LR in detecting the malicious samples that represent wormhole attack considering both AODV and LEACH routing protocol. ANN achieves 97.69% and 98.23% detection accuracy respectively for AODV and LEACH routing protocol. SVM based detection scheme performs better than LR based detection scheme (achieves approximately 96% detection accuracy) in view of AODV and LEACH. Considering LEACH routing protocol, the LR based detection scheme attains 95.28% detection accuracy which is the lowest among all the detection schemes. As we know, the performance of the machine learning techniques highly depends on the dataset. In this case, ANN distorts the two featured data samples in the higher dimension better than other two machine learning techniques; and efficiently put dynamic decision surface in between positive and negative data samples. That would help the ANN-based detection scheme to gain highest detection accuracy.

Another important observation of this research is that the three detection schemes give better performance in classifying positives data samples for LEACH protocol. In the cluster based routing protocol like LEACH, a node is nominated as a cluster head among the members of a cluster for a specific round of data transmission to the base station. Once the cluster head is selected, other members send their data packets to the cluster head. Afterward, selected cluster head transfers the data packets to the base station. For the next round, a new member is randomly chosen as cluster head from the other members who is not selected as cluster head before for any round. However, wormhole node manipulates the cluster head selection process in a particular cluster of nodes. Furthermore, the 'in-band' wormhole node can be selected as a cluster head. If it happens, the wormhole node gets a bunch of data packets easily from the other members through its neighbors. As we know, wormhole nodes create shortcut path to the base station in the network. Therefore, the cluster head is deceived throughout the data transmission process to the base station. If wormhole nodes are placed in two different clusters, the members of the cluster may also be deceived while

they are selecting closest cluster head to transmit their data packets. Hence, the neighbors around wormhole node dissipate more energy in LEACH compared to AODV. The extra dissipation of the energy reflects in the feature called AREPN collected by detector node. That would help in separating the positive data samples and negative data samples when two featured data samples are presented to the detection schemes.

9. Conclusions

Wormhole attack is one of the detrimental network layer attacks for wireless sensor networks. This thesis presents a novel detection model based on neighborhood count and AREPN using an ANN for wireless sensor networks. The goal of this proposed detection scheme is to detect wormhole attacks (In-band, out of band, hidden or active mode of wormhole attack) with higher precision and accuracy, especially in a non-uniform network environment. The experimental results confirm that the proposed detection scheme is able to identify the existence of the wormhole node without requiring any special hardware both in uniform and non-uniform sensor distribution. Another important aspect of this detection model is it doesn't increase the significant amount of network overhead flow throughout the network. The simulation results also validate that our ANN-based approach performed better than SVM or LR based detection scheme. This ANN based detection scheme achieves around 99.72% (average) and 97.52% (average) accordingly for uniform and non-uniform sensor distribution. Most significantly, the probable location of the wormhole node can be identified by this scheme. Future works are required to enhance the performance of the detection scheme and to investigate in different directions so that we can evaluate the efficacy of the proposed detection scheme perfectly.

Proposed future works are noted as follows.

a) Nowadays, deep neural networks and convolutional neural networks are used to enhance the performance internet threat detection schemes. We want to apply this advanced machine learning algorithms on the acquired data set to evaluate their performance. After that, we will compare the results with the Proposed ANN based scheme.

b) In this research, the relationship between detection accuracy and the total count of neighbors around wormhole nodes is investigated. In the future work, we want to investigate the impact of changes in radio range of sensor nodes (60m,70m, and 80m etc.) and number of the sensor nodes (deployed) and position of the wormhole nodes on the detection accuracy of the proposed model.

c) If we use more than one mobile node, the two featured data samples will be gathered more quickly (detection time) rather than using single detector node. Multiple detector nodes will help to locate the positions of the wormhole nodes by triangulation algorithm. Therefore, in the future work, we want to investigate the performance of the proposed detection scheme by deploying multiple detector nodes in the different sensor network environments.

d) As we know, the performance of the ANN depends on its own architecture. In the future work, we want to apply the acquired data set on different network architecture (Varying number of neurons in a layer, varying number of the hidden layer) to optimize the performance of the proposed ANN-based detection scheme.

e) In this detection scheme, probable location of the wormhole node is identified through D_N. We want to work further in this direction to find the exact location of the malicious nodes in the infected sensor network.

f) The energy dissipation of a sensor node depends on the routing protocol that being used in the network. In this research, the performance of the proposed detection model is verified considering on demand based and cluster based routing protocol. In the future, we want to the test the proposed algorithm on the hybrid routing protocol such as zoned based routing protocol (ZRP) and wireless ad-hoc routing protocol (WARP).

ABSTRACT

This paper describes a system to gather information from a stationary camera to identify moving objects. The proposed solution makes only use of motion vectors between adjacent frames, obtained from any algorithm. Starting from them, the system is able to retrieve clusters of moving objects in a scene acquired by an image sensor device. Since all the system is only based on optical flow, it is really simple and fast, to be easily integrated directly in low cost cameras. The experimental results show fast and robust performance of our method. The ANSI-C code has been tested on the ARM Cortex A15 CPU @2.32GHz, obtaining an impressive fps, about 3000 fps, excluding optical flow computation and I/O. Moreover, the system has been tested for different applications, cross traffic alert and video surveillance, in different conditions, indoor and outdoor, and with different lenses.

1. Introduction

Clustering is the task of grouping a set of information in such a way that information in the same group (called a cluster) are more similar to each other than to those in other groups. A clustering system, in particular regarding detection and tracking of moving objects, is a really common and important task, widely used in computer vision as low-level task for different applications like: camera surveillance [1], Cross Traffic Alert (CTA) [2], Intelligent Transport System (ITS) [3], object detection and recognition [4], people detection and recognition [5], people behavior analysis (e. g. anti-theft, falling detection, etc.) [6] and user interfaces by gesture [7]. Efficiency and robustness of clustering, considered as low-level task, is really important because it influences the performance of all higher level tasks of the aforementioned applications.

To implement the clustering task, there are in general two types of approaches: region based and boundary based. For what concerns region based, different approaches have been proposed: combined color based and region based particle filters, using multiple hypotheses for tracking objects [8], motion-based segmentation and a region-based Mean-shift tracking approach, fused by a Kalman filter, to extract object independent motion trajectory under uncontrolled environment [9], and so on. However the most popular and recent region based approaches is background subtraction [10-14]. Once the background is removed from the scene, through different kind of filters applied on the foreground, it is possible to identify moving object. Since these methods are pixel-based, they are not suitable for real time applications, also because they require a long time for estimating the background models.

In boundary based approaches, different features have been proposed: color feature descriptors, based on the spectral power distribution of the illuminant and object's surface reflectance property [15], multi-feature descriptors [16], and so on. However, many recent approaches use edge based optical flow [17-20]. Optical flow estimation gives a two-dimensional motion vector, which represents the movement of some point of an image in the following one of the sequence. Basic idea in boundary based approaches is to consider vectors with similar spatial and motion information belong to the same object [21]. Since these approaches are feature-based, they are a good choice for all real time applications, even if usually the do not reach high performances.

In this work, we propose a very low-cost clustering system, working with a generic optical flow and reaching high performances in different application scenarios. This paper is organized as follows: Section II describes the proposed system, block by block, also showing visual impact on a CTA example; Section III shows the experimental results for different application

*Corresponding Author: Giuseppe Spampinato, STMicroelectronics, Advanced System Technology, Catania, Italy | Email: giuseppe.spampinato@st.com

cases; finally, conclusion and future work are exposed in Section IV.

2. Proposed System

Since we are interested in light systems, we started our investigation with optical flow based algorithm, which system [22,23] is described in Fig. 1. The standard system takes as input the optical flow, that is the list of motion vectors between adjacent frames. First step is usually a pre-filtering to eliminate noise and/or spikes. Afterwards, labelling step inserts same label for each "similar" vector. The role of clustering step is to group vectors with the same label into clusters. At the end, "similar" clusters are merged together to obtain the final list of identified clusters. In this system, some steps (in particular pre-filtering) can be computationally heavy and no previous vector information is used. Moreover, no temporal cluster information is used to enhance clustering, but the previous clustering information is usually used only for tracking.

To overcome the aforementioned drawbacks of typical optical flow based system, we propose a novel low-cost system only based on optical flow, described in Fig. 2. The new blocks have been added to increase performances of the system. Moreover, previous frame is not necessary, but just a list of previous vectors and clusters are needed for processing. Detailed description of each block is explained in the next sub-paragraphs. Moreover, to better understand the peculiarity of various blocks, example images are shown.

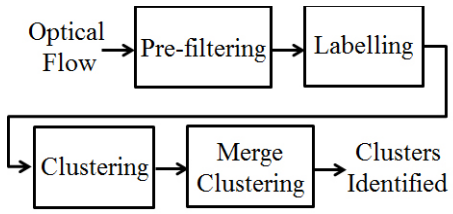

Fig. 1. Typical optical flow based system.

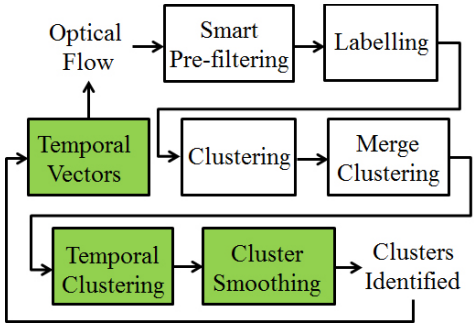

Fig. 2. Proposed system

2.1. Smart Pre-filtering

This starting block takes as input the optical flow, the set of motion vectors generated in any manner, and its role is to remove from this set all vectors which can be considered as noise. Usually complex filtering is used as for example median filters [22] and so on. We propose a new simple filtering with two different options, applied depending on the quality of incoming optical flow.

First option, called *brute-force*, just eliminates motion vectors with small movements, which are considered as noise. This option is indicated just for low quality optical flow. In particular, a motion vector $v=(dx,dy)$ is removed from optical flow if the following condition is satisfied:

$$(ABS(dx) \leq MAX_DX) \text{ and } (ABS(dy) \leq MAX_DY) \quad (1)$$

Where MAX_DX and MAX_DY are thresholds chosen depending on the precision of the optical flow and ABS is the absolute value.

Second option, called *smart*, apart applying (1), do not remove in the output optical flow, the motion vector v with the following characteristics: it lies in the area around a cluster C of previous frame and its orientation is similar to the orientation of C, that is:

$$ABS((orientation(v) - orientation(C)) \leq MAX_ORIENT1) \quad (2)$$

Where *MAX_ORIENT1* threshold should be opportunely chosen, depending on specific application. In particular, for rigid objects, as vehicles, a small value of *MAX_ORIENT1* is a good choice, while for not rigid objects, such as people, we need to increase its value.

About *orientation*, we have to distinguish between orientation of a vector $v=(dx,dy)$ and orientation of a cluster C. In the first case, the formula is the following:

$$orientation(v) = tan^{-1}(dy/dx) \quad (3)$$

Instead, orientation of a cluster C, it is defined as the mean of the orientation of all motion vectors included in C. To execute the tan^{-1} function at real-time a fixed point arctangent algorithm was implemented (http://www.coranac.com/documents/arctangent/).

Figure 3 shows an input optical flow example. In this example we have three cars moving: the middle one to the left, the other two to the right. We can easily notice in the scene some noisy vectors in particular around the leafs of the surrounding trees, which is a typical problem in these kind of applications.

Fig. 3. CTA example: input optical flow

2.2. Labelling

This block takes as input the filtered optical flow. Its role is to insert a label for each motion vector, assuring to insert the same label for motion vectors witch potentially belong to the same cluster. Two motion vectors $v_1=(dx_1,dy_1)$, spatially situated in point $p_1=(x_1,y_1)$, and $v_2=(dx_2,dy_2)$, spatially situated in point $p_2=(x_2,y_2)$, have the same label if the following three conditions are satisfied:

$$(ABS(x1-x2) + ABS(y1-y2)) \leq MAX_DIST_POINT \quad (4)$$

$$(ABS(dx1-dx2) + ABS(dy1-dy2)) \leq MAX_MOD \quad (5)$$

$$ABS((orientation(v1) - orientation(v2)) \leq MAX_ORIENT2) \quad (6)$$

Where the thresholds should be opportunely chosen: *MAX_DIST_POINT*, depending on specific application and typical objects distance; *MAX_MOD* depending on precision of optical flow; *MAX_ORIENT2* depending on specific application.

The above formulas indicate that two motion vectors are considered to belong to the same cluster if they are spatially near (4), have got similar module (5) and similar orientation (6). While (4) and (5) are commonly used for labelling [23], (6) has been added for robustness of the system.

2.3. Clustering

This block takes as input the filtered optical flow, obtained by *smart pre-filtering* block and the related labels, coming from *labelling* block elaboration. The aim of this step is to group vectors with the same label into clusters. To avoid having clusters with dimensions too small, it is important to extend the cluster found to a minimum dimension N×*M*. This dimension depends on various factors: typical object size we want to cluster, typical distance of the object from the camera and the type of the camera (liner or fish-eye).

Figure 4 shows in boxes the nine clusters, obtained from *clustering* step in the CTA example of Fig. 3. From the center of each cluster, its *orientation* is displayed to better understand the next *merge clustering* step, which will reduce the number of clusters.

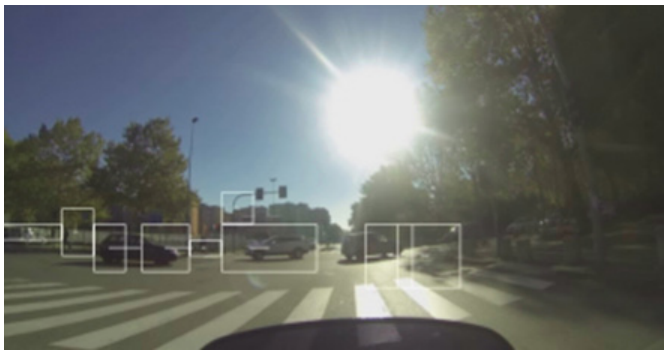

Fig. 4. CTA example: clustering step output

2.4. Merge Clustering

This block takes as input a list of clusters, coming from previous *clustering* block, and merges together similar clusters to obtain a new list of identified clusters. Two clusters C_1 and C_2 are considered similar and then merged if the following conditions are satisfied:

$$distance_X(C_1,C_2) \leq MAX_DIST_CLUSTER_X \quad (7)$$

$$distance_Y(C_1,C_2) \leq MAX_DIST_CLUSTER_Y \quad (8)$$

$$ABS((orientation(C_1) - orientation(C_2)) \leq MAX_ORIENT3) \quad (9)$$

Where the thresholds should be opportunely chosen: *MAX_DIST_CLUSTER_X* and *MAX_DIST_CLUSTER_Y*, depending on application and typical objects distance; *MAX_ORIENT3*, depending on application.

In (7) and (8), the distance for clusters concept is analogous to distance for points concept in (4) in *labelling* step; while (9) is analogous to (6). The above formula indicates that two clusters are similar if they are spatially near (7-8) and have got similar orientation (9). Since for each cluster we have its orientation, it is easy to extend the similarity also to the module, in analogous way of (5).

Looking at Fig. 4, from left to right, the first car is spit in two cluster and these clusters have got the similar orientation, so the *merge clustering* step will join these two clusters. The middle car is well detected, but since there are near clusters with similar orientation, these clusters will be joined together. In the last car, we can notice two near clusters, but since they have opposite orientation, they will be not joined together. Figure 5 shows, marked by ellipses, similar clusters that *merge clustering* step will join, while Fig. 6 shows the merged clusters, now reduced to six.

Fig. 5. CTA example: similar clusters to merge

Fig. 6. CTA example: merge clustering step output

2.5. Temporal Clustering

This block takes as input two lists of clustering: current frame list and previous frame list. The roles of this block are two: the first one is similar to the *merge clustering* block, that is to merge similar clusters in current and previous frame; while the second role is to eliminate clusters in current frame which do not have similar clusters in the previous frame. Similarly to the method described in Sub-section D, two clusters are similar if condition (7), (8) and (9) are satisfied. The difference, compared to *merge clustering* block, are the following: for *temporal clustering* block C_1 and C_2 are two clusters coming from two adjacent frames; *MAX_DIST_CLUSTER_X* and *MAX_DIST_CLUSTER_Y* thresholds can be different in value. Of course, as said before, in this block we can use the module as similarity condition. Another important note is that, to increase reliability of the system, assuming constant speed of objects to identify, the clusters of previous frame can be motion compensated.

In the CTA example, looking Fig. 6 from left to right, the first two and the last clusters will be removed, since they do not have similar clusters in previous frame. Figure 7 shows the resulting clusters, reduced to three, as the real moving objects in the scene.

Fig. 7. CTA example: temporal clustering step output

2.6. Cluster Smoothing

This block takes as input the list of clusters, coming from the previous *temporal clustering* block, and the previous frame clustering list. Clusters marked as similar, in the temporal clustering block, to avoid big discrepancy in dimensions, should be tuned according to the similar clusters in the previous frame. In particular, a weighted average between previous C_1 and current C_2 similar clusters should be calculated as follows:

$$C_2 = (C_2 * CURRENT_W + C_1 * PREVIOUS_W)/SUM_W \quad (10)$$

With:

$$SUM_W = CURRENT_W + PREVIOUS_W \quad (11)$$

Fig. 8. CTA example: cluster smoothing output

The weights *CURRENT_W* and *PREVIOUS_W* should be opportunely chosen, usually giving more weight on the previous cluster. As said for *temporal clustering* step, to increase reliability of the system, the clusters of previous frame can be motion compensated.

The final effect of this block is shown in Fig. 8, where we can note that dimensions of the three clusters are more similar to the real dimensions of objects. This is the final output of the proposed schema.

2.7. Temporal Vectors

It is important, in particular for not dense optical flow, at the end of the proposed system, to insert in the optical flow of the next frame all vectors contained in the current cluster, to limit clusters disappearing in the scene. Of course, these inserted vectors can be motion compensated, assuming constant speed.

2.8. Tracking

Since in *temporal clustering* step, we obtain similarity and then relationship between previous and current frame clusters, it is easy to calculate the trajectory of the identified object in the scene. The cluster centroid can be obtained and, according to relationship between clusters, displayed in the scene.

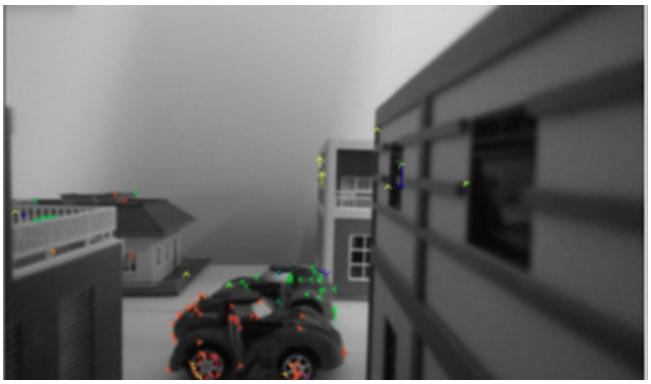

Fig. 9. Simulated example: input optical flow.

Fig. 10. Simulated example: proposed system output.

3. Experimental Results

Lots of tests have been executed with different scenarios, as CTA and video surveillance, and different cameras at different resolutions, with both linear and fish-eye lenses, obtaining really good visual results.

Speed testing has been made calculating computation time for VGA sequences on a 2.3GHz processor (ARM Cortex-A15, using a single core). About 3000 frame/sec were obtained, executing only the described ANSI-C algorithm (excluding the optical flow and I/O calculation).

Considering that the memory required by the system is really low, about 96K considering 4K optical flow for frame, and considering the aforementioned speed test, we can assure that the system is suitable also for really low-cost devices.

An example of simulated CTA with partially occluded objects is shown in Fig. 9 and Fig. 10. In particular the proposed system, with the input motion vectors in Fig. 9, correctly identifies and well spots the two partially occluded crossing cars, as shown in Fig. 10.

An example of real CTA with fish-eye lens, with multi objects moving, is shown in Fig. 11 and Fig. 12. In particular the proposed system, with the input motion vectors in Fig. 11, correctly identifies the three crossing cars shown in Fig. 12.

Fig. 11. Fish-eye example: input optical flow.

Fig. 12. Fish-eye example: proposed system output.

An example of video surveillance is shown in Fig. 13 and Fig. 14. In particular, the proposed system, with the input motion vectors in Fig. 13, correctly identifies the person in Figure 14. It is to underline that the proposed system not only correctly identifies the man leaving the bag, but also bag itself.

The last case can be useful also to recognize the unattended luggage application, really important for example for airport security.

Fig. 13. Video surveillance example: input optical flow.

Fig. 14. Video surveillance example: proposed system output.

4. Conclusion and future work

The proposed approach has been experimentally tested on a representative dataset of scenes obtaining effective results in terms of accuracy. A very reliable and low-cost clustering system has been developed with the characteristic to be very low power consumption, since it works only with optical flow information. The proposed system is also very flexible: can be used with any algorithm which estimates motion vectors between adjacent frames. An important characteristic is the consideration of previous frame clustering and vectors information for a more robust clustering determination in the current frame. Moreover, average of current and previous related cluster, to maintain more graceful clustering output for the user.

A limitation of this work is that we consider just stationary camera, so can be used for some specific applications, like CTA and video surveillance. Another limitation is related to input optical flow: if the image is too dark or blurred, or moving object is too speed, poor optical flow will be produced and the proposed method will fail.

Future work will be orientated on overcoming this limitations, leaving the system reliable also in the case of moving cameras, introducing robust filtering to remove from input optical flow the global motion vector, opportunely calculated.

Conflict of Interest

The authors declare no conflict of interest regarding the publication of this paper.

ABSTRACT

This paper presents the development and design of a methodology based on fuzzy logic to control an indoor mobile robot for a complete navigation in an unknown environment. The methodology incorporates two basic behaviors, namely: reaching the goal and avoiding obstacles. The obstacle avoidance behavior is treated using wall-following scheme based on an Interval Type-2 Fuzzy Inference technique. .This helps in handling data uncertainties to produce a better performance. The mobile robot control mechanism uses some sort of knowledge base arranged in a set of fuzzy-rule-base to implement the wanted behavior that makes the mobile robot follow the boundary of an obstacle or a wall. A constant distance to the obstacle/wall is maintained while the robot tries successfully to get around this difficulty. Once the path is clear, the obstacle avoidance behavior is inhibited and reaching the goal behavior is activated using a secondary fuzzy controller. This methodology was successfully tested on a real mobile robot for different sort of scenarios. In order to provide better insight into the work's objective, a comparison work with another method, which uses a Partial Swarm Optimization-Fuzzy method, is carried out based on some defined criteria. The experiment shows a better improvement in the results of the proposed method.

1. Introduction

Mobile robots have a special place in robotics. Their interest lies in their mobility, which covers applications in many fields (nuclear, navy, space, firefighting, surveillance, load transportation ...). The particular aspect of mobility requires a methodological and technological complexity that adds to the general problems faced by mobile robots. Solving these problems requires the use of all available resources both in technology (sensors, motor, and energy) and in information processing by using artificial intelligence techniques or special processors. The autonomy of a mobile robot is a faculty, which enables it to adapt or make a decision in order to perform a task despite a lack of preliminary or possibly erroneous information. In other cases, such as vehicle exploration of planets [1], garbage collector [2], foraging [3], autonomy is a fundamental issue because remote control is impossible due to the propagation delay. The main focus of such research directions is how to let a mobile robotic body navigate in an unstructured environment without collisions; and how to combine these two behaviors in order to achieve the required robot tasks. In fact, if we arrive to control the robot to achieve the first behavior, it would be a difficult task for the robot to navigate in a cluttered environment. One of the solutions which has been an interesting research topic over the past few years is wall following. This behavior is one of the multi-issues that can be used to avoid obstacles. In fact, the robot moves along the object while keeping a certain safe distance. This behavior may be used to follow a real wall, concave or convex objects, and labyrinths. Wall-following strategy could be very helpful when the mobile robot is being trapped in deadlocks caused by local minima. Despite the number of publications appeared in this field of research, mobile robot navigation is still considered as a topic of extensive research.

Many papers have dealt with the topic of mobile robot navigation using different approaches. Conventional approaches have limitations and cannot respond optimally to non-linear dynamics and the change of system parameters. In the literature, one can find new approaches based on artificial intelligence

developed to cope with these limitations and fuzzy logic theory was used extensively for this purpose [4]. The obstacle avoidance problem is also considered as a challenge when designing an autonomous mobile robot, and this issue has been tackled using many approaches [5]. On the other hand, signals captured by sensors, when an obstacle is detected, are contaminated with noise from different sources and probably associated with other unwanted signals. Therefore, the problem of detecting the obstacles and positioning its emplacement poses the problem of uncertainties, precision and accuracy. In this case, new control methods based on artificial intelligence, such as fuzzy logic, were introduced. Liu *et al* [6] analyzed the relationship between the motion characteristics and installation position of sensors of mobile robots and proposed a self-convergence mathematical model. The purpose of their work is to execute the wall-following activity with only a single distance proximity switch. Based on a spiking neural network controller, Wang *et al*. [7] used sonar sensory readings to guide their mobile robot to follow the wall. The idea of using fuzzy rules to implement a wall-following-based obstacle controller has been proposed in [8], a fuzzy system based on the concept of general perception was proposed to control the mobile robot navigating along walls of arbitrary shape and around obstacles. The autonomous mobile robot (MR) in [9] is equipped with two IR proximity sensors. The wall following is based merely on sensorial information given by these two IR sensors. In order to improve noise resistance ability, some researchers applied control laws based on interval type-2 fuzzy logic [10-13]. Hsu et al, [10] proposed an evolutionary wall-following control of a mobile robot using an interval type-2 fuzzy controller with Species-Differential-Evolution activated Continuous Ant Colony Optimization (SDE-CACO). All fuzzy rules are generated online using a clustering-based approach during the evolutionary learning process. . Other works investigates a control based on Inverted Ant System IAS, such as [4] and other investigated Cellular Automata and Inverted Ant System to control a swarm of robots in foraging task [3]. The control and other aspects implementation, such as, coordination and synchronization are described in [11]. An interesting work has been proposed in [14], where the authors suggested a reinforcement and optimized fuzzy controller method for mobile robot wall following. The method was successfully tested on the mobile robot Pioneer 3-DX. However, the methodology requires a learning procedure, which requires gathering data and a lot of computation time.

This paper proposes a new fuzzy logic methodology to control an indoor mobile robot for a complete navigation in an unknown environment. This methodology is based on two basic behaviors, reaching-the-goal while avoiding unforeseen obstacles. The two behaviors are designed using fuzzy logic tools inspired from human capacity reasoning with perception-based information. Type-1 fuzzy sets are precise but unable to handle data uncertainties. To incorporate these uncertainties, we need to make an extension. The idea is to consider the membership grade of an element to be a fuzzy set of type-1 rather than a number within the interval [0 1]. In this work, we propose a new scheme for obstacle avoidance based on wall following and to our knowledge, the manner we used in getting around the obstacle by partitioning the obstacle-near-region into three regions has not been used before. The mobile robot is equipped with US sensors that provide range reading, determining the distances between the robot and the obstacle. The inputs characterizing the information on the environment are fuzzified and presented to the inference engine for generating control outputs. The interesting part in this work is the way the obstacle avoidance using wall following is treated. This methodology, up to the author's knowledge, offers a new idea of tackling this problem when the obstacle neighborhood is divided into three regions. For each region, a linguistic fuzzy rule based system is defined.

1. The proposed general navigation problem.

The complete navigation problem has to deal with two important different behaviors. The main behavior is to reach the goal starting from any initial robot configuration. The second behavior is the mobile robot ability to avoid obstacles. Given these two behaviors, we should find a way to combine them in order for the mobile robot to execute the given mission successfully. In this case, one can either build a mode that switches between the two behaviors or have a blended action that combines between the two. Switching between the two behaviors can guaranty the success of the mission. However, the rapidly transitions between these two behaviors might result in a non-practical or a non-feasible action. On the other hand, the blended behavior might result in a smooth action. However, it does not guaranty the success of the task. One solution consists of weighting these two actions in order to successfully achieving the mission. Given the fact that the real world is composed of convex and concave obstacles, walls, labyrinths, etc., we need to elaborate a control action that guides the mobile robot along the obstacle boundaries toward its final destination. To detect the obstacles, we make use of the ultrasonic or infrared sensors that are provided with the wheeled mobile robot Khepera developed at the LAMI laboratory, Lauzane Switzerland.

Khepera is an automated differential drive guided vehicle specially designed and equipped for autonomous navigation utilized in many research laboratories. The execution of the task is related to the two-evocated main behaviors:

- Reaching the goal
- Avoiding obstacles

In this case, one can picture the robot as if it is subjected to two forces: an attractive force $\boldsymbol{F_a}$ due to the goal action and a repulsive force $\boldsymbol{F_r}$ due to the obstacle action as it is shown in Figure 1. The resultant force that acts on the robot may be determined by properly weighting the distance and direction. However, this would necessitate more tuning due to imperfect sensors and practical considerations. Therefore, to deal with obstacles, we choose the wall following approach while switching between the two cited behaviors with some added precautions to avoid the swinging effect. This method, which finds its application mainly to execute the corridor and wall following activity, is used in this work to avoid unforeseen obstacles. It could also help the robot reaching its goal in a blind fashion when the mobile robot makes the wall its main guidance. Tracking the wall would be an interesting application when dead-reckoning methods suffer from cumulative errors [15]. Wall following approach is as well very helpful in situations like being trapped in a cul-de-sac (Figure. 2-a) or when the mobile robot finds itself in a labyrinth-like situation (Figure. 2-b).

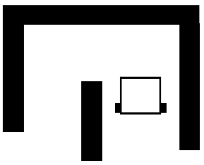

Figure 2b: Labyrinthe

3. Obstacle avoidance using wall following approach

3.1 Problem formulation

Many papers have dealt with wall following based on sensorial information such as IR sensors [16], US sensors [17], or visual navigation [18]. Ultrasonic and Infrared sensors are used for their relatively low cost, reliability and widespread availability. If the mobile robot evolves along a corridor, it will face two choices. Depending on its current situation with respect to the walls, the autonomous mobile robot should make a decision. Obviously, the robot follows the wall on its left side if the wall following task is chosen given only left sensor inputs, and likewise for the wall following on the right side. This decision may, for instance, be taken depending on the side that is closer to the wall. Hence, in case of the left wall following behavior, we use the two sensors on the left side of the mobile robot that give us the distances d_1 and d_2 as it is shown in Figure 3. But, if the mobile robot chooses to follow the wall being in its right side, the right wall following behavior is activated instead.

These two behaviors are mutually exclusive, which means that the activation of the first prevents the second to happen. This activation occurs when there are not obstacles on the front of the robot or there is only a detection of the wall that is to be followed. The implementation of the fuzzy logic controller is based on the sensorial information obtained from the two lateral US sensors, which give us the distance to the wall. In fact, this information is essential in determining the error angle between the actual current heading and the wall orientation. Our aim is to make this error equal to zero, such that the robot will always be in parallel to the wall.

3.2 The adopted strategy

Our idea lies on the following strategy. Consider the configuration of the mobile robot with respect to the wall and consider the distances d_1 and d_2 measured by the two lateral US sensors as it is shown in Figure 3. It is clear that the error angle α between the actual current robot heading and the wall orientation is given by equation (1)

$$\alpha = \alpha_l = atan\left(\frac{d_1 - d_2}{L}\right) \quad (1)$$

Where L is the length of the mobile robot. In this scheme, the desired position of the mobile robot is defined relative to the wall emplacement such that the robot maintains a desired distance. The distance that should be maintained between the mobile robot and the wall is chosen to satisfy an arbitrary security distance range $D + 2\varepsilon$, such that ε is a chosen tolerable offset error to avoid swinging or chattering behavior. In this case, the robot may be found in three possible regions, as it is clear from Figure 4.

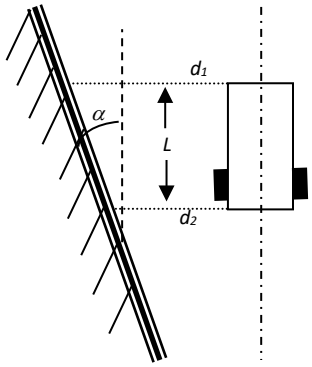

Figure 3: Robot configuration with respect to the wall

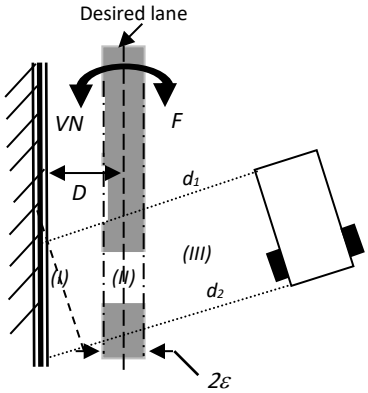

Figure 4: Desired lane following with respect to the wall

From Figure 4, one can see the inner region (I), the desired region (II) and the outer region (III). If the robot lies in the inner or outer regions, an action should be provided to drive it toward the desired region II. Considering the above stated requirement, our goal is to propose a robust fuzzy controller that maintains the mobile robot within region II.

4. Mobile robot Type-2 fuzzy motion control

The motion of the mobile robot may be controlled and adequately adjusted by many types of controllers. In this work, we choose the fuzzy logic control because we believe in its robustness for controlling nonlinear systems and its immunity in face to parameter variations and uncertainties. Introduced in 1965 by L. A. Zadeh from the University of California at Berkley [19], Fuzzy logic proved to be a strong tool for controlling complex systems. Using knowledge and experience, one can easily derive the rule base on which the fuzzy controller strongly depends. However, the presence of uncertainties in any system control requires thinking on extending type-1 fuzzy sets to type-2. In fact, the basic blocks used for designing the type-2 fuzzy controller are the same as those used with type-1; these include fuzzification, inference engine and defuzzification. The only difference lies on output processing block, where the defuzzifier is not considered as the solely block but contains a type reducer and defuzzifier blocks. The type

reducer is added because of its association with the nature of the membership grades of the elements that are no more a number within the interval [0 1], but a fuzzy set of type-1.

4.1 Interval Type-2 fuzzy logic system (IT2FLS)

The interval type-2 fuzzy set is completely described by the footprint of uncertainty (FOU). The FOU is a bounded region that uses an upper and lower type-1 membership function. By definition [14], an interval type-2 fuzzy set denoted by $\tilde{A}$ is expressed as

$$\tilde{A} = \{(x,y), \mu_{\tilde{A}}(x,y) | \forall x \in X, \forall u \in J_x \subseteq [0\ 1] \quad (2)$$

The upper bound and the lower bound of the FOU($\tilde{A}$) are expressed respectively as $\overline{\mu}_{\tilde{A}}(x)$ and $\underline{\mu}_{\tilde{A}}(x)$. Hence, J_X is just the interval $[\underline{\mu}_{\tilde{A}}(x), \overline{\mu}_{\tilde{A}}(x)]$. A type-2 Fuzzy Logic System FLS (T2FLS) is characterized by IF-THEN rules, where the premises and the consequences sets of the rules are of type-2.

More details regarding the fundamentals of fuzzy control and design can be found in many textbooks such as Mendel [20], Wang [21], Passino and Yurkovich [22].

4.2 Design of a type-2 fuzzy obstacle avoidance behavior

In this subsection, we give the appropriate design of a Type-2 fuzzy controller based obstacle avoidance behavior. This fuzzy controller is composed of primary and secondary Interval Type-2 fuzzy controllers.

4.2.1 Primary Interval Type-2 fuzzy controller

Type-2 fuzzy logic controller is similar to Type-1. The structure of the rules is the same as for that of type-1, but uncertainties are added in both the antecedent and consequent parts of each rule to account for uncertainties that come especially from sensors and/or when the circumstances are so fuzzy.

a) Fuzzifier: This input block maps a real-valued variable x to an interval Type-2 fuzzy set $\tilde{A}_x$. All the values of all variables representing the input and the output of the system are fuzzified. We consider three fuzzy membership functions for the distance d with labels $\widetilde{VN}$ standing for Very Near, $\tilde{N}$ for Near and $\tilde{F}$ for Far, as it could be seen from Figure 5. In the same manner, we consider four membership functions for the mobile robot orientation with labels $\tilde{N}$ for Negative, $\widetilde{NZ}$ for Negative Zero, $\widetilde{PZ}$ for Positive Zero and $\tilde{P}$ for Positive as it is depicted in Figure 6. The geometries of the membership functions are chosen arbitrary. The outputs of the fuzzy controller are the left and right velocities of the driving wheels, implemented with three linguistic variables defined as: Velocity: v_l, v_r= {$\tilde{S}$- Slow, $\tilde{M}$- Medium, $\tilde{H}$- High} on a normalized universe of discourse (Figure 7). Note that the symbol tilda above each label indicates that the fuzzy membership functions are of type-2. The two lateral US-sensors provide the sampled distance data d_1 and d_2, which are used to determine the two crisp input variables: d, such that $d=min(d_1,d_2)$, and the error angle α given by equation 1. These crisp inputs are converted into a fuzzy singleton and are mapped to the fuzzy sets $\tilde{A}_i^j$ with an interval degree $[\underline{\mu}_{\tilde{A}_i^j}(x), \overline{\mu}_{\tilde{A}_i^j}(x)]$.

b) Fuzzy inference engine: Once the input and output variables are defined, fuzzy inference engine is used to design the rule-base composed of IF-THEN rules to convert the inputs into output membership functions. It accomplishes the intersection and union of type-2 sets and performs compositions of type-2 relations.

The set of linguistic rules describe the desired behavior. Since the robot has the possibility to follow the wall on its right or the wall in its left side, we carefully have to set the rules adequately. The knowledge bases related to the wall on the left and the right sides of the robot are reported in Tables 1 and 2 respectively. For instance, we can have rules of the form:

$$If\ (d\ is\ \widetilde{VN} \wedge \alpha\ is\ \widetilde{PZ})\ Then\ (v_r\ is\ \tilde{S} \wedge v_l\ is\ \tilde{M})$$

$$If\ (d\ is\ \tilde{F} \wedge \alpha\ is\ \widetilde{NZ})\ Then\ (v_r\ is\ \tilde{H} \wedge v_l\ is\ \tilde{S})$$

For an Interval Type-2 fuzzy logic with p inputs and one output, the *i-th* rule might have the following form

$$Rule\ R^i: x_1\ is\ \tilde{A}_1^i\ AND\ \dots\ x_n\ is\ \tilde{A}_n^i\ THEN\ y\ is\ \tilde{B}^i, i = 1, \dots, M.$$

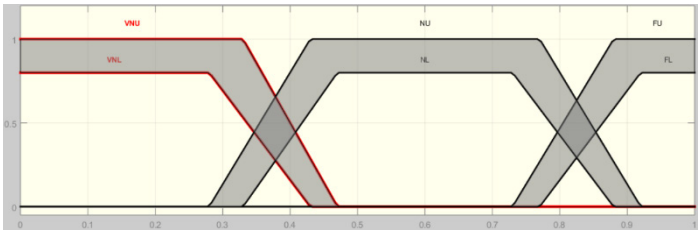

Figure 5: Membership functions of the distance d

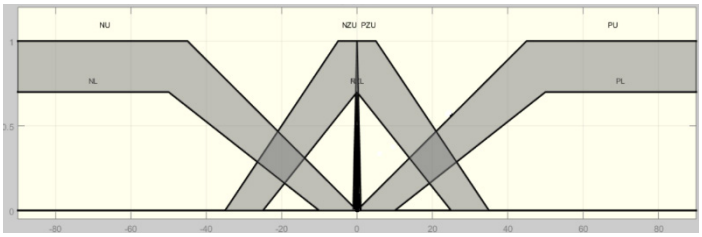

Figure 6: Membership functions of the error angle α

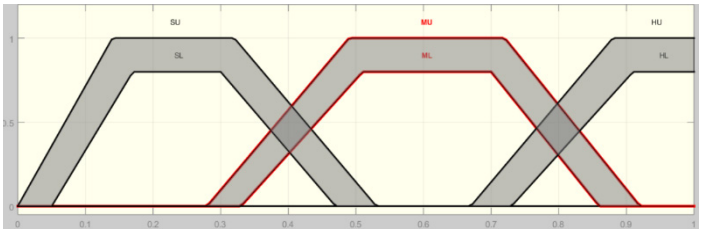

Figure 7: Membership functions of the left and right velocities

Under this bloc, the fuzzy *min t-norm* operation is implemented. For a crisp input vector, i.e., $x=x'$, the rule firing strength $F^i(x')$ is given by type-1 fuzzy set [23].

$$F^i(x') = [\underline{f}^i(x'), \overline{f}^i(x')] \quad (3)$$

Where

$$\underline{f}^i(x') = min\left(\underline{\mu}_{\tilde{A}_i^1}(x_1'),\ \underline{\mu}_{\tilde{A}_i^2}(x_2'), \dots, \underline{\mu}_{\tilde{A}_i^n}(x_n')\right) \text{ and}$$

$$\overline{f}^i(x') = min\left(\overline{\mu}_{\tilde{A}_i^1}(x_1'),\ \overline{\mu}_{\tilde{A}_i^2}(x_2'), \dots, \overline{\mu}_{\tilde{A}_i^n}(x_n')\right) \quad (4)$$

However, one can notice that no decision is taken when the robot enters the desired region II. We have marked this situation by a cross in the second row of Tables 1 and 2 to show that no decision is taken for these cases. In fact, whenever this situation is met, a secondary Interval Type-2 fuzzy controller is called to maintain the mobile robot in the desired region while keeping its orientation parallel to the wall. The details of this controller will be discussed latter.

c) Type reducer: This block found in the output processing is present in order to map the Interval T2FLS into a T1FLS. May be the most widely used type reducer among the many existing ones is the center of sets type reducer proposed by Karnik and Mendel [24]. It is characterized by the interval set determined by its left and right end points y_l and y_r and described by the following expression

$$Y_{cos} = [y_L, y_R] = \int_{y^1} \dots \int_{y^M} \int_{f^1} \dots \int_{f^M} 1 / \frac{\sum_{i=1}^{M} f^i y^i}{\sum_{i=1}^{M} f^i}, \; i=1, \dots, M \quad (5)$$

Where M is the number of rules and $f^i \in [\underline{f}^i, \overline{f}^i]$.

$y^i \in [y_L^i, y_R^i]$, is the centroid of the type-2 interval consequent set. For any value $y \in Y_{cos}$, y can be expressed as [25]

$$y = \frac{\sum_{i=1}^{M} f^i y^i}{\sum_{i=1}^{M} f^i} \quad (6)$$

To determine the left and right limits, y_l and y_r [25], the Karnik-Mendel Algorithm is used. The left and right limits are determined by the following expressions

$$y_l = \frac{\sum_{i=1}^{L^*} \overline{f}^i y_l^i + \sum_{i=L^*+1}^{M} \underline{f}^i y_l^i}{\sum_{i=1}^{L^*} \overline{f}^i + \sum_{i=L^*+1}^{M} \underline{f}^i} \quad (7)$$

$$y_r = \frac{\sum_{i=1}^{R^*} \underline{f}^i y_r^i + \sum_{i=R^*+1}^{M} \overline{f}^i y_r^i}{\sum_{i=1}^{R^*} \underline{f}^i + \sum_{i=R^*+1}^{M} \overline{f}^i} \quad (8)$$

Where $L^* = arg \min_{0 \le L \le M} \{y_l^L\}$ and $R^* = arg \max_{0 \le R \le M} \{y_r^R\}$,

$\underline{f}^i = min\left(\underline{\mu}_{\tilde{A}_i^1}(d), \underline{\mu}_{\tilde{A}_i^2}(\alpha)\right)$ and $\overline{f}^i = min\left(\overline{\mu}_{\tilde{A}_i^1}(d), \overline{\mu}_{\tilde{A}_i^2}(\alpha)\right)$

d) Defuzzifier: This second block constituting the output processing converts the T1FLS into a crisp number; i.e., the fuzzy variables from the type reducer are converted into a real valued variable. Hence the centroid of the type-1 fuzzy set contain two fuzzy singletons, and the final output is their average written as

$$y = \frac{y_l + y_r}{2} \quad (9)$$

Table. 1. Rule base for left wall following fuzzy controller

α / d	$\widetilde{N}$	$\widetilde{NZ}$	$\widetilde{PZ}$	$\widetilde{P}$
$\widetilde{VN}$	v_r=$\widetilde{S}$	v_r=$\widetilde{M}$	v_r=$\widetilde{S}$	v_r=$\widetilde{S}$
	v_l=$\widetilde{H}$	v_l=$\widetilde{H}$	v_l=$\widetilde{M}$	v_l=$\widetilde{M}$
$\widetilde{N}$	X	X	X	X
$\widetilde{F}$	v_r=$\widetilde{H}$	v_r=$\widetilde{H}$	v_r=$\widetilde{H}$	v_r=$\widetilde{H}$
	v_l=$\widetilde{M}$	v_l=$\widetilde{S}$	v_l=$\widetilde{S}$	v_l=$\widetilde{S}$

Table. 2. Rule base for right wall following fuzzy controller

α / d	$\widetilde{N}$	$\widetilde{NZ}$	$\widetilde{PZ}$	$\widetilde{P}$
$\widetilde{VN}$	v_r=$\widetilde{H}$	v_r=$\widetilde{H}$	v_r=$\widetilde{M}$	v_r=$\widetilde{M}$
	v_l=$\widetilde{S}$	v_l=$\widetilde{M}$	v_l=$\widetilde{S}$	v_l=$\widetilde{S}$
$\widetilde{N}$	X	X	X	X
$\widetilde{F}$	v_r=$\widetilde{M}$	v_r=$\widetilde{S}$	v_r=$\widetilde{S}$	v_r=$\widetilde{S}$
	v_l=$\widetilde{H}$	v_l=$\widetilde{H}$	v_l=$\widetilde{H}$	v_l=$\widetilde{H}$

In our case the *i-th* rule is written as

Rule R_i: d *is* $\tilde{A}_1^i$ AND α *is* $\tilde{A}_2^i$ *THEN* v_r *is* $\tilde{B}_1^i$ *AND* v_l*is* $\tilde{B}_2^i$,

i=1, …, 12

The speed of the right and left wheels are computed using the centroids for each aggregated Lower Membership Function (LMF) and Upper Membership Function (UMF). The speed for the left wheel v^L is

$$v^L = \frac{1}{2}(v_l^L + v_r^L) \quad (10)$$

where

$$v_l^L = \frac{\sum_{i=1}^{L^*} \overline{f}^i v_l^i + \sum_{i=L^*+1}^{M} \underline{f}^i v_l^i}{\sum_{i=1}^{L^*} \overline{f}^i + \sum_{i=L^*+1}^{M} \underline{f}^i} \quad (11)$$

$$v_r^L = \frac{\sum_{i=1}^{R^*} \underline{f}^i v_r^i + \sum_{i=R^*+1}^{M} \overline{f}^i v_r^i}{\sum_{i=1}^{R^*} \underline{f}^i + \sum_{i=R^*+1}^{M} \overline{f}^i} \quad (12)$$

The speed for the right wheel, v^R, is determined analogously.

4.2.2 Secondary Interval Type-2 fuzzy controller

The goal of the secondary Interval Type-2 fuzzy controller is to maintain the mobile robot within region II. For better compromise between good performances and reduced rules, the knowledge base is constructed using 25 rules as they are formulated in Table 3, which represent instructions to the robot to maintain its error angle to zero value. Input variables for this fuzzy logic controller

are the error angle α and its time derivative $d\alpha$. The outputs are again the right and left velocities of the driving wheels. For the design of the fuzzy logic controller, we assume that the cardinality of the input and output sets are the same and equal to 5. We propose to use the following labels for the three sets: $\{\widetilde{NL}$- Negative Large, $\widetilde{N}$- Negative, $\widetilde{Z}$- Zero, $\widetilde{P}$- Positive, $\widetilde{PL}$- Positive Large$\}$. The membership functions corresponding to the inputs α and $d\alpha$, are shown in Figure 8 and those corresponding to the outputs are shown in Figure 9. The symbol tilda above each label indicates again that the fuzzy membership functions are of type-2. For the right wall following, we either construct a new rule base or keep the previous one by making a small change in equation (1) while permuting the distances d_1 and d_2 as in equation (13).

$$\alpha = \alpha_r = atan\left(\frac{d_2 - d_1}{L}\right) \tag{13}$$

The design of the secondary Interval Type-2 fuzzy controller follows exactly the same steps as those presented in sub-section 4.2.1, for the two fuzzy inputs: the angle error α and its variation $d\alpha$.

The velocities responsible for maintaining the mobile robot within region II are equally given by equations (8) and (9), such that

$$\underline{f}^i = min\left(\underline{\mu}_{\tilde{A}_i^1}(\alpha), \underline{\mu}_{\tilde{A}_i^2}(d\alpha)\right) \text{ and}$$

$$\overline{f}^i = min\left(\overline{\mu}_{\tilde{A}_i^1}(\alpha), \overline{\mu}_{\tilde{A}_i^2}(d\alpha)\right) \tag{14}$$

On the other hand, the mobile robot should know the orientation it should take in case it is trapped in a local minimum as it is shown in Figure 2.

The obstacle avoidance algorithm must determine the sign of the orientation angle given by equation (15).

$$\theta = atan2\left(\frac{y_t - y_0}{x_t - x_0}\right) \tag{15}$$

4.3. Reaching the Goal

Reaching the goal behavior, allows the mobile robot to navigate toward the target. Meanwhile, if the robot encounters an obstacle, the control switches immediately to wall-following behavior. "Reaching the Goal" and "Wall-Following" are two mutually exclusive behaviors. The activation of the first behavior prevents the second to happen. Figure 10, illustrates this operation using a flow chart. In contrast to the obstacle avoidance type-2 fuzzy controller, reaching the goal behavior is designed using a Type-1 fuzzy controller. The input variables are the distance, from the current mobile robot location to the target, and orientation angle, which measures the heading of the mobile robot with respect to the target point. For our convenience, we define seven fuzzy membership functions for the input distance with labels *Z* for Zero, *NS* for Near Small, *S* for Small, *M* for Medium, *F* for Far, *VF* for Very Far, and *VVF* for Very Very Far. Figure 11 illustrates the corresponding membership functions. In the same manner, we define seven membership functions for the orientation angle error with labels *LN* for Large Negative, *SN* for Small Negative, *N* for Negative, *Z* for Zero, *P* for Positive, *SP* for Small Positive and *LP* for Large Positive as it is depicted in Figure 12. The shape of the membership functions are chosen arbitrary and their emplacement along the universe of discourse has been carefully and adequately fixed after some experimental trials leading to a smooth navigation. The fuzzy outputs are again the right and left velocities of the driving wheels, whose shapes are trapezoidal on a normalized universe of discourse, as shown in Figure 13. We define for this application the following labels: *Z* for Zero, *NZ* for Near-Zero, *S* for Small, *M* for Medium, *H* for High, *VH* for Very-High and *VVH* for Very-Very-High.

Table 4 illustrates the fuzzy rules responsible of guiding the mobile robot to its final destination. The implementation of the fuzzy controller follows the steps of a conventional fuzzy controller, where one can find the main three blocks: the fuzzifier, the inference engine and the defuzzifier.

5. Experimental results

5.1 The mobile robot description

The mobile robot used in this work is Khepera III, a wheeled mobile robot from K TEAM Corporation. It is a mini mobile robot with functionality similar to larger robots used in research and education. It is an automated differential drive guided vehicle designed and equipped for autonomous and intelligent tasks as shown in Figure 14. The platform operates as a client in a client-server environment. Khepera is provided with Infrared and US-range-finder. It comes standard with five US transmitter/receiver pairs covering the front and the sides of the robot. We depict in Figure 15 the Khepera US sensors. To calculate the pose information of the robot we used the dead-reckoning equations.

5.2 The real experimentation Scenarios and Results

Various scenarios were set-up to test our proposed method in a real environment with different scenarios. These experimental results will determine the robustness, accuracy, adaptability and efficiency of the proposed method. For each scenario, we use the Khepera mobile robot platform, and matlab as a programming platform language. We tested the proposed system by using tens of scenarios; in this section, we are going to illustrate six of them. We selected six scenarios with various configuration, different shapes, and unknown environment. For all scenarios, the Khepera moves from the initial ***O***(0mm, 0mm) point to the target point ***T***(0mm, 1000 mm). Note that, the *x-y* data measurements are stored during the movement of the robot and plot by Matlab to get the graphs. In the first scenario, the Khepera robot navigates in a simple environment with one obstacle, as illustrated in Figure 16. During

its motion to the target, the mobile robot encounters an obstacle. In this situation, the robot stops moving, determines the angle θ from equation 15 and turns 90° clockwise due to the negative sign of the angle. The robot activates the obstacle avoidance behavior using the wall following approach. When the path is clear, the obstacle avoidance is inhibited and the Go-to-target behavior is re-activated. Figure 17 illustrates the real experimentation of this scenario.

In a second analog scenario, we simply change the length of the obstacle by considering a taller one. We remark that the mobile robot exhibits the same behavior as it did previously. We show in Figure 18 the plot of the experimental results, while Figure 19 illustrates the real experimentation.

In the third scenario, the Khepera robot navigates in a somewhat difficult environment with two long obstacles, as illustrated in Figure 20. In this scenario, during the movement of the robot toward its target, it faces the first obstacle of size (300 mm x 20 mm) and a second one of size (700 mm x20 mm). The robot determines the angle θ and turns 90° clockwise. The robot makes a first call to the wall-following algorithm to avoid the first obstacle. After passing the obstacle, the Go-to-Target algorithm is called in order for the robot to navigate toward its final configuration. However, in its path to the target a second obstacle is encountered. Again, the go-to-target is inhibited and the wall following behavior is activated. Immediately after passing the obstacle, the mobile robot regains control on the go-to-target behavior. The plot of this scenario is shown in Figure 20 and Figure 21 illustrates the real experimentation.

In the fourth scenario, the mobile robot navigates until a cul-de-sac situation is met, as it is can be seen from Figure 22. In this scenario, the mobile robot succeeds in escaping from this situation to join its final configuration using the same procedures. Figure 23 illustrates the real experimentation of this scenario.

In the fifth scenario, the robot is used to navigate in an environment embedded with many obstacles. The purpose of this manipulation is to show the validity of the approach in case of difficult situations. As we can notice from Figure 24, the mobile robot navigates successfully around the obstacles until the target is reached. Figure 25 illustrates the real experimentation of this scenario.

Figure 26 depicts the sixth scenario, where we repeated the fifth scenario using different obstacles shapes. During its motion, the robot faces the first circle shaped obstacle. In this case, the avoid obstacle behavior is executed using the wall-following approach, immediately followed by the Go-to-Target when the path is clear. Figure 27 illustrates the real experimentation of this scenario.

6. A Comparison study with PSO-Fuzzy methodology

In this section, we aim to compare the proposed method (Obstacle Avoidance Using Wall-Following Strategy) with another work, which uses a Partial Swarm Optimization-Fuzzy (PSO-Fuzzy) for navigation and obstacles avoiding [26].

From an experimental point of view, and to compare the performance of the proposed method with PSO-Fuzzy, each method was executed in two scenarios. The first scenario is simple and the second is somehow complicated. Each method was executed from the same startup point ***O***(0 cm, 0 cm) to the target point ***T***(0 cm, 100 cm). The comparison will include the traveled distance and the execution time. Plots of the results of the first and second scenarios of the experiments are shown in Figures 28 and 29 successively. The performance indexes are listed in Table 5. In fact, we have used the distance travelled by the mobile robot to go from the starting point to the destination point, whereas the second metric used is the time spent by the mobile robot to finish its travelling distance.

In these scenarios, we applied the two methods to moving the robot from the initial point to the target with the obstacle avoidance strategy. When comparing the two methods, it is obvious from the results reported in Table 5 that the proposed method performed better than the PSO-fuzzy one.

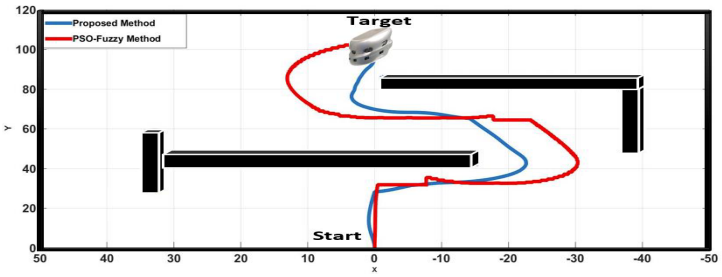

Figure 28: comparison between proposed method and PSO-Fuzzy

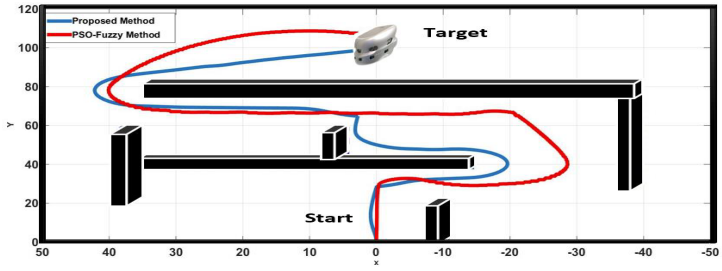

Figure 29: comparison between proposed method and PSO-Fuzzy

Table 5: Performance indexes

Parameters		Proposed Method	PSO-Fuzzy Method
First scenario	Execution time	33.83 sec	46.46 sec
	Traveled distance	124 cm	163 cm
Second scenario	Execution time	48.12 sec	69.35 sec
	Traveled distance	184 cm	219 cm

7. Conclusion

In this paper, a complete navigation mobile robot control is used to reach a given target while avoiding unforeseen obstacles. To satisfy these two requirements, a fuzzy logic design has been implemented for the two behaviors. The first behavior is achieved by designing a fuzzy controller that uses the distance and the orientation as inputs. The controller generates the required wheels velocities to drive the mobile robot to its destination along a smooth path. In case the mobile robot encounters an obstacle, it switches to the obstacle avoidance behavior designed using a wall following approach. A new fuzzy controller approach based on Type-2 fuzzy sets has been presented for obstacle avoidance using wall following methodology. To achieve this requirement, we divided the robot environment into three regions, two transient regions and one stable region. Whenever the mobile robot finds itself in the transient regions, the first fuzzy controller is activated to pull the mobile robot to the lane that is parallel to the wall. Once trapped in this region, the first fuzzy controller is inhibited and the second is activated such that the mobile robot remains within the limits of the lane. The mobile robot keeps moving within the stable region of displacement until a new situation appears, otherwise the go-to-target behavior is activated with Type-1 fuzzy controller and the mobile robot heads for the target point. Experimental works are carried out on the mobile robot Khepera III. The experimental results obtained are very satisfactory and prove the validity of the proposed approach, which is simple, and does not require complicated and burden computations compared to other methods. As an extension to this work, we plan to adapt this methodology to the mobile robot PowerBot from Adept Corporation.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

We have been developing a method of evaluating the mental health condition of a person based on the sound of their voice. Currently, we have applied this technology to create a smartphone application that shows the vitality and the mental activity as mental health condition indices. Using voice to measure one's mental health condition is a non-invasive method. Moreover, this application can be used continually through a smartphone call. Unlike a periodic checkup every year, it could be used for monitoring on a daily basis. The purpose of this study is to compare the vitality index to the widely used Beck depression inventory (BDI) and to evaluate its validity. This experiment was conducted at the Center of Innovation Program of the University of Tokyo with 50 employees of one corporation as participants between early December 2015 and early February 2016. Each participant was given a smartphone with our application that recorded his/her voice automatically during calls. In addition, the participants had to read and record a fixed phrase daily. The BDI test was conducted at the beginning of the experimental period. The vitality index was calculated based on the voice data collected during the first two weeks of the experiment and was considered as the vitality index at the time when the BDI test was conducted. When the vitality and the mental activity indicators were compared to BDI score, we found that there was a negative correlation between the BDI score and these indices. Additionally, these indices were a useful method to discriminate a participant of high risk of disease with a high BDI score. And the mental activity index shows a higher performance than the vitality index.

1. Introduction

This paper is an extension of the work originally presented in IEEE BIBE 2016 (The 16th International Conference on Bioinformatics and Bioengineering) [1].

In recent years, mental health disorders have become an issue in many developed countries and the cost of dealing with such disorders is enormous [2, 3]. There is a need for a screening technology that allows for a quick and easy way to detect depression and stress early to tackle these problems.

*Naoki Hagiwara, PST Inc., 2 Yamashita-cho, Naka-ku, Yokohama, Kanagawa 231-0023 Japan, +81-45-263-9346 & hagiwara@medical-pst.com

Currently, self-report type psychometric tests such as general health questionnaires (GHQ) [4] and Beck depression inventory (BDI) [5, 6] are used as methods of screening patients with mental health disorders. Besides these tests, there are proposals to use biomarkers such as saliva [7] and blood [8] as a method of evaluating mental health conditions. However, although self-report psychometric tests are effective in determining those conditions at their early stages and in complementing diagnoses, there are issues of reporting biases. A reporting bias refers to the effect of an undervaluation or overvaluation because of the consciousness or unconsciousness of subjects. It has been reported

that the detection rate decreases in organizations that have established hierarchies such as in fire-fighting, police, or military [6-8]. Some causes of undervaluation in self-administered screenings are prejudice, discrimination, resistance to mental health disorder, or anxiety on career disadvantage in the job [6]. Concerning evaluations with biomarkers, they are a burden to those being tested as they are invasive, and the tests cost money. Thus, they cannot be considered as easy or simple solutions. In addition, conventional screening methods such as self-report psychometric tests and biomarkers are often conducted during a routine annual checkup, making it difficult to provide care during middle periods.

On the other hand, prior to this current research, the authors of this paper have been researching and working on a way to estimate the state of a person's mental health as in their state of depression or stress through voice data [14, 15]. Using voice for analysis has the advantage of being not only non-invasive, but also not requiring any dedicated and specialized equipment; it is simple, easy, and can be done remotely. Using this technology to assess the state of one's mental health condition through his or her voice can make it possible to achieve monitoring on a daily basis, which is difficult with conventional methods.

The authors have developed and provided MIMOSYS (mind monitoring system) SDK that estimates the health condition of speakers through their voice. MIMOSYS SDK has a function of recording and analyzing voice from a microphone as input and outputs the index of health condition as a result (see section 2.2). To allow daily monitoring for many people, we have developed a smartphone application using MIMOSYS SDK [16, 17]. The purpose of this study is to compare the vitality score, which is collected and analyzed through MIMOSYS to the BDI and evaluate its validity.

2. Materials and Methods

2.1. The Experiment

The experiment was conducted as part of the University of Tokyo, Center of Innovation Program. With the support of Kanagawa Prefectural government, we provided smartphones with preinstalled application to 50 employees of a company. This company is searching for health care measures and has recruited 50 in-house participants who are interested in the experiment. The 50 participants comprise 39 males and 11 females. The breakdown of age is shown in Figure 1. The model name and Android version of the smartphones used in the experiment are given in Table 1. We required the test participants to record their voice for two months through reading out fixed phrases and through talking using the smartphone provided.

We conducted the BDI test at the beginning of the experiment. The application detects when a call is made or received and automatically records the voice and analyzes it. The fixed phrases that the test participants read out daily are listed in Table 2. The application will erase the recorded voice file after the analysis, but the analysis results and user information are sent over a network to be collected and stored into a database. All the analysis results were obtained via this database.

2.2. MIMOSYS

In mental health disorders, a decrease in emotional expression appears and the proportion of sorrow component may increase. Therefore, MIMOSYS estimates the health condition of a speaker focusing on the balance and variation of these emotional indices. MIMOSYS is based on an emotion index obtained by a sensibility technology (ST) [9-11, 18]. It is preferable that natural utterance is inputted, although it is barely affected with utterance by acting. Therefore, in the developed application, we use the voice of calls that can be uttered naturally without consciousness for the analysis. We thought that it is advantageous to continuously use the call voice as an analysis target and accumulate the result.

In emotional recognition using ST, multiple feature quantities are calculated from the input voice, and four emotional components – anger (Ang), sorrow (Srw), joy (Joy), and calmness (Clm) – in the voice are calculated from these features. The degree of excitement (Exc) is also calculated. Thus, five indicators are outputted. MIMOSYS calculates two intermediate feature quantities, namely vivacity and relaxation, from these emotional indexes in internal processing. It calculates vivacity from Joy and Srw, and relaxation from Clm and Ang respectively. From there, a short-term health index, called vitality index, is calculated. Then, a medium-term health index, called mental activity, is calculated from the vitality index accumulated for two weeks. The data calculation flow is shown in Figure 2.

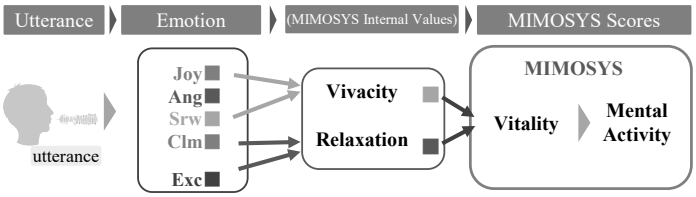

Figure 2. Data calculation flow of MIMOSYS.

Next, we will describe the implementation of the application. When analyzing using ST, it is necessary to input the voice by one utterance, and when analyzing a long voice, it is necessary to divide it into data of one utterance by detecting speech. Here, utterance is a voice uttered in a single breath. The smartphone application, MIMOSYS, implements speech detection to record and analyze a call voice. Specifically, the utterance part is detected by the volume level, and only the extracted utterance part is used for the analysis in ST. Then, an analysis of the health condition estimation is carried out with multiple utterances in one call as one set. The vitality index is outputted as a short-term health condition index from these sets of uttered voices. In addition, in order to suppress variations at individual recording timings and capture long-term trends, we outputted the medium-term health condition index, i.e., the mental activity index, calculated based on the vitality index accumulated for two weeks.

Both indicators for short term (vitality index) and medium term (mental activity) are each outputted as a real number value from 0.0 to 1.0. In addition, having both the recording and processing function on the smartphone eliminates the transfer cost of the recorded voice data that would otherwise be incurred had the recordings been performed on a separate recording device requiring a transfer to another computational device. Furthermore, considering the possibilities of information leaks from the voice recordings and to reduce the storage load, we have decided to delete the voice recordings after analysis. The results of the analysis were stored on the smartphone devices and also sent to a database server via the network for storage. As an index corresponding to the BDI test, the vitality index was calculated from the first recorded voice, and the mental activity was calculated from the voice recorded in the first two weeks.

2.3. Recording and Analyzing the Voice

There are two ways of obtaining the voice over the smartphone: the voice of the user reading some sentences (hereinafter referred to as fixed phrase recordings) and the voice while talking on the phone (hereinafter referred to as call recordings). To monitor by oneself on a daily basis, we speculate that call recordings, in which the caller is not conscious of the recording, would be more suitable. However, as there are differences in the frequency in which individuals use their phone for talking, we included in the analyzing application a function to record a fixed phrase reading on a regular basis for the experiment. In call recordings, the analysis was performed with utterances in one call; however, for fixed phrase recordings, the analysis was performed with utterances of reading the 17 phrases. Additionally, as there may be a difference in the nature of the voice between the fixed phrase recordings and call recordings that were obtained, to make it easier to differentiate them, information on which method was used to obtain the recordings was also included.

The voice to be analyzed was acquired by a microphone of the smartphone provided to the experiment participants (see Table 1). The recording format was a linear pulse-code modulation, the sampling frequency was 11,025 Hz, and the quantization bit rate was set at 16 bits. However, the recorded sound file was deleted immediately after the analysis was completed, and it was not taken out of the smartphone.

2.4. Beck's Depression Inventory

The BDI test is widely used for judgment of depression, and the scores for judgment are listed in Table 3. In this research, a score of 18 or less is considered as low risk of disease, and more than that value is treated as high risk of disease. We conducted a test to evaluate the performance of the application to determine if the voices of the test participants could be used to discriminate between high risk of disease and low risk of disease. The BDI test was incorporated into the application and was executed when the application was first launched at the start of the experimental period.

Table 3. Categories for BDI score.

BDI score	*Categories of depression*	*Judgment*
0–9	None to minimal depression	Low risk of disease (≤ 18)
10–18	Mild to moderate depression	
19–29	Moderate to severe depression	High risk of disease (> 18)
30–63	Severe depression	

2.5. Statistical Analysis of Data

The analysis result of the application is outputted to the csv (comma-separated values) file. We used Microsoft Excel functions and analysis tools to tally and analyze the data. Additionally, we analyzed the data and created diagrams using the R language.

3. Result

The analysis result was obtained from the 50 participants, and 48 valid results were obtained. In total, there were 890 call recordings and 4,357 fixed phrase recordings. The daily total recording count of the test participants in first two weeks is shown in Figure 3.

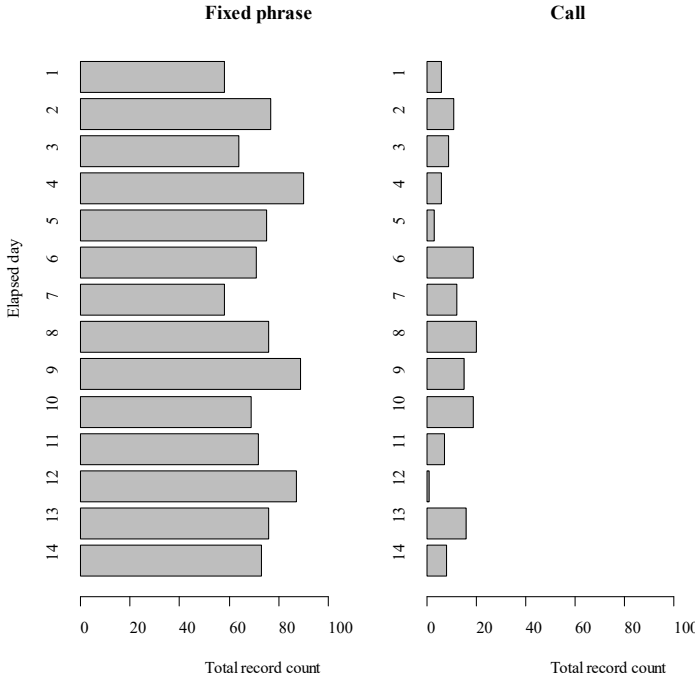

Figure 3. Total recording count of test participants with two methods.

3.1. Effect of the Recording Method

In the experiment, there were two methods in which the voice was recorded and obtained. For each method, we separately tallied the vitality index and the side of the vitality score that shows the short-term mental health condition. The average and standard deviation of the vitality index are given in Table 4. Compared to call recordings, fixed phrase recordings tended to show a lower value and are less consistent. In this research, we evaluated the fixed phrase recordings and phone conversations independently.

Table 4. Average and standard deviation of vitality index by two recording methods.

	Call	***Fixed phrase***
Average	0.554	0.460
Standard deviation	0.0759	0.0981

3.2. Correlation to BDI

The scatter plot of the vitality index by fixed phrase recordings and the BDI score is shown in Figure 4. The correlation coefficient between the vitality index and the BDI score showed a negative correlation value of 0.208. Furthermore, the correlation between the mental activity index by the fixed phrase recordings and the BDI score is shown in Figure 5. The correlation coefficient between the mental activity and the BDI score showed a negative correlation value of 0.285.

The mental activity index, which is the medium-term indicator of the mental health condition, was calculated based on the voice data collected within the first two weeks, which was considered as the mental activity index at the time of the BDI testing. We found that depending on the test participants, there were differences on how often the phone was used. Because some had too few recordings captured or none at all, there were cases when we were unable to calculate the mental activity index corresponding to the BDI. Therefore, we were able to acquire call recordings from only 17 participants, which were used to calculate their mental activity index.

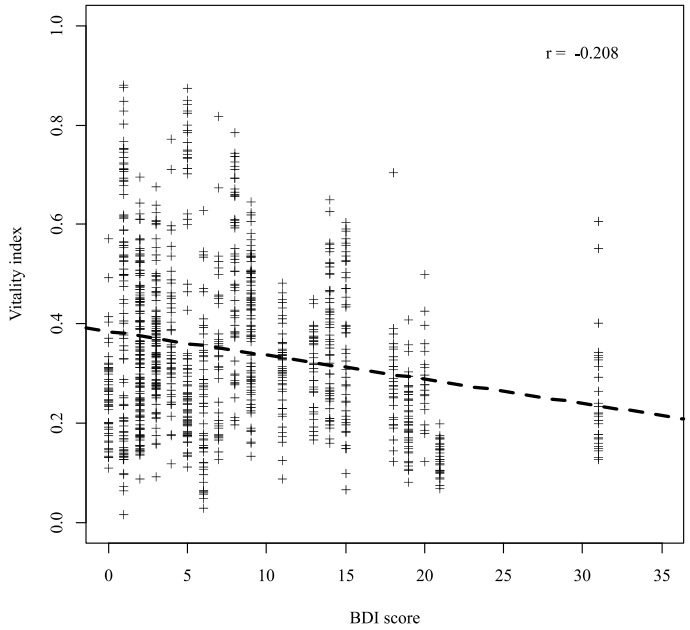

Figure 4. Scatter plot of BDI score and vitality by fixed phrase. The regression line is drawn in dashed line.

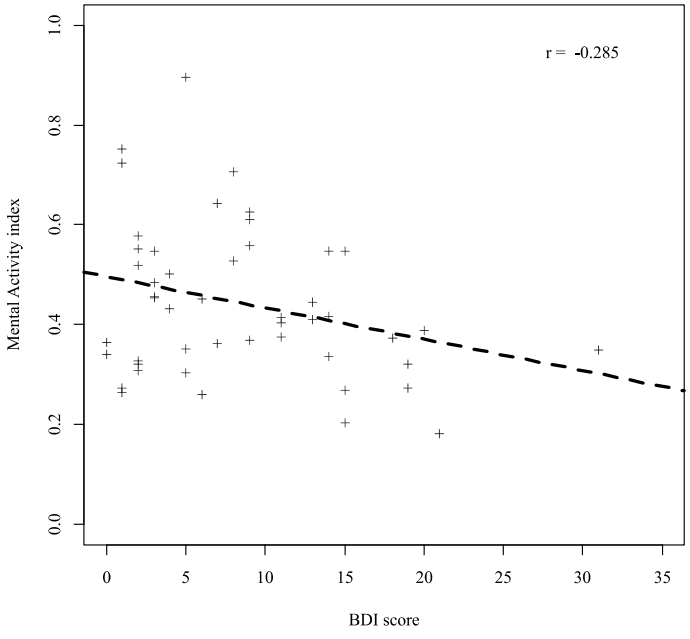

Figure 5. Scatter plot of BDI score and mental activity by fixed phrase. The regression line is drawn in dashed line.

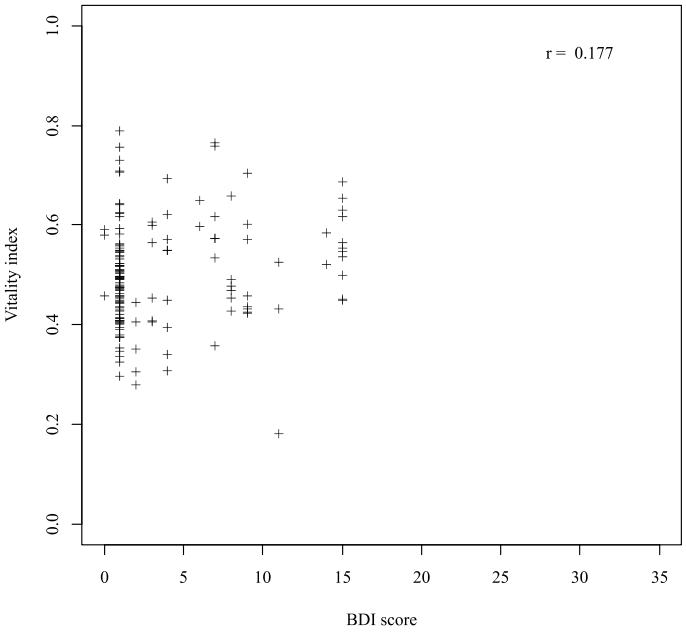

The vitality index by call recording and its correlation to the BDI score is shown in Figure 6. The correlation coefficient between the vitality index and the BDI score was 0.177, which means that there is almost no correlation between the two. The mental activity index by call recordings and its correlation to the BDI score is shown in Figure 7.

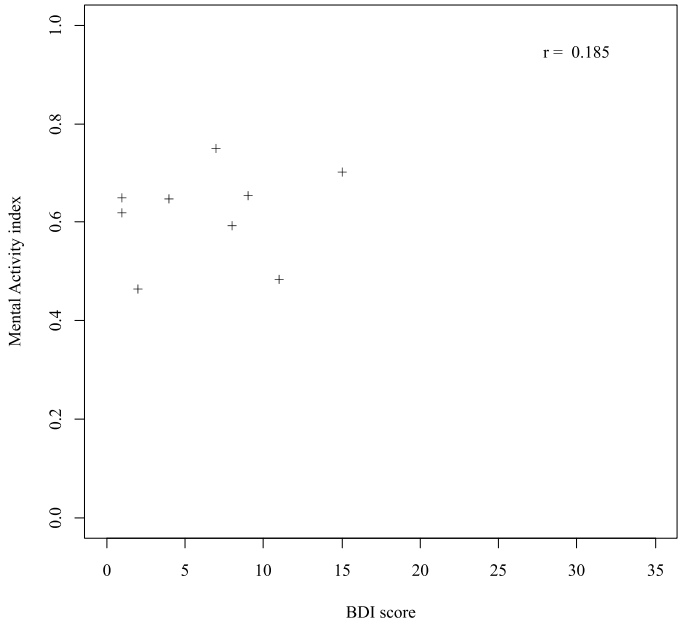

Figure 7. Scatter plot of BDI score and mental activity by call.

The correlation coefficient between the mental activity index by call recording and the BDI score was 0.185, which indicate that there is almost no correlation between the two.

The box and whisker plot is shown in Figure 8 and Figure 9. The results show that both scores showed a significant difference. However, the vitality index overlap of distribution is wider than that of the mental activity index.

3.3. Discrimination Evaluation of High Disease Risk using MIMOSYS

We then changed our perspective and evaluated the performance of discriminating high risk of disease and low risk of disease using the MIMOSYS index. However, the 17 participants with calculated mental activity from the call recordings all had a BDI score of less than 18; therefore, this evaluation was limited to using the fixed phrase recordings. With sensitivity as the vertical axis and 1-specificity as the horizontal axis, the receiver operating characteristic (ROC) curve plotted by changing the threshold is shown in Figure 10 and Figure 11. The ROC curve uses the area under the curve (AUC) as an indicator for performance evaluation. An AUC value in the range of 0.5–0.7 denotes low accuracy, 0.7–0.9 denotes moderate accuracy, and 0.9–1.0 denotes high accuracy.

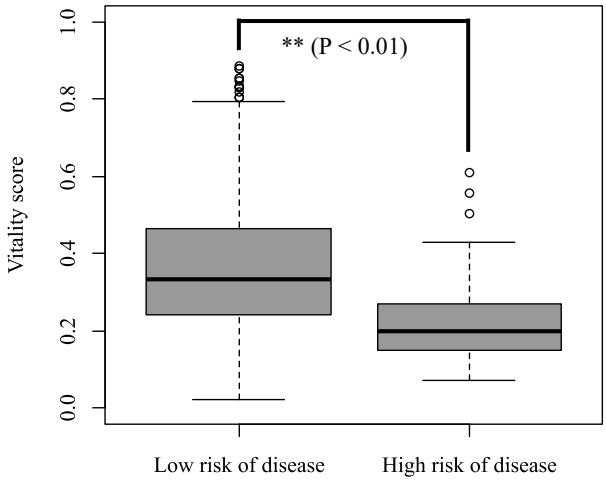

Figure 8. Box and whisker plot of vitality score by fixed phrase with low risk of disease and high risk of disease.

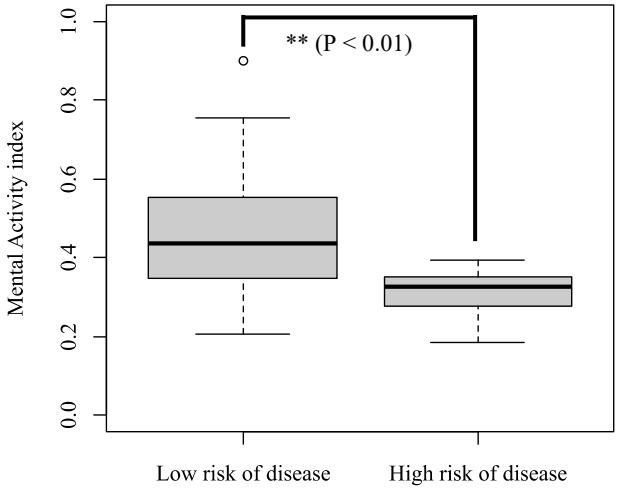

Figure 9. Box and whisker plot of mental activity score by fixed phrase with low risk of disease and high risk of disease.

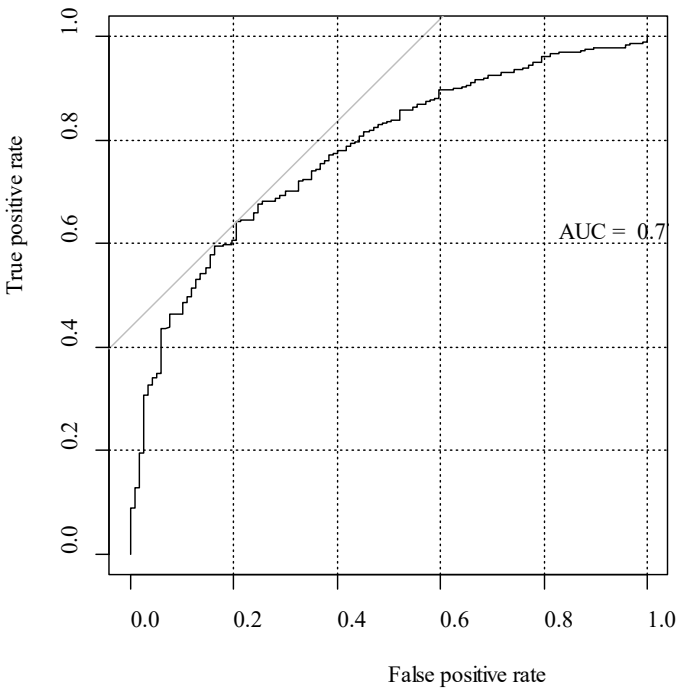

Figure 10. ROC curve used in discriminating between low and high risk of disease using vitality index.

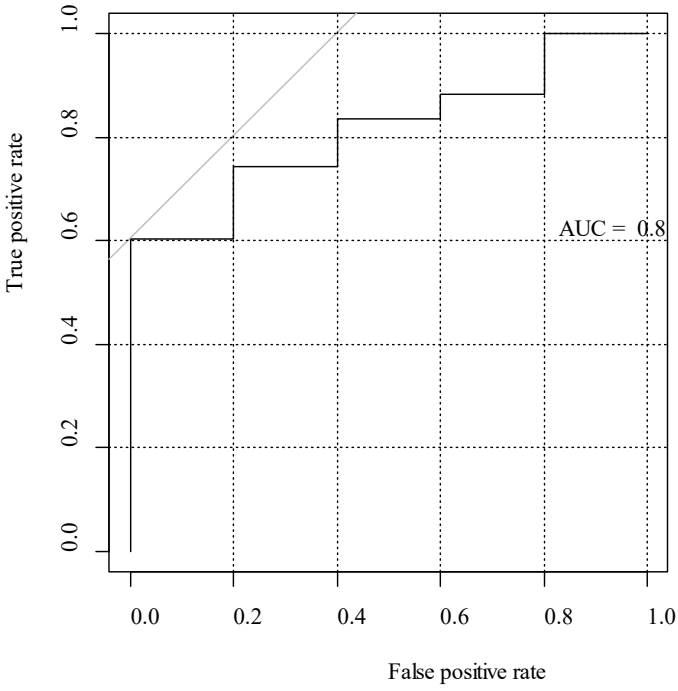

Figure 11. ROC curve used in discriminating between low and high risk of disease using mental activity index.

In the vitality index, the AUC was 0.775, while in the mental activity index, the AUC was 0.814. A well-balanced cutoff can be made at the point closest to the upper left corner in the ROC curve. Figure 12 and Figure 13 show the discriminated counts for the sensitivity, specificity, and accuracy at this point. Sensitivity, specificity, and accuracy are defined as follows:

Sensitivity = True Positive / (True Positive + False Negative)

Specificity = True Negative / (False Positive + True Negative)

Accuracy = (True Positive + True Negative) / Total Count

		BDI	
		High risk of disease > 18	Low risk of disease ≤ 18
Vitality	Positive < 0.2816	93	328
	Negative ≥ 0.2816	24	590

Sensitivity	0.795
Specificity	0.643
Accuracy	0.660

Figure 12. Accuracy of optimal cutoff in vitality.

		BDI	
		High risk of disease > 18	Low risk of disease ≤ 18
Mental Activity	Positive < 0.408	5	17
	Negative ≥ 0.408	0	26

Sensitivity	1.000
Specificity	0.605
Accuracy	0.646

Figure 13. Accuracy of optimal cutoff in mental activity.

4. Discussion

4.1. Effect of the Recording Method

As a result of comparing the vitality index obtained by analyzing the fixed phrase and the call respectively, the fixed phrase tended to have a lower value and the standard deviation was also different. As the calculation of the voice indicator is based on the change in emotion, it is likely that the act of reading a fixed phrase would call for a lesser variation in emotional expression compared to phone conversations. For further consideration, we would like to determine if these differences such as the average and the standard deviation based on the recording methods could be corrected by, for example, changing or converting the values. This is for future research.

4.2. Correlation to BDI

In the fixed phrase recording, the vitality index and mental activity index both had a weak negative correlation to BDI. In addition, a higher correlation was found in the mental activity index. These results indicate that the higher the vitality index or mental activity index, the healthier the individual, and the lower the BDI score. On the other hand, the lower the indices of MIMOSYS, the worse the mental health condition and the higher the BDI. Hence, we consider such negative correlation between the two as actually a valid result.

As for the vitality index of the two classes separated by the BDI score shown by the box and whisker plot, a t-test shows a significant difference when observing the result of the fixed phrase recording, and the reasonable performance as a classifier can be expected. Moreover, the overlapping of boxes is smaller in the mental activity index than in the vitality index, and a higher discrimination ability can be expected.

On the other hand, some participants who made call recordings did not include those belonging to a class with a high disease risk with a BDI score greater than 18in the classification based on the BDI score. Therefore, in call recordings, we were unable to evaluate the discrimination of high disease risk. This is presumably due to the fact that the number of participants was limited, and

those test participants we obtained had low BDI scores, thus skewing the samples.

4.3. Discrimination Evaluation of High Disease Risk using MIMOSYS

As for the discrimination of the high disease risk mentioned in the previous section, the result of evaluation by AUC was 0.775 for the vitality index and 0.814 for the mental activity index. We can say that this application has a moderate ability in discriminating the state of mental health. It shows that the mental activity index has a higher performance than the vitality index. In addition, the accuracy of the mental activity index was also shown to be similar to the vitality index as well.

5. Conclusion

In this research, we conducted an experiment to compare BDI to the vitality score, which was collected and analyzed through MIMOSYS, a smartphone application and a system we developed to use voice as a way of monitoring one's mental health condition. We found that the vitality score had a significant correlation to BDI. Additionally, by its performance in discriminating a person who scored high in the BDI test, we were able to confirm its validity. In addition, the mental activity as a medium-term health index has a higher discrimination ability than the vitality as a short-term health index, indicating that data accumulation is effective. The results thus indicated that this system could be used as a daily monitoring system to supplement the routine checkup. At the same time, as the different recording methods showed a difference in their numerical values, the next challenge would be to eliminate this difference.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This research is (partially) supported by the Center of Innovation Program from Japan Science and Technology Agency. I received generous support in gathering the experiment participants from Kanagawa Prefectural government.

Virtual Education Competencies

ABSTRACT

This article presents the instantiation of the Model of Adaptation of Learning Objects (MALO) developed in previous works, using the competencies to be developed in a given educational context. MALO has been developed for virtual environments based on an extension of the LOM standard. The model specifies modularly and independently two categories of rules, of adaptation and conversion, giving it versatility and flexibility to perform different types of adaptation to the learning objects, incorporating or removing rules in each category. In this work, we instance these rules of MALO using the competencies considered in a given educational context.

1. Introduction

The Information and Communication Technologies (ICT) have been introduced in the field of the education, in order to extend and improve the teaching-learning processes. In these environments, the use of learning objects (LO) is becoming more relevant every day to facilitate the teaching-learning process. LO are understood as any digital resource that can be used to support learning [1].

On the other hand, the interest of incorporating adaptive capacities, both to learning objects and virtual learning environments, has increased in recent years. However, there is no uniformity about what should be considered as an Adaptive Learning Object (ALO) [2-12]. In general, there are several works that are being developed on ALO and its application in virtual education. Most of these works are mainly focused on the adaptation of LO to the virtual teaching-learning process considering several aspects, among which we can mention: the learning style of the students; the course offered; the types and means of storages; and the learning trajectories [29], in order to create a favorable and an optimal environment for the successful development of virtual education.

Another aspect to consider is the adaptability of the LO's as support to the formation of competences, assuming that a student has previous competences that will be strengthened during the learning process until reaching an objective competence [26]. In this sense, within the learning trajectories are established states of skills and knowledge to be reached, which determine the level of customization of the LOs in terms of its granularity (knowledge) and skills required in them, for the acquisition of these competence goals [25-29]. This is the approach that we are interested in this work.

Due to the boom of virtual education and the application of emerging paradigms in the teaching-learning processes, combined with the weaknesses found in the various papers reviewed about ALO, we have presented in a previous work a Model of Adaptation of Learning Object (MALO) reconfigurable [2], based on the Learning Object Metadata (LOM) standard [3]. In this paper, we test the capability of reconfiguration of MALO, where its adaptation is guided by the competencies to be reached in a given course, that means, determining the level of adaptation of the LOs using MALO, according to the competencies to be

*Corresponding Author: Carlos Guevara, Centro de Investigaciones en Informática y Tecnologías de la Computación - CITEC, Universidad Nacional Experimental de Guayana, Venezuela | Email: carlos.guevaraf@gmail.com

reached. In this case, the rules are redefined based on an autonomous adaptation of the LO.

This article is organized as follows, the next section presents some theoretical aspects, and then we present in detail to MALO. The next section presents the example of adaptation of MALO using competencies, and finally, we compare MALO with previous work.

2. State of the art

In [4] is proposed an ALO model composed of four components, a knowledge domain model, a user domain model, a context model, and finally a session model. The fourth component is responsible for establishing relationships between the other three components, through navigation rules, content presentation rules, and rules of personalization of the information presented to the user. In that work, the rules of adaptation are specified to each ALO, which makes its implementation difficult. In addition, these are limited to navigation patterns within a LO. Finally, the proposal only presents rule statements, without any implementation. [5] presents an ALO model for t-learning, a term adopted to refer to learning through interactive digital television. The idea that they pursue is to offer LO with different behaviors, depending on the characteristics of the users. To do this, they use an XML file that contains a template with rules of adaptation of parameters, which indicate to the educational object what behavior or appearance to adopt according to the student's preferences. In this work, they do not incorporate autonomous changes in the learning process.

In order to construct Adaptive Learning Systems, in [6] is proposed a model considering the granularity properties of the LO. Its proposal is based on the adaptation of the LO, by adding four levels of functionality: courses, documents, fragments of the document and multimedia pieces. The fragments are made up of multimedia pieces related to some instructional objective and a semantic description, which allows them to assemble a new learning object from the existing ones. The architecture presented in [6] is composed of 3 main components, a Domain Model formed by the concepts that the learner must learn; a Learner Model, which represents the learner's information; and an Adaptation Model, which is responsible for the adaptation of the contents that are presented to the learner, and the way the fragments are assembled. In this model, the authors use a modular and structured treatment of the adaptation process, however, they do not consider the technological limitations, and nor do they describe the rules to be used to adapt to LO.

The work developed by [7], establishes a relationship between adaptation needs and learning materials. It considers that the needs of adaptation are influenced by the user, according to their cognitive and learning styles; the context, through the location and tasks that the user performs; and the learning material, with its own characteristics. They determine 13 adaptation criteria, which can be useful for classifying content and adapting LO. However, they do not present a model guiding how to incorporate these adaptation criteria into a LO. In [29] propose an adaptive framework of LOs, assessment items, and competences. In specific, the competencies are defined by the prerequisite.

3. Theoretical Aspects

3.1. Learning Object

There are several definitions of LO, some of them are: "any digital resource that can be used to support learning" [1], "any entity, digital or non-digital, that maybe be used for learning, education or training" [8], "an element with recyclable digital multimedia content documents, which has a purpose and use in instruction and learning" [9].

According to the definitions cited, [8] considers LO in a rather broad sense, by including in it any resource, both digital and non-digital, that can be used for learning, education or entertainment. On the other hand, [1] delimits it only to digital resources, so this definition is more oriented to digital technology. For its part, [9] makes explicit the use of digital documents with multimedia contents in the learning process.

This shows that there is no consensus on the definition of LO. For the purpose of this research, the interest is focused on LO used in virtual environments, what can be called Virtual Learning Objects. Therefore, LO will be considered a reusable multimedia digital resource, which can be used in learning, and employ metadata for description. This highlights two important aspects in LO: it is a digital resource with multimedia features for educational purposes, and the metadata is used for its description to facilitate its discovery and reuse.

In general, a LO has a set of attributes, such as reusability, portability, modularity, granularity, accessibility, flexibility, interoperability and durability. In specific, the granularity is an important property, because it facilitates its scalability and adaptation, and it simplifies the coupling or combination of different LO to form a new one. Some authors consider granularity from the point of view of the number of concepts or ideas contained in the LO [1,18]. Others, such as the LOM standard of IEEE, consider it as the amount of media or formats that are combined in a LO [6]. For purposes of this work, granularity is assumed from three approaches:

- Concepts or ideas combine in a learning object, which provide the semantic density of the LO
- Media or formats that are combined in a LO. They determine how the content is presented in LO.
- Parts or elements in which the content of the LO is organized. It is like the contents table, where, for example, the document parts, the book chapters, or the course subjects, are indicated.

3.2. Standards for production of Learning Objects

The standards for LO are grouped into metadata standards and standards for the creation of educational platforms. The first seeks to describe and provide LO properties and information to facilitate and optimize their manipulation; while the second helps to define virtual environments that integrate a set of tools that provide support to the online teaching-learning process. Among the most widely used metadata standards are the Dublin Core [10] and the IEEE LOM, while SCORM and IMS are used for the creation of educational platforms.

In our work, we use the LOM standard, which is a data model proposed by the IEEE, through the Learning Technology Standards Committee (LTSC), to describe a learning resource and its components. The purpose of the standard is to facilitate the

search, evaluation, acquisition and use of educational objects, as well as, to promote their exchange, reusability and share use. It consists of 80 descriptors, grouped into nine categories [3]. Each descriptor defines a specific aspect to be considered to describe a LO. Table 1 shows the categories defined in the LOM Standard.

Table 1. LOM Standard Summary **[3]**.

Nº	Category	Description
1	General	This category groups the general information that describes the learning object as a whole
2	Life Cycle	This category describes the history and current state of the learning object and those entities that have affected this learning object during its evolution.
3	Meta-Metadata	This category describes the metadata record itself (rather than the learning object that this record describes).
4	Technical	This category describes the technical requirements and characteristics of this learning object.
5	Educational	This category describes the key educational or pedagogic characteristics of this learning object.
6	Rights	This category describes the intellectual property rights and conditions of use for the learning object
7	Relation	This category defines the relationship between this learning object and other learning objects, if any.
8	Annotation	This category provides comments on the educational use of this learning object, and information on when and by whom the comments were created
9	Classification	This category describes where this learning object falls within a particular classification system.

The LOM standard is considered as an extension of the Dublin Core standard, with additional elements for the description of educational resource properties. For this reason, to represent the LO metadata, in this work we decided to use the standard LOM

3.3. Competencies

The definition of competence is derived from the Latin word "competere", which means "to be adequate", that implies "the combination of skills, attitudes and knowledge necessary to carry out a task effectively" [11]. In this way, the elements of the competence are the skills and knowledge. The knowledge comprises the set of topics and themes that are part of a profession and that the students need to develop, while the skill represents the abilities to use the knowledge in the development of an activity [12]. Thus, the competence defines the person's ability to perform a task [26], as a result of the relations between a specific knowledge, and a know-how [13].

In the learning contexts, the definition of competence refers to the set of skills and knowledge to solve specific problems [26], which relate the previous competences that the student has and the objective competence, i.e. the problem to be solved [29]. Depending on the objective competence, can be set the knowledge and skill levels required, and with the learner's current knowledge and skill state, can be determined the learning trajectory. Based on this learning trajectory, personalized learning paths and adequate LOs can be defined.

The Figure 1 shows the process of constructing of the objective competence: "to establish the difference between a vegetarian dish and others" proposed in Table 11. According to the Figure 1, can be set the learning trajectory knowledge and skills required to fulfill the objective competence, taking as a starting point the previous competence that the student possesses and defining evaluation moments in the learning trajectory.

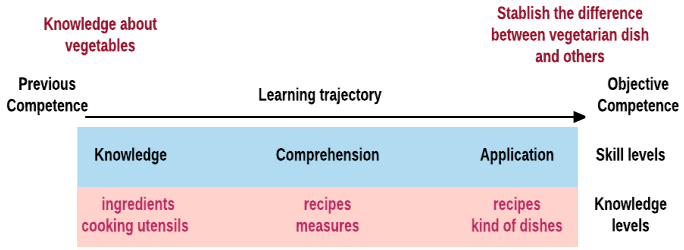

Figure 1. Objective competence construction in a learning trajectory

3.4. MASINA Methodology

MASINA (MultiAgent Systems for INtegrated Automation) is a methodology developed for the modeling of systems of engineering oriented to agents. It uses the Unified Modeling Language (UML), and the Object Systems Development Technique (OSDT), which is a tool for the formal specification of object-oriented models [23, 24]. It covers the phases of conceptualization, analysis, design, coding and testing, and integration. Now, we describe only the phase and model used in our work, for more detail see [23, 24]

- Conceptualization: allows to identify the actors of the system and their use cases. In this phase basically the extraction and acquisition of the knowledge is realized to obtain a first description of the system. The main product of this phase is a conceptualization document, which contains the analysis of the problem, and the use cases with the description of the components of the system. The use case defines the list of actions of each a role in our system, to achieve a goal.

- Analysis: it allows to describe the system, its objectives and tasks, capabilities, interactions, etc. The main product of this phase is a set of models like the task model, that describe each component of the system at the level of its procedure, condition of utilization, etc. of the different component, to be considered.

In our work, we use these two first phases to design MALO, and particularly, the task and user case models of MASINA.

4. Model of Adaptation of Learning Object (MALO)

For the formal description of the model, we used the MASINA methodology proposed in [23-24], and UML diagrams. However, before the presentation of MALO, it is necessary to define an ALO.

4.1. Definition of ALO

An ALO is considered a reusable multimedia digital resource that can be used in a learning process, which contains metadata for its description, and is able to adapt to the context. The ALO concept is presented in Figure 2, through a use case diagram, and in the Figure 3 its activity diagram.

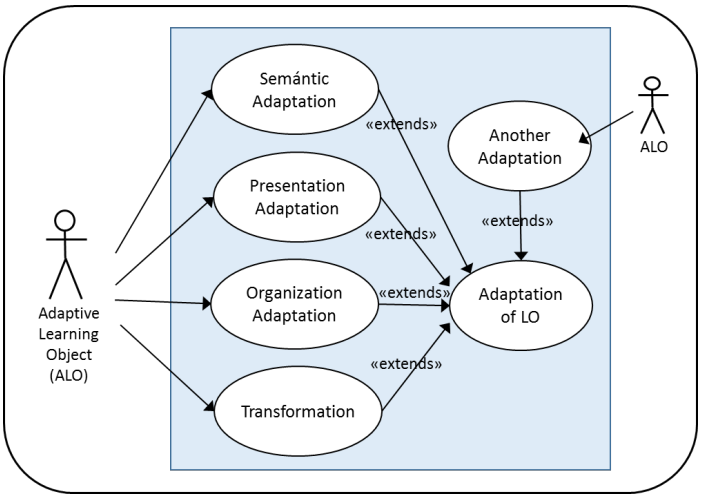

Figure 2. Use Case Diagram of an ALO

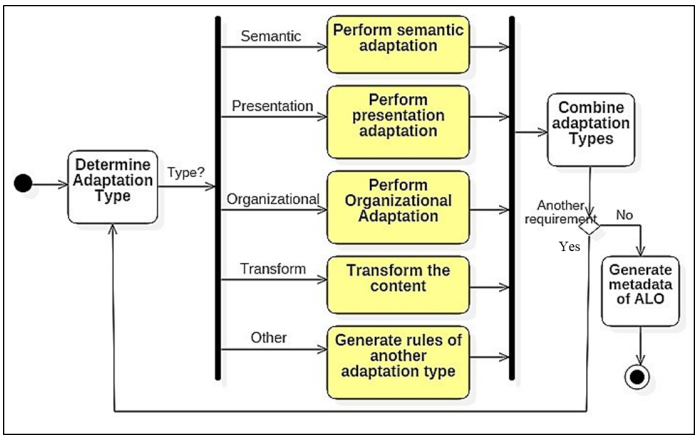

Figure 3. Activity Diagram of an ALO

As can be seen in the ALO activity diagram, its adaptation is a complex, recursive and dynamic process, where several types of adaptation can occur simultaneously, in addition, it has the flexibility to include other types of adaptation in the future. The ALO use case description is presented in Table 2, and the description of the types of adaptation is given in the following subsections. In the use case, we can see the adaptation procedure of the ALO, which can fail if there are not the services for the adaptation process. Also, the precondition conditions are very clear, we need to define the adaptation requirements that can be defined in our case, by the competencies to be reached.

Table 2. Use Case Description of an ALO

Use Case	Adaptive Learning Object
Description	It processes the requirements of adaptation of a LO.
Precondition	Adaptation requirements
Actors	Adaptive Learning Object

Procedure	Begin
	Determine types of adaptation required
	If type = semantic then
	Adapt semantically the LO
	If type = organization then
	Adapt organizationally the LO
	If type = presentation then
	Adapt the presentation of the LO
	If type = transformation then
	Transform the LO content
	If type = other then
	Generate the rules of another type of adaptation of the ALO
	Combine the types of ALO adaptation until to reach the requirements
	Generate Matadata of ALO
	End

Fail condition	Not having the necessary services to process the LO adaptation requirements
Success condition	Build a LO adapted to the required specifications

4.2. MALO Description

MALO has been defined in detail in [21]. In this section, we present a resume of MALO. Figure 4 presents MALO, which is composed of 4 elements:

- LO: are the Learning Objects to adapt, according to the information obtained from the context.
- Units: they are small blocks, such as concepts, media or pieces, that compose a LO. The number of units present in the LO, define their granularity and complexity.
- Rules: two categories of rules are defined, Adaptation and Conversion, which specify, respectively, the structural or contextual adjustments made to a LO.
- Adaptation Metadata: it is an extension of the LOM standard, which describes the data and processes required to facilitate the process of adaptation of the LO.

A LO can be decomposed into smaller units by using rules of conversion, forming a set with simpler LO, increasing its granularity; or conversely, starting from a set of LO, a more complex LO can be formed with less granularity. With the use of the rules of adaptation, the LO is adapted to certain specifications of the context in which it is immersed.

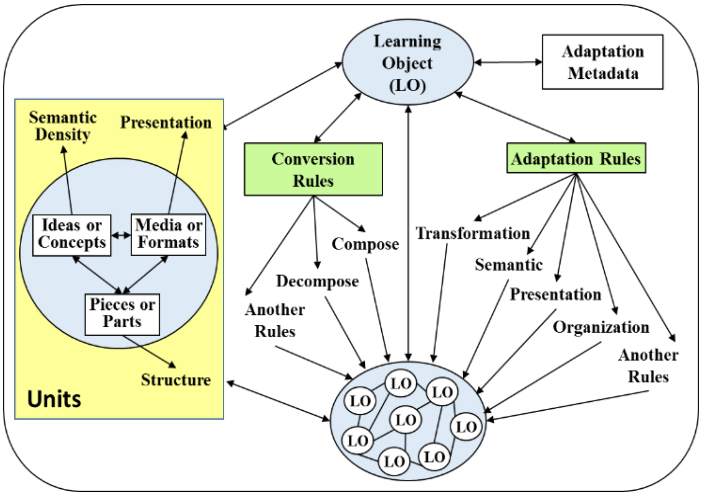

Figure 4. MALO

The result of applying the adaptation and conversion rules to an ALO is a Learning Object with a new semantic, or a new presentation format of the content, or a new organization, among

other things; based on the parameterization of an existing one, or the combination of several of them.

4.2.1. Conversion Rules

The conversion rules indicate that structural adaptations of a LO. In this article, two conversion rules are defined, however, MALO has the flexibility to allow the incorporation of new rules. The basic conversion rules are:

- Composition: based on the principle of reusability, allows to build new LO from other LOs of less granularity. The description of the composition rule is presented in Table 3, which has 5 rules.
- Decomposition: allows to decompose a LO into several LOs of less granularity, or to extract units included in a digital content. The description of the decomposition rule is presented in Table 4, which has 7 rules.

Table 3. Task Model of the Composition Rule

COMPOSITION OF A LEARNING OBJECT	
Name	Composition
Objective	Compose a LO from other LOs.
Description	Composes the content of a LO by total or partial aggregation of units (concepts, pieces, media) contained in other LOs
Precondition	Units required
Subtask	- Define the LO organization to be built - Add concepts or ideas - Add pieces or parts of the structure of a LO - Add media or formats to the contents of a LO - Generate metadata of the new LO
Product	Adaptive Learning Object
Ingredients-Compose Learning Object	
Composition Type	Indicates the type of composition to be made. Values = semantics, organization, format, mixed
Concepts List	Concepts or ideas contained in a LO
Pieces List	Different elements or part in which the LO is organized, similar to a table of contents. For example, document parts, book chapters, course topics, workshop content and activities.
Formats List	Different media or formats that are combined in a LO. Values = Text, Audio, Video, Interactive Animation, Simulator, Image, Table or Chart, Diagram.

Table 4. Task Model of the Decomposition Rule

DECOMPOSITION OF A LEARNING OBJECT	
Name	Decompose
Object	Decompose a LO in order to increase its granularity
Description	Disaggregate the content of a LO by units (ideas or concept, parts or parts, formats or media)
Precondition	Requirement of concept, piece or format
Subtask	- Search for concepts / ideas contained in a LO - Extract concepts or ideas from a LO - Extract organization of a LO - Remove parts of the structure of a LO - Search for formats / media embedded in a LO - Extract media or formats contained in a LO - Generate metadata of the new LOs
Product	Learning objects with greater granularity
Ingredients- Decompose Learning Object	
Decomposition type	- Indicates the type of decomposition required Values = semantics, structure, format, mixed
Concepts List	- Concepts or ideas contained in a LO
Pieces List	- Different elements or part in which the LO is organized, similar to a table of contents. For example, document parts, book chapters, course topics, workshop content and activities.
Formats List	Different media or formats that are combined in a LO. Values = Text, Audio, Video, Interactive Animation, Simulator, Image, Table or Chart, Diagram.

4.2.2. Adaptation Rules

The rules of adaptation define the types of adjustments to be applied to the LOs to contextualize it. In MALO, four types of rules are initially defined:

- Semantics: they allow to define new semantics in a LO, incorporating other ideas, conceptualizations or lexicons, according to its content.
- Presentation: allows to adapt the presentation of the LO, adjusting its formats to the preferences, limitations and use, both technology and user.
- Organization: they allow to reorder the content of a LO according to the pieces that make them up.
- Transformation: they change the units of measurement, of quantification, etc., in the LOs.

Tables 5, 6, 7 and 8 present the use cases of each adaptation rule. The main aspect to remark of these tables is that the *precondition* is one of the main criteria to determine what possible adaptation can be used in a given context, which can be used by a procedure of selection of adaptation mechanisms.

Table 5. Use Case Description of the Semantic Adaptation

Use Case	Semantic Adaptation
Description	It allows defining a new semantics of a LO, incorporating ideas or concepts according to their contents.
Precondition	Concepts or ideas required
Actors	Adaptive Learning Object
Procedure	Begin Determine new concepts or ideas or lexicon Find where to put them into the LO Incorporate them into the LO Generate metadata End
Fail condition	- Do not locate the required concepts in data repositories. - Not having the necessary services for the extraction of concepts, decomposition and composition of the LO
Success condition	Construct a LO with new semantics required.

Table 6. Use Case Description of the Presentation Adaptation

Use Case	Presentation Adaptation
Description	They allow to adapt the presentation of a LO modifying its format
Precondition	- Technological Preferences and limitations - User Preferences and Limitations - Conditions of use and desired functionality of the LO.
Actors	Learning Object, Context, User
Procedure	Begin Determine technological preferences and limitations Determine user preferences and limitations Determine conditions of use and functionality of LO Customize LO to those preferences and limitations Generate metadata End
Fail condition	- Not having the mechanisms to determine preferences, limitations and desired functionality of the context - Not having the necessary services to transform, customize, decompose or compose a LO
Success condition	- Build a LO with a new presentation, transformed and/or customized. - Given some preferences or limitations recommend formats, customization parameters, functionality

Table 7. Use Case Description of the Organizational Adaptation

Use Case	Organizational Adaptation
Description	It allows reorganizing the contents of a LO by rearranging its pieces.
Precondition	- Pieces or parts desired to organize the content of the LO - Concepts or ideas required
Actors	Adaptive Learning Object
Procedure	Begin Determine pieces or part of LO. Determine the reorganization parameters Rearrange LO Generate metadata End
Fail condition	- Do not locate the required pieces in the LO repositories. - Not having the necessary services for the extraction of pieces, decompose or compose a LO
Success condition	Build a LO with the new organization of its content. Recommend an organization for the LO

Table 8. Use Case Description of the Transformation

Use Case	Transformation
Description	Modifies certain properties or contents of a LO
Precondition	- Requirement of concept, piece or format. - Technological or user preferences or limitations - Usage patterns
Actors	Adaptive Learning Object
Procedure	Begin Summarize the content (concepts, organization) of a LO. Transform/Convert values of certain properties of some units to others (for example, of types of images, etc.) Generate metadata End
Fail condition	- Not finding the required units in LO repositories - Not having the necessary services for the transformation of the LO units
Success condition	Build a new LO with new features and/or units

4.3. Adaptation Metadata

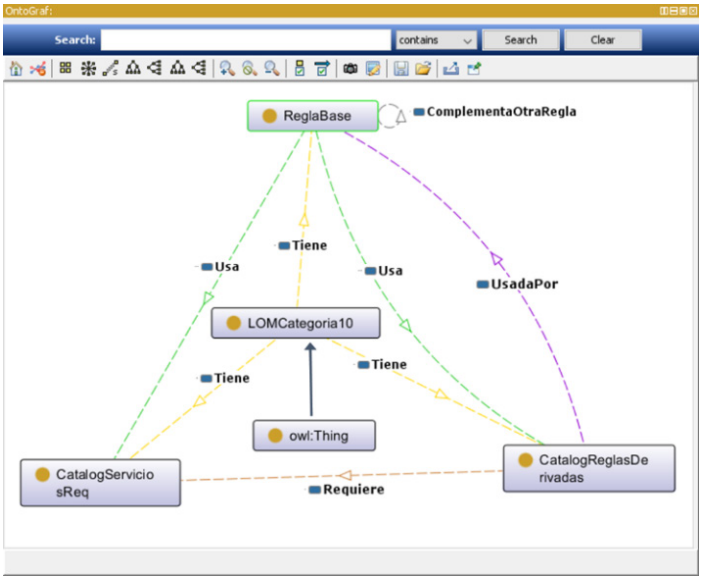
The LOM standard covers quite well the description of a LO. However, it presents limitations for the adaptation of LOs autonomously. Specifically, the adequacy of a LO is guided by a set of mechanisms, which must be defined in the metadata of the LO. The main mechanisms to be defined are for the adaptation, the conversion, according to the information about the context where will be used the LO. This information is not currently included in the LM standard. For this reason, in this paper, it is proposed to incorporate an extension to the standard (defined as category 10 of the standard), based on the data presented in Table 9.

Table 9. Category 10. Extension proposal for the LOM standard

No.	**Category**	**Description**	**Components**
10	Adaptation	This category groups the necessary information, to facilitate the process of autonomous adaptation of a Learning Object	10.1.Adaptation Rules (Name, Type, Description, Associated services, Required inputs, Procedure, Author, Date of creation, Date of modification) 10.2.Conversion Rules (Name, Type, Description, Expected Product, Associated Services, Required Inputs, Procedure, Related Tasks, Author, Date Created, Date Modified) 10.3 Context information (Knowledge Base, Rules of Inference, location of the Knowledge Base) 10.4 Restrictions 10.5 Other additional information

The proposed category specifies the information used to manage an ALO. The conversion and adaptation rules are methods to be applied to an ALO, which are implemented in some LO management platform. Thus, this category defines the knowledge base that allows the interoperability between ALOs, and their adaptation methods.

This category facilitates the search, evaluation, recovery and application of the adaptive methods for an ALO. The ontological model of the Category 10 (OLOMCat10) is presented in Figure 5.



OLOMCat10 relates Category 10 with 3 major components: a base rule, a rules catalog, and a services catalog. The base rule is the initial rule that triggers the ALO adaptation process. The Rules Catalog describes the set of conversion and adaptive rules. The Services Catalog describes and links a set of mechanisms required during the ALO adaptation process. The purpose of catalogs is ubiquity, making ALO independent of both, the rules of adaptation and the services used to implement them.

5. MALO instanced by the competencies

In this section are defined the adequacy of MALO, to consider the competencies during the adaptation process of the LOs.

Considering that the competencies that are applied in the professional field are built on the basis of the training and the professional formation, it is clear to establish a relation between the competencies and the learning results, as expressions of what a person in a learning process knows, understands, and is able to do at the end of an educational process.

As a result, a LO becomes a valid resource within the competence acquisition process, achieving an objective, a result or competence in a specific knowledge [21,25], which is conditioned to the quality of the LO, which involves aspects linked to its structure and granularity, and therefore, its adaptation in all or parts of its components [13].

Adapting a LO based on competencies requires the adjustment of the LO according to the user's previous competencies and the competencies objective (or learning result), in order that the LO has the sufficient characteristics to cover the competence objectives. In addition, should provide facilities to evaluate the competencies acquired. Thus, within the MALO model, the following aspects must be taken into account:

- Through the conversion rules, the LO must adapt its structure, to add units as required to meet the competence objectives, i.e. the composition rule can add a unit from another LO related to the skill levels of the objective competence.
- By contrast, through the adaptation rules, the LO can update its contextualization. For example, by the organization rule, the contents can be reorganized according to the competence requirements; or through the semantic rule; the LO can be enriched with links to external resources; or also through the transformation rule, the LO can incorporate measures establishing the skill level that a user must achieve after learning the specific knowledge that keeps the object.
- And also through adaptation rules, the LO can propose assessment tools to evaluate the competencies acquired in the learning process

Additionally, the enrichment of a LO with competence metadata can be incorporated into MALO, through the category 9 of the LOM standard (see Table 10), which allows the extension of the specification to a semantic model of competencies that uses a combination of pedagogical strategies and competence taxonomies to classify and evaluate the LO's performance in a learning environment [14].

Table 10. Category 9 of the LOM standard extended to include the competencies

Nro	Category	Explanation
9	Classification	This category describes where this learning object falls within a particular classification system.
9,1	Purpose	The purpose of classifying the LO (discipline, idea, prerequisite, educational objective, accessibility, restrictions, educational level, skill level, security level, competence)
9.2	Taxon path	A taxonomic path in a specific classification system.
9.3	Description	Description of the LO relative to the Purpose, such as discipline, idea, skill level, educational objective, competencies, etc.
9.4	Keyword	Keywords and phrases descriptive of the LO relative to the Purpose and competencies.

A hierarchical relationship between the different subcategories of Category 9 of the LOM standard is presented in Figure 6, where the competence (purpose) is defined by a taxonomic classification (taxon path), their description and keywords

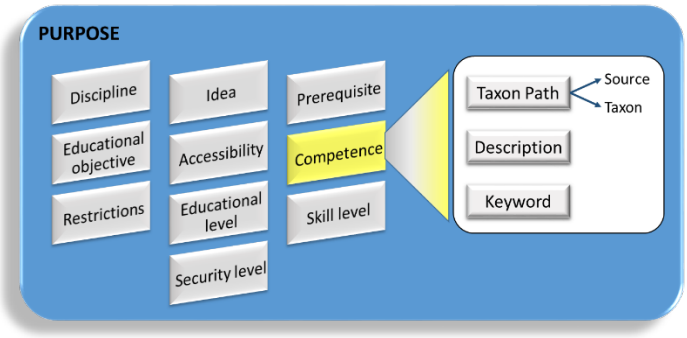


Figure 6. Category 9 of the LOM Standard. Hierarchical description of competence

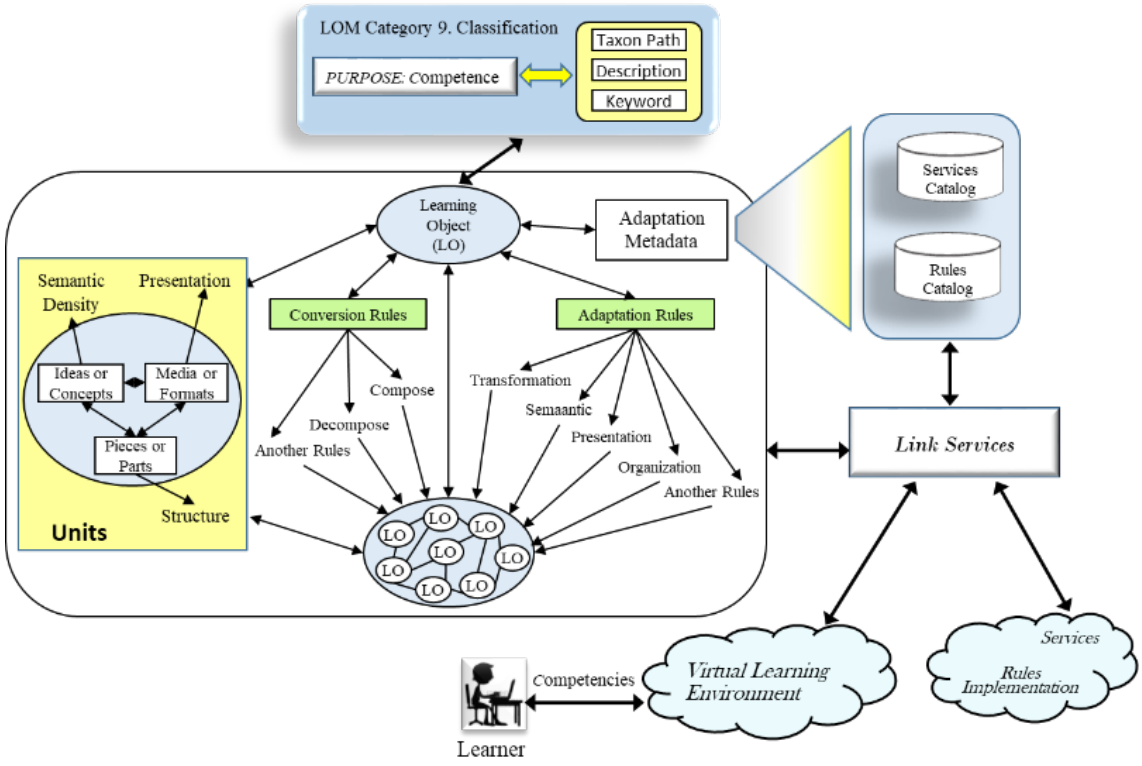
The use of LO as a resource to generate competencies in an apprentice within a virtual learning environment, requires to adapt the LO according to the required competencies, learning objective

and expected results. For this reason, Figure 7 presents a mechanism to instantiate the ALO in order to facilitate this process. For that, it is required**:**

- Virtual Learning Environment (VLE) provides the necessary environment for the development of the teaching-learning process.
- MALO defines the mechanisms for the LO adaptation
- Adaptation Metadata identifies catalogs of services and rules required to adapt to an ALO.
- Link Services provide ALO connection with VLE, to obtain context information, resources available for learning, as well as access to the Rule and Service catalogs.
- Category 9 of the LOM standard contains the metadata to facilitate the discovery of LO with contents related to the required competencies.



According to Figure 7, the required competencies by the learner are obtained from the VLE. MALO locates resources and LOs, which satisfies the required competencies and LOs. For this, it uses the information of the Category 9 of the LOM standard. MALO provides services with the conversion and adaptation rules defined in the metadata (Category 10), which access the mechanism catalog that allow the adequacy of the ALO according to the requirements. As a result of this process, an ALO is adapted to the competencies.

6. Description of a Case Study

Our case study test the capability of reconfiguration of an ALO using MALO, guided by the competencies to be reached in a given course. An application of the competence approach within MALO can be seen in the Table 11, to which the following considerations are carried out:

- It is established as a previous competence of the user: "knowledge of vegetables".
- It is established as objective competence: "Establish the difference between vegetarian dish and any other".

Table 11. Cooking course: Vegetarian dish preparation

Course activities	- Select vegetables and other ingredients (input) - Prepare mixture (process)
Learning Objects participants	LO1: Interactive virtual course, where the apprentice must follow the instructions and prepare the requested plate LO2: Digital multimedia content with a catalog of vegetables, classified by edible and non-edible vegetables.
Content of the virtual course	The content of the virtual course is composed of two (02) parts: *Ingredients:* in this part the student must demonstrate his/her knowledge, selecting the vegetables and other required ingredients. All ingredients are specified in text form *Preparation:* indicated by a video, step by step, how to prepare the dish.
Scenario	- Previous competence: student with extensive knowledge of vegetables - Limitations: reading problems. - Preference: follow hearing instructions

	- Objective competence: LO does not differentiate between vegetarian and other dishes
Classification	Establish the difference between a vegetarian dish and any other
Previous Competence	Knowledge about vegetables
Objective Competence	Establish the difference between a vegetarian dish and others
Skill Levels	Knowledge→Comprehension→Application

The Table 11 defines the LO to be used, the previous and objective competence, the content of the virtual course to be covered, among other things. Considering that scenario defines that the LO does not meet the objective competence: "Establish the difference between a vegetarian dish and others", then it is necessary to add a LO with knowledge about "Differences between vegetarian and other dishes". For this, in addition to the set of rules explained in section III, should include rules of semantic adaptation, presentation adaptation and transformation, besides to the rule of decomposition and composition. Using MALO, the following procedure will be performed:

1. Application of Presentation Adaptation rules:
   1.1. User preferences are determined.
   1.2. User Competencies are determined
      1.2.1. Previous competence
      1.2.2. Objective competence
      1.2.3. Skill levels of Objective Competence
   1.3. Limitations of the user are determined: reading problems
   1.4. Technological preferences are determined: not specified
   1.5. Technological limitations are determined: not specified
2. Application of rules of Semantic Adaptation,
   2.1. Search for a LO that covers the target competence and user preferences.
   2.2. Search for a LO assessment tool to evaluate the objective competence and its skill levels
   2.3. Using Decomposition rules
      2.3.1. Units of LO are retrieved from the source.
3. Application of Transformation rule
   3.1. According to the limitations and preferences of the user,
      3.1.1. Of the new LO found (LO3), extract audio from video
4. Application of rule of presentation.
   4.1. Adjusts the volume of the extracted audio
5. Application of Composition rules,
   5.1. The content of LO3 is integrated into the adapted LOs.
6. Application of rules of organization,
   6.1. The structure of the adapted LO is reorganized according to objective competence.
7. Generate the new ALO metadata
   7.1. Update the competence metadata in the category 9 of the LO: purpose, taxon path, description and keyword
8. Product: the LO was adapted to add the ALO3, which contains the differentiation between a vegetarian dish and others, in audio format, and assessment tools to evaluate the competencies

7. Comparison of MALO with other Models

For the comparison of MALO with the previous works described in section I, we consider the most similar that are **[4] [6]** and [29]. The comparison criteria were based on the characteristics must fulfill an ALO. We have used the next set of criteria: what adapts each one (because in an ALO we can adapt several things: organization, content, presentation, etc.), the type of rules used (that determine the adaptation of the ALO), the architecture of the framework (that determine if it can be improved very easy), the extensibility (very important for its scalability), the flexibility (in order to include new aspects in the adequacy of an ALO), and if it is based on metadata, and particularly, in a standard. The comparison is presented in Table 12.

Table 12. Comparison of MALO with other proposals

Criteria for Comparison	
Components to adapt	[5]: content and navigation patterns of a particular user, according to user preferences
	[13]: content, navigation and presentation
	[29]: organization of the ALO and assessment items,
	MALO: semantics, presentation and organization of contents. Possibility of adding other types of adaptation
Rules used	[5]: propose the use of content adaptation, navigation and evaluation rules.
	[13]: propose rules of navigation, content and presentation.
	[29]: they propose a set of services, but they do not give a guide about how they must be used
	MALO: two categories of rules, adaptation (semantics, organization, presentation, transformation) and conversion (decomposition, composition) are proposed.
Modularity	[5]: is based on rules of adaptation, knowledge of the domain and the user
	[13]: is based on content granularity, adaptive rules and user domains, context and adaptation
	MALO: modular design based on adaptation components, metadata and internal LO units
Extensibility	[5]: They do not propose it
	[13]: They do not propose it
	[29]: new services can be included
	MALO: It proposes the scalability of the model, allowing the incorporation of new rules of adaptation and conversion
Flexibility	[5]: it is fundamentally based on the preferences and limitations of the user, as well as on their learning needs.
	[13] incorporates preferences and limitations of the user, as well as learning resources, but does not consider technological aspects nor patterns of use
	[29] they use the competencies to guide the adaptation
	MALO: possibility to adapt the preferences and limitations, both user and technologies.
Adaptation Metadata	[5]: They do not propose
	[13]: They do not propose
	[29]: they do not propose an adaptive metadata
	MALO: The model works with the IEEE-LOM standard. It is proposed to incorporate into the standard an adaptation category, which describes the new elements used in the adaptation

When comparing the fourth approaches of adaptation of LO, it is observed that there are different criteria to consider. There is also no uniformity in the description of the adaptation metadata, nor in the modularity, extensibility and flexibility that each approach allows.

With respect to MALO, its modular design, extensibility, and the use of standards provide it with greater robustness and flexibility to adjust its strategies and processes. In addition, it is the most complete in terms of what it adapts, the rules it uses, the descriptions it provides in its metadata, among other things.

8. Conclusions

The main product of this work is to test the capability of adaptation of MALO using the competencies. Among the main features of the MALO are its modular and independent design based on two categories of rules, adaptation and conversion, which are complemented to facilitate the dynamic adaptation of an ALO. The flexibility and extensibility of its design, allow the incorporation and elimination of rules. In addition, MALO considers the preferences and limitations, both user and technology, as well as the Desired functionality of the LO, and the usage patterns detected in the context.

The competencies determine the skills and knowledge to be obtained in a given course, in this way they give useful information to adapt the LO to be used during the course. It determines specific conversion and adaptation rules. For example, according to the knowledge to be reached, it can define conversion rules to include new information in a given ALO. Also, according to the skills to be reached, it can define adaptation rules that allow reaching these skills.

There are several future works, in particular, the proposed extension of the LOM (category 10) and the description of the category 9 how a competence metadata, presented in this article, should be detailed. Finally, it is necessary to implement a middleware that provides services to MALO, inspired by works such as [27,28] to manage repositories of ALOs, which autonomously exploit all the knowledge around the MALO, and can adjust an ALO using different frameworks, such as the competencies.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Traceability for some people, is merely a tool to keep a history over something important that happened in the past. For others, is has no added value to their actual processes or products. In fact, it is becoming more and more valued. Traceability is still a vast area of research and an undiscovered field that if it is well used and managed, can provide a set of critical information or lead to something bigger. Many researches are still working to enhance its use and its integration by providing solutions to help users better manage and control their different elements (products, source code, documents, requirements, specifications, etc.). Nowadays, it is used in almost all domains as it can provide reliable information and helps improve efficiency and productivity. In this paper, we first present the state of the art on traceability and its use, through several examples. Then we provide a list of major techniques used in this field and propose our own traceability definition models.

1. Introduction

This paper is an extension of work originally presented in the 4th IEEE International Colloquium on Information Science and Technology [1] and was meant to show and explain the important role that traceability plays in different sectors.

Traceability, as defined in ISO (ISO 9001: 2000), is the ability to trace the history, application or location of that which is under consideration. D. Asioli, A. Boecker and M. Canavari say that it is not a new concept but a practice that we need to implement in order to comply with the standards and law rules [2]. Certainly, over the past few years, it has become a necessity in fields where the security or safety of consumers is questioned, especially in medical and food industries.

In software development also, this practice helps in the understanding, capturing, tracking and verification of software artifacts and their relationships and their dependencies during a software life-cycle [3]. As in [4], traceability was initially used to trace requirements from their source to implementation and test, when we talk about software development and now, it plays an increasing role in defect management, change management and project management.

According to the Global Traceability Standard (GS1), Traceability Systems have become an integral part of doing business as they aim to identify and locate unsafe foods and validate the presence or absence of attributes that are important to consumers [5]. Even if they are not yet considered as a catalyst for financial gains, G.G.D. Nishantha, M.K. Wanniarachchige and S.N. Jehan say that they are able to ensure consumer trust, safety, reliability, accuracy and quality [6]. Its importance is reflected through its ability to solve issues and through its power to provide strong proofs or evidences.

These Systems, along with their ability to monitor the composition as well as the position of every lot in a supply chain, are seen as a powerful tool that is capable of defining new management objectives and improve the overall performance [7].

Our personal definition of traceability would be, the ability to keep a detailed history of all activities and changes that a particular object can undergo throughout its entire life cycle, taking into account the different relationships that may appear. This particular object can be a material, a product, a model or even a class in a software development platform.

Traceability, if it is used in the right way, can provide a set of critical pieces of information such as the source, the destination, the location, the time, the link, in addition to the actors that were involved in the whole process. As in [8], ubiquitous traceability is achieved automatically, as a result of collecting, analysing, and processing every piece of evidence from which trace data can be inferred and managed.

The remainder of this paper is organized as follows: In Section 2, we will provide a set of definitions extracted from two major sectors, namely the food industry and information technology. Section 3 presents examples of traceability uses in different areas. A list of major techniques that were used to enhance the traceability will be the object of Section 4. In Section 5, we propose a set of definition models related to previously mentioned sectors. We will discuss the proposed traceability definition model in Section 6 and we will give a brief conclusion in Section 7.

2. Definitions

Traceability management is the planning, organization, and coordination of all activities related to traceability, including the creation, maintenance and use of trace links [9], not only in software development, but also in our daily life (e.g. memorizing events, tasks, activities, etc.).

In any area or sector, the definition of "traceability" is based on a number of criteria and limitations according to the used law or standards like the European General Food Law (EGFL) and the GS1 or simply, describes its purpose in a specific context.

Authors in [10] stated that there is no exact, single definition of traceability and that it has a large number of different meanings, which depend on the industry sector, on the supply chain, and on the perspectives of both the suppliers and the users of such information. However, we intend in section 5, to prove that a common definition can be established by means of models.

2.1. Food Industry

The EGFL defines traceability as the ability to trace and follow a food, feed, food-producing animal or substance through all stages of production and distribution.

According to A. F. Bollen and J.P. Emond, traceability is a well-coordinated and a well-documented movement of product and documented activities associated with the product, from producer, through a chain of intermediaries, to the final consumer [10].

M. Gooch and B. Sterling say that it is the ability to follow an item, or a group of items (whether animal, plant, food product, or ingredient) from one point in the value chain to another, either backwards or forwards [11]. Thus, food chain traceability goes from raw materials to consumption. This is almost the same definition given by F. Dabbene, P. Gay and C. Tortia, as they assume that products “moving” along the Food Supply Chain (FSC) are both tracked and traced [7].

Tracking is the process by which a product is followed from upstream to downstream in the Supply Chain. Tracing is the reverse process of tracking. The tracing process tends to reconstruct the history of a product through the information recorded in each step of the Supply Chain, identifying the source of a food or group of ingredients and consequently the real origin of a product [12]. These two primary functions of traceability are known as Trace-Back and Trace-Forward, as the movement can be traced one step backwards and one step forward at any point in the supply chain [6].

As in [13], traceability can either be internal or external. Internal traceability is within one company and relates to data about raw materials. While external traceability focuses on the product information from one link in the chain to the next (tracking a product batch and its history through the entire production chain).

In the food industry, traceability requires that each lot or amount or batch of food material is given a unique identifier which accompanies it and is recorded at all the stages of its progress through its food chain [14].

J. C.C. Martins and R. J. Machado said that a traceability system must record and follow the trail, since products that come from suppliers, are processed and distributed as end products [15]. The traceability presented by these records must contain a set of reliable pieces of information in order to ensure the minimum requirements. In fact, as stated in [11], it has three key essential information components: (1) identification of product attributes, (2) identification of premises and (3) identification of movement.

In the same context, P. Olsen and M. Borit have carried out an insightful comparative study of existing definitions [16]. By combining the best parts of these definitions, they concluded by saying that the simplest yet the most complete definition of traceability is the ability to access any or all information relating to that which is under consideration, throughout its entire life cycle, by means of recorded identifications.

2.2. Information Technology

In the field of software engineering, the IEEE Standard Glossary of Software Engineering Terminology defines traceability as the degree to which a relationship can be established between two or more products of the development process, especially products having a predecessor-successor or master-subordinate relationship to one another [17].

It is the ability to inter-relate any uniquely identifiable software engineering artefact to any other, to maintain the required links over time, and to use the resulting network to answer questions of both the software product and its development process [8]. It is a key element of any rigorous software development process that, provides critical support for many development activities [18].

When we talk about traceability in software development, we often refer to Requirement Traceability, which is an activity that allows creating links between and within software artefacts [19]. The definition of Requirement Traceability (RT), according to O. C. Z. Gotel and A. C. W. Finkelstein, is the ability to describe and follow the life of a requirement, in both a forward and backward direction [20]. Other definitions can be purpose-driven, solution-driven, information-driven or direction-driven.

These authors specify that there are two types of RT: pre-requirements specification traceability (Pre-RST), which is concerned with those aspects of a requirement's life prior to its inclusion in the Requirement Specification (RS), and post-requirements specification traceability (Post-RST), which is concerned with those aspects of a requirement's life that result from its inclusion in the RS.

More details about software traceability were listed in [8], including seven research areas and their associated directions which must be addressed in order to achieve ubiquitous traceability.

3. Uses of Traceability

In the food industry, it is considered as a mechanism used to keep the history of a raw or semi-finished unit during manufacturing and until this unit is delivered. It has a great potential to improve food safety as well as to promote consumer protection, by providing quality information [21].

In the field of Information Technology, traceability is used to list all activities of an entity on a system in execution. An example of such is the use of recovery logs or event logs in some cases. As R. Clayton explained, it is the ability to track down the originator of an action (seen as the flip side idea to "anonymity") and attempts to identify the IP address that caused an action to occur [22]. For instance, Law Enforcement Agencies (LEA) can use traceability to detect "Hi-Tech" crimes through data retention (causing logs to be preserved for a known period) and data preservation (ensuring that logs of special interest are not destroyed).

It is also used to clearly identify the sources behind some statistical analysis. Authors in [23] stated that it is the property which enables the understanding of where the analysis data come from and facilitates transparency. They have proposed a set of traceability pairs (relation criteria and factors) to define all the variables required in an analysis and hence establish the link between the final result and all the sources used. Moreover, traceability can strengthen the link between the requirements put in place, the specifications and the artefacts throughout the phases of a software development, using Requirements Traceability Matrix [19].

As authors in [9] explained in details, it allows creating and using links between software artefacts, which for example allows to connect the origin of a requirement with its specification or development artefacts to each other throughout the software lifecycle. These connections are called trace links, and link a source artefact to a target artefact. These artefacts can be of different types, such as a requirement, a model element, a line of code, or a test case.

In aerospace industry [24], traceability can be used to find the design related causes if a product does not function as expected. It is provided by establishing the relations between the design data and the requirements together with the relations between the components and the identifiers.

In Supply Chain Management (SCM), R.R. Pant, G. Prakash and J. A. Farooquie, traceability is defined in terms of what, how, where, why and when aspects of underlying product along a supply chain [25].

In logistics, traceability may be used to optimize routes and improve planning and management. It may also work with accounting applications to evaluate inventory or with controlling applications to identify process inefficiencies [15].

In electronics, traceability is used to keep track of all information related to changes and transformations which are applied to identified Printed Circuit Board (PCB) or other electronic components. Starting from the original batches and sources, this information is mainly, the Bill of Materials (BOM), the measurements, the list of operations in the process chain and the final destinations to whom or where the boards must be shipped. As stated in [26], it is required for fulfilment of safety standards such as ISO 26262.

Furthermore, traceability is also used in biology. An example of such, is to trace Genetically Modified (GM) animals that may similarly yield improvements in animal breeding, genetics and reproduction [27].

4. Techniques

In order to help users better manage their traceable items, the traceability mechanism has been enhanced by making use of different approaches that vary from using simple information retrieval techniques to the use of ontologies, graphs or even models.

4.1. Information Retrieval

A. De Lucia, A. Marcus, R. Oliveto and D. Poshyvanyk explained that Information Retrieval based methods or techniques like probabilistic, vector space and Latent Semantic Indexing models are used to recover traceability links on the basis of the similarity between the text contained in the software artefacts [28]. The higher the textual similarity between two artefacts is, the higher the likelihood that a link exists between them.

As in [29], this approach focuses on automating the generation of traceability links by similarity comparison between two types of artefacts.

4.2. Ontology

J. C.C. Martins and R. J. Machado proposed the use of software engineering methods and techniques to aggregate, disambiguate and blend existing knowledge [15]. They have used ontologies as a requirements modeling technique and developed specific traceability taxonomy in order to pursue the continuous improvement and answer the requirements of increased efficiency by tracking manufacturing activities information.

S. Bendriss and A. Benabdelhafid used DAML-S which is a generic ontology that can be applied in all areas [30]. They have adapted it by integrating and adding their specific ontology "Product Traceability Service", which describes all the web services of their traceability system. These services are dedicated to supply chain.

4.3. Graphs

As detailed in [19], "TraceMe" is an Eclipse module-based plug-in, that can be used to capture and maintain traceability links between different types of artefacts. According to the authors, this plug-in allows the software engineer to define different artefacts categories, capture traceability links between the defined artefacts categories and manage the traceability information through XML files. Traceability dependencies (trace links) are then displayed as graph.

Other researchers tend to use graph-based techniques in order to create trace links of test case scenarios and therefore, enhance the test coverage measurement and analysis [29].

Additionally, there are other plug-ins in the internet which are capable of tracing issues to both requirements and tests and creating the related traceability matrix.

4.4. Models

According to N. Sannier and B. Baudry, domain-specific modeling, which offers the capability to manipulate business domain concepts and traceability modeling, are Model-Driven Engineering (MDE) techniques that could address various aspects of requirement's formalization [31]. These authors proposed to combine both MDE and Information Retrieval (IR) techniques to improve requirements organization and traceability while handling textual ambiguous requirements documents.

MDE gives the basic principles for the use of models as primary artefacts throughout the software development phases and presents characteristics which simplify the engineering of software in various domains, such as Enterprise Computing Systems. A model is a symbolic system expressed in a language and each kind of model is represented by an appropriate modeling language and can be applied to certain purposes [3].

M. Thakur, B. J. Martens and C. R. Hurburgha defined a data model as a coherent representation of objects from a part of reality [32]. They used the modeling technique to create a database model capable of recording all the transformations related to incoming and outgoing grain lots, as well as the transformations that take place internally in the whole supply chain.

By making use of modeling techniques, C. Szabo and Y. Chen proposed "SeMMA" (Semantic Multi-Modeling Architecture), which is a multi-modeling architecture that permits the semantic integration of models defined in various languages, and ensures multi-model consistency when changes across different models occur and relies on three main modules, namely, the Change Analyzer Module, the Consistency Checker Module and the Warning Module [33].

In the same context, S. Bendriss and A. Benabdelhafid proposed a product data model which takes into account the different elements necessary for traceability, namely, the product in its various states, the various operations on the product, the occurred events, the resources used and the spatiotemporal location of the product [30].

In software development, requirement traceability can be described as a feature model to define a product [29]. It consists of a graph with features as nodes and feature relations as edges. If the number of features is very high, then the representation of features and their relations are displayed by tables.

On the other hand, the authors in [18] presented an approach on how to build a multi-domain traceability framework. It consists of defining first a Traceability Information Model (TIM) which represents the core element of any traceability framework (artefacts/relations) and may refer to artefacts (documents, models, databases, project activities context) from different domains, then deriving traceability information from sources, record the information in a Traceability Model (TM) and finally, performing traceability analyses, based on traceability goals.

Another example of such technique is presented in [26], where authors proposed an Eclipse plugin which uses the Eclipse Modelling Framework (EMF) as its base technology and stores the traceability model as an EMF model. This tool helps both users and project managers to create, customize and maintain traceability links, whose types depend on the company, development context and process used.

For more details about MDE techniques, Galvão and A. Goknil have listed many traceability approaches in MDE and evaluated them using five comparison criteria: representation, mapping, scalability, change impact analysis and tool support [3]. They classified these approaches into three categories: requirements-driven approaches, modeling approaches and transformation approaches.

4.5. Others

F. Furtado and A. Zisman proposed a new traceability approach called "Trace++", a traceability technique that extends traditional traceability relationships to support the transition from traditional to agile software development [34]. This technique extends the use of information sets and consists of six elements: the agile related problem, the trace relations, a set of all source artefacts, a set of all target artefacts, a set of additional information and finally, the type of relations.

Other techniques tend to use XML as the main tool to represent models and trace links.

As stated in [29], these techniques are classified as Hypertext-Based techniques. But there are others which can be either Rule based, Event based, Value-based or Scenario-based.

5. Definition Models

As stated before, there is no single or unique definition for traceability, since the term is described according to both its context and its purpose. Based on this and on the elements extracted from the other definitions, we hereby propose a definition model for the main sectors.

In Food Industry, the purpose of traceability is to trace the initial product with the raw materials from the start, till the very end of the production chain. Figure 1 represents the internal traceability in this field, where ***p*** is the initial item, ***P*** is the final product and $i_0, i_1 \ldots i_n$ are the set of information that describes the movement from one point to another.

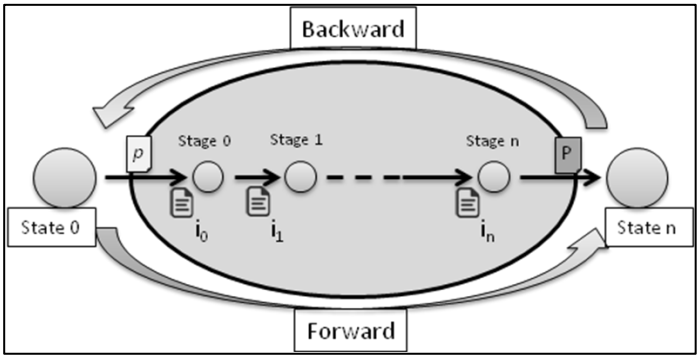

Figure 1: Traceability in Industry

By simply adjusting these elements, this representation can also describe the traceability in the Supply Chain or Logistics, tracing lots from the warehouse to every destination of the distribution chain.

Furthermore, it is only when two or more separate representations of this size are connected, that we basically speak about external traceability. Otherwise, it is still internal.

In the field of Information Technology, one example use of traceability is to create links between customer requirements or

specifications and the supplier software. As shown in Figure 2, ***s*** refers to the initial specification (requirement) or source, while ***O*** refers to the final object. The relation between the different stages of development is represented by $r_0, r_1 \dots r_n$.

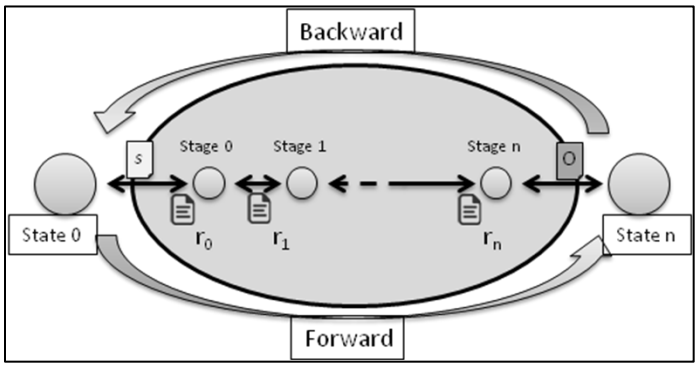

Figure 2: Traceability in Software Development

When this definition is applied to the model driven engineering (Figure 3), relations are replaced by a set of transformations $t_0, t_1 \dots t_n$ between predecessors and successors, representing the same system **S**. Elements ***s*** and ***O*** will be replaced respectively by ***m*** for the initial model and ***M*** the final model. Not to mention that each transformation can be represented likewise.

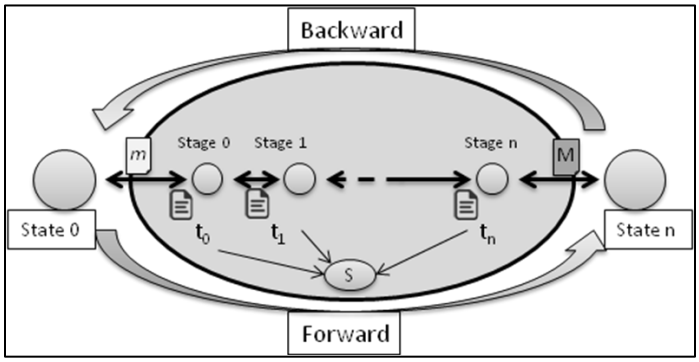

Figure 3: Traceability in Model Transformation

To sum up, we can say that the three proposals have a set of elements in common:

- Items: units that need to be traced and followed.
- Stages: positions where the units are processed.
- Relations: links between predecessors and successors.
- Activities: set of processes that were applied to the units

These elements will lead us to set a common model for traceability, which will be the basis of our future studies.

6. Discussion

Traceability in our point of view, as stated before, is the ability to keep a detailed history of all activities and changes that a particular object can undergo throughout its entire life cycle, taking into account the different relationships that may appear. It can be internal or external and can be used in two different ways either forward or backward.

As presented in the previous section, every traceable item is moving from an initial state to a final state, through numerous stages. In each stage, the output is the result of an activity that takes into account inputs from the previous stage and keeps the link to the origin. At the end, and since inputs and outputs are interrelated, tracing forward and backward is possible.

Thus, we can combine these facts to establish a common definition model that can be used to define "Traceability" everywhere (Figure 4).

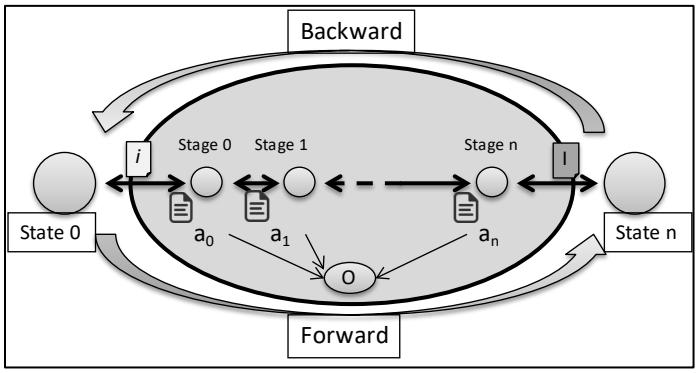

Figure 4: Generic Traceability Model

Here, ***i*** refers to the initial traceable item, where ***I*** is the final traceable item. The activities that the traceable item undergoes are represented by $a_0, a_1 \dots a_n$. ***O*** is the origin or the representation of all original characteristics of the traceable item. These characteristics do not change and are only updated if a new property was discovered when moving from one stage to another.

Certainly, once this generic model is deployed on a particular platform, it will be a subjected to a large amount of data, of different types. Hence, is it mandatory to consider the following challenges:

- How to address the problem of time vs Big Data during information access?
- How can we manage to order the accessed traceability information by degrees of priority or importance?

We intend on enhancing our model by adding a set of rules and other traceability related properties.

For instance, a "weight" or a "priority" measure can be introduced and assigned to each traceability information, after the classification process, or we can improve the representation of trace links by including additional factors. Thus, only the most important set of information is shown when tracing an item, either backward or forward.

7. Conclusion

Traceability can ensure quality, safety, reliability and accuracy. Furthermore, it can help companies improve productivity, reduce costs and gain consumer's trust.

According to GS1 [5], traceability may assess other business systems and tools such as quality management, risk management, information management, logistical flows, commercial advantage and evaluation of management demands.

In this paper, we have listed recent definitions related to traceability from two major sectors. We have presented definition models for these sectors and proposed our generic traceability

model, by combining a set of common elements, which stands as the basis of our research. In the same context, we have listed also, the uses and purposes of traceability as well as the major techniques applied in this research field.

In future work, we intend to refine our model with new elements and then, deploy it and use it in E-learning environments. Furthermore, a study will be initiated to decide whether or not this model can be applied to other fields or needs further enhancements. The final purpose will be to implement a general model, able to satisfy all traceability needs and requirements.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

L-band SiGe HBT active differential equalizers with variable, positive or negative gain slopes have been designed and fabricated for frequency and temperature compensation of microwave and optical systems. The active equalizer employs dual-resonant RLC circuits in the series feedback path of the differential amplifier for positive gain slopes or in the load for negative gain slopes. The implemented active equalizers have achieved positive gain slopes of +54 to +87dB/GHz across 0.2 to 0.6GHz as well as negative gain slopes of -50 to -100dB/GHz over 0.6 to 1.2GHz. The active differential equalizers presented in this paper have an outstanding feature of providing variable, positive or negative gain slopes, which can be easily adjusted to meet with various stringent requirements for frequency and temperature compensation in microwave and optical systems.

1. Introduction

First of all, this paper is an extension of the work originally presented in the 46th European Microwave Conference, 2016 [1]. The research and development of active equalizers have started at the beginning of 1970s as active RC filters with IC operational amplifiers in the audio band because of having many advantages over passive equalizers in terms of inductor-less, cheaper, smaller, easily manufactured and tuned circuits [2]. Since then, various types of active, adjustable amplitude and delay equalizers have been developed, including classical Bode variable equalizers, transfer-function types and switched-capacitor equalizers [3, 4, 5]. With the tremendous growth in semiconductor NMOS, CMOS devices, the R&D activities of active equalizers have moved toward wideband, high speed data transmission systems, a variety of analog adaptive equalizer architectures have been developed to eliminate signal distortions [6, 7, 8, 9]. Meanwhile, wideband microwave and optical receivers have been long tackled with the pass-band negative gain slope due to the falling off of gain of transistors and the insertion loss of passive elements as frequency increases [7, 10]. To address this issue, several types of passive equalizers have been reported, having fixed positive or negative gain slope as a function of frequency [11]. In addition, to realize the adjustability for the required gain slopes, a variety of active equalizers using diodes or transistors have been reported, having variable positive or negative gain slopes [10, 12, 13]. Although these circuits employ active devices, the circuit configuration is basically a passive type where fixed capacitances are replaced by diodes or transistors to provide variable gain slopes. Therefore, the insertion loss is seriously large. To address this problem, the authors have presented various types of the active equalizer with variable, positive or negative gain slopes. The advanced feature is in that active devices are used as an amplifier in place of the conventional switching or variable-capacitance device to achieve high gain. Moreover, to achieve higher frequency operation as well as miniaturized size, LC-resonators in place of the traditional RC filters are employed in the series feedback path or load circuit of the differential amplifier for positive or negative gain slopes. The active differential equalizers are as follows: Capacitance-selectable bridged-T attenuators were incorporated into the series feedback path to achieve variable positive gain slopes, which can be digitally controlled [14]. Series LC resonators were employed in the base or collector bias circuits to realize variable, positive or negative gain slopes [15]. Single-band series or parallel LC resonators were used in the feedback path of the differential amplifier for the same purposes [16]. These active equalizers, however, can vary gain slopes but the frequency positions were fixed. To overcome this problem, a novel active differential equalizer having variable inclination and position of the positive or negative gain slopes have been presented in [1]. It employs dual-resonant RLC circuits in the feedback path of the differential amplifier for positive gain slopes or in the load for negative gain

*Corresponding Author: Yasushi Itoh, 1-1-25 Tsujido-Nishikaigan, Fujisawa, Kanagawa, 251-8511 Japan, +81-466-30-0185 | Email: itoh@elec.shonan-it.ac.jp

slopes. To extend the work, the theory and design for the active differential equalizer using the dual-resonant RLC circuits are described in more detail. Then the circuit design, simulation and performance are newly added for the case that dual capacitors (actually two varactor diodes) consisting of the dual-resonant RLC circuit are independently varied. These active differential equalizers are relatively narrowband as well as provide abrupt gain slopes but can be easily extended to wideband design with the proper choice of circuit parameters.

2. Active Differential Equalizer Using Dual-Resonant RLC Circuits

Two types of the active differential equalizers with variable inclination and position of the positive or negative gain slopes are graphically shown in Figure 1. f_{PP} and f_{PN} are peak frequencies. f_{BP} and f_{BN} are bandstop frequencies. The conventional active equalizers [14, 15, 16] can vary either a peak or bandstop frequency. Thus only gain slope can be varied. On the other hand, the novel active equalizers can vary both peak and bandstop frequencies. Thus both the inclination and position of gain slopes can be varied.

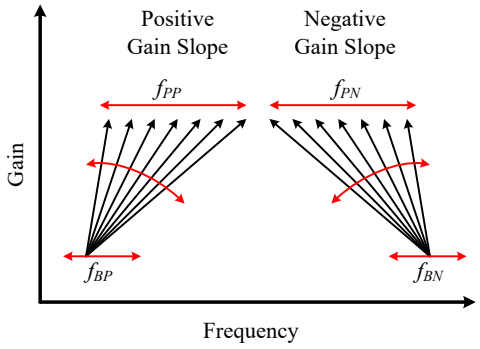

Figure 1 Two types of the active differential equalizers with variable inclination and position of the positive or negative gain slopes

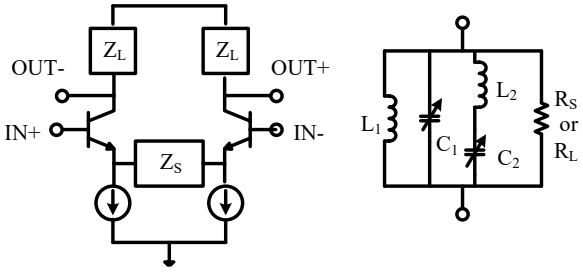


(a) Differential amplifier (b) Dual-resonant RLC circuit

Figure 2 Schematic diagram of the differential amplifier and dual-resonant RLC circuit

Schematic diagrams of the differential amplifier and dual-resonant RLC circuit are shown in Figure 2. The dual-resonant circuit consists of series LC (L_2, C_2) and parallel LC (L_1, C_1) circuits combined with a resistor (R_S or R_L). The dual-resonant RLC circuit becomes purely resistive at the frequency f_1 and f_2, which are given as follows:

$$f_1 = \frac{1}{2\pi}\sqrt{\frac{b-\sqrt{b^2-4a}}{2a}} \tag{1}$$

$$f_2 = \frac{1}{2\pi}\sqrt{\frac{b+\sqrt{b^2-4a}}{2a}} \tag{2}$$

$$a = L_1L_2C_1C_2 \tag{3}$$

$$b = L_1C_1 + L_2C_2 + L_1C_2 \tag{4}$$

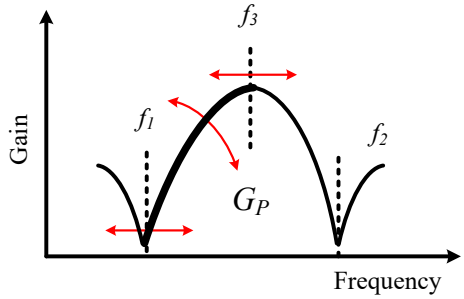
The circuit also becomes short-circuited at the frequency f_3.

$$f_3 = \frac{1}{2\pi\sqrt{L_2C_2}} \tag{5}$$

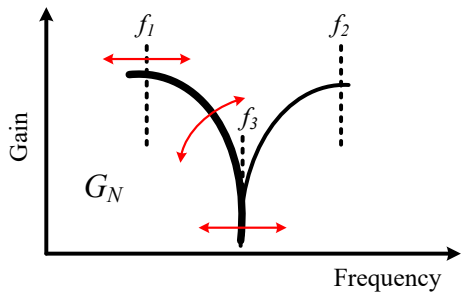
The voltage gain of the differential amplifier (G_V) in Figure 2(a) can be approximated as the following equation, where Z_L and Z_S are an impedance of the load and feedback circuits.

$$G_V = \frac{Z_L}{Z_S} \tag{6}$$

When the dual-resonant RLC circuit is applied to Z_S, G_V becomes minimum at f_1 and f_2 as well as maximum at f_3, which is graphically shown in Figure 3(a). Whereas, when the dual-resonant RLC circuit is applied to Z_L, G_V becomes maximum at f_1 and f_2 as well as minimum at f_3, which is graphically shown in Figure 3(b). The differential amplifier provides variable, positive gain slopes (G_P) between f_1 and f_3 by adjusting f_1 or f_3. Actually, f_1 or f_3 can be varied with C_1 or C_2. It must be noted here that both f_1 and f_3 can be varied with C_1. Meanwhile, the differential amplifier produces variable, negative gain slopes (G_N) between f_1 and f_3 by adjusting f_1 or f_3. In the similar way, f_1 or f_3 can be varied with C_1 or C_2. However, it must be also noted that both f_1 and f_3 can be varied with C_1.

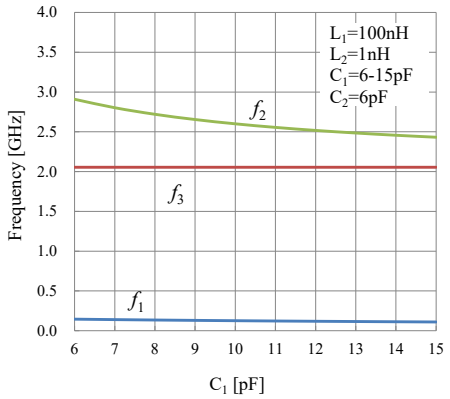


(a) Positive Gain Slope

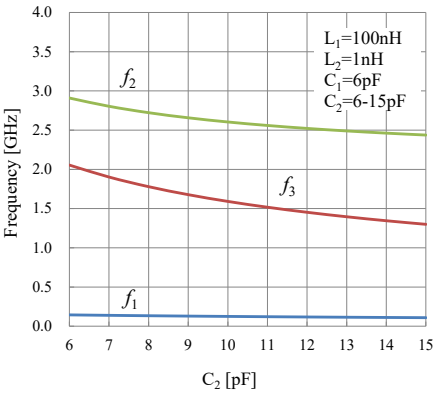


(b) Negative Gain Slope

Figure 3 Voltage gains of the differential amplifier when the dual-resonant RLC circuit is applied to Z_S or Z_L.



(a) Variable C_1 and fixed C_2



(b) Variable C_2 and fixed C_1

Figure 4 Calculated resonant frequencies f_1, f_2 and f_3

Table 1 Circuit element values

Element	Value
R_L [Ω]	56
R_S [Ω]	10
L_1 [nH]	100
C_1 [pF]	6 to 15
L_2 [nH]	1
C_2 [pF]	6 to 15

The resonant frequencies f_1, f_2 and f_3 are calculated by using (1) to (5) and are shown in Figure 4. The circuit element values are listed in Table 1. It is clearly shown that the inclination and position of positive or negative gain slopes can be tuned by varying C_1, C_2 or both. As described above, f_1 and f_3 cannot be varied independently with C_2 changes in Figure 4(b).

3. Circuit Design

Schematic diagrams of the active differential equalizer with variable, positive or negative gain slopes are displayed in Figures 5 and 6, respectively. Dual-resonant RLC circuits are employed in the feedback path of the differential amplifier for positive gain slopes or in the load for negative gain slopes.

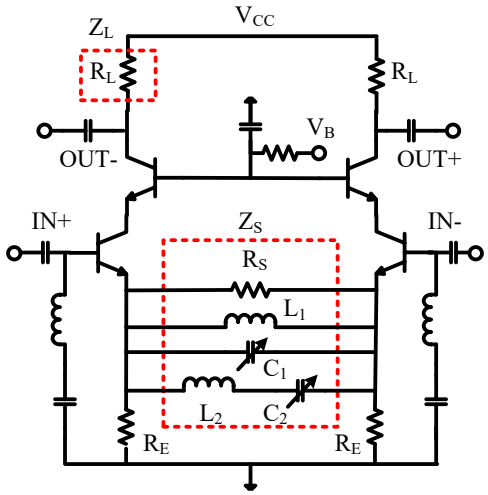


Figure 5 Schematic diagram of the active differential equalizer with variable, positive gain slopes

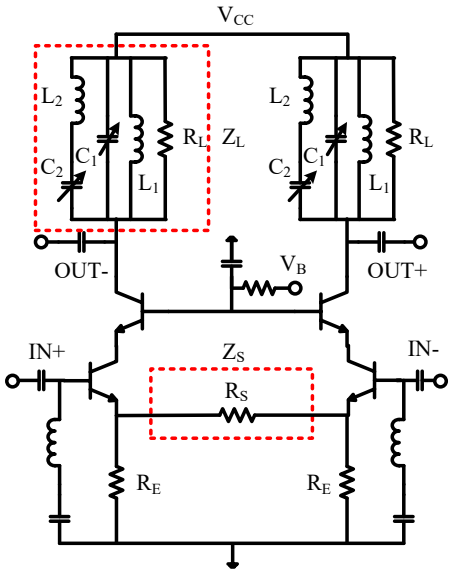

Figure 6 Schematic diagram of the active differential equalizer with variable, negative gain slopes

As shown in Figure 2(b), the dual-resonant RLC circuit consists of a series LC circuit (L_2, C_2), a parallel LC circuit (L_1, C_1) and a resistor (R_S or R_L). R_S or R_L plays an important role of circuit stability and impedance matching. R_L is basically chosen as 50 ohms for impedance matching. But R_S has to be carefully determined to achieve both high stability and high gain. When the dual-resonant RLC circuit is employed in Z_S, R_L is used in Z_L. Meanwhile, the dual-resonant RLC circuit is employed in Z_L, R_S is utilized in Z_S.

Now the voltage gain with positive gain slopes (G_P) and that with negative gain slopes (G_N) can be given from (6) as follows:

$$G_P = R_L\sqrt{\mathrm{Re}[Y_S]^2 + \mathrm{Im}[Y_S]^2} \tag{7}$$

$$\mathrm{Re}[Y_S] = \frac{1}{R_S} \tag{8}$$

$$\mathrm{Im}[Y_S] = \mathrm{Im}[Y_L] \tag{9}$$

$$G_N = \frac{1}{R_S\sqrt{\mathrm{Re}[Y_L]^2 + \mathrm{Im}[Y_L]^2}} \tag{10}$$

$$\mathrm{Re}[Y_L] = \frac{1}{R_L} \tag{11}$$

$$\mathrm{Im}[Y_L] = \frac{\omega^4 L_1 L_2 C_1 C_2 - \omega^2 (L_1 C_1 + L_2 C_2 + L_1 C_2) + 1}{\omega L_1 (1 - \omega^2 L_2 C_2)} \tag{12}$$

G_P and G_N are calculated by using (7) to (12) and the circuit element values in Tables 1. The calculation was done for variable C_1 and fixed C_2 or variable C_2 and fixed C_1. The calculated G_P and G_N are plotted in Figures 7 and 8, respectively. It is clearly demonstrated that variable, positive or negative gain slopes can be obtained. Due to a large value of L_1, a variation of the bandstop frequency f_1 is small in Figure 7. Thus the positive gain slopes greatly change with f_2 (C_2) in Figure 7(b). In the similar way, due to a large value of L_1, a variation of the bandstop frequency f_1 is also small in Figure 8. The negative gain slopes largely vary with f_2 (C_2) in Figure 8(b).

(b) Variable C_2 and fixed C_1

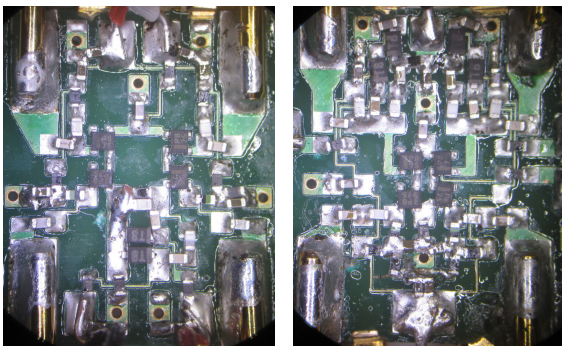
Figure 10 Simulated gains of the active differential equalizer with variable, negative gain slopes

4. Circuit Simulation

Based on the schematic diagrams of Figures 5 and 6, the circuit simulation was accomplished by using ADS. A cascode connection of SiGe HBTs is employed to control gain. In order to improve input and output matching, reactive elements of L and C are employed in the input matching circuit as well as the value of R_L was determined as 56 ohms. The value of R_S was finally chosen as 10 ohms to keep high gain and stabilize the circuit. The simulation was done for variable C_1 and fixed C_2 or variable C_2 and fixed C_1. The simulated gains of the active differential equalizer with variable, positive or negative gain slopes are plotted in Figures 9 and 10, respectively. The variation of positive gain slopes is a little bit larger for f_3 (C_2) changes, which is in good agreement with Figures 4 and 7. In the similar way, the variation of negative gain slopes is also larger for f_3 (C_2) changes. In Figure 10(b), both the inclination and position of negative gain slopes have drastically changed.

5. Circuit Fabrication

Photographs of the active differential equalizer with variable, positive or negative gain slopes are shown in Figure 11. The active differential equalizers were fabricated on the FR-4 substrate with a dielectric constant of 4.5. 0.35μm SiGe HBTs with an f_t of 25GHz (Toshiba MT4S102T), 1005-type resistors, inductors and capacitors are mounted on the substrate by soldering. A surface mount type of the varactor diode with a capacitance ratio of 2.5 (Toshiba 1SV279) was used. The circuit size is 14 x 16 x 1.2 mm^3.



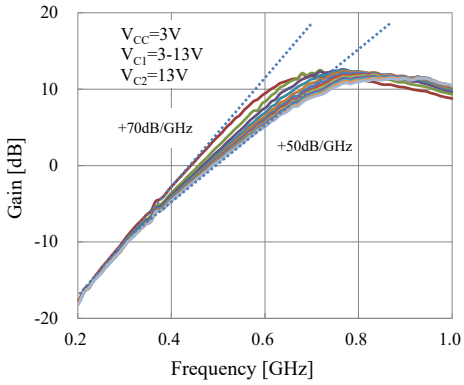
(a) Positive Slope (b) Negative Slope

14 x 16 x 1.2 mm^3

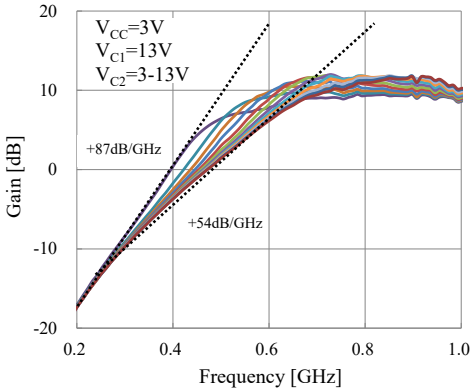
Figure 11 Photographs of the active differential equalizer with variable, positive or negative gain slopes

6. Circuit Performance

The measured gains of the active differential equalizers are plotted in Figure 12 for the positive gain slopes and in Figure 13 for the negative gain slopes. The measurement was done for variable C_1 and fixed C_2 or variable C_2 and fixed C_1. Actually C_1 or C_2 was varied with a control voltage V_{C1} or V_{C2} of the varactor diode. The measurement conditions are shown in Figures 12 and 13, respectively.

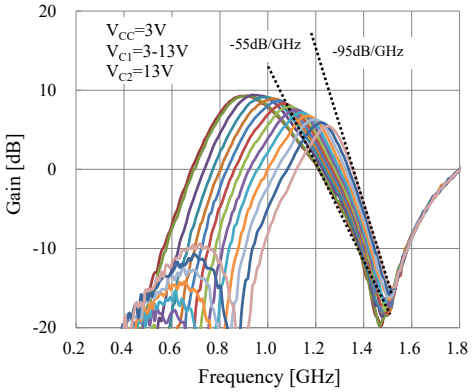


(a) Variable V_{C1} and fixed V_{C2}

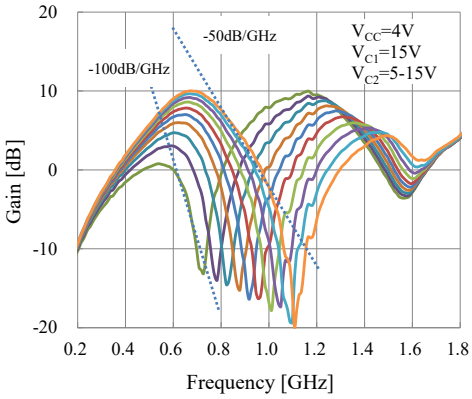


(b) Variable V_{C2} and fixed V_{C1}

Figure 12 Measured gains of the active differential equalizer with variable, positive gain slopes



(a) Variable V_{C1} and fixed V_{C2}



(b) Variable V_{C2} and fixed V_{C1}

Figure 13 Measured gains of the active differential equalizer with variable, negative gain slopes

The active differential equalizer with variable, positive gain slopes has achieved a gain slope of +50 to +70dB/GHz over 0.2 to 0.6GHz in Figure 12(a) as well as +54 to +87dB/GHz across 0.2 to 0.6GHz in Figure 12(b). The input and output return losses were better than 2dB and 15dB, respectively, which can be easily improved by employing a lossy match circuit in the input matching circuit.

The active differential equalizer with variable, negative gain slopes has achieved a gain slope of -55 to -95dB/GHz over 1.1 to 1.5GHz in Figure 13(a) as well as -50 to -100dB/GHz across 0.6 to 1.2GHz in Figure 13(b). The input and output return losses were better than 2dB. In a similar way as the positive gain slope, the input and output matches can be further improved with the use of a lossy match configuration.

These performances were compared with the conventional active equalizers and summarized in Table 2. It is clearly shown that the active differential equalizers presented in this paper can provide narrow-band but abrupt gain slopes as well as higher gain. With the proper choice of the circuit parameters, it is very easy to meet with the moderate gain slopes over a wide bandwidth.

Table 2 Summary of performances of active equalizers

Ref.	Active Device	Role	Equalizer Type	Circuit Topology	Frequency Band	Gain Slope	Gain
[10]	GaAs MESFET	Swiching	Negative Slope	Bridged-T Attenuator	DC - 18GHz	-0.67dB/GHz	<-2.7dB
[11]	unkown	Filter	Positive, Negative Slope	Non-reflective Transmission Filter	2 - 4GHz	plusmin 30dB/GHz	unkown
[12]	PIN Diode	Variable R	Positive, Negative Slope	Tee Attenuator	3 - 5GHz	plusmin 16dB/GHz	<-2dB
This work	0.35 micron SiGe HBT	Amplifier	Positive, Negative Slope	Differential Amplifier	0.2 - 0.6GHz, 1.1 - 1.5GHz	+54 to +87dB/GHz, -55 to -95dB/GHz	< +10dB

7. Conclusions

Two types of the active differential equalizers with variable, positive or negative gain slopes have been presented. With the use of the dual-resonant RLC circuit in the feedback or load circuit, the active differential equalizers have achieved positive gain slopes of +54 to +87dB/GHz across 0.2 to 0.6GHz as well as negative gain slopes of -50 to -100dB/GHz over 0.6 to 1.2GHz. The active differential equalizers presented in this paper show narrow bandwidth but abrupt gain slopes, which can be easily extended to wide bandwidth and moderate gain slopes with the proper choice of the circuit parameters. Moreover, the input and output matches can be improved with the use of a lossy match structure. It can be concluded from these results that the active differential equalizers would be one candidate for frequency and temperature compensations in microwave and optical systems.

Reliability Centered Maintenance

A B S T R A C T

Infrastructure Asset Management was first adopted in 1980s for challenges faced by the utilities, road and rail transport systems, mining, process and manufacturing industries in asset life cycle value optimization. International standards ISO 55000 and PAS 55 were subsequently developed to provide a basis for a structured methodology in the development of Asset Management System. This methodology with the basic framework is considered inadequate in addressing the changing and challenging environment faced by the Energy, Power and Transportation sectors. This paper introduces the concept of Reliability-Centred Management System that could leverage on the advancement in Information and Communication Technologies and the entry of the 'Big Data' and 'Smarter Grid' era.

1. Introduction

Incidents in the late 1980's, such as the North Sea Piper Alpha disaster that caused 167 fatalities, and the ensuing oil price crash and the falling levels of service, escalating costs and poor planning in the public sector of Australia and New Zealand has necessitate a radical change in managing the assets, such as the oil platforms and the public infrastructures. The lessons learnt from these widely different environments have been remarkable similar, with significant convergence of conclusions. This has led to the approach of asset life cycle value optimization for the utilities, road and rail transport systems, mining, process and manufacturing industries at an accelerating rate. [1]

On the other hand, international standards, such as PAS 55 and ISO 55000 developed in the last decade provide a basis for a structured methodology in the development of Asset Management System. However, this methodology with the basic framework is not adequate in addressing the changing and challenging environment faced by the power utilities. How utilities manage their assets is undergoing profound changes. Asset Management approaches and analytical tools have finally matured to the point where decisions can be based on data and facts – not just "gut feel" instincts and intuition.

2. Current Asset Management Concepts

Facing with the changing and challenging environment brought about in the global economic and local political pressures, the Asset Management mind-set for the energy, power and transportation sectors needs to focus on:

- Prudent performance targets, not maximum performance;
- Risk management not risk avoidance; and
- Spending justified by performance improvement and risk mitigation not blanket budgets.

The quality of assets managed by the energy, power and transportation sectors cannot therefore be assured by simple compliance with the general ISO 9001 management system standard [2]. This is because ISO 9001 provides little guidance on what constitutes good Asset Management practice with regard to capital-intensive infrastructures with relatively long asset lives.

The crux of Asset Management in these sectors is to have an integrated, whole-life and risk based approach. The issues faced by the energy, power and transportation sectors are many and varied. These sectors are required by their stakeholders to procure, operate, maintain and subsequently replace their assets at acceptable risk levels with satisfactory quality of service and reasonable return of capital investments. These assets comprise complex assets which typically have operational lives of several decades. At the same time, the sectors have to avoid unnecessary investments planning while ensuring the reliability, security and quality of services provided by these assets.

Cost-effective operation and maintenance of the assets are particularly important in the management of the assets throughout

*Corresponding Author: Loc K. Nguyen, Clean Technology Centre, DNV GL - Energy, 118227, Singapore | Email: khanh.loc.nguyen@dnvgl.com

the useful life of these assets. Figure 1 shows the possible strategies that can be adopted in the maintenance of the assets.

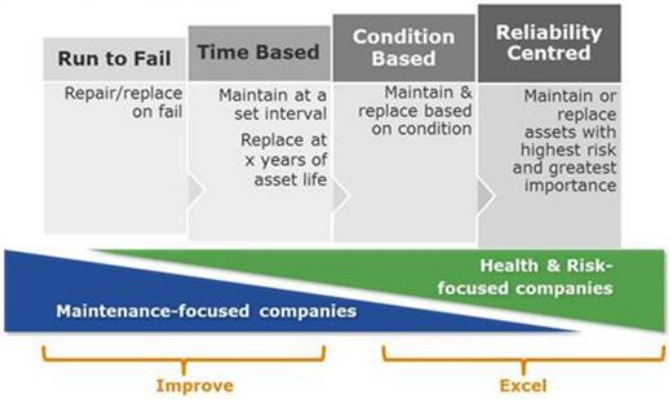

Fig. 1. Maintenance Strategy Evolution

3. Technical Asset Management System

Figure 2 shows a typical step-wise implementation approach that has been developed for Asset Management Systems of energy, power and transportation sectors under ISO 55000. [3,4]

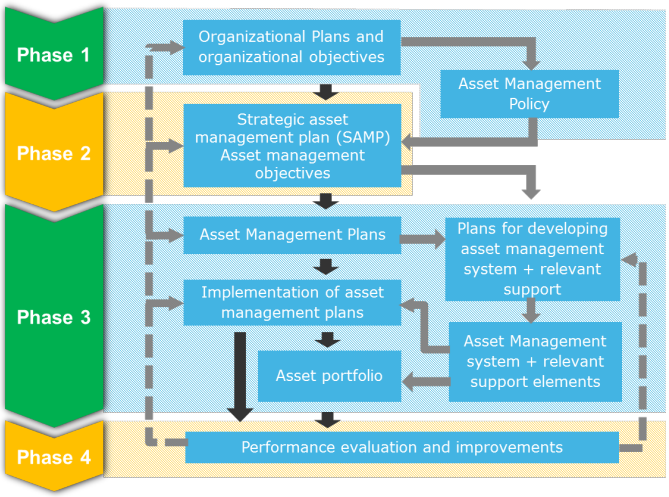

Fig. 2. Typical Four-Phase Approach for Asset Management System Implementation

Phase 1 is to have an in-depth understanding of the organizational objectives and goals for meeting both the internal and external requirements. Demand growth, failure behaviour and other major trends and drivers impacting the power utility with regard to reliability, financial, safety, social, political, legal, and regulatory perspective are the most common external considerations.

Phase 2 is the scoping of the Asset Management System. In this phase, the power utility needs to develop Asset Management objectives and a Strategic Asset Management Plan (SAMP) which are in alignment with organizational objectives. The SAMP is developed in consideration of expectations and needs from all stakeholders, and includes business values and Key Performance Indicators (KPIs); decision making processes and criteria; boundaries of the Asset Management System with scope; and plans and programs to achieve the Asset Management System objectives.

Phase 3 is the resource planning and implementation phase, which is dedicated to the actual implementation of the Asset Management System including the required resources. This involves the development of processes and procedures, development of the right technical and IT tools and systems, and competence building, and awareness & communication on a regular basis.

The technical scope of Asset Management needs to be aligned with the asset life cycle. In particular, different Asset Management practices should address the following four different stages of life span of the assets: - specification and design, commissioning, maintenance and operation, and retiring.

According to Kristian Steenstrup, VP and Gartner Fellow, Energy and Utilities, "There are many strategies to improve reliability. Rather than thinking of them as conflicting or contradictory, develop a road map that matches the best tool to the characteristics of specific assets."

Technical Asset Management is therefore focusing on complex assets, where maintenance and analytics are used to support the reliable operation of the asset and to extend its useful life.

Technical Asset Management methodologies in each stage of the life span of the asset are shown in the Figure 3. The methodologies have to be selected to manage the asset in each stage properly in order to reduce the risk, achieving the real advantages and benefits of the Asset Management System.

Fig. 3. Technical Asset Management Methodologies in Different Stages of Asset Life

Phase 4 is the evaluation and improvement phase as the Asset Management System should be continuously evaluated for possible improvements and corrections to be in alignment with inherent objectives. In this respect, systematic measurement of performance with quantitative and qualitative indices can contribute to the Asset Management System improvement with SMART targets for a specific process or the system.

However, technical and financial constraints of the energy, power and transportation sectors usually hinder Asset Management System realization as planned. In order to overcome such constraints and to plan the Asset Management System in a tailor-made manner for short/long-term goals, a technical gap analysis can be carried out to understand the gap between current practices with technical competence and required scenario's, prioritizing required technologies, tools or competences in an appropriate order.

This technical gap analysis not only enables the energy, power and transportation sectors in assessing their current practice, but can also be used to list and prioritize the technologies and methodologies to which the energy, power and transportation sectors have to pay attention to within their objectives and resource boundary in order to plan for the resourcing of required tools on a short or long-term basis. Asset Management supporting Information Technology (IT) tools therefore play an important role to support the technical performance of the Asset Management System in order to maintain, control, and analyse the information and its trend over the time, understanding of assets and their risks throughout their lifecycle. [5]

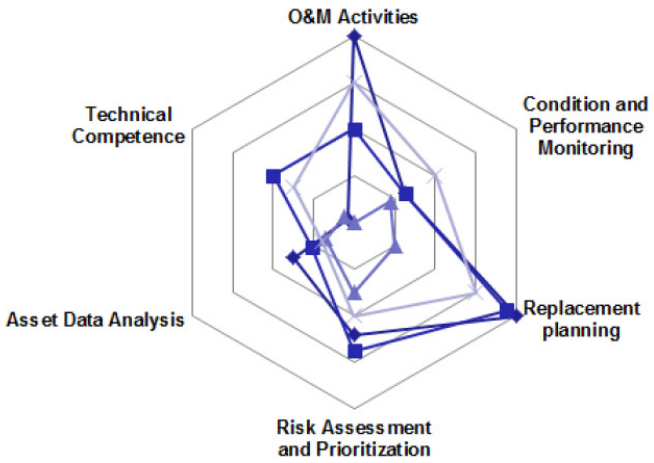

Fig. 4. Example of a Technical Gap analysis

Since sound decisions can be highly dependent on having a high quality of information, support by efficient IT tools for data acquisition and analysis is therefore critical. In this sense, some considerations of IT tools are

1. *Scalability*: IT tools should accommodate all assets the power utility likes to include for monitoring and maintenance;

2. *Lifecycle Coverage*: IT tools should cover all available information and its trend over the lifecycle of the asset;

3. *Compatibility*: When energy, power and transportation sectors decide to adapt new condition assessment or monitoring software solution, IT tools should communicate core condition information on assets to one another; and

4. *Flexibility*: IT tools should support any specific methods and information as a template in which the energy, power and transportation sectors like to add or remove at any time.

In recent years, more and more energy, power and transportation sectors are considering to utilize on-line monitoring devices to extract meaningful dynamic condition parameters such as Partial Discharge, Tangent Delta, or Dissolved Gas Analysis for their power assets and other parameters such as vibration, temperature, corrosion, etc. for other critical assets.

4. Asset Management Decision Support Modeling Using Health Indexing

With the rapid growth of demand and the maturing electricity sectors in Asia, energy, power and transportation sectors are facing many challenges in managing their power assets, such as increasing demands from stakeholders with regard to safety, reliability, environmental impact and financial results, aging assets with increased risks of failure, and, as a result, a decreased level of reliability and (possibly) safety, etc. In planning maintenance and replacement of the vast number of growing assets, asset managers of these energy, power and transportation sectors need to identify which assets require attention, and what is the best action to take at what time. The choice becomes all the more complex as each asset type has different failure modes, and each failure may have different ways to influence the network. An ability to estimate the expected time to failure of assets will help the energy, power and transportation sectors make the optimal maintenance and replacement programs.

We will describe a Health Index model, which has been adopted by several energy, power and transportation sectors and enables their asset managers to oversee the health of all installed assets, recognizing the required additional maintenance or replacement need per asset, and representing the results as a function of time. [5, 6,7, 8]

The model combines Health Indexing and Risk Analysis, thereby providing full decision support on intervention actions to manage the power asset. The Health Index is a single indicator that represents the condition of an asset in relation to its specified performance and lifetime. The Health Index Tool is a dashboard for the asset manager and provides condensed information on the status of all relevant assets.

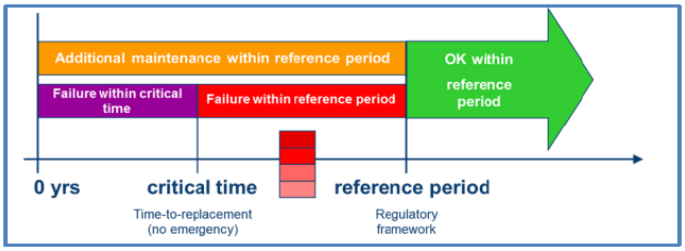

Fig. 5. Health Index Classification Scheme

The Health Indexing Methodology developed by DNV GL assesses the Health Index as accurately as the available data allow, and presents the results in a clear way, enabling the user to interpret the results in a blink of an eye. A simple colour scheme has been selected to represent asset health categories, each colour directly representing the required replacement or required additional maintenance need and urgency. A reference period is defined by the user, as an analysis horizon. Further to this, a critical time period is used to distinguish critical replacements from regular replacements. The reference period may be tuned to the regulator review period, or to any other relevant timeframe, and is typically 10 to 15 years. The critical time is set to the time required for a "standard" replacement plan, typically 1 to 3 years. These timeframes are defined as health classes as indicated in Figure 5. These classes are characterized by the colours green, orange, red and purple, which represent "good condition", "additional maintenance required", "replacement within reference period" and "immediate replacement" respectively.

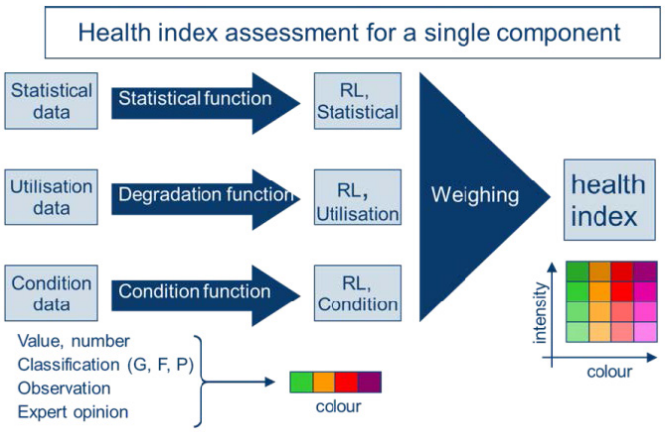

Fig. 6. Health Index Concept Using Three Types of Assessment Functions

The core of the Health Index Model is formed by the assessment functions that estimate the remaining life of the asset from available data. This estimation is based on whatever information is available, be it asset type, failure data, age, utilization data, maintenance and condition data. The most direct way of assessing the remaining life is direct condition data. However, often sufficient data are not available. Under such a situation, alternatives are built in, based on statistical information or operational (utilisation) information. In other words, if the remaining life cannot be assessed directly, the model produces an estimation based on statistical expectations, or on expected degradation due to stress.

As a result, three different types of assessment functions are used as shown graphically in Figure 6, i.e.:

- the statistical remaining life function;

- the degradation (utilisation) remaining life function; and

- the condition remaining life function.

Each of the above assessment functions estimates the most likely remaining life of the asset under study.

Energy, power and transportation sectors may also use a risk-based Asset Management System to support decision making in managing the power assets. To run a risk-based Asset Management model, there is a need to estimate the risks the assets are facing. Ideally, the risk of all assets shall be estimated individually, enabling a prioritization of all assets requiring attention.

In order to apply the Health Index model to risk-based decision support, the model is extended to include a Risk Index. The Health Index, estimating the remaining life of assets based on failure probability, is combined with the assets criticality or failure impact, thereby opening the option to plot all assets in a risk matrix, tuned to the specific power utility's core business values and circumstances.

To match best practice Asset Management processes, this risk matrix can be defined for the typical most relevant business values and KPIs such as reliability (frequency and duration of service disruptions), safety (number of accidents / injured persons) and financial (revenue lost/money spent). For example, the reliability impact of failure may be estimated by the load and number of customers connected to the individual assets and the system topography, like redundancy applications. The safety impact may be analysed using the probability of fire and explosion per asset type, in combination with the asset's housing, type of substation and distance to the public areas.

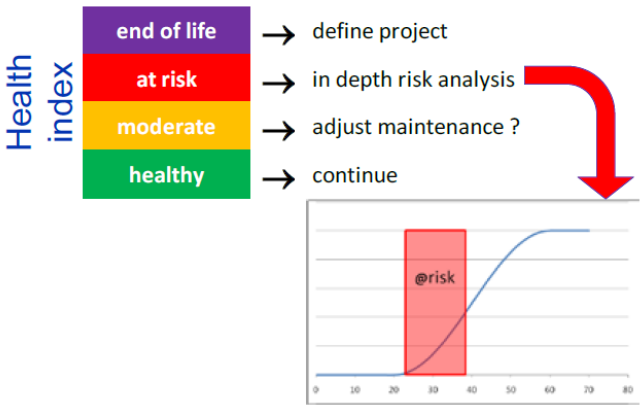

Fig. 7. Focused In-Depth Risk Analysis

With the risk matrix in place, and the health and criticality indices available, it is possible to plot all assets into the risk matrix and identify the assets that require urgent and critical attention. Assets that require attention may then be prioritized in terms of both on safety and reliability.

Once the assets with the highest risks are identified, individual in-depth analysis can be performed on selected assets, if required. For assets in the purple category, replacement is required as soon as possible. In case of a high level of uncertainty, the asset may require further detailed analysis before a replacement decision is made; whereas, assets with a low level of uncertainty may be replaced with minor or without risk analysis.

For assets in the red category, a longer timeframe is available for more detailed studies and condition assessment. This enables focused in depth analysis if needed to better substantiate a decision. Figure 7 gives a graphical representation of this principle.

The Health and Risk Indexing approach is part of the Asset Management decision cycle, an example of which is shown in Figure 8.

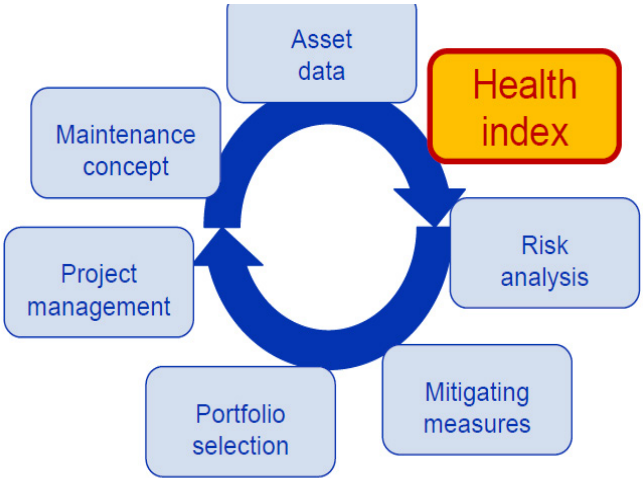

Fig. 8. Health Indexing as part of the Asset Management Cycle

Health and Risk Indexing processes data to produce information to decide what measures are required with what urgency and priority. The way in which it is embedded in the Asset Management process differs from user to user, but often it consists

of a two-step approach. The first step, as indicated in Figure 7, divides the assets in one of four categories based on the remaining life and the additional activities required to survive the reference time period. The assets that score excellent or very poor need no detailed further analysis as they will be either continued, or replaced on short notice. For the other assets, before deciding on the basis of lifetime (equivalent to failure probability), the impact of failure is assessed, yielding a risk ranking.

Starting with the highest risk, solutions can then be generated. Each solution is again ranked on the basis of Solution Added Value. Finally, the asset manager will decide on a prioritization in the portfolio of solutions. The highest risk does not necessarily lead to the highest priority as this also depends on the cost and risk reduction potential of the solution.

After prioritization of the solutions, the asset manager will be able to select and plan the actions. For this he will use the ranking obtained. However, the decision will of course be influenced by the budget available and by the (un)acceptability of the risks assessed. Some actions are mandatory for meeting the power utility's directives and policies, and others may be highly relevant but not mandatory for the short term.

This will ultimately develop asset management strategy and policy leading towards reliability-centred maintenance for critical assets.

5. Asset Management System Based on Reliability–Centered Maintenance

Reliability-Centered Maintenance (RCM) is a structured process to determine the maintenance strategies. Various maintenance strategies have been evolved over time, i.e. Reactive maintenance (RM), Preventive maintenance (PM), Predictive maintenance (PdM). RM and PM approaches have been implemented in the earlier stage of maintenance strategies. However, these strategies were recognized as ineffective methodologies in 1960s because they do not capture the asset condition and the impacts and risks of the failures. Soon after, RCM has been first introduced by Nowlan in 1978 and applied to the Department of Defense of the US. Thanks to its effectiveness, RCM has been applied widely to other industries.

An example of RCM hierarchy is shown below:

Table 1: An example of RCM Approach

Reactive Element Applications	Preventive Element Applications	Predictive Element Applications
Small parts and equipment	Equipment subject to wear	Equipment with random failure patterns
Non-critical equipment	Consumable equipment	Critical equipment
Equipment unlikely to fail	Equipment with known failure patterns	Equipment not subject to wear
Redundant systems	Manufacture recommendations	Systems which failure may be included by incorrect preventive maintenance

In terms of methodologies, the three maintenance strategies, i.e. RM, PM and PdM, are broken down into four maintenance methodologies, i.e. Run-to-Fail maintenance, Time-based maintenance, Condition-based maintenance, and Risk-based maintenance. Figure 9 below shows the relationship between the maintenance strategies and methodologies.

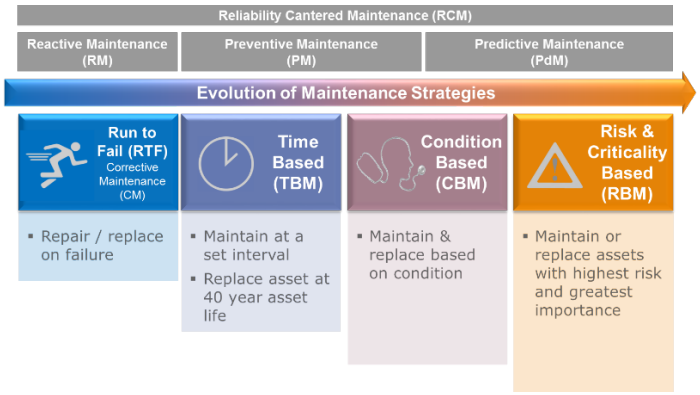

Fig. 9. Consistent and Technically Sound Process towards a Reliability-Centred Asset Management System

The condition-based approach:

The condition based approach bases on the understanding of asset's condition i.e. health index of the asset, which indicate how good or bad the condition of asset is. It also indicates the remaining life time of the asset, the likelihood of the asset's failure. The health index system enables asset managers to oversee the health of all installed assets, recognize the required additional maintenance or replacements per location and plotted in time. An example of asset health index result is shown in Figure 10 below.

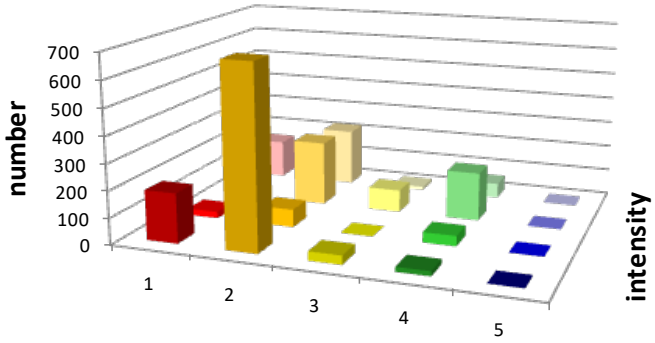

Fig. 10. Example of health index results of a fleet of assets

A simple color scheme presents the results indicating the required replacement or required additional maintenance attention. A reference period is agreed with the asset managers and usually a critical planning time period is defined to distinguish critical replacements from regular replacements. Based on these timeframes we can now define health classes as indicated in **Error! Reference source not found.**. The classes are characterized by the colors blue, green, yellow, orange, and red.

Risk-based approach:

Once the Health Index has been developed and determined for an asset, that asset can also be graded according to its Criticality of failing. Its Criticality can be determined with reference to all relevant asset management business values, like safety, reliability etc. The level of Criticality will be determined by the asset type, location, local grid situation etc. Once the Criticality and the Health Index are ready, an asset management risk matrix can be developed with on one axis the Criticality and on the other axis the Health Index. The Health Index gives an indication of remaining

life, but it can also be seen as an indicator of probability of failure. Criticality indicates the impact of the failure. Combining both will show the risk level of each asset in the risk matrix. An example of a risk matrix is shown in Figure 11.

Remaining Life	Catastrophic	Severe	Moderate	Small	Negligible
≤ 1 year	Unacceptable	Unacceptable	High	High	Medium
2-3 years	Unacceptable	High	High	Medium	Low
3-7 years	High	High	Medium	Low	Low
7-15 years	High	Medium	Low	Low	Negligible
> 15 years	Medium	Low	Low	Negligible	Negligible

Fig. 11. Example of a risk matrix specifically for the health index

As a general observation, the following trend has started to emerge [9, 10, 11, 12]:

- Moving from time-based to condition-based maintenance and further from condition-based to risk-based maintenance for most critical assets - Using Fukushima Nuclear Power Station as an example, an incident in a nuclear power station can have dire consequences to the environment, human life, properties and the livelihood of the population in vicinity. The reliability-centred design and maintenance based on multiple KPIs will be the most appropriate choice in maintaining such an asset;
- Moving from risk-based Asset Management to Reliability-Centred Asset-Management, whereby
  - Near-real-time information is captured and analysed; and
  - Real-time failure prediction function plays a key role in decision making support.
- Moving from Big Data to Smart Data
  - With a more comprehensive data considered in the Smarter-Asset-Management, the Big Data will be the next challenge in Asset Management;
  - Smart Data is the next level of dealing with Big Data in a smarter and more effective way; and
  - More advanced data analytics techniques will be adopted such as machine learning/artificial intelligence approach.
  - Integrated Energy Asset Management System - merging Asset Management System (AMS) with Energy Management System (EMS): - The merger between the EMS and AMS will help address the Big Data more effectively.

Energy, power and transportation sectors are moving in the data analytics era. This is the result of several global forces - one being the proliferation of less expensive electronic monitoring technologies and the speed and availability of communications systems. Furthermore, more and more energy, power and transportation sectors want to embark on developing the 'Smartest' asset systems possible. As a result, an unprecedented amount of raw data is being collected by energy, power and transportation sectors each day.

On the other hand, criticality and health of each of the assets are influenced by the asset operational environment. A systematic approach to assess the criticality and health will deliver a practical approach to risk assessment across the entire asset base.

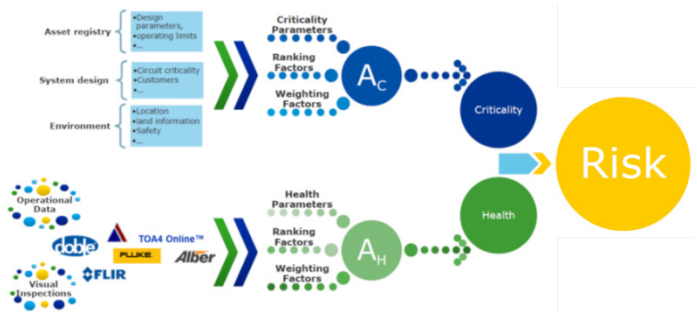

Fig. 12. Consistent and Technically Sound Process towards a Reliability-Centred Asset Management System

Using the ranking factors and weighting factors, we are able to tailor the assessment to specific business priorities and objectives in achieving reliability-centred Asset Management strategy and policies.

As criticality and health are two essential factors in assessing asset risks, the trend mentioned in the start of this section enables the integration of Asset Management Systems with other IT systems, such as Geospatial Systems, distribution management systems, energy management systems, signalling and control systems, etc. will help these systems in:

- improving the accuracy in identifying critical contingencies by making use of more accurate component's criticality and utilization information;
- improving the performance by filtering out low failure probability;
- better big-data management by using a single database;
- improving the effectiveness by avoiding redundancy of assessments and processes; and
- optimising decision making processes based on a more comprehensive assessment considering both global and local aspects

6. Conclusion

The energy, power and transportation sectors need to move from time-based to Predictive Maintenance / Condition Based Maintenance of their asset and ultimately towards Reliability-Centred Asset Management strategy and policies. This will involve:

- Apply Reliability-Centred Maintenance philosophy in selection of effective maintenance tasks;
- Apply Reliability-Centred Maintenance philosophy to determine what operational and conditional data is required;
- Reliability-centred maintenance provides a platform for developing an effective Reliability-Centred Asset Management strategy; and
- Lastly, a platform with appropriate software applications to ensure a sustainable Reliability-Centred Asset Management strategy.

To achieve this state of managing the assets, particularly the critical asset, cost-effectively with minimum risks, energy, power and transportation sectors need to embark on a journey to develop resources and capability within the organisation to manage such changes. External helps from experts with in-depth knowledge, vast experience and up-to-date competency will definitely be necessary to leverage on the evolving trends in the ICT infrastructures.

Optimal Scheme
Dissimilar fading
Rician-K Factor

ABSTRACT

Application-oriented Wireless Sensor Networks (WSNs) promises to be one of the most useful technologies of this century. However, secure communication between nodes in WSNs is still an unresolved issue. In this context, we propose two protocols (i.e. Optimal Secure Path (OSP) and Sub-optimal Secure Path (SSP)) to minimize the outage probability of secrecy capacity in the presence of multiple eavesdroppers. We consider dissimilar fading at the main and wiretap link and provide detailed evaluation of the impact of Nakagami-m and Rician-K factors on the secrecy performance of WSNs. Extensive simulations are performed to validate our findings. Although the optimal scheme ensures more security, yet the sub-optimal scheme proves to be a more practical approach to secure wireless links.

1 Introduction

Wireless sensor network (WSN) consist of a collection of sensors nodes which monitor the specific elements from the surrounding and eventually transmit this information to other nodes or sink. In addition to different types of sensors, these nodes are also equipped with a small battery and a low power transceiver. Sensors periodically sense the environment and collects measurements. Depending on the application, these measurements are transmitted to one or multiple nodes for processing. Therefore, WSNs are found to be useful in multiple areas of life. In military, these networks are found to be useful for surveillance and monitoring of hostile territories [1]. Similarly, WSNs are also used to monitor the growth of forests and vegetation. They also evaluate temperature, humidity and pressure of these areas to examine the gradual variations in environment. In health care, these sensor networks monitor the condition of patient and in case of any abnormalities, these networks immediately alert the concerned authorities [1, 2].

Despite the advancements in WSNs over the past decade, security at Physical Layer of WSNs has not been sufficiently explored. Since sensor nodes are low powered and energy limited devices, therefore, security techniques that consume large amount of power are not feasible for WSNs [3, 4]. In addition to this, provisioning of security under minimal hardware complexity is also a daunting task. In this backdrop, research community is being gravitated towards Physical Layer Security (PLS) techniques. PLS exploits the physical characteristics of the wireless channel such as random fading and thermal noise, for securing the wireless link between two legitimate users [5]. In this regard, many existing works suggest that WSNs experience multiple type of fading (i.e. Rayleigh, Rician and Nakagami-*m*). Rayleigh fading channel has been used in literature to model the fading characteristics of the wireless channel. In [6], Cheng et.al concluded that in mobile to mobile communication, the line of sight (LOS) component gradually diminishes and the received signal amplitudes follow Rayleigh distribution. The empirical studies conducted in [6] also suggest that in 5.9 GHz range when the distance between transmitted and received node is less than 5 m the fading characteristics of channel follow Rician distribution. The authors in [7] proposed as a result of extensive simulations that Rayleigh fading is most suitable in congested city roads. In [8], the authors describe that Nakagami-*m* being a versatile model is suitable for various channel conditions. In case when nodes are close to each other it converges to Rician fading. Similarly, when nodes are far from each other it approaches Rayleigh fading channel.

Recently, a few studies have considered PLS in wireless networks. Saad et.al in [9] utilized tree based formulation of network to provide secure communication in uplink wireless networks. A distributed tree formation algorithm was proposed which converged

*Furqan Jameel, COMSATS Institute of Information Technology, 44000, Islamabad, Pakistan, Email: furqanjamil01@yahoo.com

https://dx.doi.org/10.25046/aj020348

to equilibrium state. The authors in [9] also evaluated secrecy per node and path qualification probability based on tree formation algorithm. In [10], Pinto et.al studied the PLS of a Poisson distributed network. The authors quantified the isolation probability and secrecy capacity of all the neighbors of a node. It was found that there exist innate connection between spatial position of eavesdropper and secrecy capacity. Similarly, the authors in [11] derived secrecy outage expression for wireless sensor networks under correlated Weibull fading. Using graph theory, Zhang et.al in [12] provided in-depth analysis of secrecy, rate and network connectivity. The authors illustrated that there exist a trade-off between secrecy capacity and network connectivity. Finally, in [13], authors provided a resource allocation scheme under the constraints of PLS. The paper applied Kuhn-Munkres (KM) algorithm on weighted bipartite graphs to gain significant improvements in secrecy capacity.

It may be highlighted that above mentioned works considered similar fading at the main and wiretap link. However, due to random attributes of fading channel (considering mobility of objects such as vehicles and human beings in the environment), two sensor nodes may experience completely different kind of fading. Therefore, the assumption of similar channel fading is not true for all practical scenarios. Moreover, these studies assumed that the Channel State Information (CSI) of eavesdropper is available at the transmitter. Since a passive eavesdropper does not frequently communicate, therefore, it is very difficult to obtain the CSI of all the eavesdroppers in the network. In view of foregoing arguments, this paper provides a comprehensive analysis of outage probability of secrecy capacity under dissimilar fading at the main and eavesdropper link. Moreover, intermediate trusted relays have been used to provide Optimal Secure Path (when CSI of receiver and eavesdropper is available) and Sub-optimal Secure Path (when CSI of receiver is available only). Random Selection (RS) of nodes has been used as a benchmark scheme to prove the significance of our proposed schemes.

The remainder of this paper is organized as follows. Sec. II provides details of system model; Sec. III derives the outage probability when links are subjected to Rician and Nakagami-m fading. In Sec. IV detailed discussion on simulation results is presented. Finally, Sec. V, provides concluding remarks.

2 System Model

Let us consider a group of $N \times M$ sensor nodes deployed in a two dimensional square area as shown in Figure 1. It is assumed that all the sensor nodes are equipped with communication and sensing capability. Also, all network entities are assumed to have single antenna which experience statistically independent flat fading. The nodes share information from one end of the network to another end using the intermediate sensor nodes. This scenario can occur quite often in area where sensor nodes are deployed far away from each other and direct communication link is not available between source and destination nodes. Some common examples are forest fire detection system and industrial WSNs. Let us now consider that a source node wants to send a message to destination node. In the absence of a direct link between source and destination, the source node delivers the confidential message to nodes present in the very next hop i.e. receiving node. The received signal with power P at the next hop from can be expressed as

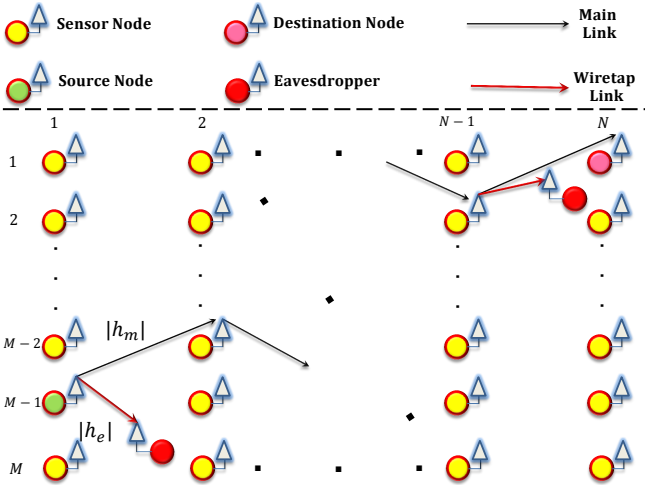

Figure 1. System Model.

$$y_m(t) = \sqrt{P} h_m s(t) + n_s, \tag{1}$$

where s is the transmitted signal, h_m represents the main channel between source node and the receiving node. Additionally, n_s represents the zero mean additive white Gaussian noise (AWGN) with variance N_0 due to the electronics at receiver. Then the instantaneous signal-to-noise ratio (SNR) for the received signal is written as $x_m = \frac{|h_m|^2 P}{N_0}$.

Due to the broadcast nature of wireless signal, the eavesdropper also receives the transmitted signal. It is assumed that all the eavesdroppers in the network are passive and do not participate in the network to jam or interfere the transmission of messages. Moreover, these eavesdroppers do not collude and work independently. In view of above, the received signal at a single eavesdropper (Eve) is written as

$$y_e(t) = \sqrt{P} h_e s(t) + n_e, \tag{2}$$

where n_e is the AWGN at eavesdropper, h_e represents the wiretap channel between Tx and Eve. The instantaneous signal-to-noise ratio (SNR) at eavesdropper for the received signal is given as $x_e = \frac{|h_e|^2 P}{N_0}$.

The channel capacity for both the main link and wiretap link can be written as $C_m = \log_2(1 + x_m)$ and $C_e = \log_2(1 + x_e)$, respectively. According to Wyner, the positive difference between main link capacity and

wiretap link capacity is called the secrecy capacity and expressed as [14]

$$C_{sec} = [C_m - C_e]^+. \tag{3}$$

3 Outage Probability Analysis

Following section derives a closed-form outage probability expression under the consideration of dissimilar fading at main and wiretap link. To be specific, we consider two different scenarios: (1) When Eavesdropper link experiences arbitrary fading and main link experiences Rayleigh fading; and (2) when main link experiences arbitrary fading and wiretap link experiences Rayleigh fading. In this regard, an outage event occurs when C_{sec} falls below some target rate $R_s > 0$. Hence, the probability of outage is given as

$$P_{out} = \Pr\{C_{sec} < R_s\}\,. \tag{4}$$

The outage probability can also be re-written as

$$P_{out} = 1 - P_{cov}, \tag{5}$$

where $P_{cov} = \Pr\{C_{sec} > R_s\}$ is the coverage probability, which can be expressed as

$$P_{cov} = \Pr\left[\log_2\left(\frac{1+x_m}{1+x_e}\right) > R_s\right]. \tag{6}$$

$$P_{cov} = \Pr\left(x_m > 2^{R_s}(1+x_e) - 1\right). \tag{7}$$

Using (7) we can define probability limits as

$$P_{cov} = \int_0^\infty \int_{2^{R_s}(1+x_e)-1}^\infty f_{X_m,X_e}(x_m, x_e)\, dx_m dx_e, \tag{8}$$

where $f_{X_m,X_e}(x_m, x_e)$ is the joint PDF of x_m and x_e. By exploiting the independence of x_m,x_e, we get

$$P_{cov} = \int_0^\infty \left[1 - F_{X_m}\left(2^{R_s}(1+x_e) - 1\right)\right] . f_{X_e}(x_e)\, dx_e, \tag{9}$$

where F_{X_m} is the Cumulative Distribution Function (CDF) of x_m.

3.1 Random Fading at Eavesdropper

If the main link is subjected to Rayleigh fading then F_{X_m} is written as

$$F_{X_m}(x_m) = 1 - \exp\left(-\frac{x_m}{\bar{x}_m}\right), \tag{10}$$

where $\bar{x}_m$ is the average SNR of the main link. After simplification we obtain above equation as

$$P_{cov} = \exp\left(-\frac{2^{R_s}-1}{\bar{x}_m}\right) \int_0^\infty f_{X_e}(x_e) \exp\left(-\frac{2^{R_s} x_e}{\bar{x}_m}\right) dx_e\,. \tag{11}$$

According to the definition of Moment Generating Function (MGF), the MGF of a positive random variable β is written as

$$\mathcal{M}(r) = \int_0^\infty f_\beta(t) \exp(rt)\, dt, \tag{12}$$

where f_β is the PDF of β.

3.1.1 Rician Fading

Let us now consider the case when eavesdropper experiences Rician fading then the CDF of instantaneous SNR can be written as

$$F_{X_e}(x_e) = 1 - Q\left(\sqrt{2K}, \sqrt{2\frac{1+K}{\bar{x}_e} x_e}\right), \tag{13}$$

where K is the ratio of power of LOS component and the power of multipath components and $Q(.,.)$ is the Marcum - Q function. The MGF is given by [15]

$$\mathcal{M}_{Rician}(r) = \left(\frac{1+K}{1+K-r\bar{x}_e}\right) \exp\left(\frac{rK\,\bar{x}_e}{1+K-r\bar{x}_e}\right), \tag{14}$$

then the outage probability is given as

$$P_{out} = 1 - \exp\left(-\frac{2^{R_s}-1}{\bar{x}_m}\right) \mathcal{M}_{Rician}(r). \tag{15}$$

3.1.2 Nakagami-m Fading

When the wiretap link undergoes Nakagami-m fading, then the CDF of instantaneous SNR is given as

$$F_{X_e}(x_e) = \frac{\gamma\left(m, \frac{m x_e}{\bar{x}_e}\right)}{\Gamma(m)}, \tag{16}$$

where m is the Nakagami Shape factor which represents the number of multipath clusters in the environment and $\gamma(.,.)$ and $\Gamma(.)$ are the incomplete and complete Gamma function respectively.

$$\mathcal{M}_{Nakagami}(r) = \frac{1}{\left(1 - \frac{r\bar{x}_e}{m}\right)^m}. \tag{17}$$

Hence, the expression of outage probability, when eavesdropper experiences Nakagami-m, is obtained as

$$P_{out} = 1 - \exp\left(-\frac{2^{R_s}-1}{\bar{x}_m}\right) \mathcal{M}_{Nakagami}(r). \tag{18}$$

Also note that for $K = 1$ or $m = 1$, (18) resolves to well known case of Rayleigh fading.

3.2 Random Fading at Transmitter

Now we consider the case when main link experiences random fading and the wiretap link undergoes Rayleigh fading. To evaluate this condition the above mentioned expression of outage probability can be re-written as

$$P_{cov} = \Pr\left(x_e < \frac{1+x_m}{2^{R_s}} - 1\right). \tag{19}$$

After some mathematical manipulations, above expression can be written as

$$P_{cov} = \int_{2^{R_s}-1}^{\infty} F_{X_e}\left(\frac{(1+x_m)}{2^{R_s}} - 1\right) . f_{X_m}(x_m)\, dx_m$$

$$P_{cov} = 1 - F_{X_m}\left(2^{R_s}-1\right) - \exp\left(-\frac{1-2^{R_s}}{\overline{x}_e}\right)$$

$$\times \int_{2^{R_s}-1}^{\infty} f_{X_m}(x_m)\exp\left(-\frac{x_m}{2^{R_s}\overline{x}_e}\right) dx_m. \qquad (20)$$

It is to be noted that the incomplete MGF of a random variable β is given as

$$\mathcal{M}(r,\omega) = \int_{\omega}^{\infty} f_{\beta}(t)\exp(rt)\, dt \qquad (21)$$

where f_β is the PDF of β.

3.2.1 Rician Fading

Using the above expression of CDF of Rician fading, we can obtain the incomplete MGF of x_m as [15]

$$\mathcal{M}_{Rician}(r,\omega) = \left(\frac{1+K}{1+K-r\overline{x}_m}\right)\exp\left(\frac{sK\overline{x}_m}{1+K-r\overline{x}_m}\right)$$

$$\times Q\left(\sqrt{2\frac{(1+K)K}{1+K-r\overline{x}_m}}, \sqrt{2\left(\frac{1+K}{\overline{x}_m} - r\right)\omega}\right). \qquad (22)$$

Now P_{out} is given as

$$P_{out} = F_{X_m}\left(2^{R_s}-1\right) + \exp\left(-\frac{1-2^{R_s}}{\overline{x}_e}\right)\mathcal{M}_{Rician}(r,\omega)\,. \qquad (23)$$

3.2.2 Nakagami-m Fading

Similarly, Using the CDF of Nakagami-m fading,the incomplete MGF of x_m is given as [15]

$$\mathcal{M}_{Nakagami}(r,\omega) = \frac{\Gamma\left(m, \left(\frac{m}{\overline{x}_m} - r\right)\omega\right)}{\Gamma(m)\left(1-\frac{r\overline{x}_m}{m}\right)^m}. \qquad (24)$$

where $\Gamma(.,.)$ is the complementary incomplete Gamma function. Outage probability now yields

$$P_{out} = F_{X_m}\left(2^{R_s}-1\right) + \exp\left(-\frac{1-2^{R_s}}{\overline{x}_e}\right)\mathcal{M}_{Nakagami}(r,\omega)\,. \qquad (25)$$

4 Secure Path Algorithms

This section proposes two algorithms namely, Optimal Secure Path (OSP) and Sub-optimal Secure Path (SSP) as shown in Figure 2 and Figure 3, respectively. The objective of both algorithms is to find the most secure path from source to destination under specified constraints. However, before discussing these algorithms individually, it is pertinent to highlight that following assumptions are made regarding the characteristics of sensor devices:

(1) Each sensor node is given a unique ID.
(2) Each sensor node is able to locate its position using techniques like trilateration and multilateration or with the help of GPS.
(3) Each sensor node has the ability to acquire the position of nodes that fall under its communication range.
(4) Eavesdroppers are uniformly distributed in the network.

4.1 OSP

In the literature of PLS, a common assumption is that the CSI of eavesdropper is available at the transmitter [16, 17]. In this case, transmitting node can decide by calculating the secrecy capacity of each node in the next hop. After performing calculations, the transmitter can select a node which ensures maximum secrecy capacity. The objective function for OSP can be written as

$$\arg\max_{i\in M} C_{sec} \qquad (26)$$
$$\textbf{s.t.}\ R_s > 0$$

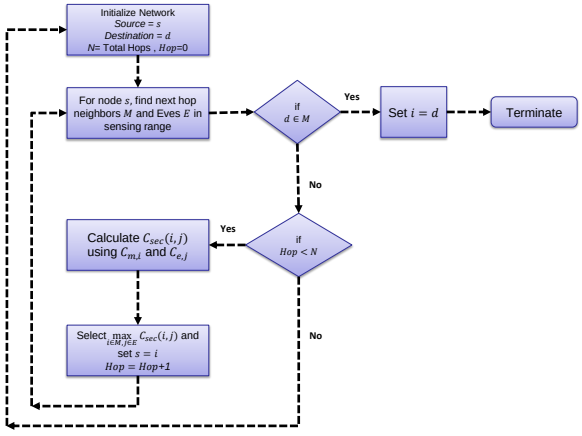

Figure 2. Optimal Secure Path (OSP).

4.2 SSP

In contrast, it is more realistic approach to assume non-availability of eavesdroppers' CSI. It is due to the fact that CSI of passive eavesdroppers' is difficult to obtain. Moreover, the CSI obtained during one time slot may become outdated after a while, which may lead to imperfect estimation. In this context, it is feasible to select a path which maximizes the capacity of main link. Hence, the objective function for SSP becomes

$$\arg\max_{i\in M} C_s \qquad (27)$$
$$\textbf{s.t.}\ R_s > 0$$

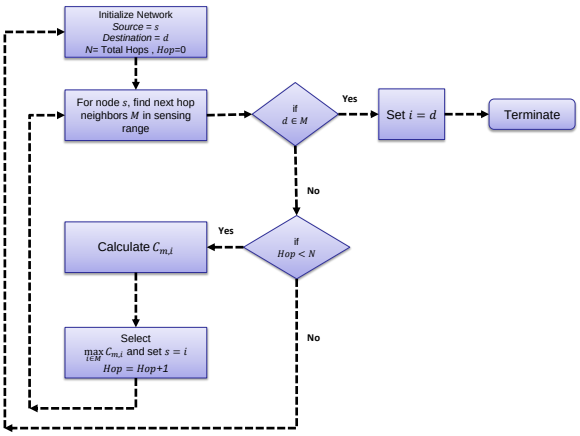

Figure 3. Sub-optimal Secure Path (SSP).

It is worthwhile to note that our proposed schemes can easily be reduced to the case when partial information of eavesdroppers is available, i.e. the CSI of some of the eavesdroppers is available. This scenario can occur in WSNs where some of the eavesdroppers are legitimate nodes of the network, while others are not part of the networks.

5 Results and Discussion

This section provides comparison of results obtained from the simulation of OSP and SSP algorithms when main/ wiretap link undergo random fading as discussed in Section 3. For generation of simulation results, we have considered sparse network and dense network as shown in Figure 4 and Figure 5, respectively. Simulation parameters are provided in Table 1.

Parameter	Value
Simulation Area	1000×1000
Sensor Nodes (Sparse Network)	25
Sensor Nodes (Dense Network)	361
No. of Eavesdroppers	10
Rayleigh Channel Variance	1
Rician Channel Variance	1
Nakagami-m Channel Variance	1
Rician K factor	10
Nakagami-m shape parameter (m)	3
Channel Realizations	10^3
Noise	-50 dB
Target Secrecy Rate (R_s)	1 bit/s/Hz

Table 1. Simulation Parameters

Figure 6 plots the end to end outage probability against the increasing values of transmit power for OSP, SSP and RS schemes for sparse network shown in Figure 4. It can be easily observed from the graphs (a) and (b) that the outage probability reduces with the increase in transmit power. Moreover, it can be seen that OSP out performs SSP and RS in case of both Rician and Nakagami-m fading.

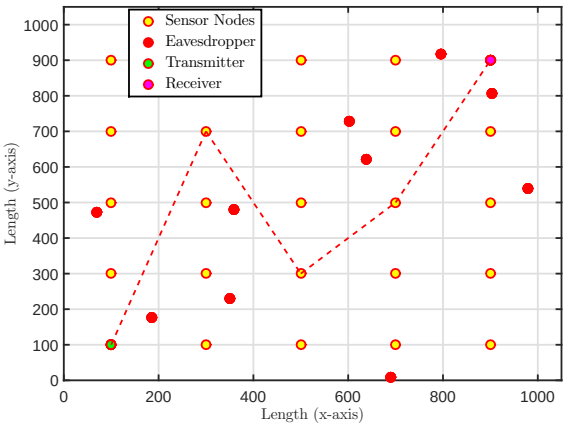

Figure 4. Sparse Network.

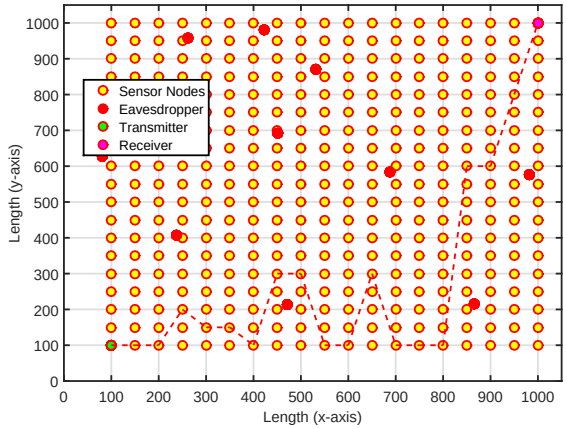

Figure 5. Dense Network.

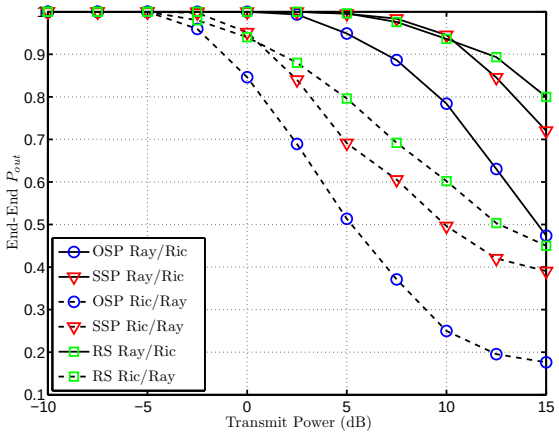
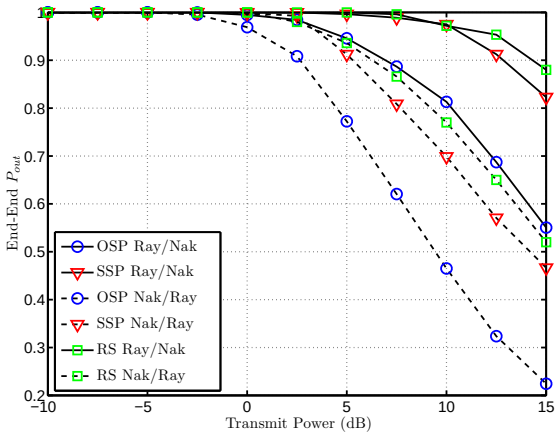
In Figure 6(a) it can be observed that outage performance of Rician/Rayleigh link is better than Rayleigh/Rician link for all schemes. It is due to the fact that in case of Rician/Rayleigh link the main link undergoes Rician fading with $K = 10$. Since $K > 1$ refers to improvement in LOS power over the power of multipath components, therefore the main link experiences less fading in comparison to wiretap link and the outage probability is reduced. Similarly, in Figure 6(b), it is evident from the plot that for a particular value of transmit power, the outage probability of Nakagami-m/Rayleigh link is less than Rayleigh/Nakagami-m link where $m = 3$. It is due to the fact that $m > 1$ corresponds to reduction in fading and therefore reduction in outage probability.

Figure 7 reiterates the observations highlighted in Figure 6 by plotting end to end outage probability as a function of (a) Rician-K factor and (b) Nakagami-m shape parameter for sparse network. In Figure 7(a) it can be seen that the end to end outage probability rapidly decreases with the increase in Rician-K parameter when main/wiretap link undergoes Rician/Rayleigh fading. Conversely, the outage performance deteriorates with the increase in Rician-K parameter when main/wiretap link undergoes Rayleigh/Rician fading.



(a)

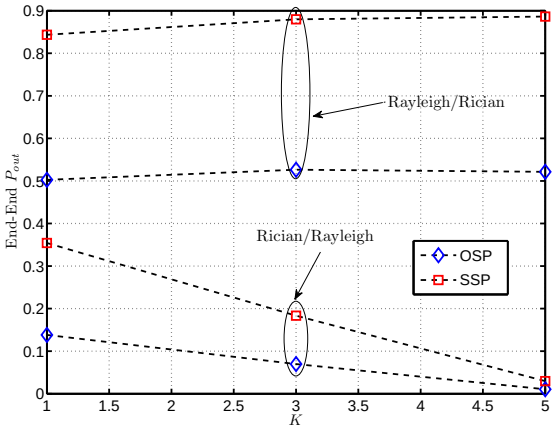


(b)

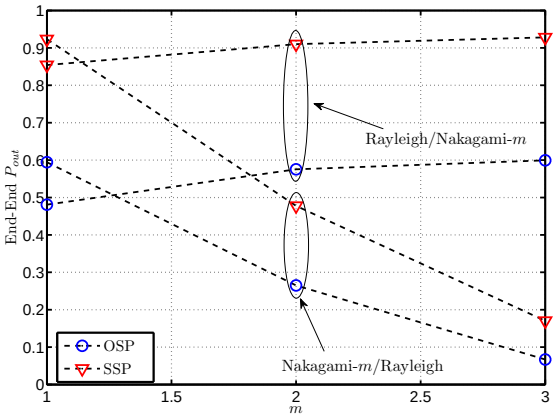
Figure 6. End-End outage probability versus transmit power OSP, SSP and RS (a) Rician (b) Nakagami-m.

The Figure 7(b) shows similar response for Nakagami-m channel. It can easily be observed that for the increasing values of shape parameter m, the Nakagami-m/Rayleigh channel performs better than Rayleigh/Nakagami-m. It is worth noting that for both Rician and Nakagami-m fading, OSP performs better than the SSP. However, if the main link experiences less fading in comparison to the wiretap link then the sub-optimal scheme (i.e. SSP) performs very close to OSP. This fact signifies the importance of using SSP in practical scenarios where legitimate channel is better than eavesdropper's channel.

Figure 8 plots the end to end outage probability against the target secrecy rate R_s for (a) Rician fading (b) Nakagami-m fading for sparse network. It can be seen from the graphs that with the increase in R_s, the outage probability also increases for both OSP and SSP. It is due to the fact that as the target threshold increases, it becomes difficult to maintain secure communication under given channel conditions. This leads to increase in the occurrence of outage events which eventually increases the outage probability. It is can also be observed that in case of Rayleigh/Rician and Rayleigh/Nakagami-m, OSP and SSP converge to 1 with increase in R_s. On the contrary, the curves of OSP and SSP diverge with the increase in R_s for Rician/Rayleigh and Nakagami-m/Rayleigh.



(a)



(b)

Figure 7. End-End outage probability versus (a) Rician-K factor (b) Nakagami-m shape parameter.

Figure 9 shows the end to end outage probability against the increasing values of transmit power for sparse and dense network. It can be seen that the end to end outage probability in case of dense network is better than that of sparse network for same number of eavesdroppers. The advantage obtained by using multiple relays is also evident from the plot. We can see that using multiple relays offers spatial diversity, due to which the end to end outage probability decreases as the network become dense. It can be observed that effect of spatial diversity is more pronounced where main link is better than wiretap link.

6 Conclusion

In this article, we have discussed implications of dissimilar fading on the secrecy performance of WSNs. We derived closed form expression of outage probability for four scenarios i.e. Rayleigh/Rician,

Rician/Rayleigh, Rayleigh/Nakagami-m, Nakagami-m/Rayleigh. We then provided two algorithms i.e. OSP and SSP to enhance link security. A detailed comparison of OSP, SSP and RS was presented with OSP performing better than SSP and RS. However, when CSI of eavesdropper is unavailable to the transmitter, the SSP algorithm is a better and more practical choice. Finally, it was revealed that OSP performs better in dense network due to increased spatial diversity.

Weibull Shape Parameter

ABSTRACT

Simultaneous wireless information and power transfer (SWIPT) has drawn significant research interest in recent years. In this paper, we investigate the information theoretic secrecy of a SWIPT system under Weibull fading channel. To be specific, we analyze the information security in the presence of an energy harvesting and information decoding eavesdropper. All links are subjected to Weibull fading which is more complex than traditional Rayleigh fading. Moreover, we derive closed-form expressions for the probability of strictly positive secrecy capacity and the ergodic secrecy capacity. We evaluate the effect of Weibull shape parameter and power splitting factor on the secrecy performance of SWIPT system. Numerical and simulation results are provided to demonstrate that our findings are instantly applicable on the design of wireless power networks.

1 Introduction

Most of the conventional electrical energy transfer takes palace with the help of conductors between power source and load. However, in case of wireless power transfer (WPT), the transmission of energy from source to load takes place without interconnecting conductors. In other words, this simply means that WPT allows transfer of energy without wires [1]. In WPT, a power source connected to a wireless transmitter conveys the energy wirelessly across an intervening space to once or more wireless receivers. At the receiving end, electromagnetic energy is again converted to electrical current which can be stored and used by the device. Since most wireless devices are powered either through power cables or battery replacement, which limits the scalability, sustainability, and mobility of wireless communications [2]. In practice, wireline charging and battery replacement may be infeasible under some conditions; for instance, it is very difficult to replace the battery of implanted medical devices in human bodies. Besides, wireline charging and battery renewal shortens working period of wireless mobile devices. The WPT technique becomes appealing since it can be used to wirelessly charge the devices in hazardous conditions.

In this context, simultaneous transfer of power and information is emerging as one of the most promising technique to increase the lifetime of wireless devices [2]. However, provisioning of security over a Simultaneous wireless information and power transfer (SWIPT) system has remained a daunting task due to the broadcast nature of wireless networks. Traditional cryptographic techniques are not suitable for SWIPT because they require complex hardware and consume large amounts of energy that are typically not affordable by wireless devices. Moreover, an eavesdropper with unlimited computing power may still decipher these techniques using brute-force attack. In this context, Physical Layer Security (PLS) has emerged as an attractive solution for securing wireless transmissions by exploiting the wireless channel characteristics [3]. The PLS techniques such as artificial noise generation and cooperative relaying are not suitable for day to day wireless devices due to the latters limited energy resources.

Weibull distribution was studied by authors in [4] to understand the effect of small scale fading (SSF) in outdoor environment for 800/900 MHz frequency band. The authors in [5] performed channel measurements for indoor channels and found Weibull distribution to conform closely with measurements for less than 10 dB of fading variations. In [6] the authors found the Weibull model to be a good fit for the SSF in narrow-band channel measurements for wireless body area networks. Authors in [7] and [8]investigated the SSF for 5 and 10-GHz band and proposed to use the Weibull distribution with its parameter β taking values between 1.77 to 3.9 to perfectly match the measurement curves. Authors in [9] measured the wireless channel based on pedestrians movement in a forest environment for 5-GHz band. These measure-

*Furqan Jameel, COMSATS Institute of Information Technology,Islamabad, 44000, Pakistan, Email: furqanjamil01@yahoo.com

https://dx.doi.org/10.25046/aj020349

ments suggested that Weibull distribution can be used to specify amplitude fading in a forest environment.

Despite this importance, a handful of studies have investigated Weibull fading from security point of view. Moreover, most of the existing work in SWIPT security is limited to analysis of Rayleigh fading which is a special case of Weibull fading. In this regard, it is pertinent to note that this paper is an extension of our previous work [10], where expressions of optimal power splitting and time switching were derived under Weibull fading. However, this paper evaluates the secrecy performance of SWIPT system under the influence of Weibull fading. Here, we provide closed-form expressions of probability of strictly positive secrecy capacity and ergodic secrecy capacity in the presence of power splitting eavesdropper. Additionally, we evaluate the impact of power splitting factor and Weibull parameter β, on determining the overall secrecy of information in SWIPT system.

The rest of this paper is organized as follows. System model is provided in Sec. 2; Sec. 3 contains derivation of the SPSC probability and Secrecy capacity under Weibull fading. In Sec. 4 numerical results are discussed. Finally, in Sec. 5, conclusions are highlighted.

2 System Model

A downlink SWIPT system is assumed which consists of a Base Station (BS) and an information receiving node S in the presence of an energy harvesting and information decoding node represented as E, as shown in Figure 1. BS conveys information to S and transfers energy to E during a single scheduling slot. Energy harvesting node is assumed to store energy from received radio signal. The BS, node S and eavesdropper E are equipped with single antenna. Antennas in all the network entities are assumed to be experiencing statistically independent flat Weibull fading. Moreover, we assume quasi-static fading to incorporate the effect of fading during each block of time. The BS is assumed to have channel state information (CSI) for the channels to node S. Being part of the coverage range of the BS, the energy harvesting node can act as a potential eavesdropper. It is assumed that eavesdropper uses power splitting (PS) scheme [1] to incorporate the process of energy harvesting and information decoding. According to PS, signal is divided into two streams for with ratio ρ and $(1-\rho)$for information decoding and energy harvesting, respectively; where $0 \leq \rho \leq 1$.

When BS transmits its signal s to S with power P; the received signal at S can be expressed as

$$y_m = \sqrt{\frac{P}{P_{Loss,s}}} h_m s + n_m, \tag{1}$$

where h_m represents the main channel between BS and S with $|h_m|$ being Weibull-distributed. Furthermore, n_m represents the zero mean additive white Gaussian noise (AWGN) with variance N_0 due to the receiver electronics at node S. $P_{Loss,s} = \frac{(4\pi)^2 d_s^{\gamma}}{G_t G_r \lambda^2}$ is the path loss at main link, d_s is the distance between BS and S. γ is the path loss exponent, G_t and G_r are transmitting and receiving antenna gains. Since the transmission from BS is also picked up by the eavesdropper, the signal received at the eavesdropper is given as

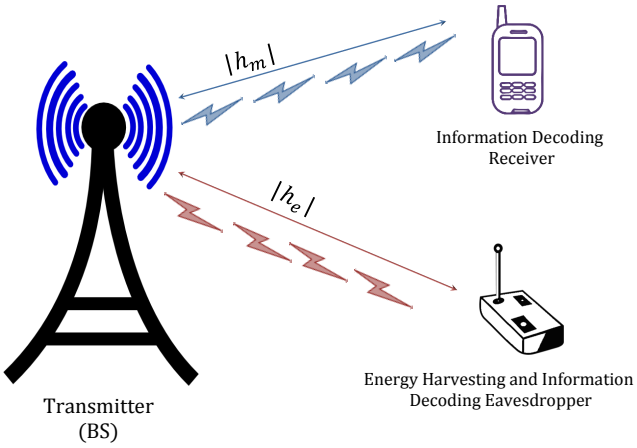

Figure 1. System Model.

$$y_e = \sqrt{\rho}\left(\sqrt{\frac{P}{P_{Loss,e}}} h_e s + n_e \right) + z, \tag{2}$$

where n_e is the AWGN at eavesdropper, h_e represents the channel between BS and eavesdropper with $|h_e|$ being Weibull-distributed. Also, $P_{Loss,e} = \frac{(4\pi)^2 d_e^{\gamma}}{G_t G_r \lambda^2}$ is the path loss at wiretap link, d_e is the distance between BS and E and n_e represents the zero mean additive white Gaussian noise (AWGN) with same variance as N_0 . z is the signal processing noise which is modeled as AWGN with zero mean and variance σ.

Then the instantaneous signal-to-noise ratio (SNR) at S for the received signal is written as

$$x_m = \frac{|h_m|^2 P}{P_{Loss,s} N_0}. \tag{3}$$

The instantaneous signal-to-noise ratio (SNR) at eavesdropper for the received signal is

$$x_e = \frac{\rho |h_e|^2 P}{P_{Loss,e} N_0 \left(\rho + \frac{\sigma^2}{N_0}\right)}. \tag{4}$$

Since main and wiretap link are subjected to Weibull fading, therefore, the Probability Density Function (PDF) and Cumulative Distribution Function (CDF) of the SNR of received signal at S and E is given by

$$f_{X_a}(x_a) = \beta_a \left(\frac{\Gamma\left(1+\frac{1}{\beta_a}\right)}{\bar{x}_a} \right)^{\beta_a} x_a^{\beta_a - 1} \times e^{-\left(\frac{\Gamma\left(1+\frac{1}{\beta_a}\right) x_a}{\bar{x}_a} \right)^{\beta_a}}. \tag{5}$$

$$F_{X_a}(x_a) = 1 - e^{-\left(\frac{\Gamma\left(1+\frac{1}{\beta_a}\right)x_a}{\bar{x}_a}\right)^{\beta_a}}, \quad (6)$$

where $a \in (m,e)$ for main and wiretap link, β_a represents the Weibull shape parameter and $\Gamma(.)$ is the well-known Gamma function. The channel capacity for both main and wiretap link can be written as $C_m = \log_2(1+x_m)$ and $C_e = \log_2(1+x_e)$, respectively [11]. Now, the positive difference between main link capacity and wiretap link capacity is called the secrecy capacity which is expressed as [12]

$$C_{\text{sec}} = [C_m - C_e]^+. \quad (7)$$

3 Analysis of Secrecy Performance

In this section, we will derive closed form expression of probability of SPSC and Ergodic Secrecy Capacity.

3.1 Probability of Strictly Positive Secrecy Capacity (SPSC)

Let us now derive an expression for the probability of strictly positive secrecy capacity (SPSC) which is the probability that the secrecy capacity is greater than zero. Mathematically it is written as

$$\Pr(C_{\text{sec}} > 0) = \Pr\left[\log_2\left(\frac{1+x_m}{1+x_e}\right) > 0\right]. \quad (8)$$

$$\Pr(C_{\text{sec}} > 0) = \Pr(x_m > x_e). \quad (9)$$

The above expression can be written as

$$\Pr(C_{\text{sec}} > 0) = \int_0^\infty \int_{x_e}^\infty f_{X_m,X_e}(x_m,x_e)dx_m dx_e, \quad (10)$$

where $f_{X_m,X_e}(x_m,x_e)$ is the joint PDF, which can be decomposed by using independence of x_m, x_m. Consequently (10) can be written as

$$\begin{aligned}\Pr(C_{\text{sec}} > 0) &= \int_0^\infty \int_{x_e}^\infty f_{X_m}(x_m) f_{X_e}(x_e)dx_m dx_e \\ &= \int_0^\infty f_{X_e}(x_e)[1 - F_{X_m}(x_e)]dx_e. \end{aligned} \quad (11)$$

Using the definition of CDF of a random variable Y we can write

$$F_Y(y) = \Pr(Y < y) = \int_{-\infty}^{y} f(t)dt. \quad (12)$$

Replacing values from (5) and (6) in (11) we can write above equation as

$$\begin{aligned}Pr(C_{\text{sec}} > 0) = \beta_e \left(\frac{\Gamma(1+\frac{1}{\beta_e})}{\bar{x}_e}\right)^{\beta_e} \times \int_0^\infty x_e^{\beta_e - 1} e^{-\left(\frac{\Gamma(1+\frac{1}{\beta_e})x_e}{\bar{x}_e}\right)^{\beta_e}} \\ \times e^{-\left(\frac{\Gamma\left(1+\frac{1}{\beta_m}\right)x_e}{\bar{x}_m}\right)^{\beta_m}} dx_e, \end{aligned} \quad (13)$$

where $\bar{x}_m = \frac{\Omega_s}{P_{Loss,s}}$ and $\bar{x}_e = \frac{\rho\Omega_e}{(P_{Loss,e}(\rho+\sigma^2/N_0))}$; also Ω_s and Ω_e is the average SNR of main and wiretap link, respectively.

Assuming $\beta_e = \beta_m = \beta$ and substituting $u = \left(\frac{\Gamma\left(1+\frac{1}{\beta_e}\right)x_e}{x_e}\right)^{\beta_e}$ in (10), we can solve integral as

$$\Pr(C_{\text{sec}} > 0) = \frac{(\bar{x}_m)^\beta}{(\bar{x}_m)^\beta + (\bar{x}_e)^\beta}, \quad (14)$$

3.2 Ergodic Secrecy Capacity (C)

Another measure of interest is the ergodic secrecy capacity. It is defined as the average of secrecy rate over x_m and x_e. It can be mathematically written as

$$\begin{aligned} C &= \mathbf{E}\{[\log_2(1+x_m) - \log_2(1+x_e)]^+\} \\ &= \int_0^\infty \underbrace{\int_0^{x_m} [\log_2(1+u) - \log(1+v)] f_{x_e}(v)dv}_{\mathcal{G}} f_{x_m}(u)du \end{aligned} \quad (15)$$

Using integration by parts, the above expression can be simplified as

$$\begin{aligned}\mathcal{G} &= \log_2(1+u)F_{x_e}(u) - \left[\log_2(1+u)F_{x_e}(u) - \frac{1}{\ln 2} \right. \\ &\quad \left. \times \int_0^u \frac{1}{1+v} F_{x_e}(v)dv\right] \\ &= \frac{1}{\ln 2}\int_0^u \frac{F_{x_e}(v)}{1+v}dv. \end{aligned} \quad (16)$$

Replacing (16) in (15) and by changing the order of integration, we get

$$\begin{aligned} C &= \frac{1}{\ln 2}\int_0^\infty \frac{F_{x_e}(v)}{1+v}\left[\int_v^\infty f_{x_m}(v)du\right]dv \\ &= \frac{1}{\ln 2}\int_0^\infty \frac{F_{x_e}(v)}{1+v}[1 - F_{x_m}(v)]dv. \end{aligned} \quad (17)$$

After replacing (6) for $\beta_e = \beta_m = \beta$ in (17) and performing some algebraic manipulations, we obtain

$$\begin{aligned} C = \frac{1}{\ln 2}\int_0^\infty \frac{1}{1+x_e} e^{-\left(\frac{\Gamma\left(1+\frac{1}{\beta}\right)x_e}{\bar{x}_m}\right)^\beta} - \frac{e^{-\frac{(\bar{x}_m)^\beta + (\bar{x}_e)^\beta}{(\bar{x}_m\bar{x}_e)^\beta}}}{1+x_e} \\ \times e^{-2\left(\Gamma(1+\frac{1}{\beta})x_e\right)^\beta} dx_e. \end{aligned} \quad (18)$$

Above equation contains single integral which can be readily solved using computational software packages such as MATHEMATICA and MATLAB.

4 Numerical Results

In the following section we provide some numerical results along with discussion on the above analysis. Unless mentioned otherwise, the simulation parameters along with their respective values are provided in Table 1.

S No.	Simulation Parameter	Value
1.	Path loss at Main Link $P_{Loss,s}$	0 dB
2.	Path loss at Wiretap Link $P_{Loss,e}$	0 dB
3.	Power splitting factor ρ	0.8
4.	Weibull shaper parameter β	2
5.	Noise at main/ wiretap link	- 60 dB
6.	Channel realizations	10^6

Table 1. Simulation Parameters

Figure 2 shows the SPSC probability plotted against $\bar{x}_m$ for different values of $\bar{x}_e$. It is vividly clear from the figure that probability of SPSC increases with the increase in $\bar{x}_m$. It is because with the increase in $\bar{x}_m$ the channel capacity of the main link increases which resultantly increases the SPSC probability. Moreover, it is also evident from the graph that increase in x_e, decreases the probability of SPSC. In addition to this, we can observe that for the same values of $\bar{x}_m$, $\bar{x}_e$ and $P_{Loss,e}$, the probability of SPSC significantly decreases with the increase in $P_{Loss,s}$. Furthermore, we observe that the impact of decrease in $P_{Loss,s}$ is more significant for larger values of $\bar{x}_e$ as compared to smaller $\bar{x}_e$. It can also be seen that the simulation results closely coincide with the analytical results which proves the accuracy of our analysis.

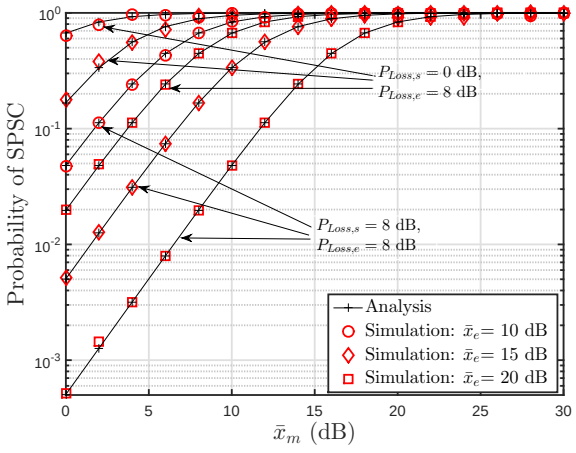

Figure 2. SPSC probability plotted as a function of $\bar{x}_m$.

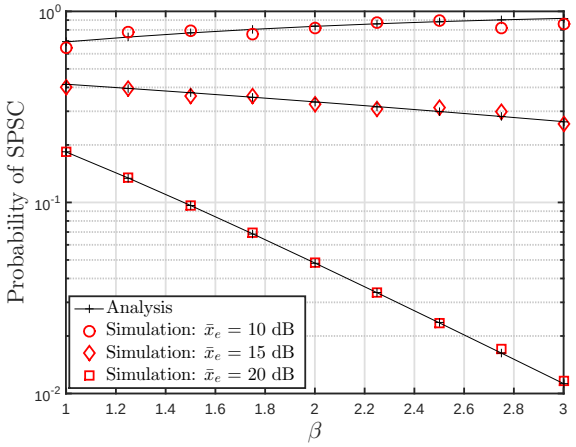

Figure 3. SPSC probability against Weibull shape parameter β.

Figure 3 plots SPSC probability as a function of Weibull shape parameter β. It is observed from the figure that the SPSC probability increases with the increase in β until main links SNR is equal or greater than eavesdroppers SNR. However, when $\bar{x}_m < \bar{x}_e$ then the probability of SPSC decreases with increase in β. Additionally, this effect is more significant for large values of $\bar{x}_e$ as compared to small values.

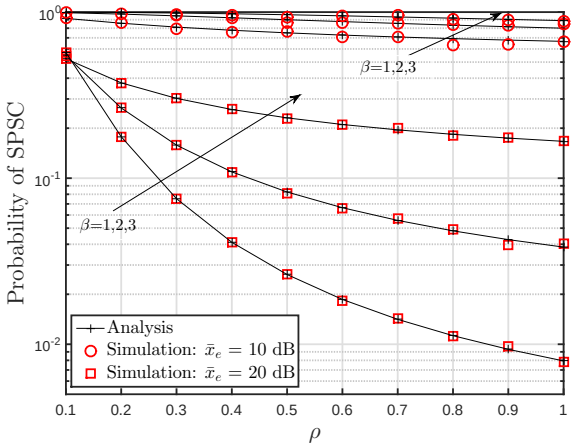

Figure 4. Probability of SPSC vs power splitting factor ρ.

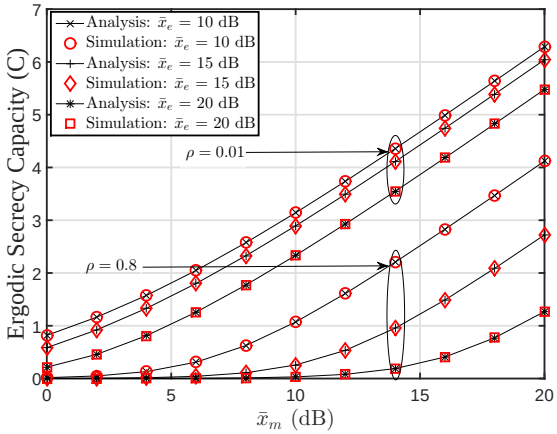

Figure 5. Ergodic secrecy capacity as a function of $\bar{x}_m$.

Figure 4 gives the SPSC probability as a function of ρ for different values of $\bar{x}_e$. It can be observed from the figure that for the increasing values of ρ the probability of SPSC decreases. It is due to the fact that larger values of ρ indicate that more power at the eavesdropper is being used for information decoding which results into reduction in the secrecy capacity. Furthermore, the reduction in probability of SPSC is more significant at higher values of eavesdroppers SNR. Additionally, it can be seen from the plot that influence of β increases with the increase in ρ and $\bar{x}_e$.

Finally, Figure 5 illustrates the achievable secrecy capacity as a function of increasing values of main links average SNR. It is well established by now that the increase in $\bar{x}_m$ increases the secrecy capacity. It is noteworthy that for a specific value of $\bar{x}_m = 12$ dB and $\bar{x}_e = 10 \rightarrow 20$ dB, the secrecy capacity increases from 3 to 3.8 for $\rho = 0.01$, whereas, secrecy capacity increases from 0.1 to 1.8 for $\rho = 0.8$. This result is shows that secrecy capacity varies rapidly for higher values of ρ as compared to lower ones.

5 Conclusion

In this article we have analyzed the performance of SWIPT system from the perspective of physical layer security. We have derived the closed-form expression for probability of SPSC. We have characterized the effect of Weibull shape parameter in SPSC. Our results also demonstrate the significance of power splitting factor on the confidentiality of information. Finally, we evaluated the impact of power splitting factor on ergodic secrecy capacity while varying the Weibull shape parameter. These findings can be of utility for ensuring data security for wireless communication.

ABSTRACT

Radar ambiguity function is widely employed to analyze a radar system's time delay (range) resolution, Doppler frequency (range rate) resolution, mainlobe width and sidelobes in both range and Doppler. In this paper, ambiguity functions of frequency diverse array (FDA) which offers range-angle dependent transmit beampattern and Phased array which yields angle transmit beampattern is investigated. The FDA and Phased array radar ambiguity function is derived and evaluate its performance characteristics in terms of time-delay and Doppler frequency resolutions. Performance analysis has also been done in terms of empirical cumulative distribution function (ECDF). Simulation and results have verified the effectiveness of both radar systems by comparing their performance characteristics.

1 Introduction

Phased array radar system has been widely utilized in many modern communications, radar and navigation systems [1, 2, 3]. In a standard phased-array antenna, the elements are fed coherently and phase shifters or time-delayers are used to scan the beam to the desired direction in space [4]. The offered directional gain is beneficial for target detection and tracking weak targets in the antenna looking direction and at the same time suppressing strong sidelobe interferences from other directions. The phased-array antenna beam steering is fixed in an angle for all ranges and thus, the range and angle of targets cannot be directly estimated from its beamforming output due to an inherent range ambiguity [5].

Recently, a flexible array, namely, frequency diverse array (FDA) has been proposed [6, 7, 8]. The most significant FDA difference from its counterpart phased-array is that a small frequency increment, compared to the carrier frequency, is applied between the FDA elements. This frequency increment yields a range-angle-dependent beampattern for which the beam focus direction will be a function of the angle, range and time [9, 10, 11]. FDA has sparked much investigations because of its promising applications. In [12, 13, 14] FDA have been investigated in terms of range-dependent beam with applications in suppressing range ambiguous clutter. FDA for synthetic aperture radar (SAR) high-resolution imaging was reported in [15]. Furthermore, [16, 17] exploited FDA capabilities in range and angle localization of targets.

It is well established that the radar ambiguity function is a useful tool for evaluating performance metrics of radar system, such as time delay (range) and Doppler frequency resolutions and the probabilities of detection and false alarm. Moreover, it helps in selecting appropriate waveforms depending on the required performance parameters.

Therefore, in this perspective, this paper derived and analyzed the performance characteristics of phased array and FDA radar ambiguity functions in time delay and Doppler frequency resolutions. Ambiguity function performance metric is also provided in terms of empirical cumulative distribution function (ECDF). The performance characteristics are compared and FDA radar exhibited better performance results than the phased array radar.

The remaining sections are organized as follows: In Section II, conventional ambiguity function is reviewed. Section III, ambiguity functions for FDA and phased array is derived. Section IV, provides simulation results. Finally, Section V, concludes the paper.

2 Review Of The Conventional Ambiguity Function

In a conventional radar system, the radar ambiguity function (AF) is a common tool for investigating radar signals [18, 19, 20, 21]. The AF is a two dimensional function that describes the output of a matched filter when the input signal of time delay t_d and Doppler frequency f_d relative to

*Shaddrack Yaw Nusenu, Koforidua Technical University, Ghana, Email: nusenu2012gh@yahoo.com

https://dx.doi.org/10.25046/aj020350

nominal values for which the matched filter has been designed. The AF can be expressed as

$$|\chi(t_d, f_d)| \triangleq \left| \int_{-\infty}^{\infty} u(t)\, u^*(t+t_d) \exp\{j2\pi f_d t\}\, dt \right| \quad (1)$$

where $(\cdot)^*$ denotes the conjugate operator, $u(t)$ is the radar waveform, t_d and f_d are the mismatch in time delay and Doppler frequency, respectively. The ambiguity function plays a great role in determining the t_d and f_d resolutions of radar. The value of this function is maximum at $(t_d, f_d) = (0, 0)$, and it represents the matched filter output without any mismatch. Hence, the narrower the AF around origin, the better the t_d and f_d resolutions. Therefore, the ideal AF would be an impulse at the origin, however, there is no waveform promising such kind of an AF.

3 Frequency Diverse Array And Phased Array Radar Ambiguity Function

First, we will analyzed FDA signal model and its ambiguity function derivation and then followed by phased array radar. FDA elements can be either excited by the same waveform or different waveforms. Consider N elements of FDA radar signal model. Assume the nth element transmitted signal is given by

$$\psi_n(t) = \exp(j2\pi z_{n,1} t)\, s(t) \quad (2)$$

where $z_{n,1}$ denotes the nth transmit signal pulse carrier frequency and $s(t)$ can be expressed as

$$s(t) \triangleq \begin{cases} 1, & t \in [0, T_\psi] \\ 0, & otherwise \end{cases} \quad (3)$$

with T_ψ denotes the pulse duration. The nth FDA element emits the signal $\psi_n(t)$ with a frequency increment Δf_n. The signals radiated by the nth element can be expressed as

$$\begin{aligned} s_n(t) &= \sqrt{N}\psi_n(t) \exp(-j2\pi f_n t)\, w_n^* \\ &= \sqrt{N} u_n(t)\, w_n^* \end{aligned} \quad (4)$$

where $f_n = f_0 + \Delta f_n$, with f_0 denotes the FDA radar carrier frequency, w_n being weights and $u_n(t)$ defined in (5)

$$u_n(t) = \exp(-j2\pi(f_0 - z_{n,1} + \Delta f_n)t)\, s(t) \quad (5)$$

By following [16], the transmitted signal propagating along (θ, r) in the far-field is given by

$$S_n(t, \theta, r) = \sqrt{N} \sum_{n=1}^{N} w_n^* a_n(t, \theta, r)\, u_n(t) \quad (6)$$

and $a_n(t, \theta, r)$ can be written as [22]

$$a_n(t, \theta, r) = e^{\left\{ j2\pi \left(\Delta f_n t - \frac{\Delta f_n r}{c} + n \frac{d f_0 \sin\theta}{c} \right) \right\}} \quad (7)$$

Without loss of validity, a single-antenna is employed in the receiver. Assumed the round-trip time delay to a target in the angle θ and range r is t_d and $w_n = 1$ is used. The received signal is written as

$$\hat{r}_s(t, t_d, f_d, \theta, r) = \sqrt{N} \sum_{n=1}^{N} a_n(t, \theta, r)\, u_n(t - t_d) \exp(j2\pi f_d t) \quad (8)$$

where f_d denotes the Doppler frequency. When the received signal is matched with the assumed parameters $(t_d', f_d', \theta', r')$, the output of the matched filter is used to define FDA radar ambiguity function as expressed in (9), where the cross-ambiguity function is

$$\chi_{n,n'}(t_d, f_d) \triangleq \int_0^{T_\psi} u_n(t)\, u_{n'}{}^*(t + t_d) \exp(j2\pi f_d t)\, dt \quad (10)$$

The following summarized FDA radar characteristics:

(1) If the frequency increment Δf_n is fixed, the beam direction is a function of range r dependent.

(2) If the range r is fixed, the beam direction is a function of Δf_n dependent.

(3) If the frequency increment Δf_n is not employed $(\Delta f_n = 0)$, the corresponding FDA simplified to phased array radar.

(4) As the frequency increment Δf_n influences the beamwidth, a higher resolution may be achieved for the FDA as compared to the phased array radar.

By using the expression of the FDA radar ambiguity function derived in (9), the phased array ambiguity function can also be derived in a similar manner as in (11)

4 Simulation Results And Discussions

For the simulations, we consider a uniform linear FDA and phased array antenna with 16 elements spaced by d. The radar operational frequency is $10GHz$, frequency increment adopted is $30kHz$, $r = 10kHz$ and $\theta = \frac{\pi}{3}$.

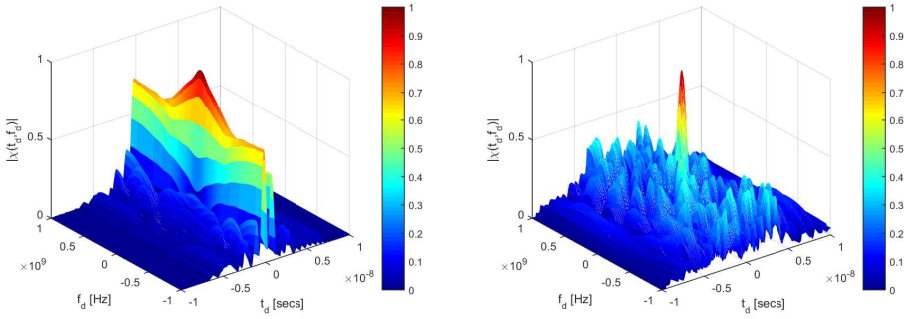
Figure 1(a) shows phased array radar ambiguity function when $\theta = \frac{\pi}{3}$ is adopted and Figure 1(b) depicts FDA radar ambiguity function when $r = 10kHz$ and $\theta = \frac{\pi}{3}$ is also adopted. It can be seen in Figure 1(a) that the phased-array radar has range-Doppler coupled and defocused ambiguity function. This implies that the phased-array radar cannot effectively distinguish range-angle dependent targets, while in Figure 1(b), FDA radar ambiguity function accumulates into a spike with relatively low sidelobe peak. It is evident from Figure 1(b) that, FDA radar can effectively distinguish range-angle dependent targets.

Figure (2a) and 2(b) illustrates the ambiguity functions in time delay and Doppler frequency dimensions. It can be observed in Figure 2(b) that by employment of frequency increment in FDA radar system produces a more focused peak which is useful in target localization than the phased array radar in Figure 2(a).

Figure 3(a) and 3(b) shows the comparisons of ambiguity function versus time delay of phased-array and FDA

$$\chi(t_d, f_d, \theta, r, t_d', f_d', \theta', r') = \int_{-\infty}^{\infty} \hat{r}_s^H(t, t_d', f_d', \theta', r')\, \hat{r}_s(t, t_d, f_d, \theta, r)\, dt$$
$$= N \cdot \sum_{n=1}^{N} \sum_{n'=1}^{N} \left\{ \exp\left\{ j2\pi \left(\begin{array}{l} T_0(\Delta f_n - \Delta f_{n'}) - \frac{(\Delta f_n - \Delta f_{n'})}{c} \\ + \frac{f_0 d((n-1)\sin\theta - (n'-1)\sin\theta')}{c} \end{array} \right) \right\} \chi_{n,n'}(t_d, f_d) \right\} \tag{9}$$

$$\chi(t_d, f_d, \theta, t_d', f_d', \theta') = \int_{-\infty}^{\infty} \hat{r}_s^H(t_d', f_d', \theta')\, \hat{r}_s(t_d, f_d, \theta,)\, dt$$
$$= N \cdot \sum_{n=1}^{N} \sum_{n'=1}^{N} \left\{ \exp\left\{ j2\pi \left(\frac{f_0 d((n-1)\sin\theta - (n'-1)\sin\theta')}{c} \right) \right\} \chi_{n,n'}(t_d, f_d) \right\} \tag{11}$$



(a) (b)

Figure 3: Comparisons of ambiguity function versus time delay: a) Phased-array radar, b) FDA radar.

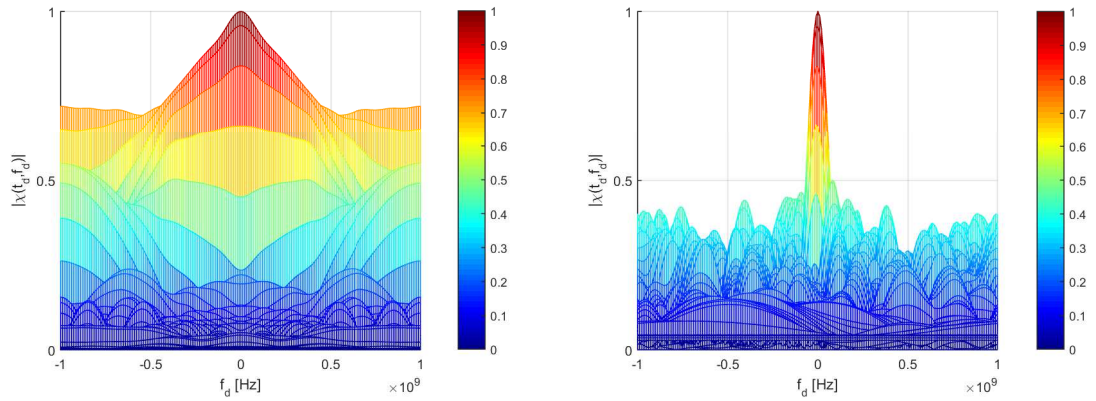

Figure 4: Comparisons of ambiguity function versus Doppler frequency: a) Phased-array radar, b) FDA radar.

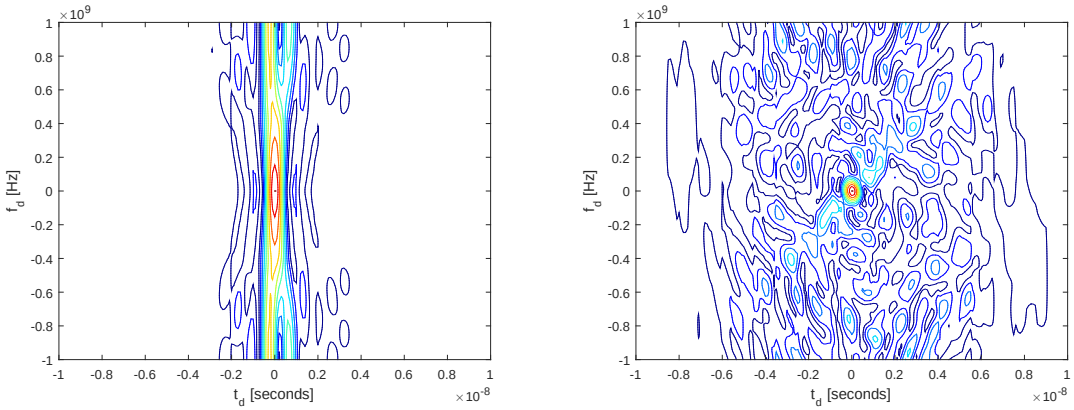

Figure 5: Comparisons of contour plot: a) Phased-array radar, b) FDA radar.

radar, respectively. It can be noticed in Figure 3(a) that the phased-array radar produces narrow beamwidth with maximum sidelobe peak ratio of 0.5510 dB. On the other hand, the FDA radar in Figure 3(b) also achieves a narrow beamwidth with maximum sidelobe peak ratio of 0.5003 dB. Hence, FDA radar outperforms phased array in terms of sidelobe peak ratio.

Figure 4(a) and 4(b) compares the ambiguity function versus Doppler frequency of phased-array and FDA radar, respectively. It can be observed in Figure 4(a) that the phased-array radar produces poor Doppler frequency resolution which is coupled. In contrast, the FDA radar in Figure 4(b) produces a narrow beamwidth Doppler frequency resolution with maximum sidelobe peak ratio of 0.5003 dB. Therefore, FDA radar can estimates Doppler frequency effectively than phased array radar.

Figure 5(a) and 5(b) examines the contour plots of phased-array and FDA radar systems, respectively. It can be seen in Figure 5(b) that the FDA radar contour plot produces a narrow resolution in time delay and Doppler frequency dimensions than the phased array radar in Figure 5(a). It is also evident from Figure 5(b) that the fuzzy area will reduce with increase in N, which would also finally affect the time delay and Doppler frequency resolutions of the system.

Finally, an effective metric used to evaluate the ambiguity function is the empirical cumulative distribution function (ECDF), which represents the percentage of samples of $|\chi(t_d, f_d)|$ lower than a given magnitude. Figure 6 illustrates the ECDF curve to compare both radar systems. The ECDF performance means that the FDA radar yields smaller sidelobe energy than the phased array radar.

5 Conclusion

In this paper, FDA radar and Phased-array radar ambiguity functions has been formulated. Simulation results shows that the phased-array radar has range-Doppler coupled and defocused ambiguity functions. This implies that the phased-array radar cannot effectively distinguish range-angle dependent targets. In contrast, the FDA radar ambiguity obtained lower maximum sidelobe level without degrading the mainlobe performance and can effectively distinguish range-angle dependent targets. In addition, the performance analysis has also been done in terms of empirical cumulative distribution function (ECDF) which proved that FDA radar ambiguity function outperforms the phased array radar ambiguity function. Furthermore, FDA radar ambiguity function produces narrow resolution in time delay and

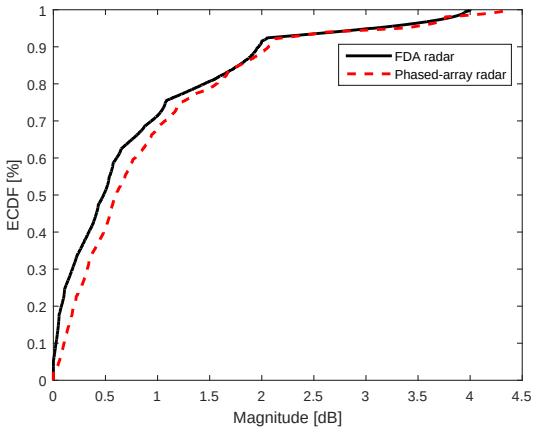

Figure 6: Comparisons of ECDF performances.

Doppler frequency dimensions than its counterpart phased-array radar.

Conflict of Interest The author declare no conflict of interest.

Discrete time chaotic system

ABSTRACT

In this paper, we propose an adaptive discrete-time fuzzy sliding mode control for a class of chaotic systems. For this aim, a discrete sliding mode controller and a fuzzy system are combined to achieve an adequate control. The Laypunov stability theorem is used to testify the asymptotic stability of the whole system and the consequence parameters of the adaptive fuzzy system are tuned on-line by adaptive laws. The simulation example of the 3D Henon chaotic model is giving to confirm the effectiveness and the robustness of the proposed method.

1 Introduction

In recent years, the control of chaotic systems has increasingly interested researchers. The first chaos control method has been proposed by Ott et al. [1], nowadays known as the OGY (Ott-Grebogi-Yorke) method. This is a discrete technique that considers small perturbations applied in one system parameter when the trajectory approaches the vicinity of the desired orbit when crossing a specific surface. Since then, numerous control techniques have been proposed for controlling chaos in different chaotic systems such as backstepping [2–4], adaptive control algorithms [5–7] and sliding-mode control [8–10].

The sliding mode control (SMC) has undergone extensive and detailed studies in the last three decades. It is noted that SMC is a powerful robust control strategy treating the model uncertainties and external disturbances. The design and the implementation of discrete time sliding mode control have later been considered, and still in progress because a large classes of continuous systems are controlled by digital signal processors and microprocessors. Indeed, discrete sliding mode control is well studied in the literature [11–14]. The aim of this work is to give a further contribution in this field. The main objective is to design a discrete time sliding mode control strategy and enhanced by a stable adaptive fuzzy inference system to cope with modeling inaccuracies and external disturbances that can arise. Many researches on introducing the concept of fuzzy logic and especially fuzzy approximators into sliding mode control have been developed in the past years [15–18]. Historically, fuzzy logic systems have been proposed in an attempt to control nonlinear systems whose parameters are inaccuracy, and presenting neglected dynamics as well as time varying systems [19]. Since then, fuzzy logic control becomes an active research area and it has been implemented in several industrial applications. Accordingly, fuzzy logic with discrete sliding mode control are proposed to improve system control performances. Thus, the overall control system drives the tracking error to zero even in the presence of external disturbances. This paper is organized as follows: Section 2 and 3 deal with discrete sliding mode and fuzzy system respectively. Moreover, the detailed design procedure of fuzzy sliding mode controller is explained in section 4. Numerical simulations are carried out in section 5 for illustration and verification of the proposed controller. Finally some concluding remarks are given in section 6.

2 Discrete-time sliding mode controller

Consider the following nonlinear discrete time system

$$\begin{cases} x_1(k+1) = x_2(k) \\ x_2(k+1) = x_3(k) \\ \vdots \\ x_{n-1}(k+1) = x_n(k) \\ x_n(k+1) = f(x(k)) + u(k) + d(k) \end{cases} \quad (1)$$

[*]Corresponding Author: Hanene Medhaffar, Email:medhaffar_hanene@yahoo.fr, hanene.medhaffar@isgis.rnu.tn

https://dx.doi.org/10.25046/aj020351

where $x(k) = [x_1(k), x_2(k), \ldots, x_n(k)]^T$ is the state vector and $u(k)$ is the input signal.
$f(x(k))$ is unknown but it is a bounded function and $d(k)$ is a bounded external disturbance such that $|d(k)| < D$.
When $u(k) = 0$, system (1) behaves chaotically. Therefore, the aim of this work is to apply a discrete-time sliding mode controller $u(k)$ in order to track a desired trajectory.
Let $x_d(k) = [x_{d1}(k), x_{d2}(k), \ldots, x_{dn}(k)]^T$ the well known desired trajectory. Then, the tracking error can be expressed as

$$e(k) = x(k) - x_d(k) \tag{2}$$

where $e(k) = [e_1(k), e_2(k), \ldots, e_n(k)]^T$.
The sliding surface can be defined as

$$\begin{aligned} s(k) &= c_1 e_1(k) + c_2 e_2(k) + \ldots + c_{n-1} e_{n-1}(k) + e_n(k) \\ &= Ce(k) = 0 \end{aligned} \tag{3}$$

where $C = [c_1, c_2, \ldots, c_{n-1}, 1]$ can be selected as $h(z) = z^{n-1} + c_{n-1} z^{n-2} + \ldots + c_2 z + c_1$ is stable. The sliding mode controller is designed by adopting the reaching law defined by [12]

$$\Delta s(k+1) = s(k+1) - s(k) = -Qs(k) - Ksign(s(k)) \tag{4}$$

where $0 < Q < 1$ and $K > 0$.
If $f(x(k))$ is supposed known and $d(k) = 0$ then

$$s(k+1) = \sum_{i=1}^{n-1} c_i e_i(k+1) + f(x(k)) + u(k) - x_{dn}(k+1) \tag{5}$$

therefore $\Delta s(k+1)$ can be expressed as

$$\begin{aligned} \Delta s(k+1) &= \sum_{i=1}^{n-1} c_i e_i(k+1) + f(x(k)) + u(k) \\ &- x_{dn}(k+1) - \sum_{i=1}^{n-1} c_i e_i(k) - e_n(k) \end{aligned} \tag{6}$$

The equivalent control $u_{eq}(k)$ can be derived by using $\Delta s(k+1) = 0$ such that

$$\begin{aligned} u_{eq}(k) &= -\sum_{i=1}^{n-1} c_i e_i(k+1) - f(x(k)) + x_{dn}(k+1) \\ &+ \sum_{i=1}^{n-1} c_i e_i(k) + e_n(k) \end{aligned} \tag{7}$$

Since $d(k) \neq 0$ then a switching type control must be added such that

$$\begin{aligned} u(k) &= u_{eq}(k) + u_s(k) \\ &= -\sum_{i=1}^{n-1} c_i e_i(k+1) - f(x(k)) + x_{dn}(k+1) \\ &+ \sum_{i=1}^{n-1} c_i e_i(k) + e_n(k) + u_s(k) \end{aligned} \tag{8}$$

where $u_s(k)$ is defined by

$$u_s(k) = -Qs(k) - Ksign(s(k)) \tag{9}$$

where the switching gain K will be determined afterwards .
Furthermore, if $f(x(k))$ is unknown then a fuzzy system $\hat{f}(x(k))$ will be used to approximate $f(x(k))$ in order to obtain the sliding mode control law. Moreover, an adaptive adjusting law will be designed.

3 Fuzzy system

The knowledge base for the fuzzy logic system comprises a collection of fuzzy IF-THEN rules of the form:

$$\begin{aligned} \mathbf{R_1^{(j)}}: \quad & \text{If} \quad \left[(x_1(k) \text{ is } A_1^j) \ldots \text{and } (x_n(k) \text{ is } A_n^j)\right] \\ & \text{then} \quad \left[(y(x(k)) = b^j)\right] \end{aligned} \tag{10}$$

pour $j = 1, \ldots, H$. H is the rule number of the fuzzy logic system.
$x_i(k)$, $i = 1, \ldots, n$ and $y(x(k))$ denote the linguistic variables associated with the inputs and the output of the fuzzy logic system.
By the use of the singleton fuzzification strategy, product inference and center-average defuzzification, the output of the fuzzy system is expressed as:

$$y(x(k)) = \frac{\sum_{j=1}^{H} y^j(x(k)) \left(\prod_{i=1}^{n} \mu_{A_i^j}(x_i(k)) \right)}{\sum_{r=1}^{H} \left(\prod_{p=1}^{n} \mu_{A_p^r}(x_p(k)) \right)} \tag{11}$$

where $\mu_{A_i^j}$ is the membership function of the linguistic variable A_i^j.
By introducing the concept of fuzzy basis function vector $\xi(x(k))$, (11) can be rewritten as:

$$y(x(k)) = \theta^T \xi(x(k)) \tag{12}$$

where

$$\theta = \begin{bmatrix} y^1(x(k)) \\ : \\ y^H(x(k)) \end{bmatrix}, \quad \xi(x(k)) = \begin{bmatrix} \xi^1(x(k)) \\ : \\ \xi^H(x(k)) \end{bmatrix} \tag{13}$$

and

$$\xi^j(\mathbf{x}) = \frac{\prod_{i=1}^{n} \mu_{A_i^j}(x_i(k))}{\sum_{r=1}^{H} \left(\prod_{p=1}^{n} \mu_{A_p^r}(x_p(k)) \right)} \tag{14}$$

$\xi^j(x(k))$ which are called fuzzy basis functions (FBF's). It has been proved that these FBF's are universal approximators [20].

4 Fuzzy Sliding mode control

In order to derive the sliding mode control, the fuzzy system $\hat{f}(x(k)/\theta_f)$ is used to approximate $f(x(k))$ [21]. The fuzzy logic system $\hat{f}(x(k)/\theta_f)$ is expressed by:

$$\hat{f}(x(k)/\theta_f) = \theta_f^T \xi_f(x(k)) \tag{15}$$

where $\xi_f(x(k))$ is the vector of fuzzy basis supposed to be fixed, while parameters θ_f are variables which will be designed by adaptive laws.
Let θ_f^* the optimal parameter vectors of the fuzzy logic system. Minimum approximation error can be defined as follows:

$$w_f(k) = f(x(k)) - \hat{f}(x(k)/\theta_f^*) + d(k) \tag{16}$$

Then, we can select the control law as:

$$\begin{aligned} u(k) &= u_{eq}(k) + u_s(k) \\ &= -\sum_{i=1}^{n-1} c_i e_i(k+1) - \hat{f}(x(k)/\theta_f) + x_{dn}(k+1) \\ &+ \sum_{i=1}^{n-1} c_i e_i(k) + e_n(k) - Qs(k) - Ksign(s(k)) \end{aligned} \tag{17}$$

where $0 < Q < 1$ and K will be determined afterwards. Therefore, $\Delta s(k+1)$ can be rewritten as

$$\begin{aligned} \Delta s(k+1) &= f(x(k)) - \hat{f}(x(k)/\theta_f) - Qs(k) - Ksign(s(k)) \\ &= \hat{f}(x(k)/\theta_f^*) - \hat{f}(x(k)/\theta_f) + w_f(k) \\ &- Qs(k) - Ksign(s(k)) \\ &= \Phi_f^T(k)\xi_f(x(k)) + w_f(k) \\ &- Qs(k) - Ksign(s(k)) \end{aligned} \tag{18}$$

where $\Phi_f(k)$ represent the fuzzy parameter errors such that:

$$\Phi_f(k) = \theta_f^* - \theta_f(k) \tag{19}$$

Theorem 1 *The following adaptive law for adjusting the parameter vector* θ_f

$$\Delta\theta_f(k) = -\alpha\xi_f(x(k))s(k) \tag{20}$$

asymptotically stabilizes system (1) *controlled by* (17), *where* α *is a positive constant which determines the rate of adaptation.*

Proof: The Lyapunov function candidate is chosen as

$$V(k) = \frac{1}{2}s^2(k) + \frac{1}{2\alpha}\Phi_f^T(k-1)\Phi_f(k-1) \tag{21}$$

Then, $\Delta V(k)$ can be obtained as

$$\begin{aligned} \Delta V(k+1) &= V(k+1) - V(k) \\ &= \frac{1}{2}s^2(k+1) - \frac{1}{2}s^2(k) + \frac{1}{2\alpha}\Phi_f^T(k)\Phi_f(k) \\ &- \frac{1}{2\alpha}\Phi_f^T(k-1)\Phi_f(k-1) \end{aligned} \tag{22}$$

Let

$$\Delta\tilde{\theta}_k = \frac{1}{2\alpha}\Phi_f^T(k)\Phi_f(k) - \frac{1}{2\alpha}\Phi_f^T(k-1)\Phi_f(k-1) \tag{23}$$

then

$$\begin{aligned} \Delta V(k+1) &= \frac{1}{2}s^2(k+1) - \frac{1}{2}s^2(k) + \Delta\tilde{\theta}_k \\ &= \frac{1}{2}(\Delta s(k+1) + s(k))^2 - \frac{1}{2}s^2(k) + \Delta\tilde{\theta}_k \\ &= \frac{1}{2}\Delta s(k+1)^2 + s(k)\Delta s(k+1) + \Delta\tilde{\theta}_k \\ &= \frac{1}{2}\Delta s(k+1)^2 + \Delta\tilde{\theta}_k \\ &+ s(k)\Big[\Phi_f^T(k)\xi_f(x(k)) + w_f(k) - Qs(k) - Ksign(s(k))\Big] \\ &= \frac{1}{2}\Delta s(k+1)^2 + s(k)\Phi_f^T(k)\xi_f(x(k)) + s(k)w_f(k) \\ &- Qs^2(k) - Ks(k)sign(s(k)) + \Delta\tilde{\theta}_k \end{aligned} \tag{24}$$

Moroever, $\Delta\tilde{\theta}_k$ can be transformed as

$$\begin{aligned} \Delta\tilde{\theta}_k &= \frac{1}{2\alpha}\Phi_f^T(k)\Phi_f(k) - \frac{1}{2\alpha}\Phi_f^T(k-1)\Phi_f(k-1) \\ &= \frac{1}{2\alpha}\Phi_f^T(k)\Phi_f(k) \\ &- \frac{1}{2\alpha}(\Phi_f(k) - \Delta\Phi_f(k))^T(\Phi_f(k) - \Delta\Phi_f(k)) \\ &= \frac{1}{\alpha}\Phi_f^T(k)\Delta\Phi_f(k) - \frac{1}{2\alpha}\Delta\Phi_f^T(k)\Delta\Phi_f(k) \end{aligned} \tag{25}$$

Substituting (25) into (24), we obtain

$$\begin{aligned} \Delta V(k+1) &= \frac{1}{2}\Delta s(k+1)^2 + s(k)\Phi_f^T(k)\xi_f(x(k)) \\ &+ s(k)w_F(k) - Qs^2(k) - Ks(k)sign(s(k)) \\ &+ \frac{1}{\alpha}\Phi_f^T(k)\Delta\Phi_f(k) - \frac{1}{2\alpha}\Delta\Phi_f^T(k)\Delta\Phi_f(k) \\ &= \frac{1}{2}\Delta s(k+1)^2 + s(k)w_f(k) - Qs^2(k) - Ks(k)sign(s(k)) \\ &+ \Phi_f^T(k)(s(k)\xi_f(x(k)) + \frac{1}{\alpha}\Delta\Phi_f(k)) \\ &- \frac{1}{2\alpha}\Delta\Phi_f^T(k)\Delta\Phi_f(k) \end{aligned} \tag{26}$$

By applying the adaptive law (20), equation (26) can be rewritten as

$$\begin{aligned} \Delta V(k+1) &= \frac{1}{2}\Delta s(k+1)^2 + s(k)w_F(k) - Qs^2(k) \\ &- Ks(k)sign(s(k)) - \frac{1}{2\alpha}\Delta\Phi_f^T(k)\Delta\Phi_f(k) \end{aligned} \tag{27}$$

According to (18), we have

$$\begin{aligned} |\Delta s(k+1)| &\leq |\Phi_f^T(k)\xi_f(x(k))| + |w_f(k)| \\ &+ |Qs(k)| + |Ksign(s(k))| \end{aligned} \tag{28}$$

Furthermore, it's obvious that $\xi_f(x(k))$ remains bounded such that

$$\|\xi_f(x(k))\| \leq \psi_\xi \quad \forall k \geq 0 \tag{29}$$

where ψ_ξ is a positive constant.
According to (20) and (29) and from $k > N_0$, we have

$$|\Delta\theta_f(k)| \leq \psi_\theta|s(k)| \tag{30}$$

where ψ_θ is positive constant.
Consequently, we can deduce that

$$|\Phi_f(k)| \leq \psi_\Phi|s(k)| \tag{31}$$

It is obvious that the term $|w_f(k)| \leq \psi_w$ where ψ_w is a positive constant.
If we define $u_{sgn} = -Ksign(s(k))$ then

$$\begin{aligned} |\Delta s(k+1)| &\leq \psi_\xi \psi_\Phi |s(k)| + \psi_w + Q|s(k)| + |u_{sgn}| \\ &\leq (\psi_\xi \psi_\Phi + Q)|s(k)| + \psi_w + |u_{sgn}| \\ &\leq \beta|s(k)| + (\psi_w + K) \end{aligned} \quad (32)$$

where $\beta = (\psi_\xi \psi_\Phi + Q)$. By taking square from both sides of (32), we can get

$$\begin{aligned} |\Delta s(k+1)|^2 &\leq \beta^2|s(k)|^2 + (\psi_w + K)^2 \\ &+ 2\beta|s(k)|(\psi_w + K) \end{aligned} \quad (33)$$

Then,

$$\begin{aligned} \frac{1}{2}|\Delta s(k+1)|^2 &\leq \frac{1}{2}\beta^2|s(k)|^2 + \frac{1}{2}(\psi_w + K)^2 \\ &+ \beta|s(k)|(\psi_w + K) \end{aligned} \quad (34)$$

Thus, we can obtain

$$\begin{aligned} &\frac{1}{2}\Delta s(k+1)^2 - Qs^2(k) + s(k)u_{sgn} \\ \leq\ & \frac{1}{2}(\psi_w + K)^2 + \frac{\beta^2}{2}|s(k)|^2 + \beta|s(k)|(\psi_w + K) \\ -\ & Q|s(k)|^2 + K|s(k)| + \psi_w|s(k)| - \psi_w|s(k)| \\ \leq\ & \frac{1}{2}(\psi_w + K)^2 + (\beta+1)|s(k)|(\psi_w + K) - \psi_w|s(k)| \\ +\ & (\frac{1}{2}\beta^2 - Q)|s(k)|^2 \end{aligned} \quad (35)$$

If we choose

$$Q > \frac{1}{2}\beta^2 \quad (36)$$

and

$$\begin{aligned} K &= \left(-(\beta+1) + \sqrt{[(\beta+1)^2 + 2(Q - \frac{1}{2}\beta^2)]}\right)|s(k)| \\ &- \psi_w \end{aligned} \quad (37)$$

then

$$\begin{aligned} \frac{1}{2}(\psi_w + K)^2 &+ (\beta+1)|s(k)|(\psi_w + K) \\ &+ (\frac{1}{2}\beta^2 - Q)|s(k)|^2 = 0 \end{aligned} \quad (38)$$

Therefore, (27) can be expressed as

$$\begin{aligned} \Delta V(k+1) &\leq s(k)w_f(k) - \psi_w|s(k)| \\ &- \frac{1}{2\alpha}\Delta\Phi_f^T(k)\Delta\Phi_f(k) \end{aligned} \quad (39)$$

It's clear that $s(k)w_f(k) - \psi_w|s(k)| \leq 0$ since $|w_f(k)| \leq \psi_w$, furthermore $\Delta\Phi_f^T(k)\Delta\Phi_f(k) \geq 0$, then

$$\Delta V(k+1) \leq 0 \quad (40)$$

By using the Barbalat's lemma [23], we can readily prove that $s(k) \to 0$ as $k \to +\infty$ thus $\lim_{k\to+\infty} e(k) = 0$.

5 Simulation results

To illustrate the above design approach, a 3D Henon chaotic model is considered.
The model for the discrete-time 3D Henon map is given as [22]

$$\begin{cases} x_1(k+1) &= x_2(k) \\ x_2(k+1) &= x_3(k) \\ x_3(k+1) &= -0.2x_1(k) - 0.3x_2(k) - 1.65x_3(k) - x_3^2(k) \\ &\quad +u(k) \end{cases} \quad (41)$$

The non controlled ($u(k) = 0$) Henon map has a chaotic strange attractor. The result of computation is shown in figure 1 where $[x_1(0), x_2(0), x_3(0)]^T = [0.1, 0, 0.1]^T$.

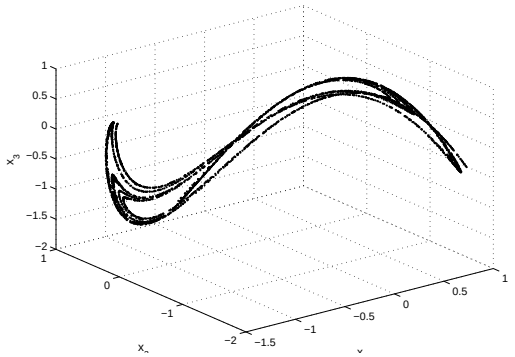

Figure 1: Hénon map attractor.

In order to control this autonomous chaotic system, controller $u(k)$, given by (8), is applied at $k = 60$ to reach the desired trajectory $x_d(k) = [0, 0, 0]^T$.
For the estimation of $f(x(k))$, we consider five fuzzy levels, i.e. NB, NS, EZ, PS and PB on x_1, x_2 and x_3. We use fuzzy logic systems with center-average defuzzifier, product inference, singleton fuzzifier and Gaussian membership functions to approximate $f(x(k))$. Slopes c_i are chosen as $c_1 = 0.1$ and $c_2 = 0.9$.
In figure 2, we represent the evolution of system states which converge rapidly to the desired values. Figure 3 represent the sliding surface and the control signal whose amplitude is always within an acceptable range compared to the system states.

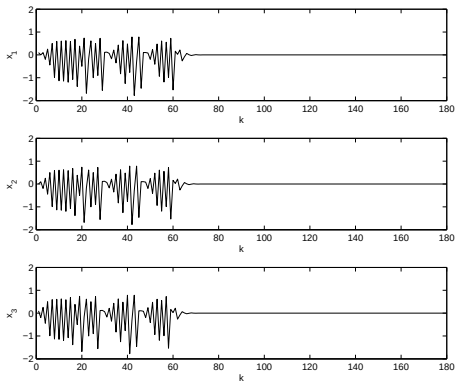

Figure 2: Evolution of system states

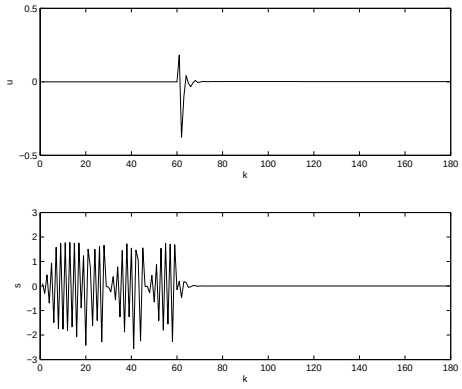

Figure 3: Representation of the sliding surface and the fuzzy sliding mode controller.

In order to illustrate the robustness of our design, a white gaussian noise with variance equal to 0.01 has been considered as an external disturbance. The control objective has been achieved as is illustrated in figures 4 and 5. Thus, the robustness of the discrete fuzzy sliding mode controller is proved.

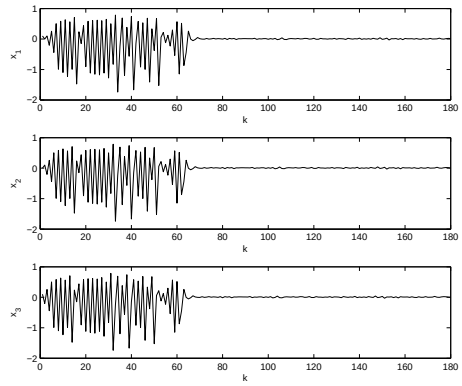

Figure 4: Evolution of system states in presence of a white gaussian noise.

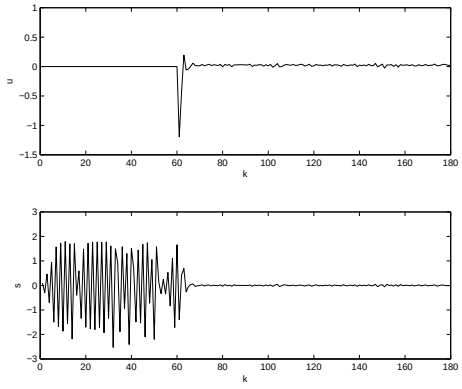

Figure 5: Representation of the sliding surface and the fuzzy sliding mode controller.

6 Conclusion

In this paper, an adaptive discrete-time fuzzy sliding mode controller is proposed. This controller, inherits the advantages of both sliding mode control and fuzzy systems. It has been proposed for stable control of a class of chaotic systems. The sliding mode control is proposed as a robust method to control nonlinear and uncertain systems. Consequence parameters of fuzzy control rules have been adjusted on-line in order to guarantee the reaching condition. Simulation results of a 3D Henon chaotic model show the applicability and the effectiveness of the proposed approach.

ABSTRACT

The paper describes the results of the system analysis of various options of electric inverter topologies for the use in the traction drive of an electrical helicopter. The paper explains the optimal choice, in terms of the design requirements and future operational conditions, and the type and topology of the electric inverter to supply the traction permanent magnet synchronous motor with the batteries. The main focus has been set on the study of the overload capacity, thermal behavior, and the fault tolerance of the multilevel electric inverter. In order to estimate these parameters, the Markov models of the multi-state system's reliability evaluation were used.

1 Introduction

Nowadays, according to the long-term plans for the electrification of various types of vehicles, the task of the electrification of air traffic has now become very important. First of all, the application of electric drives is a promising one for small helicopters designed for search and rescue operations with a nominal power of 510 kW, a rotational speed of 400 rpm, and a voltage of 800 V. Regarding the choice of an optimal electric inverter topology for the traction drive the main attention was paid to the flight safety.

The simplest solution would be to maximize the number of redundant equipment, but strict limitations on weight and dimensions do not allow this. The papers [1, 2] show that only multi-phase electric motors are capable to satisfy the requirements to the fault tolerance ($\lambda \leq 10^{-9}$/h), set up for the electric traction drive of the helicopter.

Taking into account the safety and sustainability of helicopter's operations, the relevant options for inverter topologies were evaluated. Thus according to [2] for the comparative analysis the semiconductor inverters for 6-, 7-, and 9-phase motors were taken.

Due to the great relevance of the creation of electric inverters for special applications, there are many publications describing the topologies and the analysis of inverters with different levels of fault tolerance for various vehicle types. The results of these studies were taken into account by the authors at carrying out of their investigations. Hence, the main task of this research is to find the decision, how it becomes possible to achieve the required values of the inverter's fault tolerance.

2 Approach and Parameters for Evaluation

For each component of the helicopter's traction drive, based on the project requirements and conditions of future operations, the most important parameters are:

- reliability and fault tolerance;
- weight, volume, and dimensions.

2.1 Reliability and Fault Tolerance

For the safety-critical aircraft applications accurate assessment of reliability and fault tolerance indices of the electric inverter at the design stage of the helicopter is crucial for further operation.

The operating experience of electric inverters indicates that the most vulnerable elements of inverter are the capacitors, semiconductors, and printed circuit board (PCB) [3, 4]. Statistical data of failure in various parts of inverter are shown in Figure 1. The main reason of the failures is the overheating of the semiconductors caused by current overloads, as can be seen in Figure 2.

https://dx.doi.org/10.25046/aj020352

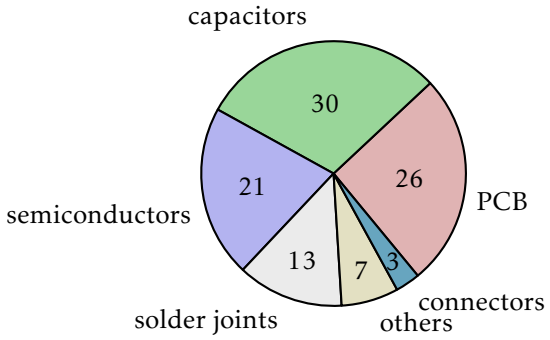

Figure 1: Failure statistics of the components [3].

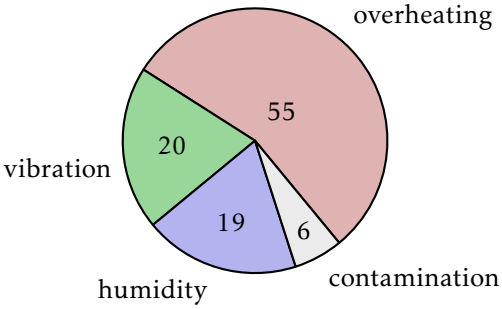

Figure 2: Causes for the failures [3].

Based on the above data charts, reliability level of an electric inverter λ_{EI} can generally be estimated considering the reliability values of its components by the equation:

$$\lambda_{\mathrm{EI}}(t) = \Sigma\lambda_{\mathrm{T}i}(t) + \Sigma\lambda_{\mathrm{D}j}(t) + \Sigma\lambda_{\mathrm{C}k}(t) + \Sigma\lambda_{\mathrm{B}n}(t) \qquad (1)$$

where $\lambda_{\mathrm{T}i}(t)$, $\lambda_{\mathrm{D}j}(t)$, $\lambda_{\mathrm{C}k}(t)$, and $\lambda_{\mathrm{B}n}(t)$ are the failure rates of the all components of electric inverter, respectively of transistor, diode, capacitor and printed circuit board.

In accordance with [3–6] the following failure cases were considered, shown in Figure 3.

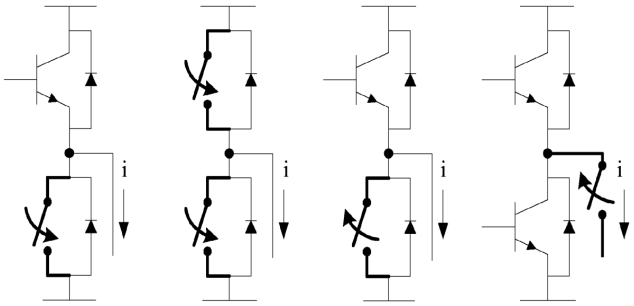

Figure 3: Considered inverter failures [6].

Thus, the considered failures are (Figure 3):

1. single inverter switch short-circuit;
2. phase-leg short-circuit;
3. single inverter switch open-circuit;
4. single phase open-circuit (internal or external).

In these cases for the fault-tolerant operation either the inverter module must be shut down or must be switched to the possibly existing redundant inverter leg or module. Each of these modes is connected with a rapid increase in the current at the emergency site and an overload of semiconductors. On the basis of data on the standard overload capacity of power electronics has been plotted the graph presented in Figure 4.

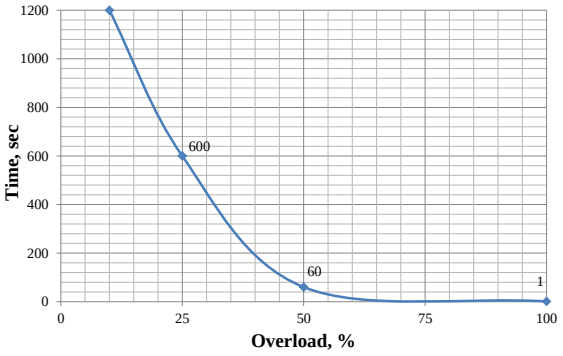

Figure 4: Overload capacity of the inverter.

The most of the fail operational modes caused by technological overloads. At the overload power losses occur in the p-n-transition and its temperature due to the low heat capacity increases dramatically. In the case of exceeding a certain critical temperature of p-n-transition, the semiconductor device fails. So overheating temperature is the main parameter characterizing the overload capacity of semiconductor devices as can be seen in Figure 5.

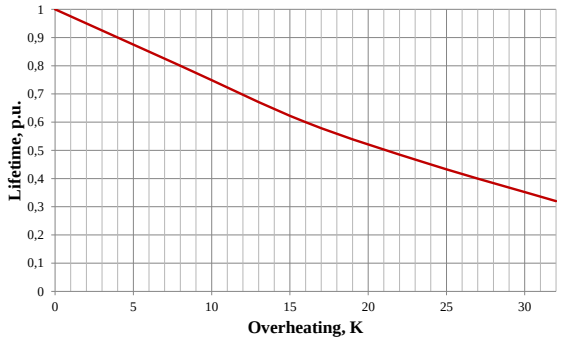

Figure 5: Dependency of the inverter's lifetime on overheating.

So, the consequences of overload in failure operational modes are overcurrent and overheating of an inverter, which lead to a reduction of the reliability indices of the motor and to a decrease in lifetime [7].

2.2 Weight, Volume, and Dimension

The modern options of the fault tolerant topologies of electrical inverters [6, 8–10] have a different number of components designed for different values of operating parameters. Therefore, the number of components, the flexibility of their placement, and the inverter parameters are largely determining such important characteristics of the helicopter, such as weight, volume, and dimensions. The comparative analysis of these values for different inverter topologies are presented in the next sections of this paper.

3 Topologies for the Comparative Analysis

The first part of this section explains the conventional topologies, such as 6-pulse-bridge (B6-bridge) and the H-bridge. However, the second part analyzes the use of multilevel inverters, i.e. cascaded H-bridge (CHB) inverters.

3.1 Conventional Full- and Half-Bridge Topologies

One of the previous papers [2] compared multi-phase permanent magnet synchronous motors (PSM) for safety-critical drive trains. As a result, 6-, 7-, and 9-phase motors are preferable in order to reach the requirements regarding fault tolerance. Hence, possible 9-phase machine topologies are presented in Figure 6, as well as in Figure 7. Those are commonly used and can be adapted to all different numbers of phases.

The already mentioned inverter topologies are compared for a failure case (open circuit) in one phase. This is also valid for a short circuit failure, if the fault is instantaneously detected and isolated, as described in [11, 12]. Hence, the advantage of H-bridges is the separation of every single phase in order to monitor failures. For this inverter topology comparison, an existing electrical machine with three phases serves as an exemplary machine for the failure simulations. At first sight, the results can relatively be adapted to other power requirements.

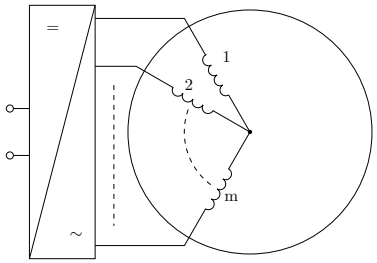

Figure 6: General visualization of a multi-phase topology with windings connected in one star.

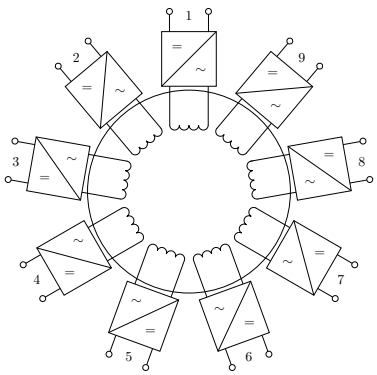

Figure 7: General visualization of a multi-phase modular topology with galvancally insulated windings.

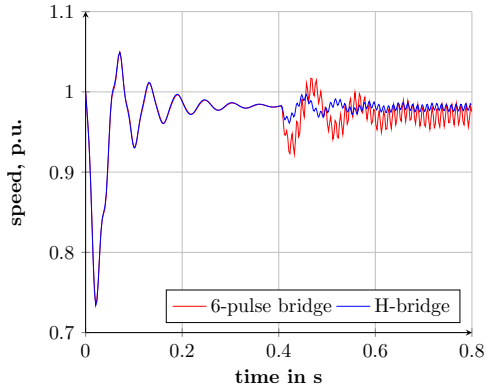

Figure 8: Simulation results for a failure case after 0.4 s for both the 6-pulse-bridge and the H-bridge considering speed over time.

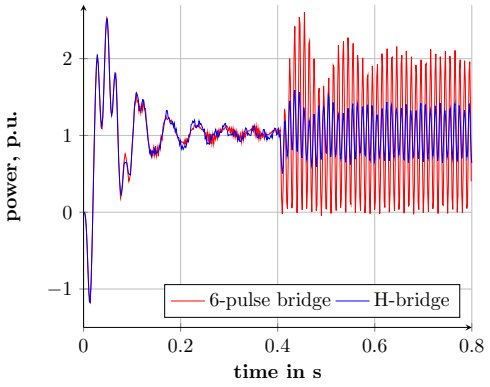

Figure 9: Simulation results for a failure case after 0.4 s for both the 6-pulse-bridge and the H-bridge considering power over time.

After the transient response of the simulation model, the failure takes place at 0.4 seconds and the results are shown in Figure 8 and Figure 9. The speed fluctuations are clearly visible for both machines in Figure 8, whereas the amplitude of the 6-pulse bridge is higher, as well as the speed ripple. Considering Figure 9, the results show, that the power or torque ripple get a lot smoother for the H-bridge, since the peaks for the B6-bridge even drop down to 0. The peak to peak value equals up to ±100% for the 6-pulse-bridge, compared to approximately ±40% for the H-bridge.

In summary, considering a one phase failure and hence fault tolerance, the H-bridge is recommendable for machines with multiple phases, because of the lower power degradation. Due to the high requirements, the machine is already highly saturated in nominal operation; hence, overload in a failure case is not applicable. Thus, in case of a 6-pulse-bridge, three phases fail, since the inverter is unable to drive two out of three phases. In contrast, each H-bridge drives one phase and consequently in case one phase fails, eight phases still operate. Assuming an equally distributed power per phase, the H-bridge topology provides 89% of the nominal power and the B6-bridge only 67% respectively for a 9-phase machine. For the 6-phase machine the situation gets even worse.

However, after first analytical approximations and

considering the application case, weight is 20%, volume 60% higher, and the power losses are slightly higher (10%) for the H-bridge compared to the 6-pulse-bridge topology. This results out of the increased number of semiconductors being necessary for the H-bridge topology. Therefore, the next section includes the analysis of a multilevel inverter trying to solve the problems regarding weight, volume, and power losses, since there is no definitely preferred option. [11–13]

3.2 Multilevel Inverter – Cascaded H-Bridge Inverter

Multilevel inverters offer several advantages compared to their two-level counterparts [14]: smaller power filters, smaller voltage ratings for semiconductors, lower switching frequencies, and less power losses. They offer also more modularity and are more reliable. The inverter with three H-bridges and the B6-bridge inverter need higher voltage range semiconductors (1000V range).

Considering [15–17], CHB inverters with the lower number of components than other classic multilevel counterparts, such as the Neutral Point Clamped (NPC) or Flying Capacitor (FC), are the best candidate for the use in electric drives. They need more components than CHB and have less modularity, due to the central storage unit. The number of components (power switches, diodes and capacitors) for one phase with 17-level output voltage steps is: 288 for the NPC, 168 for the FC and 40 for the CHB (see Figure 10).

Figure 10 shows, that the cascaded H-bridge topology has the most advantages with more than 5-level. CHB inverters offer higher modularity and have the capability for embedding energy storage units in a split manner, given the existence of several submodules operating at low voltages (see Figure 13).

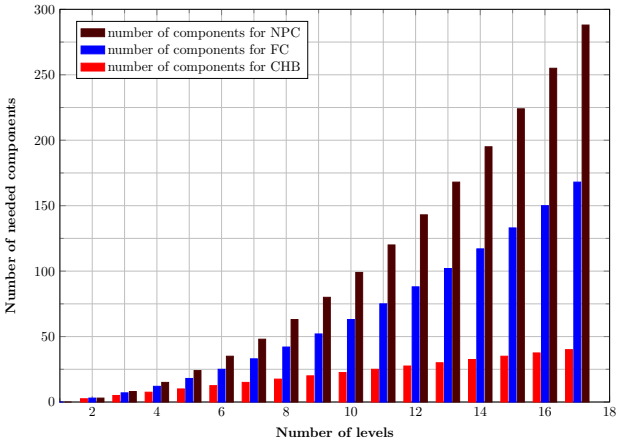

Figure 10: Number of components using three multilevel inverter topologies.

Table 1 shows the parameters of the system. It also shows the structure of the batteries used for the B6-bridge inverter with centralized energy source (battery rack) and CHB inverter with decentralized energy sources (battery modules). V_L is the phase voltage of the machine, V_{cell} the battery cell voltage, V_{mod} the battery module voltage, and V_{rack} the battery rack voltage. The capacity/energy content of the storage units is neglected.

A multilevel inverter with 17 level output voltage steps needs 8 battery modules in each phase. The number of required submodules depends on the value of the minimal phase voltage of the machine and on the minimal battery module voltage $V_{battmin}$ and is calculated as follows:

$$n_{submodules} = \frac{v_{L1}}{V_{battmin}} = \frac{353\,V}{44.8\,V} = 7.88 \approx 8 \qquad (2)$$

Using a higher number of submodules the output voltage is near to a sinusoidal wave form and the harmonics on the electrical machine are lower.

The CHB inverter uses battery modules as shown in Figure 13. Each module is connected to an H-bridge with 4 MOSFETs. The use of MOSFETs enhances the efficiency of the CHB inverter, because of the low conduction losses. Usually, IGBTs are used for a higher voltage range, such as for B6-bridge inverters.

The prototype of the three phase CHB inverter is compared to a commercial B6-bridge inverter (Siemens S120) with the same nominal power 36 kW, taking into account weight, volume, and efficiency. The power-to-volume ratio of the B6-bridge inverter including the power filter is 36 kW/30.8 l = 1.17 kW/l.

Finally, Table 2 shows the results of the comparison between B6-bridge and CHB inverter and it proofs the advantages of CHB over the B6-bridge inverter in volume and weight. The next section discusses results of reliability and fault tolerance analysis.

In conclusion and based on the given project parameters, a 17-level version with MOSFETs was selected, thus, 8 submodules per phase. [14–17]

4 Preliminary Assessment

Based on initial data and the technique for reliability evaluation described in [4,9,18–23], reliability and fault tolerance indices were analyzed. Statistical data for calculating the reliability function of the multilevel inverter in 6-, 7-, and 9-phase implementation are shown in Table 3 and Table 4.

Figure 11 shows the reliability function of the multilevel inverter. It can be seen that the probability of failure-free operation of 6-phase inverter is higher than 7- and 9-phase, due to a smaller number of components. However, the difference between the 6- and 9-phase options does not exceed 20% for 10,000 operating hours.

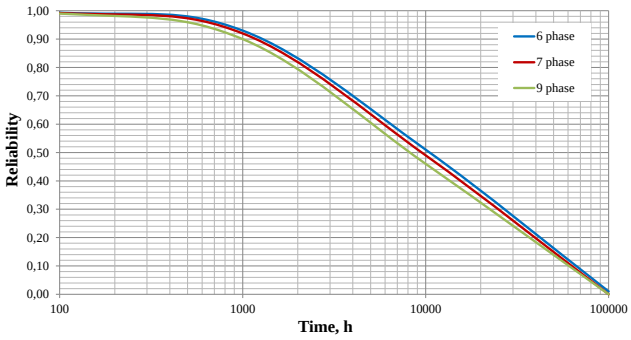

Figure 11: Reliability function of a CHB inverter.

On the basis of the schedule of acceptable inverter's overload (see Figure 4) and the method described in [24], the qualitative analysis of the inverter's ability to function was carried out in case of a failure of 1, 2, and 3 submodules in a single phase. The analysis results are summarized in Table 5 and Table 6.

Considering the requirements of the project, the most critical failure mode of the traction drive, as can be seen from Table 5, is when it is necessary to maintain stably during 2 minutes 113% of nominal power. Further, this mode will be more carefully simulated and estimated for the failure cases using a Markov model.

5 Multi-State System Reliability Markov Model

For the maximum accurate estimation of the fault tolerance value of each comparable inverter option and its compliance (or non-compliance) with design requirements, a Multi-State System Reliability Markov Model (MSS MM) was constructed, which theoretical base is described in [25, 26].

5.1 State Diagram of Markov Model

For the present study the phase open-circuit failure has been considered as the main dangerous failure for electric inverter, i.e. it is the most severe kind of failure, to which less dangerous failures can be summarized. The impact of this failure on the safety operation of the power drive is very significant. In this way, the phase open-circuit failure of a multilevel inverter's submodule can be considered as one of the main causes of failures in traction electric drives, since practically all other electrical failures of the inverter can be attributed to it [7].

Thus, the multilevel inverter can be considered as a multi-state system with a loaded functional redundancy and consequently, with an appropriate reserve of the fault tolerance. A more accurate approach to build the Markov model is described in [2, 27].

The number of the degraded states of the MSS MM has to be determined in accordance with the requirements of the project on the fault tolerance and on the technical capabilities of the object to continue functioning with reduced performance as a result of the critical failure.

Regarding the above requirements on the fault tolerance of safety-critical drives, as well as statistical data on the reliability of electric inverters, it was determined that the optimal model for the analysis of fault tolerance in such conditions is a multi-state Markov model with a minimum of five states, as shown in Figure 12. With one degradative state of inverter, it is not feasible to realize the required values of fault tolerance.

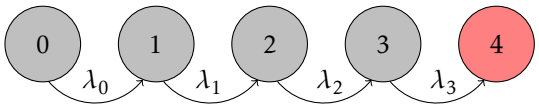

Figure 12: State diagram of MSS MM for a not repairable system.

The first state "0" corresponds to a completely failure-free operation of the inverter. The second, third, and fourth state are the states of degradation and correspond to failure cases. The last red state of the model corresponds to the failure of one phase considering the CHB (see Table 6) or respectively, a completely failed conventional inverter (see Table 5) when the traction motor does not receive the necessary power for a safe flight. Thus, every following state of the degradation corresponds to the worst case – a loss of an inverter's submodule in the same phase.

Table 1: Parameter of the system.

Parameter	Value	Unit
Machine nominal power P	510	kW
$V_{\text{L1min}} \dots V_{\text{L1nom}} \dots V_{\text{L1max}}$	$353 \dots 565 \dots 636$	V
$V_{\text{cellmin}} \dots V_{\text{cellnom}} \dots V_{\text{cellmax}}$	$1.4 \dots 2.2 \dots 2.5$	V
Battery rack structure	360s	
$V_{\text{rackmin}} \dots V_{\text{racknom}} \dots V_{\text{rackmax}}$	$500 \dots 800 \dots 900$	V
Battery module structure (1 of 24)	32s	
$V_{\text{modmin}} \dots V_{\text{modnom}} \dots V_{\text{modmax}}$	$44.8 \dots 70.4 \dots 80$	V

+++ 0–10 %; ++ 10–25 %; + 25–40 % overload; PhF – phase failure

5.2 Transition Probabilities

The most important and difficult fact for a simulation by Markov models is to determine the transition probabilities and determination of the number of states with a reduced level of functionality.

The values of the Markov Model transition probabilities $\lambda_1, \lambda_2, \ldots, \lambda_k$ are derived from the results of calculations of the Degree of Fault Tolerance ($DOFT$) for the states $1, 2, \ldots, k$, respectively, according to the method [28] based on the analysis of an overload capacity and thermal stability of an inverter:

$$\lambda_{\mathrm{R}i} = 1 - DOFT_{\mathrm{R}i} \tag{3}$$

Here R is the value of reduced level of performance according to the project requirements and i is the number of critical failures. A large number of different factors affect the magnitude of the transition probabilities, from the environmental parameters to the used maintenance strategies, monitoring, and diagnostics.

As can be seen from (3), for the calculation of the transition probabilities the main challenge is the correct calculation of $DOFT$ for given project required performance levels. The method of determining its value in accordance with [24] is presented below.

Considering the definition of fault tolerance of a technical system as an ability to maintain the required functional level of the system, in case of one or more failures of its components, the $DOFT$ can be defined as the amount of time, in which the system may remain in a degraded state without irreversible changes in its functionality. Mathematically, in general form this can be written as in (4):

$$DOFT_{\mathrm{R}i} = \frac{W_{\mathrm{R}}}{W_{\mathrm{N}}} \cdot \frac{\Delta t_i}{\Delta t_{\mathrm{N}}} \tag{4}$$

where W_{R} and W_{N} are the reduced (R) and nominal (N) values of the performance of technical system; Δt_i and Δt_{N} are the duration of functioning after i failures and without failure, respectively.

For quantitative assessment of the overload capability and thermal stability of the inverter's submodule, their thermal behavior for various load modes has been experimentally investigated and is discussed below.

5.3 Thermal Behavior of the Inverter

The thermal stability and overload capacity of the power electronic inverter is an important part for a save and sustainable operation of an electrical helicopter. Therefore, the definition of these parameters must be performed with the great accuracy.

On the basis of an experimental study, the compliance of the graph of Figure 4 with the real values of the inverter's overload capacity was verified, as well as the legitimacy (or illegitimacy) of its use in determining the transition probabilities for MSS reliability Markov Models.

As mentioned above the optimal option, considering the project requirements is a cascaded H-bridge 17-level inverter as shown in Figure 13. It consists of 8 submodules in each phase and 9 similar phases. Each submodule consists of a battery storage unit and a MOSFET full bridge and is connected in series with other submodules.

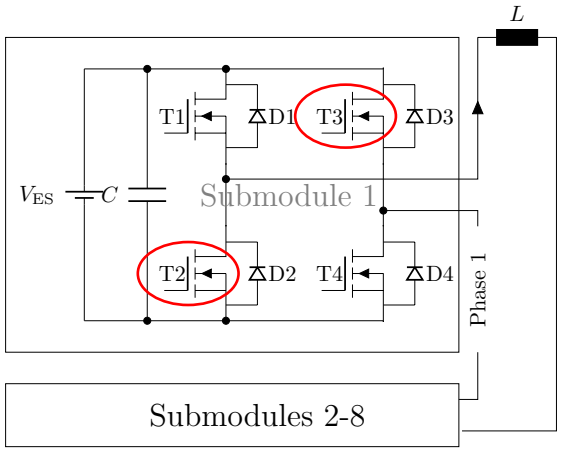

Figure 13: Multilevel CHB inverter submodule.

A full bridge used in a cascaded H-bridge multilevel inverter with lithium batteries was taken into account for an experimental verification of the normative thermal stability of the MOSFET's power inverter.

For this verification of EN61000-2-4 [29] was the full bridge tested for 20 min with 10% more current than the nominal current, 10 min with 25%, 60s with 50% more current and 1 s with 100% (double of the nominal current). Furthermore the thermal capacity of the inverter has been estimated and the thermal behavior of the full bridge was observed.

Table 7 shows the characteristics of the MOSFET type IPP023NE7N3, which has been investigated.

Figure 14 shows an experimental test bench for investigating the thermal behavior of the inverter's submodule. For the construction of the test bench, the results of the research, discussed in [30–32], were taken into account.

Figure 14: Test bench setup for the thermal tests of the full bridge.

In general, the test bench consists out of a power

Table 7: Description of the used MOSFET.

Type	IPP023NE7N3
Maximum voltage	75 V
On-state resistance	2.3 mΩ
Maximum continuous drain current	120 A

supply, the submodule, load resistors, and the measurement devices. The submodule is directly connected to the power supply on the DC-side and the resistors on the AC-side. The DC current at the power supply was set by adjusting the resistance of the load resistors. Therefore the power supply was working in control voltage mode, excepted from the last test (double nominal current), which would exceed the capabilities of the power supply.

The output voltage of the power supply had to be reduced in order not to exceed the maximum output power of 3 kW. The full bridge was working with a pulse width modulated (PWM) signal. The constant pulse width of 500 s was generated by a PWM frequency of 1 kHz and a duty cycle of 50%. The submodule had to operate covered under a box with just a few holes near the top and bottom side. This box ensures that only natural convection can take place and a possible airflow in the measurement environment would not affect the measurement results.

The measurement data consists out of the timestamps and two MOSFET temperatures, namely MOSFET 2 and MOSFET 3 of the submodule from Figure 13. The temperature measurements of the test item, as can be seen in Figure 15, were taken by a thermocouple sensor. Two bimetal temperature sensors, which were evaluated by multi-meters, were used as measuring means. Thermal imaging was also used to validate the temperature measurement by the thermocouple. The measurement was evaluated as representative.

Figure 16 shows the picture of the thermal imaging camera. It illustrates that the heat transfer to the cooling elements work properly and that the chosen measurement points offer a representative result. A STM32F4 controller generates the PWM signal for the control of the full-bridge. The standard PWM frequency within the inverter is 1 kHz. It should be noted that each experiment with different load levels continued until the failure of the tested MOSFETs or when the normative values of the duration of fail-safe operation were significantly exceeded.

The Figures 17–21 show the thermal characteristics of the submodule for various load modes, i.e. nominal load, 10%, 25%, 50%, and 100% overload of power electronic devices. The experiments were stopped when the time range significantly exceeded the normative values of Figure 4 for every load mode. The experimental targets were clearly exceeded. The tested submodule has shown large reserves in the overload capacity. During the tests no unexpected defects have been occurred. Thus, the normative overload data (Figure 4) can be used to determine the transition probabilities of MSS MM without any restrictions.

6 Results of Simulation

By the simulation has been considered the worst case, critically dangerous variant of failure – the submodule failures occur consistently in the same phase. In case of the simulation of a not safety-critical failure, as well as the possibility of partial recovery of power drive's operating ability in the degraded state, the value of the fault tolerance will be significantly higher. Considering the design requirements on the fault tolerance, the sustainable functionality of the inverter in the failure cases was analyzed using the above MSS MM for a power demand of 113% of the nominal value. The corresponding graphs for a different number of phases are presented in Figure 17.

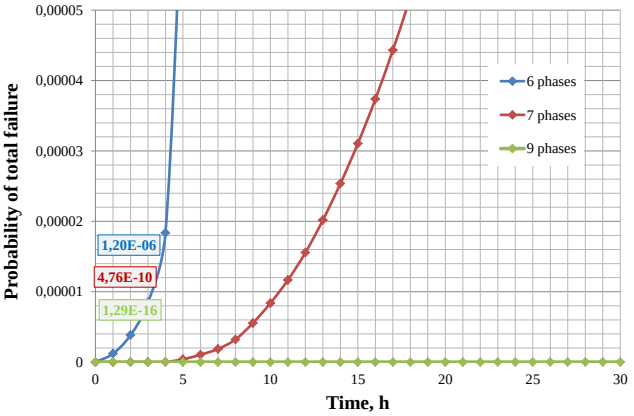

Figure 22: Probability of total failure one inverter phase.

The results of simulation of three consecutive critically dangerous failures allow quantifying the degree of fault tolerance of a multilevel inverter, which is a one important part of the traction drive of helicopters. The 7- and 9-phase options have shown the maximum compliance with the requirements relating to the safety-critical drives. For further studies of reliability and fault tolerance of safety-critical electrical drives, it is advisable to evaluate the integrated performance of electric drive as a whole, considering the reliability characteristics of electric power source, power electronics, and electric motor.

It is also of significant interest to quantitatively assess the impact of the maintenance strategy on the reliability and fault tolerance of electrical drive of the helicopter.

7 Conclusion

The paper presents the results of complex comparative analysis of an important part of the safety-critical drive train – the electric inverter, including an analysis of the reliability and fault tolerance of inverter in emergency operational modes.

On the basis of the developed techniques and models, taking into account the strict requirements on the safety-critical drive of an electrical helicopter, the authors carried out a comparative analysis of the fault tolerance degree of considered inverter topologies, which, in turn, led to the conclusion about the optimal range of applicability and feasibility of each compared variant of topology considering the specified safety requirements.

ABSTRACT

In recent years pattern recognition of power quality (PQ) disturbances in smart grids has developed into crucial topic for system equipments and end-users. Undoubtedly analyzing the PQ disturbances develop and maintain smart grids effectiveness. Voltage sags are the most common events that affect power quality. These faults are also the most costly. This paper represents performance comparisons of different computer intelligence methods for voltage sag identification. PQube Analyzer which is installed in Ondokuz Mayis University Computer Laboratory for collecting real time disturbances data for each three phases in order to test for proposed algorithms. Firstly, we used Hilbert Huang Transform to genarate Instantaneous Amplitude (IA) feature signal. Then Characteristic features are attained from IA. The 4 features, mean, standard deviation, skewness, kurtosis of IA are calculated. Support Vector Machines (SVMs) and C4.5 Decision Tree methods are conducted for classification of the disturbance. Secondly we used Fishers Discriminant Ratio for selecting statistical features such as mean, standard deviation, skewness and kurtosis of the normal and voltage sag signals for this part K Means Clustering Method were performed for classification of the disturbance. Consecuently, SVMs, C4.5 Decision Tree and K Means Clustering Methods were performed also their achievements were matched for error rates and CPU timing.

1. Introduction

PQ problems occur due to frequency, voltage swells, voltage sags, light flicker, voltage transients, harmonics, unbalanced 3-phase signal. All equipments influence the grid by the reproduction harmonics, voltage variations. Also the performance of transformers and generators are affected by the power quality on the distribution network. Unanticipated alteration of the voltage and current signal from healthy conditions can devastate or stoppage the critical electrical machineries created for various aim [1-5].

1.1. Voltage sag

Voltage sags are short-duration (less than 1 second) reductions in voltage magnitude. The sag is mostly related with the short circuit faults single-line to ground, line to line, and for three-phase to ground faults. This type of disturbance is nowadays one of the main PQ disturbances. Momentary increase of current has many origins in power systems such as energizing of transformers, short circuits, earth faults and starting of induction motors. Voltage sags are the most typical disturbances that affect power quality in smart grids. Moreover, they are the most costly. When voltage sag happens, the power supply inside electronic devices uses some of its stored energy to make up for the failure of input voltage. If enough energy is lost owing to the sag, then the power supply may fail its task to maintain adequate

DC voltage to components. Even for nanoseconds such integrated circuits, inside the device are affected by. This is very short moment to destroy data in microprocessor based electronics and to bring about malfunctions of digital equipment especially PCs. Malfunction of PCs integrated. in a real-time system is linked with conceivably bigger results, because there are losses correlate with the controlled process. The sensitivity of PCs to voltage sags is mostly expressed only in terms of the magnitude and duration of the voltage sag [25, 26, 30, 31, 40]. Considering previous studies about PQ disturbances analysis, Short-Time Fourier Transform (STFT) have been applied for stationary and periodic signals in frequency domains. But when handling non-stationary signals, it is problematic to analyze with STFT [47, 48, 49]. It was experimentally verified and demonstrated the WT is better than STFT [47]. Wavelets are employed in PQ when the time information is crucial however, it is not crucial to perceive the specific frequency of a fault in waveforms. Using WT, high time resolution is arranged for high- frequency components and low time resolution is attained for low-frequency components of the disturbance. Another method, ST is acquired by multiplying WT

*Turgay Yalcin, Ondokuz Mayis University, Electrical&Electronic Engineering Faculty, 55139, Samsun, TURKEY, +903623121919,turgay.yalcin@omu.edu.tr

with a phase correction factor. This method's disadvantage is having large computation time. Since ST is a Fourier-based technique, it also deteriorates from the handicaps of Fast Fourier Transform (FFT) [18, 20, 47, 48, 49]. On the other hand, the Hilbert Huang Transform (HHT), signals are extracted for different oscillation modes called intrinsic mode functions (IMFs). These functions are related to different time scales. Application of Hilbert transform to these IMFs can indicate the instantaneous amplitudes (IA) and the instantaneous frequencies (IF). Therefore, HHT can give a reasonably better time-frequency pattern representations for non-stationary signals [6, 11, 12, 13, 18, 19, 21]. In the light of this information, we used the HHT for generating IA signals from the voltage sag signal Firstly, for 3 phases (L1-N, L2-N, L3-N) real time processing the first intrinsic mode function is removed with the addition (superposition) of remain components to reconstruct the analyzed signal. Secondly, we generate features with the help of statistical functions such as mean, Standard deviation, skewness and kurtosis. For Diagnosis part we utilized Support Vector Machines, Decision Tree, and K Means Clustering Methods. These methods have performed also their achievements were matched for error rates and CPU timing.

2. Material and Methods

2.1. Signal Processing Methods for Feature Generation

Unlike the traditional methods such as STFT (Short time fourier Transform), Wavelet Transform (WT) and Stockwell Transform (ST), Hilbert Huang Transform (HHT), especially for noise assisted PQ disturbances signals, provides better and useful representation in order to detect the disturbance. Disadvantages and advantages of signal processing methods for feature generation procedure summarized in Table I.

Table I. Comparison of feature extraction methods for PQ disturbances [11, 18, 21]

	Disadvantages	Advantages
STFT	**Basis: Non-adaptive Completely Theoretical** Not acceptable for non-stationary signal as it does not follow signal oscillation accurately because of limitation of fixed window width	Profitably handle for stationary signals where properties of signals do not derive in time. Quite simple in application.
WT	**Basis: Non-adaptive Completely Theoretical** Fully affected by noise present in the signal, adversity from spectral leakage effects	Gives local illustration in both time and frequency. Thus, suitable good time– frequency resolution is appropriate.
ST	**Basis: Non-adaptive Completely Theoretical** Does not accomplish real-time requirement based on block processing, false harmonics measurement owing to dependency of frequency window width	Maintain time and frequency representation. Good time-frequency resolution.
HHT	Limited for narrow band conditions Mode mixing and end effect problems	**Basis: Adaptive Empirical** Conveniently applicable to non-linear and non-stationary processes. Generates perpendicular IMFs whereby instantaneous amplitude and phase can be easily assessed be easily evaluated

2.2. Stockwell transform (S- transform)

The S-transform is a time–frequency plane gadget produced by the mixture of wavelet and short time fourier transform It generates a time– frequency plane of a time series. It individually merges a frequency dependent resolution that contains the real and imaginary part of spectrum. Gaussian modulated co-sinusoids are the primary function for the S-transform [6, 7]. The Short Time Fourier Transform (STFT) of signal $x(t)$ is explained in equation 1.

$$STFT(\tau, f) = \int_{-\infty}^{\infty} x(t) g(\tau - t) e^{-j2\pi ft} dt \quad (1)$$

τ and f stand for the time of spectral localization and Fourier frequency, $g(t)$ shows a window function. The S transform could stem from (1) by putting into $g(t)$ with the Gaussian function, explained in equation 2.

$$g(t) = \frac{|f|}{\sqrt{2\pi}} e^{-\frac{t^2 f^2}{2}} \quad (2)$$

Ultimately the S transform is achieved in equation 3.

$$S(\tau, f) = \int_{-\infty}^{\infty} x(t) \frac{|f|}{\sqrt{2\pi}} e^{\frac{(\tau - t)^2 f^2}{2}} e^{-j2\pi ft} dt \quad (3)$$

If the window of S transform is wider in time, it gives better frequency resolution for lower frequency. Whereas the window is narrower, it gives superior time resolution for higher frequency, namely trade-off between time and frequency resolution [18, 20].

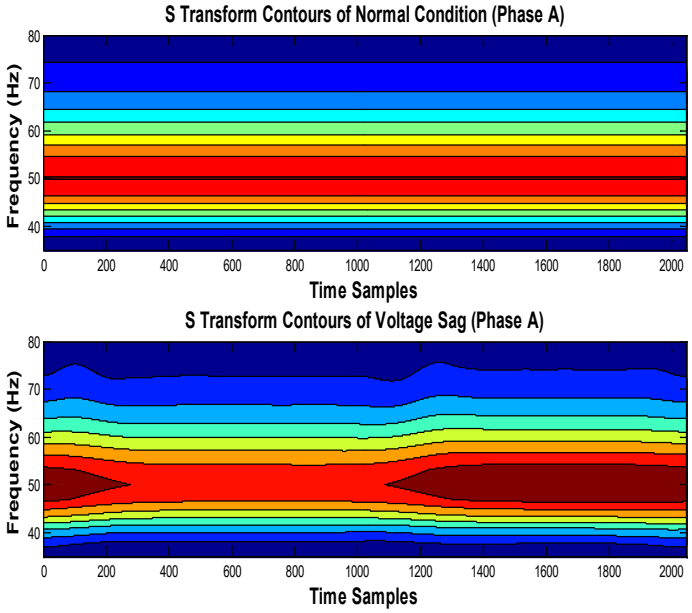

Figure 1. STransform Contours of Normal – Voltage Sag Cases

S-Transform is not capable of detecting noise as much as HHT in real time measurements [8, 32] (Figure 1). However, it is clearly shown that ST can produce valid features for detecting voltage sag.

2.3. Proposed Method: Hilbert Huang transform

HHT, a self-adaptive signal-processing method, which has been applied in non-stationary signal-processing successfully, was developed by Huang. EMD method is a ***sifting*** iteration, to decompose one Intrinsic Mode Function (IMF) component needs many times sifting till obtaining last IMF, residual monotonic function [9, 10]. Main steps of HHT shown in figure 2.

The EMD [11, 12, 13] algorithm the steps:

Beginning of Sifting Process

1. Find all maximas and minimas of the signal $x(t)$.
2. Attain the upper and lower envelope by the cubic spline interpolation.
3. Find the mean function of the upper and lower envelope $mean(t)$.
4. Calculate the difference signal $f(t) = x(t) - mean(t)$.
5. When $f(t)$ becomes a zero-mean process, then the iteration stops and $f(t)$ is an Intrinsic Mode Function IMF1, $c_1(t)$; otherwise, go first step and replace $x(t)$ with $f(t)$.
6. Calculate the residue signal $res(t) = x(t) - c_1(t)$. Iterate the procedure from steps (i) to (vi) to obtain IMF2, named $c_2(t)$. To attain $c_n(t)$, continue steps (1) till step (6) after n iterations.

End of the Sifting Process

7. The algorithm stops when the final residual signal $res(t)$ becomes a monotonic function.

2.3.1. Ensemble EMD (EEMD) Algorithm

The major challenge of the EMD algorithm is the appearance of mode mixing. Therefore the EEMD algorithm was performed for overcoming the problem in this study [12, 13].

Analyzed signal is decomposed using the ensemble empirical mode decomposition (EEMD) into intrinsic mode function (IMF) that includes instantaneous frequencies (IF) and instantaneous amplitudes (IA). When the signal is turn into IMFs, the Hilbert transform can formerly be carried out to each IMF giving the IA and IF versus time plot. This merging of EEMD process and Hilbert transform is known as the HHT [6, 11, 12, 13, 18, 19, 21].

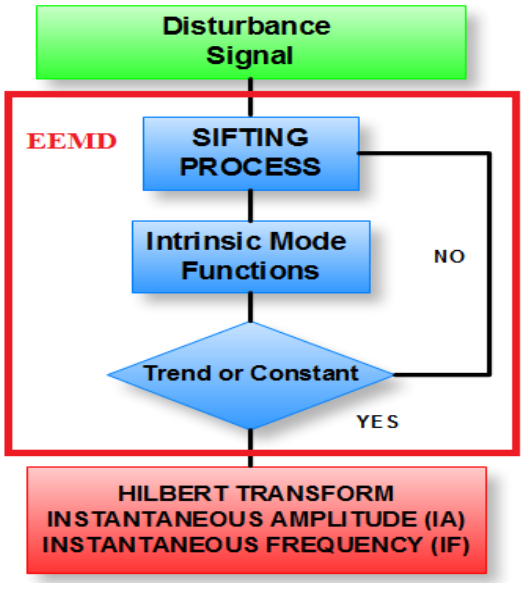

Figure 2. Main steps of the feature generation routine with HHT

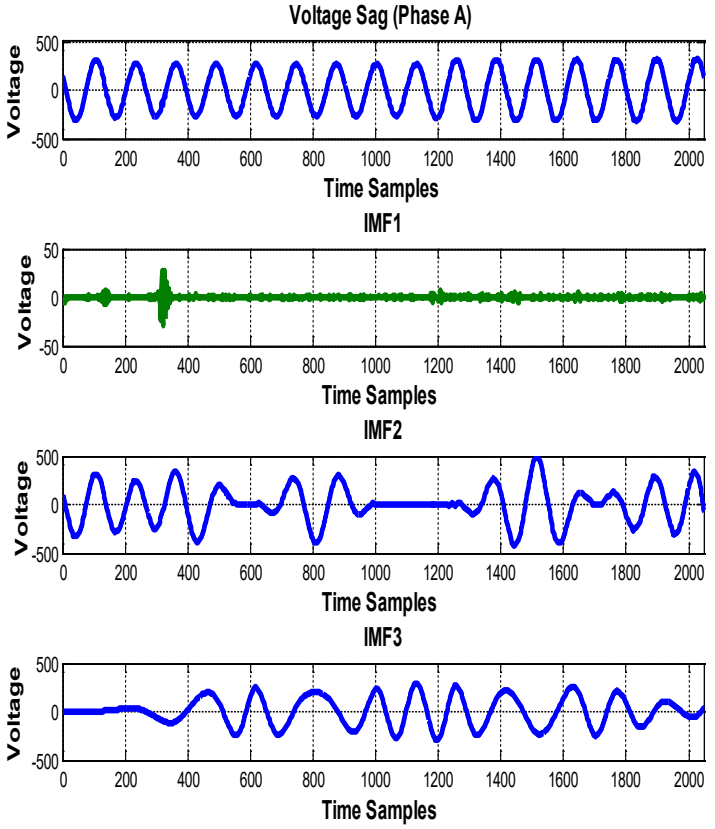

Figure 3a. Feature vectors (IMF1 (noise) to IMF3) for a voltage sag signal with EEMD

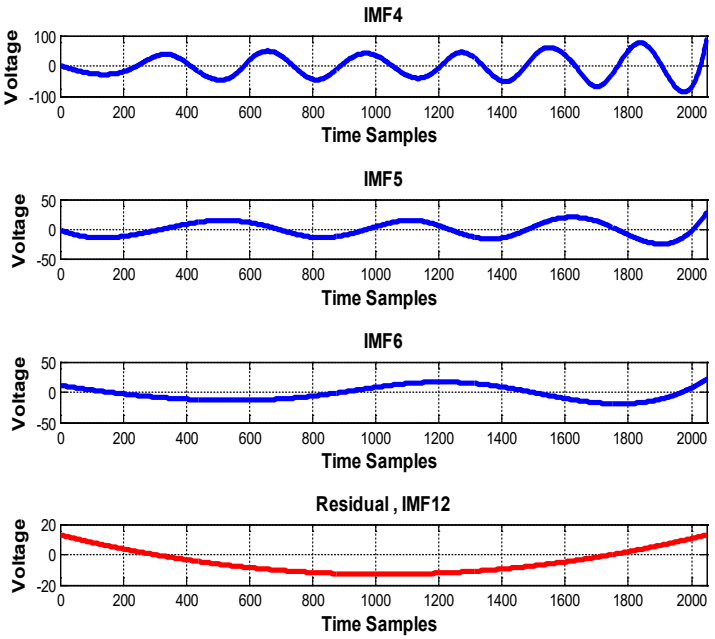

Figure 3b. Feature vectors (IMF4 to Residual (IMF12)) for a voltage sag signal with EEMD

For 3 phases (L1-N, L2-N, L3-N) real time processing the first intrinsic mode function is removed with the addition (superposition) of remain components to reconstruct the analyzed signal. Fig 3 illustrates first component IMF1 the noise (lowest

magnitude highest frequency signal) on the line (L1-N) to the lowest frequency component residual, last IMF12.

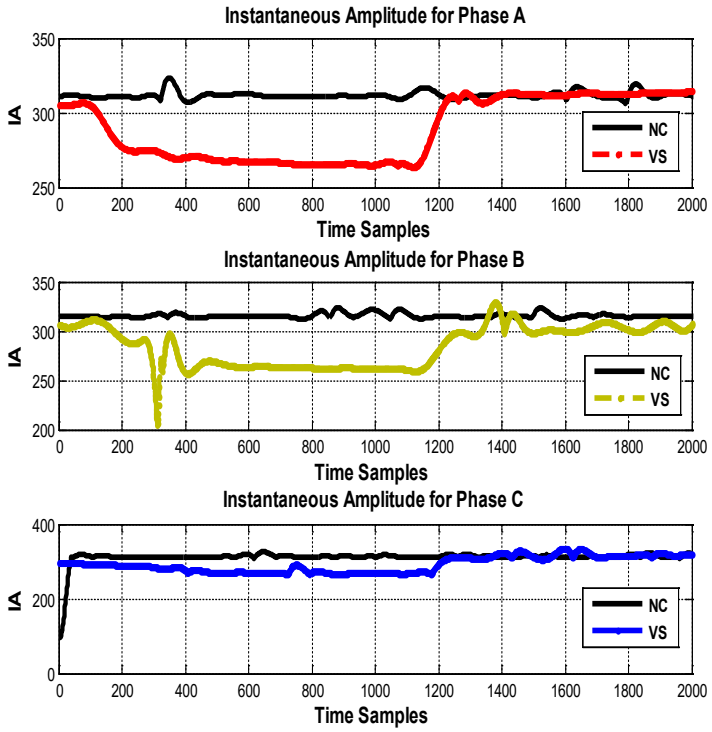

Figure 4. IA corresponding to remove first IMF voltage sag condition of signal

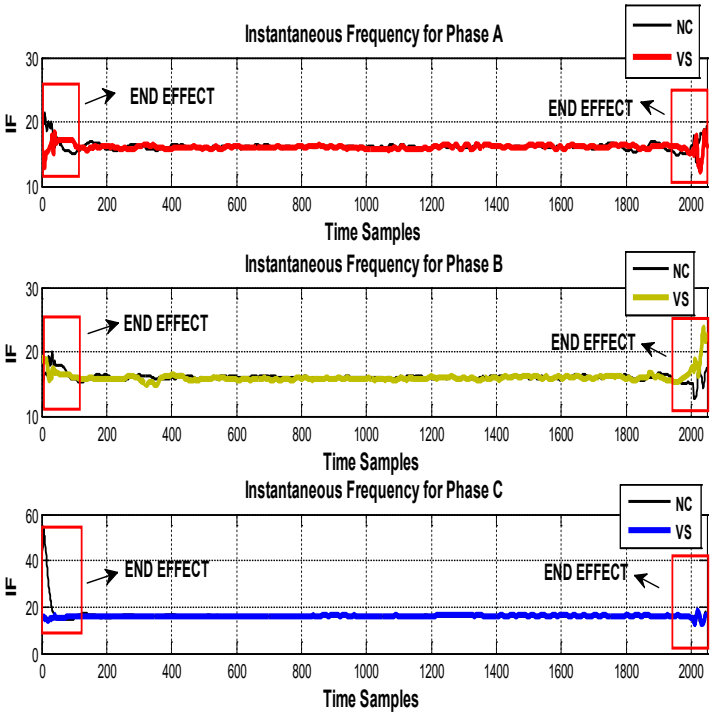

Figure 5. IF corresponding to remove first IMFs voltage sag condition of signal

IF signal can be used for separation for two cases but there is end effect problem that has to be solved. When cubic spline fitting is computationally demanding, it generates distortions near the end points. This is a technical problem that causes data failures and peaks at the beginning and at the end of the signal. This fault will be investigated on Hilbert-Huang transform (Figure 5).

3. PQ Disturbances Computational Intelligence Methods

3.1. Support vector machine (SVM)

SVM methods, is developed by Vapnik, whereby statistical learning technique being the basis contributes a novel machine learning method. SVMs are linked supervised learning methods used for classification and regression. SVMs target obtaining optimal hyper-planes different classes of input data in a high dimensional feature space, thus new test data can be classified by acquired the hyper-planes Support vectors lie closest to the optimal hyper-plane [7, 14, 18, 21, 28, 34].

Let $\{x_i,y_i\}$, $i = 1,2,\ldots,M$ be M training data vectors x_i with class label y_i. Given an input vector x, an SVM constructs a classifier of the form:

$$f(x) = sign(\sum_{i=1}^{M} a_i y_i K(x_i, x) + b) \quad (4)$$

a_i denotes non-negative Lagrange multipliers each of which corresponds to a training data, b denotes bias, $K(.\ ,\ .)$ is a kernel fullfilling the conditions of *Mercer's theorem* [11, 34]. In this study we performed two kernel functions are the polynomial kernel $K(x_i, x_j) = (x_i . x_j + 1)^d$ we tested for d=2, 3. Gaussian Radial Basis Function (RBF) $K(x_i, x_j) = e^{-\frac{|x_i - x_j|^2}{2\sigma^2}}$ we tested sigma 0.01 and 1 in this study.

3.2. Decision Trees

Decision trees are methods that utilize divide-and-conquer approaches as structure learning by induction [15, 16]. The C4.5 algorithm was developed by Qinlan, contains the generation of a tree whereby a training set, finding the information gain criterion with the help of Shannon Entropy in order to find the finest attribute/feature to be used at each node.

3.2.1. Shannon Entropy

It is given a probability distribution $D = (d_1, d_2, \ldots, d_m)$ the Information carried by this distribution entropy of D is explained in equation 5.

$$Entropy(D) = -\sum_{i=1}^{m} d_i \log(d_i) \quad (4)$$

3.2.2. The Information Gain

The Information defines the gain for a test t and a position d

$$Gain(D,t) = Entropy(D) - \sum_{j=1}^{m} d_j Entropy(d_j) \quad (5)$$

that values (*dj*) is the set of all possible values for attribute *t*. Equation 5 can calculate highest ranking attributes and build the decision tree where at each node is located the attribute with the highest information gain. Furthermore, the algorithm applies the post pruning approach to diminish the size of the tree and prohibit over fitting. C4.5 is a technique for approximating discrete-valued functions that is powerful tool to noisy data and suitable for learning distinctive statements [16, 17, 18, 19, 20, 21, 28, 29].

3.3. K-Means Clustering

K-means clustering algorithm is a significant unsupervised classification technique to separation of set of dissimilar patterns. Same featured patterns are arranged into same clusters, different features are replaced in different sets [22, 23].The steps of the algorithm:

1. Apply K points into the space illustrated by objects being clustered. These points symbolize first group centroids. Determine each object to the nearest centroid group.
2. As objects have been completed, recalculate the localizations of the K centroids.
3. Iterate Steps 1 and 2 until the centroids do not change anymore. This creates a separation of the objects into groups from which the metric with squared Euclidean distance objective function which is defined in equation 6, can be calculated.

The objective of this algorithm is to make an objective function, minimize the squared error function [35, 36, 37].

$$Obj(x) = \sum_{i=1}^{K} \sum_{x_j \in S_i} \left\| x_i - \mu_i \right\|^2 \qquad (6)$$

K denotes clusters S_i, $i = 1, 2, \ldots, k$, and μ_i is the mean points of centroids.

3.3.1. Fisher's discriminant ratio (FDR)

FDR or SNR (in machine learning) is commonly performed to compute the inequitable way of specific features between two clusters. Linked with the values of a feature in two classes, μ_1 and μ_2 be the respective mean values and σ_1^2 and σ_2^2 the respective variances defined in equation 7 [38, 39].

$$FDR = \frac{(\mu_1 - \mu_2)^2}{(\sigma_1^2 + \sigma_2^2)} \qquad (7)$$

4. Experimental Set up and Discussions

For experimental studies, we installed PQube Analyzer in Ondokuz Mayis University Computer Laboratory for collecting real time disturbances data for each three phases in order to test for proposed algorithms. 3 phases connected with totally 28 numbers of PC loads. PQube power meter installation properties explained in appendix of the paper. This paper includes computational intelligence methods in order to classify voltage sag disturbance. Figure 6 shows 3 phase voltage sag condition PQube sample measurements from Computer Laboratory in Ondokuz Mayis University including July 2016 to December 2016.

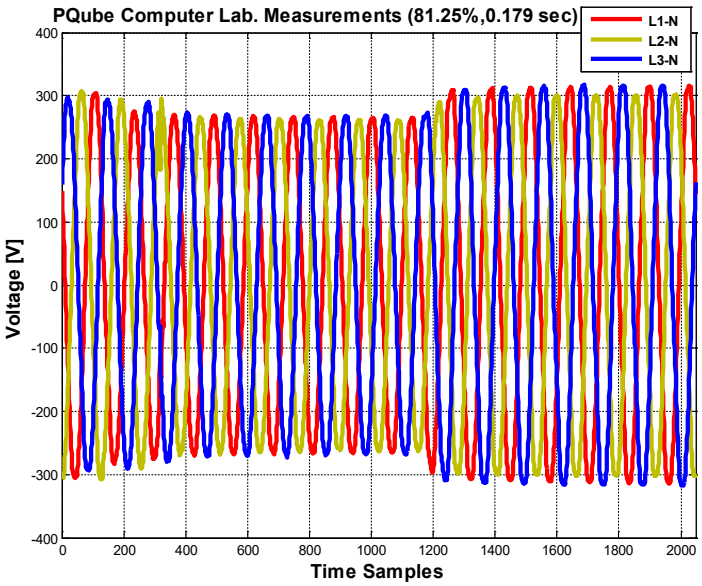

Figure 6. Computer laboratory power quality monitor with PQube voltage sag

In this study, we apply two methods for identification of voltage sag. Selecting appropriate features of voltage sag events are highly crucial for diagnosing of the fault properly. Classification process of real-time voltage sag disturbances are shown in Figure 7.

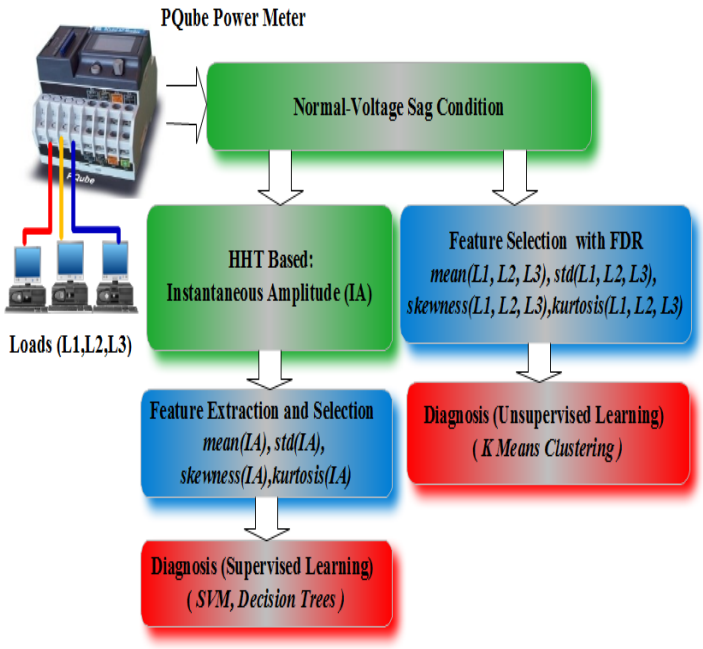

Figure 7. Schematic model of Voltage Sag Classification

First Method, firstly extracted features are produced from ensemble empirical mode decomposition (EEMD) method so as to classify the voltage sags in grid. After reconstruction signal without noisy part, removing first intrinsic mode function (IMF). Then instantaneous amplitude (IA) is generated by means of HHT. The following features were extracted: mean, standard deviation, skewness function results of IA.

Second Method, we generated the statistical features from PQube 3 phase line voltages. In order to select the best feature from the functions, we performed Fisher Discriminant Ratio criteria. Selected features which give high ratio for Phase A and B are standart deviation and kurtosis, for phase C are mean and skewness. Then we used generated features for K Means Clustering Methods. Figure 8 shows selected features space and cluster assignments and centroids of normal and voltage sag condition sets.

Table II. Performances of disturbance diagnose algorithms

	Phase A (L1-N)		Phase B (L2-N)		Phase C (L3-N)	
	Error rate (ER)(%)	Execution time(ET) (sec)	ER	ET	ER	ET
SVM-poly d=2	10	4.088	0	3.321	20	5.883
SVM-poly d=3	10	3.929	0	3.636	20	5.489
SVM-RBF sigma =0.01	50	0.738	**0**	**3.064**	20	5.805
SVM-RBF sigma =1	**0**	**5.254**	0	5.368	50	0.674
DecisionTree C4.5	20	6.20	20	6.835	20	3.514
K-Means (Euclidean distance)	6.66	0.693	16.6	0.510	**13.3**	**0.480**

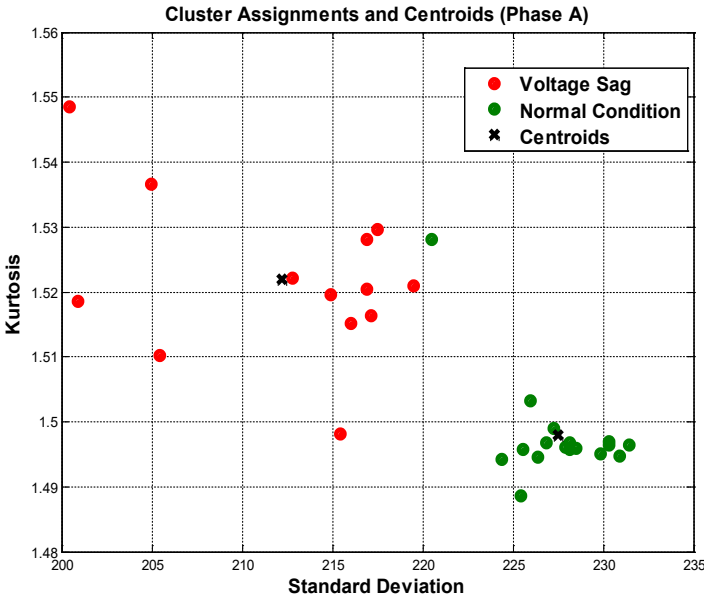

Figure 8. Feature Space and Clusters for Phase A

To figure out the performance of the proposed power quality classification algorithm, a total number of 30 PQube Analyzer real time disturbances data were used 15 for normal conditions 15 for voltage sag conditions. The PQ signals are divided into two categories; 20 of them were used for training and 10 of them were used for testing the proposed algorithm with shuffling the data.

We analyzed for each three phases separately owing to main source connected with different loads (number of computers). This study is the first step of our work, second step will be searching relations with number of computers for each phases and fault percentage.

- In the light of Table II., for phase A, it is concluded that for radial basis kernel function sigma 1, gives more proper result precision of 100% and CPU time (5.254 sec) in non linear SVM. Kernel function for SVM is $K(x_i, x_j) = e^{-\frac{|x_i - x_j|^2}{2(1)^2}}$

- For phase B, it is deduced that for radial basis kernel function sigma 0.01, gives more accurate result precision of 100% and CPU time (3.064 sec) in non linear SVM.

  Kernel function for SVM is $K(x_i, x_j) = e^{-\frac{|x_i - x_j|^2}{2(0.01)^2}}$

- For phase C, it is deduced that for K-Means clustering (Euclidean distance function ($d_{i,j}$)), gives better result precision of 86.7% and CPU time (0.480 sec). $Euclidean(d_{i,j} = \sqrt{\sum_{k=1}^{n}(x_{ik} - x_{jk})^2})$

- It is clearly shown in Table II when examining each phases K- means clustering algorithm is the fastest algorithm.

- For phase A and B, SVM with RBF sigma=1 gives better results for detection voltage sag.

- For three phases, C4.5 decision tree gives same 80% recognition rate.

(Note: the most proper and robust classifiers for each phase are showed by Red font in Table II).

5. Conclusion

In this study, we aimed to generate non-time consuming features for detection voltage sag in smart grid. We also process and classify real time 3 phase voltage sag signals. In contrast to literature studies we do not normalize the features. Thus we can relate load types and fault magnitude and duration. Also it is processed real-time noise- assisted data. For this reason this study gives effective ideas about real time disturbance detection. As a result, SVMs, C4.5 Decision Tree and K Means Clustering Methods were performed also their achievements were matched for error rates and CPU timing. Simulations indicate that K-means clustering algorithm is the fastest algorithm. For phase A and B, SVM with RBF sigma=1 gives better result for detection voltage sag. Simulation results will be using for relation with loads types and the magnitude and duration of the voltage sag.

Table III provides discussions about related signal processing methods such as WT, ST HT and for decision part SVM, DT, k-nearest neighbor (k-nn), Probability Neural Network (PNN). It also gives percentages error rates literature studies and the proposed methods. It is clearly shown in Table III most of the studies reported the results on synthetic normalized an done phase data which are absolutely far from real PQ disturbances. Apart from the previous studies, detection capability validates the potential of the proposed algorithm. To analyze the real time power signals and classification techniques were employed with Matlab ™ Toolboxes.

Table III. Performances of disturbance diagnose algorithms

APPENDIX

Table IV. PQUBE MAINS VOLTAGE MEASURING CHANNELS [33]

Connection	L1, L2, L3, N PQube screw terminals
Frequency Range	40 Hz ~ 70 Hz and 320 Hz ~ 560 Hz. Nominal 50 Hz, 60 Hz, or 400 Hz auto, 320-560 Hz manually selected.
Specifications below apply at 50/60 Hz.	
Mains Configuration	Single-phase, split-phase, delta, wye or star. User selected or auto-selected.
Range of Nominal Input Voltage	100 VAC ~ 690 VAC L-L (69 VAC ~ 400 VAC L-N). User selected or auto-selected.
Measurement Channels	Line-to-Neutral, Line-to-Line, Neutral-to-Earth.
Sampling Rate	256 samples per cycle, phase-locked to input frequency.
Measurement Range	0 VAC ~ 900 VAC L-L (520 VAC L-N)
Accuracy	±0.05% rdg ±0.05% FS typical (10%~150% of nominal). Factory tested at better than ±0.04% rdg ±0.04% FS. Note: FS = 345 VAC or 520 VAC, selected based on nominal line-to-earth voltage.

ABSTRACT

Side-Channel Attack (SCA) is an effective method in extracting the secret key of cryptographic algorithms by correlating the physical leakage information with the processed data. In this paper, we propose an arithmetic hiding cum Look-up Table (AHLUT) based Substitution-Box (S-Box) in AES-128 cryptographic algorithm implementation to countermeasure against SCA. There are three key features in our proposed AHLUT S-Box. First, the arithmetic hiding performs four types of arithmetic operations such that their total physical leakage information sufficiently overshadows the correlated physical leakage information of the S-Box operation. This is to reduce the correlation of the AES-128 physical leakage information with the processed data. Second, the AHLUT S-Box pre-stores all the 256 bytes of possible output values based on the conventional S-Box and selects a corresponding output value with respect to the input accordingly. In this context, it dissipates significantly lower power when compared to the conventional S-Box which performs multiplication inversion and affine transformation. Third, we propose a methodology to determine a minimum number of the arithmetic operations to sufficiently overshadow the physical leakage information of the S-Box operation. Based on the measurement results of performing AES-128 algorithm on Sakura-X FPGA encryption-board and in term of power dissipation, our proposed AHLUT S-Box dissipates 1.6mW and features 11.56× lower power dissipation than the conventional S-Box. In term of security which is based on Correlation Power Analysis attack, it requires 73× more power traces to reveal the secret key for our proposed AHLUT S-Box than the conventional S-Box. As for the non-invasive Correlation Electromagnetic Analysis attack, it requires 25× more electromagnetic traces for our proposed AHLUT S-Box than the conventional S-Box.

1. Introduction

Side-Channel Attack (SCA) is an effective method to extract the secret key of cryptographic algorithms, such as Advanced Encryption Standard-128 (AES-128) algorithm, by correlating physical leakage information, generated during the encryption process, with processed data. The physical leakage information such as power dissipation [1], Electromagnetic (EM) emanation [2], temperature [3] and timing [4] information, which are measured during the encryption process, are dependent on the processed data, determined based on plaintext/ciphertext. Due to the simplicity, in term of measurement, the power dissipation and EM emanation are the most preferred by adversary to be employed in the SCA compared with other physical leakage information [1].

Fig. 1 depicts the attacking scenario of the SCA, by intercepting wireless communication, transmitting the encrypted plaintext, ciphertext, to receiver and at the same time, measuring the physical leakage information. In this scenario, the correlation based SCA, such as Correlation Power Analysis (CPA), is employed to compute and analyze the correlation between the processed data and power dissipation measurements (power traces). To protect the secret key against SCA, countermeasure techniques are employed to reduce (break) the correlation between the physical leakage information with processed data.

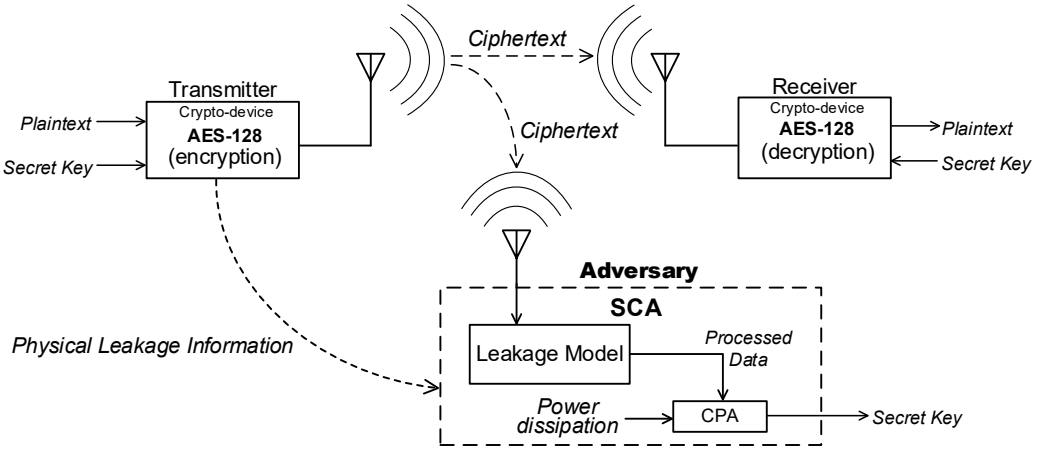

Fig. 1: Attacking scenario of SCA of wireless communication based on AES-128 implementation

The countermeasure technique is classified into two main classifications, hiding and masking, which are based on hardware and software approaches respectively [1]. The hiding technique breaks the correlation between power dissipation and processed data by balancing the power dissipation for different processed data whereas the masking technique employs masking variable (*m*) to mask the processed data against SCA. The main drawback of the masking technique is to mask and unmask of the *m* which can degrade the performance of the cryptographic algorithm implementations, such as low throughput, speed reduction and high power dissipation [2].

There are two main approaches of hiding technique, cell and block level approaches. In the cell level, several techniques have been reported such as Sense Amplifier Based Logic (SABL) [5], Wave Dynamic Differential Logic (WDDL) [6], Three-phase Dual-rail Pre-charge Logic (TDPL) [7] and Pre-Charge Static Logic (PCSL) [8]. The concept of SABL is to balance internal charges by fully charging and discharging all internal node for different processed data (i.e. bit-0 or bit-1). However, during the implementation in crypto-device, the internal charges is not fully discharged at high frequency (>100MHz) due to small variation on the internal parasitic capacitance [6]. The WDDL and PCSL implement Pre-charge and Evaluation cycle with differential logic to make a constant power dissipation for different logic transition. In the AES-128 implementation, the WDDL occupies over 3.1× area, dissipate 3.7× dynamic power and 3.8× reduction in throughput compared with standard cell implementation [5]. For the PCSL implementation, the power dissipations tend to leak information during the pre-charge cycle [6] and hence vulnerable against CPA attack. The TDPL employs dual-rail dynamic logic with three-phase clocking system (Pre-charge, Evaluation and Discharge). The three-phase clock is to ensure that the remaining internal charge is fully discharge to make a constant amount of charge for each cycle. However, the TDPL features 4.6× slower speed compared with conventional CMOS implementation [1].

For the hiding approach at the block level, the power dissipation is balanced directly at the main power supply, V_{DD} point, of the crypto-device. The hiding techniques based on block level approach are a Switching Capacitor Current Equalizer (SCCE) [9], an intermittent Supply-Current Equalizer (iSCE) [10] and A Dynamic Voltage and Frequency Switching (DVFS) [11]. The SCCE is the same principal as in the TDPL. The current equalizer implemented with integrated switching capacitors, which isolates the encryption circuits activity by equalizing the current. However, it is 33% power overhead 2× slower than conventional differential logic [8]. The iSCE is an improvement of the SCCE performance, which is only at the vulnerable round of AES-128 (i.e. 1st and 10th rounds) implement the equalizer. The current equalizer techniques (i.e. SCCE and iSCE) are both vulnerable against EM based attack by measuring the EM emanation generated after the equalizer module. The DVFS hides the correlated power dissipation against SCA by dynamically changing the scale of the voltage and frequency during the encryption. The noise generated during the operation can be filtered by Finite Impulse Response (FIR) filter with optimized parameters to increase the Signal-to-Noise Ratio (SNR). Therefore, the correlated power dissipation still can be detected and the secret key can be revealed with required low number of power traces.

In this paper, we propose an arithmetic hiding cum Look-up Table (AHLUT) based Substitution-Box (S-Box) in AES-128 cryptographic algorithm implementation to countermeasure against SCA. There are three key features in our proposed AHLUT S-Box. First, the arithmetic hiding performs four types of arithmetic operations such that their total physical leakage information sufficiently overshadows the correlated physical leakage information of the S-Box operation. This is to reduce the correlation of the AES-128 physical leakage information with the processed data. Second, the AHLUT S-Box pre-stores all the 256 bytes of possible output values based on the conventional S-Box and selects a corresponding output value with respect to the input accordingly. In this context, it dissipates significantly lower power when compared to the conventional S-Box which performs multiplication inversion and affine transformation. Third, we propose a methodology to determine a minimum number of the arithmetic operations to sufficiently overshadow the physical leakage information of the S-Box operation. Based on the measurement results of performing AES-128 algorithm on Sakura-X FPGA encryption-board and in term of power dissipation, our proposed AHLUT S-Box dissipates 1.6mW and features 11.56× lower power dissipation than the conventional S-Box. In term of security which is based on the CPA attack, it requires 73× more power traces to reveal the secret key for our proposed AHLUT S-Box than the conventional S-Box. As for the non-invasive Correlation Electromagnetic Analysis (CEMA) attack, it requires 25× more electromagnetic traces for our proposed AHLUT S-Box than the conventional S-Box.

This paper is organized as follows. Section II reviews the AES algorithm, various S-Box implementations, CPA and CEMA. Section III presents the proposed AHLUT S-Box. Section IV describes the measurement results on CPA and CEMA attack and finally, conclusions are drawn in Section V.

2. Advanced Encryption Standard, Substitution-Box operation, CPA and CEMA

In this section, an overview of the AES algorithm is briefly described followed by a description of the various topologies of the S-Box operation and the correlation based attack, the CPA and CEMA.

2.1. Advanced Encryption Standard

The AES algorithm has been employed in a variety of security systems including the defense and banking applications since 2001 [6]. It is categorized as a symmetric-key encryption algorithm, in which the transmitter and receiver employ the same secret key for encryption and decryption respectively. The AES algorithm transforms a plaintext into a ciphertext using the secret key by several iterative processes. The processed data block length is fixed at 128 bits, while the key length can be 128, 192, or 256 bits [1]. For the 128, 192 and 256 secret key length, there are 10, 12 and 14 round of iterations are required respectively.

Fig. 2 depicts the flow chart of the encryption process in the AES algorithm. Each round of iteration consists of four operations, namely S-Box, ShiftRow, MixColumn and AddRoundKey, except for the last round which does not have MixColumn operation. The decryption is a reverse operation of the encryption process, i.e. transforming the ciphertext into plaintext (original message) using the same secret key. The decryption structure can be derived by inverting the encryption structure directly [12]. The equivalent decryption structure has the same sequence of operation as in the encryption structure, thus, the resources sharing is allowed for the encryption and decryption process.

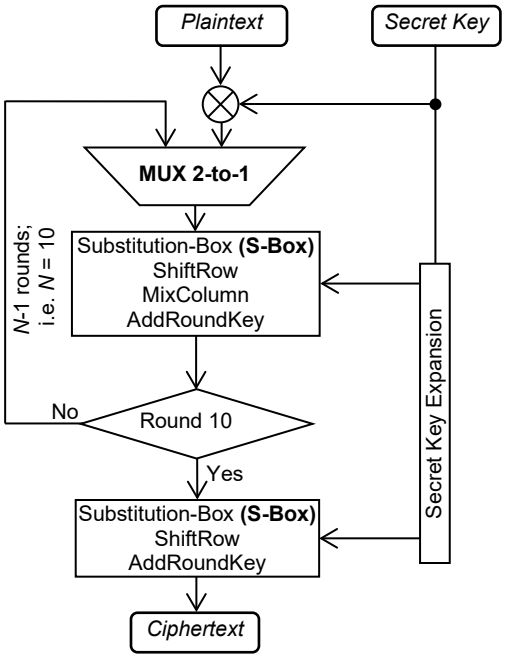

Fig. 2: Flow chart of the encryption process of the AES-128 algorithm with 10 round iterations

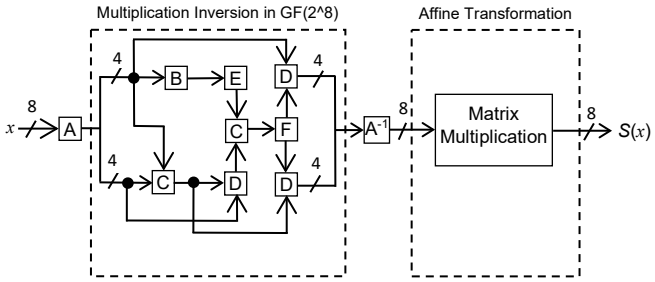
2.2. Substitution-Box

The S-Box is one of the critical operations in AES algorithm and it consists of two sub-modules [1], namely the multiplicative inversion sub-module in GF(2^8) and the Affine transformation sub-module as depicted in Fig. 2. Each input to the S-Box is a 1-byte of intermediate data, x, and the S-Box will generate 1-byte of output $S(x)$. In term of power, it dissipates 65% - 80% of the total power dissipation of the AES implementation [1]. Based on these two sub-modules, the S-Box features a non-self-inverse function, which effectively protects the data against the brute force attacks.



A = isomorphic mapping
A^{-1} = inverse isomorphic mappings
B = square operation in GF(2^4)
C = sum operation in GF(2^4)
D = multiplication operation in GF(2^4)
E = multiplication with constant operation
F = inverse operation in GF(2^4)

Fig. 3: The two sub-modules of a conventional S-Box of AES algorithm

The S-Box operation can be implemented in the form of the LUT, in which all the possible output (2^8 = 256) are pre-stored in the LUT memory, as depicted in Fig. 4. The analysis of the LUT S-Box [13] shows that the power dissipation is reduced significantly by 5.5× lower than conventional S-Box (reduces from 10.5mW to 1.9mW). However, the security features can only protect the key against CPA attack up to 13×10^3 power traces. This is due to the selection function (in the multiplexer) dissipates relatively small differences of the dynamic power for different input and output values of the S-Box.

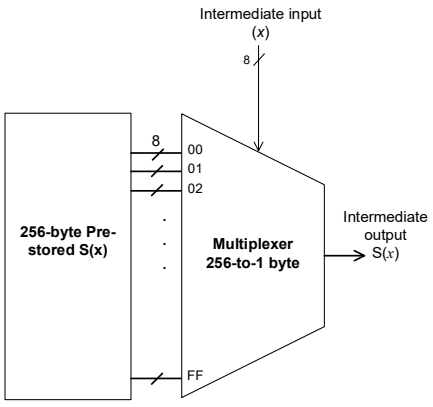


Fig. 4: LUT S-Box implementation

The data dependency with physical parameters is relatively high in the S-Box although the power dissipation can be significantly reduced by LUT technique. The variance of power traces for different input values is still detectable by CPA attack [13]. However, the low power dissipation at LUT architecture is possible to apply dummy operations, which hide the correlated power dissipation against CPA attack without sacrificing the power overhead.

2.3. CPA and CEMA

The CPA attack is a byte-based power analysis attack. Each byte of key (sub-key) is estimated by means of 256 possible values ($2^8 = 256$). The CPA attack is performed by analyzing the correlation coefficient ($r_{i,j,t}$) of two variables, power model ($X_{i,j,m}$), and the power traces ($Y_{t,m}$), for i = 1, …, 16 sub-keys, j = 1, …,256 sub-key candidates, t = 1, …, N sampling points, as follows:

$$r_{i,j,t} = \frac{\sum_{m=1}^{n}\left(X_{i,j,m} - \overline{X}_{i,j}\right)\left(Y_{t,m} - \overline{Y}_{t}\right)}{\sqrt{\sum_{m=1}^{n}\left(X_{i,j,m} - \overline{X}_{i,j}\right)^2 \left(Y_{t,m} - \overline{Y}_{t}\right)^2}} \quad (1)$$

The correct sub-key, i, corresponds to the highest $r_{i,j,t}$ at the particular sub-key candidate, j, and sampling point of power traces, t. The common power model used is either Hamming Distance (HD) or Hamming Weight (HW). The higher number of power traces required to reveal the correct sub-key, the higher CPA-resistant to the hardware, hence more secured.

The CEMA attack applies the same procedure as the CPA attack. However, the process of acquiring the physical leakage information is less invasive compare with the CPA. The adversary can simply measure the EM emanation by placing the EM probe on the crypto-device and apply the Eq. (1) to reveal the secret key.

3. Proposed AHLUT S-Box

The power dissipation generated from the crypto-device is resulted from current (I_{DD}) and voltage (V_{DD}) consumed during the processing one plaintext (consists of 16 bytes). The collection of power dissipation ($P = I_{DD} \cdot V_{DD}$) measurements form power traces [1] and the power traces can be decomposed as the total sum of power dissipations of an operation, P_{OP}, processed data, P_{DATA}, noise, P_{NOISE} and constant power (static power dissipation), P_{CONST} as described in Equation (2).

$$P_{TRACES} = P_{OP} + P_{DATA} + P_{NOISE} + P_{CONST} \quad (2)$$

The P_{OP} and P_{DATA} are generated when performing the operations of the AES-128 algorithm with different value of input data, which are the main physical leakage information employed for the SCA. The P_{NOISE} can be generated from the crypto-device and measurement tools (i.e. oscilloscope) which exhibit different noise level for different application (i.e. ASIC or FPGA) and specification respectively. The P_{NOISE} can be filtered out by means of FIR filter with optimized parameters and hence increase the SNR value of the power traces. The P_{CONST} is relatively irrelevant to the SCA, since the value is generated constantly for different operation and processed data. In this context, the SCA only consider two power dissipation components, P_{OP} and P_{DATA}, to leak out the information of the secret key.

The proposed arithmetic hiding based LUT S-Box technique, in this paper, is focused on the P_{OP} and P_{DATA}, to decorrelate between the physical leakage information and the processed data, based on the CPA attack. The main idea is to generate dummy power dissipation by performing dummy operation (P_{D_OP}) with dummy input data (P_{D_DATA}). Therefore, the total power traces measurement is the sum of main power dissipation and dummy power dissipation as expressed in Equation (3).

$$TP_{TRACES} = P_{OP} + P_{D_OP} + P_{DATA} + P_{D_DATA} \quad (3)$$

To break the correlation between power dissipation measurement and processed data, based on the CPA attack, the dummy power dissipation must be able to dominate the total power traces. In other words, the dummy power dissipation is generated in such a way that overshadow the main power dissipation of the AES-128 algorithm, as expressed in Equation (4). In this context, the changes of P_{OP} and P_{DATA}, are negligible respect to the total power traces which are used in the CPA attack as expressed in Equation (5). Eventually, the broken correlation, between power dissipation and processed data, is achieved due to the total power traces measured during the encryption is always referring to dummy operation, which is performing irrelevant operation and data with the operations in the AES-128 algorithm.

$$TP_{TRACES} = P_{OP}\downarrow + P_{D_OP}\uparrow + P_{DATA}\downarrow + P_{D_DATA}\uparrow \quad (4)$$

When P_{OP} and P_{DATA} are negligible respect to P_{D_OP} and P_{D_DATA}, the Eq. (4) can be rewrite as follows.

$$TP_{TRACES} \simeq P_{D_OP} + P_{D_DATA} \quad (5)$$

The total power traces as expressed in the Eq. (5) can be realized by performing the arithmetic operations in parallel with the operation (i.e. S-Box) of the AES-128. The S-Box operation dissipates 80% of the total power dissipation [13] and leak more information about the secret key, whereas other three operations (AddRoundKey, ShifRow and MixColumn) insignificantly leak the information of the secret key [1] due to non-data dependent operations. To overcome the power overhead and yet secure S-Box, we adopt LUT S-Box which is performed in parallel with arithmetic operation to overshadow the P_{OP} and P_{DATA} of the S-Box. The LUT S-box is adopted due to the power dissipation is 5.5× lower than the conventional S-Box (1.9mW) [13]. Consequently, it is worthwhile to implement the arithmetic operation with sufficient power overhead to overshadow the power dissipation of the S-Box operation. Fig. 5 depicts our proposed AHLUT S-Box implementation, performed in parallel with LUT S-Box. Four types of arithmetic operations, implemented, Addition (ADD), Subtraction (SUB), Division (DIV) and Multiplication (MULT) are implemented which generate unused output, Dummy output, D(x).

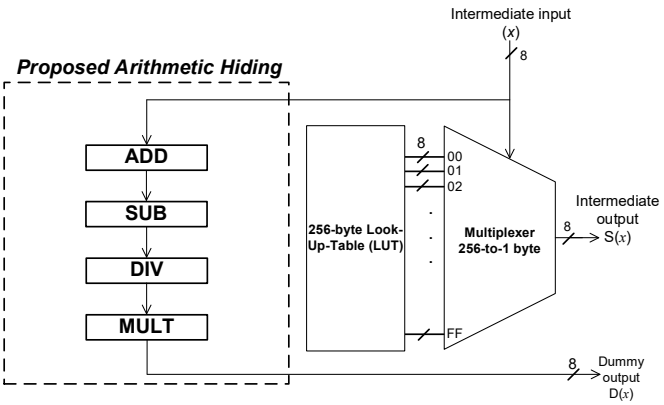

Fig. 5: Proposed arithmetic hiding is performed in parallel with LUT S-Box

In term of circuit implementation, each type of arithmetic operation requires different number of gates and dissipate different power. In addition to our proposed arithmetic hiding based LUT S-Box, we propose a methodology to select the number of arithmetic operations such that the power dissipation of these arithmetic operations sufficiently overshadows the S-Box power dissipation. Table I tabulates the number of gates and power dissipation for each arithmetic operation based on frequency of 16MHz.

TABLE. I. GATE COUNTS AND POWER DISSIPATION IN AHLUT S-BOX

Arithmetic Operations	Number of Gates			Power dissipation (mW*)
	XOR	AND	OR	
ADD	2	2	1	0.094
SUB	2	2	2	0.102
DIV	2	6	2	0.123
MULT	2	7	2	0.160

*dynamic power dissipation @16MHz

The methodology of selecting the number of arithmetic operations of our proposed AHLUT S-Box is explained as follow:

1. The power dissipation of the LUT S-Box is measured at the first stage to estimate the minimum power dissipation which will be generated by arithmetic hiding (overshadow power dissipation).
2. The power dissipation for each arithmetic operation is measured and sorted from lowest to highest, which are denoted as *a*, *b*, *c* and *d* in ascending order respectively.
3. The rule of thumb for estimating the overshadowed power dissipation is $P_{Arithmetic_operations} > P_{LUT_S\text{-}Box}$, in which $P_{Arithmetic_operations} = a{\cdot}P_{ADD} + b{\cdot}P_{SUB} + c{\cdot}P_{DIV} + d{\cdot}P_{MULT}$; $a = b = c = d \geq 1$, as expressed in Equation (6).

$$a \cdot P_{ADD} + b \cdot P_{SUB} + c \cdot P_{DIV} + d \cdot P_{MULT} > P_{LUT_S-Box} \quad (6)$$

4. The number of arithmetic operations are increased starting from *d* and evaluating the power dissipation in the Eq. (6) every increment.
5. If power dissipation of arithmetic operation is overshoot as in Eq. (6), the selection is gradually descended from *c* to *a*.
6. The overshoot power dissipation is only allowed with incremental number of *a*, which is the lowest power dissipation in the arithmetic operation.
7. The selection process for the number of arithmetic operation is terminated when the $P_{Arithmetic_operations}$ is slightly higher than $P_{LUT_S\text{-}Box}$

The output of the arithmetic operation is unconnected to the AES-128 encryption process and therefore, the output ciphertext will not be affected. The flow chart of selecting the arithmetic operation is depicted in the Fig. 6.

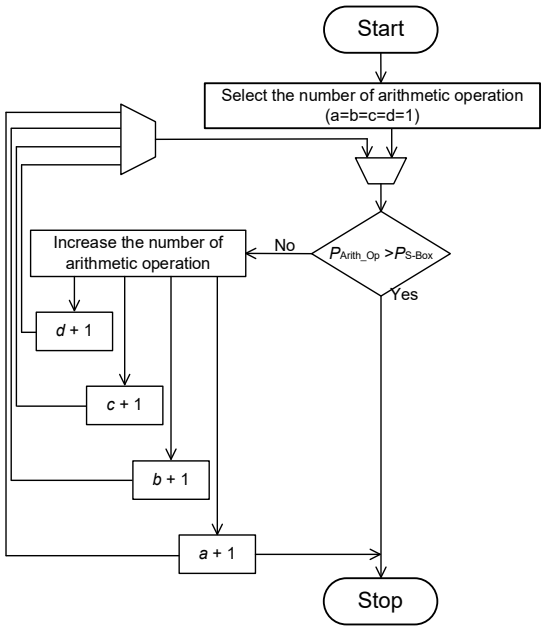

Fig. 6: Flow chart of selection the Arithmetic operations

4. Measurement Results

The experiment is performed based on Sakura-X, FPGA board [2], incorporating our proposed arithmetic hiding LUT S-Box in the AES-128 with operating frequency of 16MHz. The experimental setup comprises two parts, power dissipation and EM emanation measurements as depicted in Fig. 7. A 10-bit ADC 2.5Giga samples/second oscilloscope is used to record the power dissipation and EM emanation of the AES-128 implementation. We attack the last round of the AES-128 designs with the HD leakage model (power and EM model).

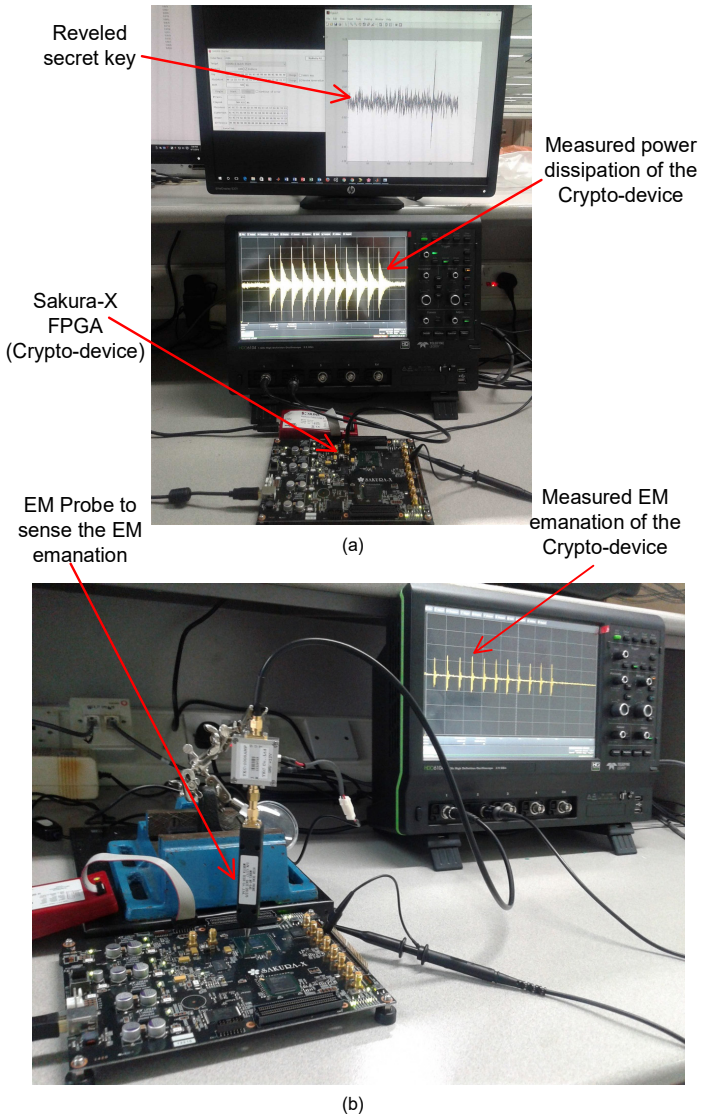

Fig. 7: The experimental setup (a) power dissipation measurement for CPA and (b) EM emanation measurement for CEMA attacks

Based on the power dissipation measurement of the AES-128 with LUT S-Box, we can estimate the number of the arithmetic operations can be employed to overshadow the power dissipation LUT S-Box as depicted in the Fig. 5. Table II tabulates the measurement result of LUT S-Box and the number of arithmetic operation required to overshadow the LUT S-Box.

TABLE. II. CIRCUIT MODULE IMPLEMENTATION OF AHLUT S-BOX

Circuit Module	Power dissipation (mW)
LUT S-Box	0.785
Arithmetic Operations*	0.813

*2 ADD; 1 DIV; 1 SUB; 4 MULT

The power dissipation of the arithmetic operation in the Table II is slightly higher than LUT S-Box with 0.028mW power overhead. The implementation of the arithmetic operation performed in parallel with LUT S-Box is depicted in Fig. 8. The AND logic gate is embedded to activate the arithmetic operations only when the LUT S-Box is performing the operation to prevent leakage current and dissipate additional power at the arithmetic operation (static power dissipation). The input data for arithmetic operation is 16-bit which comes from input LUT S-Box (x). The 8-bit input is inverted to make the input value opposite against the x such that uncorrelated with processed data.

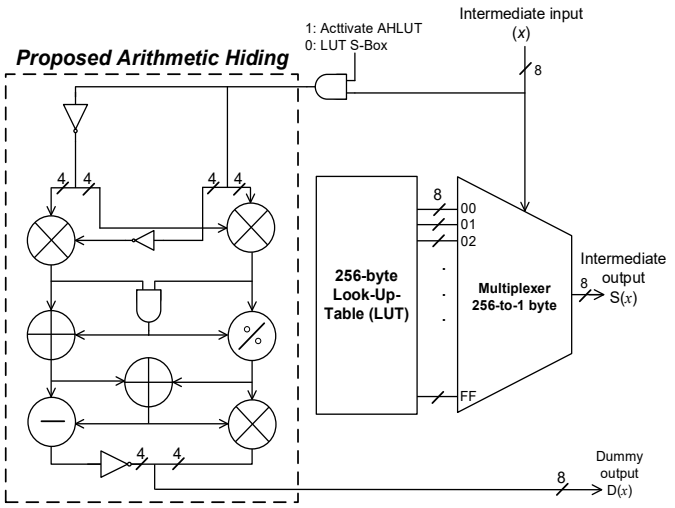

Fig. 8: Arithmetic operation is performed in parallel with LUT based S-Box

During the implementation in the circuit level, both modules (LUT S-Box and arithmetic operations) are performed at the same clock cycle, to hide the correlation with processed data, with the total power dissipation is 1.598mW. The power dissipation for AES-128 with LUT S-Box only and the AES-128 with arithmetic operation performed in parallel with LUT S-Box are depicted in Fig. 9. The grey color is indicated as arithmetic operations with LUT S-Box dissipates higher power as to overshadow the LUT S-Box as plotted in black color. As resulted from implementation of the controller, the static power dissipation is remined the same as in the LUT S-Box (~0.95mW) which implies the leakage current is negligible during the performance of arithmetic operations.

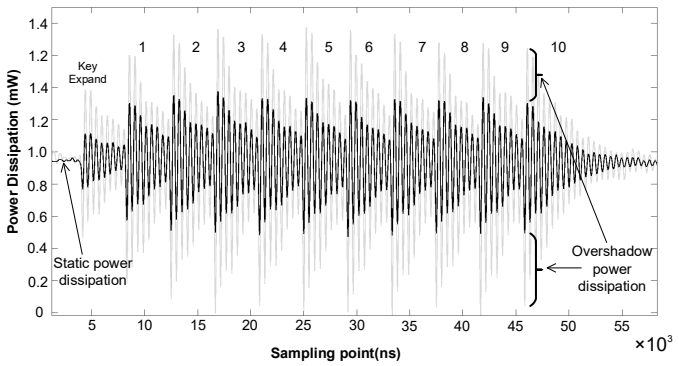

Fig. 9: Power dissipation measurement of 10 rounds iterations AES-128 with LUT S-Box and our proposed arithmetic hiding.

It is worthwhile to note that although in our proposed AHLUT S-Box, the power dissipation overhead is ~2× higher than LUT S-Box, but it is much lower than conventional S-Box implementation, which is 5.6× lower than conventional S-Box. Table III depicts the power dissipation of three S-Box implementations, LUT S-Box, proposed AHLUT S-Box and conventional S-Box.

TABLE. III. POWER DISSIPATION OF THREE DIFFERENT S-BOX TOPOLOGIES

S-Box Topology	Power dissipation (mW)	Normalized Power
LUT S-Box	0.785	0.5×
Conventional S-Box	18.37	11.56×
Proposed AHLUT S-Box	1.589	1×

In this experiment, the CPA attack is performed based on the proposed AHLUT S-Box and compare the result against LUT S-Box. Fig. 8 depicts the number of traces required to reveal the most difficult sub key of AES-128. It shows that the Fig. 10(a) requires 516 power traces to reveal the secret key while with our proposed AHLUT S-Box requires 1,751 power traces to reveal the same secret key as depicted in Fig. 10(b). Based on the CPA attack on single byte secret key, our proposed arithmetic hiding features 3.4 × secured than LUT S-Box implementation with ~2× power dissipation overhead.

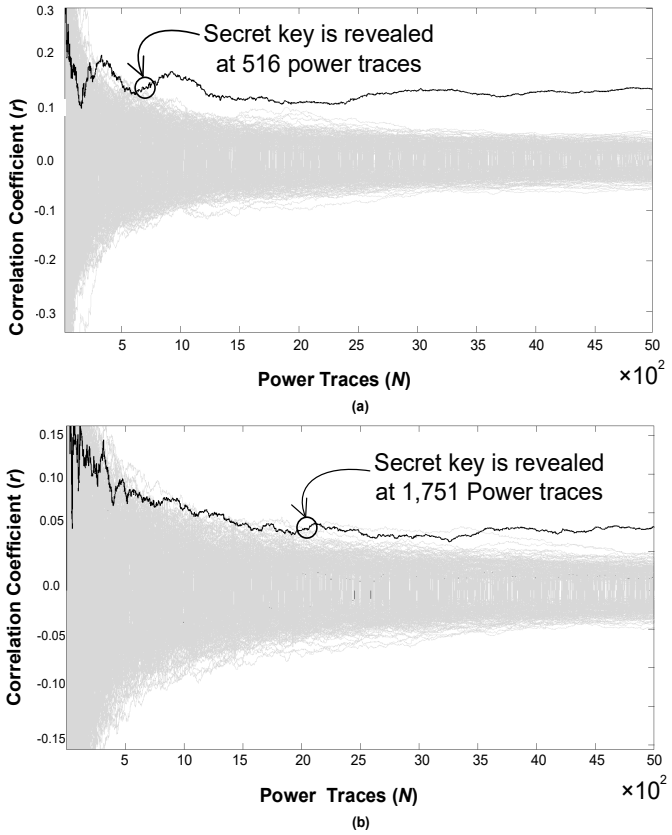

Fig. 10: Evaluation of the CPA as security features of (a) LUT S-Box and (b) our proposed AHLUT S-Box

Fig. 11 depicts the CPA and CEMA attack based on the proposed AHLUT S-Box. It shows that the 16-byte sub-secret key has been successfully revealed at 38×10^3 and 44×10^3 of the power and EM traces respectively. In this context, the security features of the AES-128 has been increased against CPA and CEMA by 73× and 25× respectively when compared with conventional S-Box.

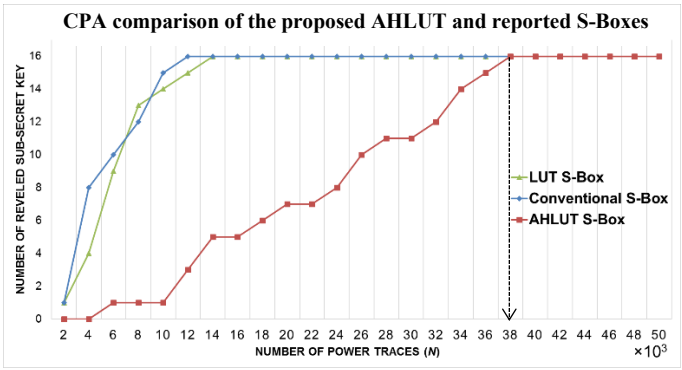

Fig. 11: Comparison of proposed AHLUT S-Box and reported hiding based on CPA attack

When comparing with reported hiding counterparts, SCCE [9] and iSCE [10], which can only protect the AES-128 algorithm against CPA attack, our proposed AHLUT S-Box can protect the AES-128 algorithm against EM based attack (CEMA) as well as in the CPA. Fig. 10 depicts the performance result of the CEMA attack for various hiding techniques. As shown in the Fig. 12, our proposed AHLUT S-Box outperforms the reported hiding techniques, which is requires 44×10^3 EM traces to reveal all the 16-byte secret key. The result is 5.5×, 4.8× and 44× higher than SCCE, conventional S-Box, iSCE and LUT based S-Box respectively. This is due to the physical leakage information (EM emanation) is generated by arithmetic operation, can dominate the EM generated by LUT S-Box and reduce the correlation between the EM signal of the LUT S-Box and the processed data of the AES-128 algorithm.

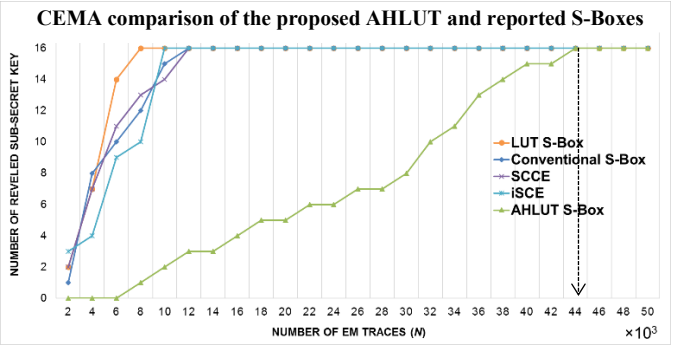

Fig. 12: Comparison of proposed AHLUT S-Box and reported hiding based on CEMA attack

5. Conclusions

We have proposed an AHLUT S-Box in the AES-128 cryptographic algorithm implementation to countermeasure against SCA. There are three key features in our proposed AHLUT S-Box. First, the arithmetic hiding performs four types of arithmetic operations such that their total physical leakage information sufficiently overshadows the correlated physical leakage information of the S-Box operation. Second, the AHLUT S-Box pre-stores all the 256 bytes of possible output values based on the conventional S-Box and selects a corresponding output value with respect to the input accordingly. Third, we propose a methodology to determine a minimum number of the arithmetic operations to sufficiently overshadow the physical leakage information of the S-Box operation. Based on the measurement results of performing AES-128 algorithm on Sakura-X FPGA encryption-board and in term of power dissipation, our proposed AHLUT S-Box dissipates 1.6mW and features 11.56× lower power dissipation than the conventional S-Box. In term of security of the CPA attack, it requires 73× more power traces to reveal the secret key for our proposed AHLUT S-Box than the conventional S-Box. As for the non-invasive CEMA attack, it requires 25× more EM traces for our proposed AHLUT S-Box.

ABSTRACT

The increasing impact of services on economic wealth and income in high-wage countries calls for a detailed examination of service productivity and complexity in current research projects. This paper describes the development of a measurement model of service productivity and complexity within the domain of medical service provision. While the measurement model of service productivity is partly literature-based, a novel construct is developed for service complexity. The reliability and validity of these constructs have been analyzed by a survey with 454 employees of German medical rescue service providers. Reliability of the construct is estimated by analyzing Cronbach's alpha, average variance extracted, variance inflation factors and the significance, weights and loadings of the items. Furthermore, the relationship between the partial productivities (capacity, internal and external) as well as complexity and service performance is analyzed by using the structural equation modeling approach with partial least square method (PLS-SEM). The results indicate that the developed constructs have sufficient reliability, although the examination of validity highlights difficulties in quantifying service productivity and complexity. While a significant and substantial effect of internal and external efficiency on service performance could be proved, complexity influences performance only marginally and positively while capacity efficiency has no effect at all. Thus, further research is needed in order to foster the measurement model and to investigate possible nonlinear relationships between the constructs in more detail.

1. Introduction

1.1. Service Productivity and Complexity

The service sector represents the largest part of the economy in the majority of the developed countries. In Germany, the tertiary sector's proportion of the gross domestic product (GDP) was 69% in 2015. In the US, the proportion was even higher, reaching 78%. This highlights the importance of services in overall economy [1]. Focusing the impact services have on economic growth, employment and international competitiveness, scientific studies are essential for a comprehensive understanding of service productivity and complexity [2].

In previous research [3-6] different models describing service productivity and complexity were developed. Thus, different ways to operationalize service productivity were assessed. Based on these results, service productivity and complexity within the domain of medical services are discussed in this paper.

1.2. Rescue Services and Electric Mobility

Due to technological advances in electric mobility, changes in process of provision of emergency services are inevitable. Ambulance services are not only essential for society, they also occur with a high frequency. During 2012/2013 there were more than 14 million rescue missions in Germany. More than 270,000 rescue missions were caused by traffic accidents [7]. Driven by technological change and growing environmental awareness as

*Corresponding Author: Markus Harlacher, Bergdriesch 27, 52062 Aachen, Germany | Email: m.harlacher@iaw.rwth-aachen.de

well as falling prices the number of electrically-powered vehicles increases. In consequence, the increasing number of electric mobility vehicles in road traffic will affect the provision process of ambulance services. For example, the measures to guarantee the personnel protection in road traffic accidents will be more challenging and more varied caused by the higher number of vehicle variants. Moreover, novel injury patterns will occur in the context of road traffic accidents. These changes in service provision must be examined and the employees need to be sufficiently and appropriately trained for safe rescue missions with electric vehicles. Thus, higher acceptance of electric mobility can be reached.

1.3. Objectives and Structure

This paper aims to empirically measure and evaluate the relationship between service productivity and complexity and the effect on medical rescue service performance. For this purpose, a measurement model of service productivity and complexity is developed. Furthermore, reliability and validity of the measurement model is assessed by specific criteria. Following the findings, the process of the rescue service can be adapted for increasing service productivity and performance.

The paper is structured as follows: First, a literature based definition of service productivity and complexity is given. The hypotheses and the study design are presented in chapter 3. The model evaluation in chapter 4 is divided in the measurement model evaluation focusing reliability and validity and structural model evaluation focusing on testing the hypotheses. The results and the limitations of this study are discussed in chapter 5. Finally, key findings for practitioners and academia are presented.

2. Literature Review

2.1. Defining Service Productivity

Starting point of any productivity measure is the goods-based definition of productivity as the ratio of output to input. It measures the performance of the operational factor combination: e.g. number of vehicles produced in one hour. Usually traditional performance indicators of productivity are made out of the same physical dimensions in numerator and denominator. Due to specific characteristics of services like customer integration and their immediate effect on productivity and complexity the traditional concept of productivity is too narrow. Researchers have proposed different concepts for service specific productivity evaluation and service system design.

Production-oriented approaches go back to Levitt [8] and Jones [9] as well as Corsten [10]. They define partial productivities in different, subsequent stages of service provision focusing on capacity utilization and one sided, technical quality management. A more comprehensive view was taken by Johnston and Jones [11] as well as Grönroos and Ojasalo [4]. Grönroos and Ojasalo define service productivity as a function of three elementary measures of performance [4]:

1. Efficiency of transforming input resources to output result for the customer (internal efficiency)
2. Perception of the quality of the service process and of the outcome (external efficiency)
3. Efficiency of utilizing the capacity of the service process (capacity efficiency)

Customer integration and internal processes were identified as the relevant influencing factors of internal efficiency. Customer satisfaction as well as corporate and customer benefits are key figures of external efficiency. Finally, quantitative and qualitative congruence (accordance of supply and demand) defines the core of capacity efficiency [5, 6].

2.2. Defining Service Complexity

Complex services, like emergency medical services, consist of a variety and diversity of interdependent system elements [5]. Service complexity as the property of these elements assumes a variety of emergent states in a defined period of time [12]. This in turn causes variety, makes complex services hardly predictable and uncertain in their behavior [13].

Blockus [14] defines service complexity as the characteristic of the system "service provider" concerning the variety, diversity, interdependencies and dynamic of the three dimensions of service: potentials, processes and outcomes. The "service potential" dimension describes the resources of a service provider for fulfilling the demand for services. Considering Bruhn and Georgi [15] these particularly involve the employees with their administrative and operative abilities, capacities and their qualifications including applied technologies and physical environment such as subsidiaries, information leaflets and blank forms.

The "service processes" dimension includes the complexity of direct and indirect processes of service provision as well as the autonomous customer process. The direct processes regard the actual service provision taking customer into account. The indirect processes are supporting processes as planning and procuring the resources or marketing the services. Autonomous customer processes are to be executed by the customer without direct involvement of the service provider. Moreover, the service processes dimension considers the complexity of external factors. External factors are characterized by not being predictable and influenceable by the service provider. These include the customer itself, its mobile and immobile properties as well as necessary permissions and information for service fulfillment. [14]

The "service outcomes" dimension refers to service results, which can be sold as market products. It considers the complexity of the applied service portfolio and of the single investigated service itself. [14]

3. Method

3.1. Study Design

The data for testing the hypothesized relationships were gathered by a questionnaire survey. 454 persons employed in the knowledge-intensive medical rescue service sector in Germany participated in the survey. A structural equation modeling method (SEM) was used for statistical analysis of the service productivity model. An empirical validation study was carried out and analyzed using partial least squares (PLS) path modeling as well as SPSS (v.21) for data preparation, data cleaning and descriptive statistics. The measurements and the structural model were analyzed using the SmartPLS 3 software package [16].

3.2. Hypotheses

Productivity describes the relation between process result and its means deployed. Considering the economical definition of productivity, service productivity and service performance are correlated positively. Thus, measures of efficiency should also correlate positively with service performance. The influence of the single efficiencies still remains uncertain.

An increasing internal efficiency means transforming input to output by minimizing input while maintaining the output or maximizing output while keeping inputs constant [11]. Thus service productivity increases and we posit:

H_1: Increasing internal efficiency positively influences service performance.

The better the perceived quality by using a specific amount of input resources, the better is the external efficiency, which results in an improved service performance. A decreasing perceived quality in turn causes a lowered "revenue-generating capability" which has a negative impact on service performance. [17]. Therefore hypothesis 2 is as follows:

H_2: Increasing external efficiency positively influences service performance.

The capacitive efficiency correlates positively with service productivity up to its optimum – demand equal to supply – because the costs for resources decrease for a single service. Assuming that service capacities in rescue services can only be overloaded in extreme situations (as they are highly important for society safety), overloaded resources should not affect the quality of service performance negatively [17]. Thus hypothesis 3 implies:

H_3: Increasing capacitive efficiency influences service performance positively.

A high complexity implies more procedures for handling it [18]. These extra activities disturb the working process and thus reduce service performance. Therefore hypothesis 4 can be derived as follows:

H_4: High complexity due to increased electro mobility influences service performance negatively.

3.3. Questionnaire

In order to operationalize the constructs items were formulated based on existing questionnaires as well as on literature on the dimensions of complexity [4-6]. Items were formulated and evaluated in semi-structured interviews with a group of experts. Furthermore, a pre-test was conducted for optimization purpose.

The structure and content of the questionnaire are depicted in Figure 1. The questionnaire can be divided into four parts. The first two parts collect personal and organization-specific information. The third part deals with already gained experience concerning electric mobility and expected problems caused by increased number of licensed electric vehicles with impact on service productivity and complexity. Finally respondents were asked to evaluate their performance regarding service productivity and complexity in the fourth part.

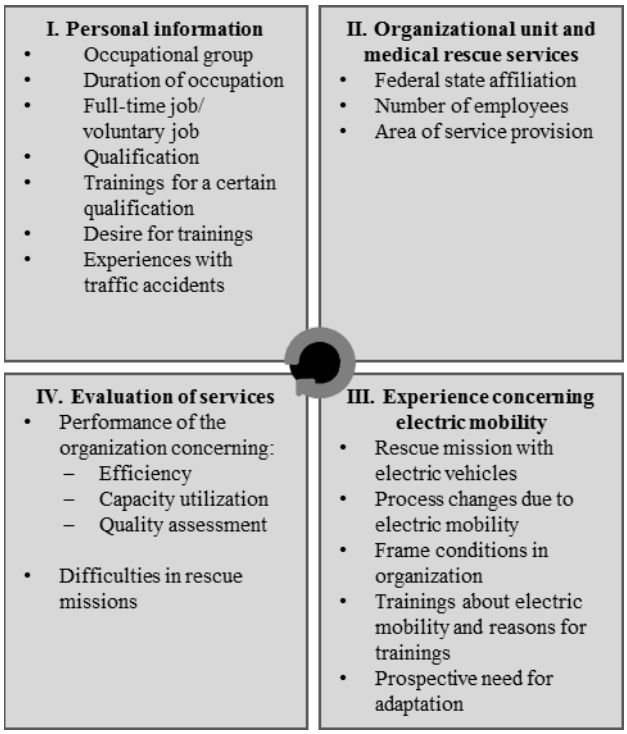

Fig. 1. Structure of the questionnaire.

Measurement Model of Service Productivity

In order to operationalize the constructs of service productivity 12 items were formulated based on the work of Grönroos and Ojasalo and Garrel et al. [4, 6]. In summary, there are five items that quantify internal efficiency. Customer integration is operationalized by an item assessing whether frequent interactions with involved parties in accidents takes place without problems. Quality of internal processes is measured by the following statements:

1. The rescue mission is predominantly smooth.
2. There are delays in the rescue mission caused by insufficient technical equipment.
3. Rescue teams always get the most recent information to fulfill the task.
4. The work structure (e.g. authority and decision making) enables an interference-free operation.

External efficiency is measured by four items. Two items assess customer satisfaction regarding the level of medical and psychological care during the rescue mission. Organizational and customer benefit is mapped by items addressing the level of standardization of the procedures during the rescue process as well as by the aspect of achieving the target time. The operationalization of the quantitative congruence includes bottlenecks due to technical equipment. The qualitative congruence is operationalized by the following items:

1. Problems occur due to unavailability of sufficiently trained employees.
2. The technical equipment is optimized for the tasks of ambulance service.

Measurement Model of Service Complexity

The results of the pre-test did not confirm a differentiation into the three dimensions of potential, process and outcome complexity. Thus, the measurement model of service complexity was revised in the final questionnaire. In order to assess complexity, rescue service processes of accidents with electric vehicles were compared to rescue service processes of accidents with conventional vehicles. Service complexity was measured by the following items:

1. Known algorithm can be used at car accidents with an e-car.
2. It is more difficult to ensure occupational safety on rescue missions with electric vehicles.
3. Handling electrical vehicles in accidents is more ambitious than handling conventional vehicles.

All items were answered on a six-point Likert scale. The response format ranged from ´Does not apply at all` (1) to ´Does fully apply` (6). For assessing the quality of the measurement model, both models of productivity and complexity were analyzed by means of correlation, reliability, and validity.

3.4. Participants

The nationwide survey was conducted online as well as paper-based on training events for rescue personnel. In total, 454 persons have completed the questionnaire. The majority completed the paper-based version of the survey. Less than 150 participants completed the online version, which was promoted solely within the organizations of the project partners (especially Red Cross Germany and the Interdisciplinary Training Center for Medical Education in Aachen).

65.4% of the subjects were directly involved in the medical care of casualties. The majority of them were paramedics and emergency physician. More than 20% of the participants were firemen focusing the technical aspects of rescue. The remaining subjects held an administrative position in a rescue service organization.

About 75% of the participants were employed in rescue service as their main profession. Most subjects had work experience of more than two years, therefore a sufficient level of experience in rescue services can be assumed. 10% of the participants were already previously involved in a traffic accident with electric-powered vehicles. Given the market share of electric cars of only .4% in Germany, the quota of respondents with electric-powered vehicle experience surpasses the expectations on the survey [19].

4. Model Evaluation

For model validation, we considered empirical measures of the relationships between the proposed indicators and constructs as well as between the constructs. We also evaluated the measurement model by means of reliability and validity.

4.1. Measurement Model Evaluation

The questionnaire used in the survey was based on previous research of Garell et al. [6]. The items used to measure the latent variables were defined as reflective and reliability was analyzed accordingly.

The formal accuracy of the model is assessed by Cronbach`s alpha. The results of the reliability analysis of the measurement model of service productivity are visualized in Figure 2. Only external efficiency exhibits a sufficient reliability. Cronbach`s alpha of the total measurement model of service productivity achieves an unsatisfactory value of .407.

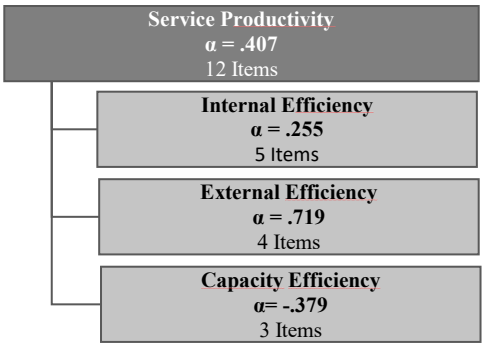

Fig. 2. Cronbach's alpha of the construct service productivity.

Due to the unsatisfactory results of the reliability analysis we examined a formative model as well. Based on the definition of the constructs it seems likely, that while adapting the constructs for the field of medical rescue services the cause-effect-relationship between items and construct changed. Therefore a confirmatory factor analysis is unsuitable. Thus, the structural equation modelling (PLS-SEM) approach is adopted. By using this method we can evaluate the multiple dependencies between productivity, complexity, and actual performance of medical rescue services.

For model validation, we considered empirical measures of the relationships between the proposed indicators and constructs as well as between the constructs. We also evaluated the measurement model by means of reliability.

First, the single reflective measured variable of the self-assessed service performance was analyzed. In order to do so, we looked at composite reliability for evaluating internal consistency. Individual indicator reliability and convergent validity where evaluated by average variance extracted and predictive relevance [20]. Discriminant validity was not investigated due to the fact that the latent variable service performance is the only reflective operationalized construct in the model, so a comparison with other variables is not possible.

Internal consistency reliability is usually measured by Cronbach's alpha. However, due to the PLS-SEM method, the preconditions for applying Cronbach's alpha (equal outer loadings of the indicators) were not satisfied. Thus, composite reliability (ρ_c) was used instead. Composite reliability can vary between zero and one, with a high value indicating high reliability. An acceptable level of .6 to .7 in exploratory research is regarded as satisfactory [20]. The composite reliability of the performance is .635, hence slightly above the required .6. This argues for sufficient internal consistency (measuring the same construct) in the proposed indicators of the self-assessed performance.

Individual indicator reliability is evaluated by the indicators' outer loadings. Their outer loadings should be .7 or higher [20]. In our study, two of three loadings were significantly above .7, thus revealing high individual reliability. For convergent validity, we

considered average variance extracted (AVE). AVE evaluates communality not for a single item but for the whole construct, analogous to individual indicator reliability. AVE indicates the degree to which a construct explains the variance in the indicators. In our study, AVE accounted .44, so the construct explains more than 40% of variance. Table 1 summarizes the results of the assessment.

Table 1. Criteria for reflective measurement model evaluation

Items		$\rho_c \geq .6$	AVE ≥ .5	λ ≥ 0,7
	Self-assessed service performance	**.663**	**.44**	
Perf_1	Please estimate the workload of your organization.			.723
Perf_2	Please estimate the efficiency of your organization.			.098
Perf_3	Please estimate the quality of the performance of your organization as measured by the standard treatment methods (e.g. "Golden Hour", ETC, PHTLS, ITLS).			.887

The majority of the latent variables were operationalized using formative indicators. Compared to reflective indicators, formative indicators define the latent variable as a whole. The indicators describe and specify the content of the construct in a logical manner according to the underlying theory. Formative indicators are the source of the latent construct and therefore are not necessarily intercorrelated. They complement each other within the construct and form a self-contained variable. Thus, reliability measures are inappropriate for evaluating the goodness of the formative measurement model. Instead, content validity is evaluated by collinearity, significance and relevance of the indicators, and discriminant validity at the construct level [20, 21].

Before the relationship and the predictive relevance of the model can be analyzed, the collinearity of the latent variables should be evaluated. In contrast to reflective indicators, where high levels of collinearity between indicators are important, in the case of formative indicators this is counterproductive because they increase standard errors and influence weight estimation negatively. In order to evaluate collinearity, we considered the variance inflation factor (VIF). The square root of the VIF is defined as the degree to which the standard error increases due to collinearity. Removing indicators should be considered in cases where the VIF value is higher than 5 [21]. All of the indicators analyzed showed an acceptable degree of collinearity (VIF<5). Thus, all items were considered for further analysis.

To evaluate the relevance of formative measures, we considered the outer weights of the indicators. In the proposed measurement model, 7 out of 15 items have a significant weight at a significance level of $\alpha = .1$ ($t = 1.65$). Second, we also evaluated the significance of the outer loadings. After analyzing the outer loadings, only 3 out of 15 indicators proved to be non-significant. Two of the items measure complexity and one capacity efficiency. Considering the acceptable degree of collinearity, we retained the items in the model in order to preserve the logical, content-oriented composition of the constructs.

At the construct level, we considered discriminant validity by evaluating the correlations between the latent variables. Scores should be below .9 to ensure that no substantial relationship between different constructs exists [21]. All latent variables were found to be below the given limit. The highest correlation between internal efficiency and external efficiency of provided service (.57) is reasonable and in line with the content. A highly selective specification of the constructs is desirable but not practicable.

Table 2. Criteria for formative measurement model evaluation

Items		VIF<5	weight t>1,65	loading t>1,65
	Complexity			
Comp_1_R	Known algorithm can be used at car accidents with an e-car.	1.015	6.172	5.806
Comp_2	It is more difficult to ensure occupational safety on rescue missions with electric vehicles.	1.404	.223	.124
Comp_3	Handling of electrical vehicles in accidents is more ambitious than handling of conventional vehicles.	1.395	.438	.362
	Capacity Efficiency			
CE_1_R	Problems occur due to unavailability of sufficiently trained employees.	1.227	1.846	1.903
CE_2	The technical equipment is optimized for the tasks of ambulance service.	1.324	1.325	1.604
CE_3_R	There are always bottlenecks with the technical equipment.	1.436	.297	1.798
	Internal Efficiency			
IE_1	The rescue mission is predominantly smooth.	1.242	4.354	10.600
IE_2_R	There are delays in the rescue mission caused by insufficient technical equipment.	1.035	1.648	2.884
IE_3	Rescue teams always get the most recent information to fulfill the task.	1.329	.781	5.106
IE_4	The work structure (e.g. authority and decision making) enables an interference-free operation.	1.430	5.636	13.758
IE_5	The inclusion of other participants (e.g. patients, eyewitnesses, emergency responder) into the rescue process is unproblematically.	1.228	.117	3.677
	External Efficiency			
EE_1	The patient can be treated satisfactorily.	1.690	3.060	11.317
EE_2	We try to rescue crashed persons with standardized procedures.	1.632	4.402	18.146
EE_3	We always manage to keep the planned times (reaching the place of the accident).	1.283	1.235	5.454
EE_4	The patients (eyewitnesses, emergency responder) feel excellently looked after during the rescue.	1.306	.017	3.740

4.2. Structural Model Evaluation

After the measurement model has been evaluated as reliable and valid, the structural model can be assessed accordingly. The structural model is evaluated by the relevance and significance of path coefficients, the coefficient of determination (R^2), effect size (f^2) and predictive relevance (Q^2) [20, 21]. By analyzing the path

coefficient, we examined the hypothesized relationships. The posited relationships were assessed according to the magnitude, significance, and direction of the effect. The results are shown in Figure 3. The path coefficients can take values between -1 and 1, with values close to ±1 representing a strong positive/negative relationship and values close to or equal to 0 indicating no relationship. In addition, the significance is evaluated by computing t-values with the help of the bootstrapping procedure. Based on the t-value, the probability of error is calculated, with t-values of 1.65 (10% probability of error) and above considered to be significant. The results show that three out of four postulated relationships were significant. All significant relationships were found to be positive.

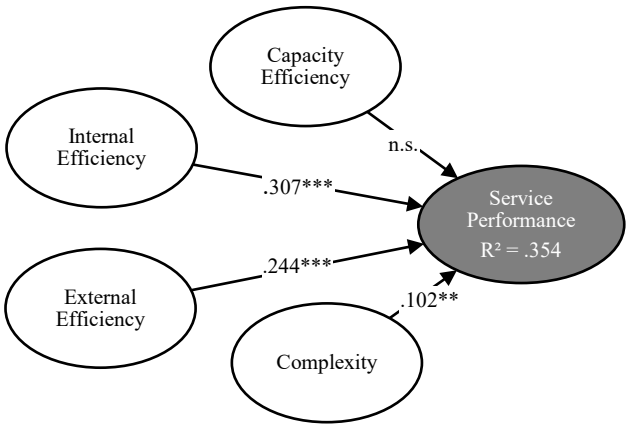

Fig. 3. Path coefficients and probability of error for the structural equation model of medical rescue service performance. *** p<.01; ** p<.05; * p<.1

Thus, hypotheses 1 and 2 can be confirmed. No significant effects were found with regard to hypothesis 3. Contrary to hypothesis 4 the examination of the relation between service complexity and service performance results in a positive interdependence. Bruhn and Blockus [5] explain these improvements of productivity with increased motivation and satisfaction of the employees. Up to a specific level complexity of the task can be motivating and can increase thus the service performance.

The model's predictive accuracy is evaluated by the coefficient of determination (R^2). This coefficient is defined as the squared correlation between a specific endogenous construct's actual and predicted values representing the amount of variance explained by all of the exogenous constructs ranging from 0 to 1, with higher values indicating greater predictive accuracy. There are no generally accepted intervals for good coefficients of determination since they are specific to individual research disciplines [20]. Thus, we consider the intervals from Chin [22] used in explorative research cases. The limit starts at .190, with values above this limit considered to have weak predictive accuracy, values above .330 moderate predictive accuracy and values above .670 very high predictive accuracy.

Self-assessed service performance shows a moderate predictive accuracy and thus is considered to be explained adequately by productivity (internal efficiency, external efficiency and capacitive efficiency) and complexity (R^2 = .354).

The effect size f^2 of exogenous constructs is regarded as another measure for evaluating predictive accuracy. The limits for small, medium and large effects are given as .02, .15 and .35 respectively [20]. The exogenous variables of internal and external efficiency plus capacitive efficiency are found to have a small effect on service performance. Furthermore, complexity shows a non-effect on the service performance (f^2 = .016).

Finally, we evaluated predictive relevance (Q^2). The Stone-Geissers Q^2 value assesses the fitness to rebuild the latent variable out of the associated indicators. Therefore, a value above zero is required. This final assessment criterion was also fulfilled with a value of .277 for the service performance variable.

5. Discussion and Implications

5.1. Hypotheses

In order to get a more sophisticated understanding of the interrelation of service productivity and service complexity, a total of four hypotheses were formulated. The results of the study show the importance of different efficiencies with regard to service performance. Both, internal (hypothesis 1) and external efficiency (hypothesis 2) are crucial to optimize service performance in medical rescue services. Hence, perceived customer satisfaction with service provision, or as in our case patient satisfaction, are just as equally important to service success as are internal processes.

However, capacity efficiency does not have a significant effect on service performance. Thus, hypothesis 3 cannot be confirmed. Since the setting of the described study was in medical rescue service, it was assumed that due to the importance of medical provision there would only be a theoretical resource limit which would be reached only in extreme situations. This assumption, however, does not hold true for the majority of service organizations in Germany. Limited resources can still be a limiting factor in service provision. Therefore, possible effects between capacitive efficiency and overloading of resources cannot be revealed in the present study and have to be addressed in future research in different settings.

Statistical analysis of hypothesis 4 indicated that, contrary to initial expectations, service complexity influences service performance positively. Again, as with hypothesis 3, a possible explanation for this finding might be in the special setting of the study. As a consequence of good education employees of medical rescue providers are well prepared to handle the often highly individual situations, so that increased complexity even with relatively unknown variables as electric vehicles seems to pose a challenge and increase service performance rather than deter it. This finding also has to be reexamined in future research. Moreover it is to be reflected, if complexity is just driven by a rising electro-mobility or if there are other factors that have a more significant impact on medical rescue service complexity.

5.2. Implications for practitioners

The results show a clear dependency between service productivity and performance. Surprisingly capacity efficiency does not influence medical rescue performance. Conversely, increases in complexity seem to have only a marginal though positive contribution on performance.

According to the magnitude and significance of the path coefficients between the latent variables we distinguish a clear order in decreasing importance of the relationships. Internal efficiency is regarded to be of uttermost importance. Therefore practitioners should focus on increasing the efficiency of service provision by reducing disturbing factors and optimizing the process and information flow. Practitioners should install work structures that enable a smooth and interference-free service provision.

Second, external efficiency should be regarded as an important lever for improving medical rescue service performance. Key drivers are not necessarily in time arrival to the location of accident, but the utilization of effective and standardized procedures in order to safely rescue persons directly involved in an accident. The overall goal is to not only medically treat the patient but also taking care of him regarding any other aspects during the entire process of provision.

Last but not least there is – contrary to our expectations – no significant effect of capacity efficiency on performance. Thus, availability of personnel and material resources seems not to be an issue in medical rescue. The results suggest that performance is independent of the capacity utilized. This should be treated with caution, since it is possible that some other interaction effects were neglected or not considered at all in the study. For example it is not known whether the respondents were able to assess the capacity efficiency as the majority was not in a management position. Another possible explanation might be that there were no capacity problems and thus no influence on performance.

Complexity due to increased electric mobility is also of marginal impact on performance of rescue services. It is plausible that existing rescue procedures in Germany are also suitable and can be applied in mission which involves electric driven vehicles. Thus, an increase on complexity does not negatively impact performance. With existing skills and equipment the rescue personnel is able to fulfill a broader and more demanding rescue mission.

5.3. Implication for future research

The results of the analyses point out, that further research is needed. There is still little known about reliable measures for service productivity and complexity, especially in context of medical rescue services. In this paper a first approach for operationalizing service productivity and complexity was made. The results show that further in depth research for every single specific influencing factor on service performance is needed. Furthermore, different skill levels (with and without knowledge about electric driven vehicles as well as standardized procedures) and even different management levels should be considered and evaluated separately. Moreover, further research should also address patient in a dyadic survey.

The effect of complexity and capacity efficiency should be analyzed in more detail. It seems likely that linear models are unable to represent the real relationship between the constructs. Thus, novel approaches should be developed in order to operationalize these constructs as well as to analyze the impact on medical rescue performance.

5.4. Limitations

Despite the complexity of the developed measurement models and the limitation of extent of the questionnaire the reliability of the measurement model are on a sufficient level. Construct validity is also given on a sufficient level. Thus, the measurement of the latent variables has to be improved. Higher level of reliability and validity are desirable. On the one hand further investigations should stronger differentiate between internal and external efficiency of medical rescue services. On the other hand measurement models focusing on technical equipment and employees characteristics and influence on service productivity could be developed and proved.

Medical rescue services are unique caused by its framework conditions e.g. high individuality, federal financing models and deficient suggestibility of the content of the services. Thus, the transferability of the results to other kinds of services should be considered with caution. Moreover, the application to rescue service providers of other nationalities has to be evaluated.

6. Conclusion

Caused by the big impact of services generated in high-wage countries it is of utmost importance to increase service productivity and handle complexity. In order to do this service productivity and complexity have to be measured and evaluated. Based on extensive literature review a measurement model of service productivity was developed. The reliability and validity of this measurement models were demonstrated although there are still possibilities for improvement. A novel measurement model for service complexity was developed and is considered to be reliable and valid. To foster the measurement model and investigate possible nonlinear relationships between the constructs in more detail, further research is needed.

In the structural model evaluation a significant, positive relation between internal efficiency respective external efficiency and service performance is found. The dependency between capacitive efficiency and service performance is not significant. The positive influence of complexity on service performance should be investigated in more detail. Overall, by a focused productivity management the performance of medical rescue services can be increased accordingly.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This research is funded by the German Federal Ministry of Education and Research (BMBF) within project SafetE-car - “Scenarios Supported development of the service system - Secure supply in case of accidents and mishaps with electric vehicles" according to Grant No. 02K12A015 (formerly 01FE13009). Responsibility for the contents of this publication rests with the authors. The authors would like to express their gratitude for this support.

Flavonoids

A B S T R A C T

Flavonoid is one of the bioactive compounds that are currently used in pharmaceutical and medicinal industries due to their health benefit. The focus of current research is mainly on the extraction and isolation of bioactive compounds; however non to date has explored on the identification of flavonoids classes under the Fourier Transform Infrared spectroscopy (FTIR). This gap presents an opportunity for the application of statistical analysis which can identify the distinct wavenumbers range of flavone, flavanone and flavonol for their characterization in the FTIR spectrum. Development of algorithm based on principal component analysis (PCA) for the analysis and identification of flavonoids classes based on FTIR spectrum was introduced. Based on the results, five wavenumbers ranges have been identified as the distinct characteristics of flavonol, flavone and flavanone hence used for their identification.

1. Introduction

This paper is an extension of work originally presented at IEEE Student Conference on Research and Development (SCOReD) 2016 [1]. Currently, flavonoids have received much attention especially in medicinal and pharmaceutical industries because of its biological properties such as high antioxidant activity, high radical scavenging, anti-inflammatory, anti-cancer and anti-allergic [2]. Flavonoids are one of the active ingredients used for the formulation of drugs and potential to treat many diseases. Increasing research performed (in vitro) on the importance of flavonoids consumption such as reducing the risk of Parkinson disease [3], may lower risk of ovarian cancer [4] and protecting brain damage [5]. Besides, flavonoids are widely distributed in fruits, plants, vegetables and microorganisms [6].

Flavonoid have C6-C3-C6 general structure backbone which consists of two phenolic structures, ring A and ring B attached to heterocyclic ring C as in Figure 1. There are more than 7000 structures of flavonoids from different subgroups have been reported [7]. All flavonoids share a basic C6-C3-C6 phenyl-benzopyran backbone; however differ in their substituents (type, number and position) and in their insaturation [8]. Individual differences within each group are due to variations in number and arrangement of the hydroxyl groups and their extent of alkylation and/ or glycosylation.

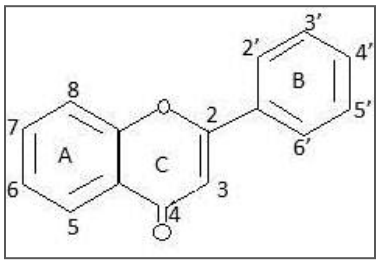

Figure 1: Flavonoids backbone

As the multiple bioactive compounds presence in compound, the characterization and identification of the bioactive compounds remain challenging due to complicated isolation procedures [9]. Several analytical techniques have been developed for the identification of flavonoids such as the application of High Performance Liquid Chromatography (HPLC) [10], HPLC coupled with photodiode array and mass spectrometry detectors [11], nuclear magnetic resonance (NMR) spectroscopy and mass spectrometry (MS) evidences [12], Thin Layer Chromatography (TLC) plate [13] and many more. However, some disadvantages possessed are less sensitive, expensive and the need for chemist to analyze.

*Corresponding Author: Che Hafizah Che Noh, Department of Biotechnology, International Islamic University Malaysia, 53100 Kuala Lumpur, Malaysia. Email: chehafizah8989@gmail.com

Today, the applications of Fourier Transform Infrared spectroscopy (FTIR) has increased in food, pharmaceutical as well as medicinal applications for the identification of active compounds in plants, fruits, vegetables and microorganisms [14,15,16,17] and particularly has become a powerful analytical tool in the study of active compounds presents in samples. In fact, there have been several studies concerning with the characterization, classification and identification of flavonoids using FTIR [18,19,20].

FTIR has become well-accepted method due to its ease of samples preparation, fast, need little samples size, and does not require the use of solvents which is more economical [21].

FTIR spectrums however are difficult to interpret, unless for the expertise since the library spectrum are limited, and the software used to interpret the results somehow expensive [22]. Principal component analysis (PCA) is one of the chemometric methods that can be used to identify the similarities and differences of the chemical information [23]. Infrared spectroscopy, combined with chemometric, has been used for the identification of active compound [24].

Studies have been performed on the identification of flavonoids [11,12], however non to date has explored on the identification of individual flavonoids under FTIR spectrum coupled with chemometric analysis, which is PCA. Despite some studies performed on the identification of compound using few combination of chemometric techniques such as hierarchical cluster analysis [24], PCA, partial least square (PLS) and factor discriminant analysis (FDA) [25], the application of PCA into the characterization model has not been undertaken yet.

Introduction of the characterization model based on computational method provides the valuable tools with the application of PCA into the model algorithm for rapid identification. The proposed method are unique, since adapted both the structural information provided by PCA based on spectrum data of flavonoids structure with the interaction information from the compound, unlike most current methods [26,27,28]. The adapted characterization model is based on nested if and if else statement builds as an algorithm for the characterization.

Therefore, the objectives of this study are to develop an algorithm utilizing the PCA as the base for the interpretation and analysis of FTIR spectrums and to identify the distinct wavenumbers range of flavone, flavanone and flavonol as for their identification under the FTIR spectroscopy.

2. Literature review

2.1. *Fourier Transform Infrared Spectroscopy and Principal Component Analysis Applications*

FTIR offers high speed of analysis and needs little or no sample preparation [29]. Moreover, it also provides information on multiple parameters simultaneously [30]. The chemical bonds in material will vibrate once the infrared radiation that interacts with matter is absorbed hence producing the infrared spectrum. Regardless of the structure of the rest of the molecule, the functional groups tend to absorb infrared radiation in the same wavenumber range [22].

Band assignments for flavonoids identification have been studied in some details [31]. Based on studies, different peak shown due to wavenumber shift of different molecules with the same functional group under their wavenumber range; indicate the uniqueness of the molecules under FTIR spectrum hence used for the fingerprint of the molecules. The correlation shows between the infrared band positions and chemical structure becomes the fundamental information for the analyst to identify the unknown molecules or even the structural identification.

According to [22], the wavenumber range between 3500-3200 cm^{-1} is corresponds to the OH functional group and studies indicated that the overall arrangement of molecular structure will cause the wavenumber shift of the functional groups in their range [31]. Studies performed on phenolic compound for their antioxidant nature using FTIR [32,33]. From the studies, the presence of OH group under FTIR region will cause wavenumber shift depend upon to its oxidant nature.

FTIR spectra on flavonoids structure has been studied extensively [34]. The study highlighted the spectrum wavenumber range which are common for the flavonoid structure is the C=O bond (1630 and 1665cm^{-1}), C-O bond (1000 and 1300 cm^{-1}), and in-plane deformation vibrations of C-H (600 and 980cm^{-1}). Other studies has identified the OH group at the wavenumber at 3300cm^{-1}, 2970cm^{-1} and 2856cm^{-1}; meanwhile C=C at 1644cm^{-1}.

Previous studies shown that appropriate application of statistical analysis or chemometric has provides accurate and rapid characterization of plant extract based on analytical spectroscopy that contain multidimensional information [35]. The correlation factors obtained from the PCA analysis within a set of observed variables provides the pattern of the sample [36]. Henceforth, with the application of PCA, the spectrum analysis can be performed for rapid and easier identification.

The application of PCA from the FTIR spectrums has successfully discriminated the Romanian sea buckthorn berries and leaves groups based on its phenolic contents [37]. Correlation between the content of flavonoid in certain frozen fruits pulps with free radical scavenger activity has been identified using the PCA [38]. From the study, flavonoid has shown to exhibit high scavenging activity against hydroxyl radical.

3. Methodology

The main purpose of this study is to develop an algorithm for flavonoids identification utilizing the PCA based on FTIR spectrums. Therefore, following were the steps performed to achieve the objectives.

3.1. *FTIR Measurements*

Samples of three flavonoids (flavone, flavanone and flavonol) in powder form were purchased from Bumi Pharma Sdn Bhd (Malaysia) that was imported from Sigma Aldrich (UK).

The flavonoids were sent to Centre for Research and Instrumentation, Universiti Kebangsaan Malaysia for FTIR analysis.

(i) Spectrum 400 FT-IR, Perkin Elmer was used for the sample analysis. The wavenumber range set for the FTIR is 4000-650 cm^{-1} which is under mid infrared region. The FTIR was performed using the ATR (Attenuated Total Reflectance) where the solid samples (in powder form) were directly applied to the plate for measurements.

(ii) Using the built in algorithm provided from software package of FTIR, the spectrum was preprocessed using baseline correction to produce horizontal baseline shift and smoothing to reduce the noise.

(iii) The preprocessed data extracted in Excel form which consists of absorbance versus wavenumber (cm^{-1}) was recorded for statistical data analysis.

3.2. *Statistical Data Analysis*

(i) Data matrix, Xn where (n=1…x) which comprises of transposed data matrix of all flavonoids spectrum under selected wavenumber region (n), was analyzed with PCA on a MATLAB platform.

(ii) Commonly data preprocessing procedures such as standardization and normalization are required prior to performing PCA on a data matrix. Standardization is used to center and scale the data meanwhile normalization is generally used for data which have different units and scale. In this study, only standardization was performed since the data have same units. Figure 2 shows the configuration of the data matrix X, mxp (types of flavonoids x spectral range).

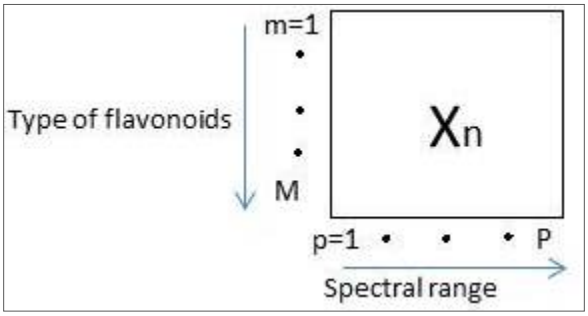

Figure 2: Two dimensional array, X_n of spectrum where n=1…N that represent the number of region, m=1…M that represent type of flavonoids and p=1…P that represent the spectral range. The weighted used for the data is the absorbance value of spectral data corresponds to the wavenumber range.

(iii) The similarities and differences based on chemical structure of the flavonoids provide a basis for the flavonoids characterization based on functional group identification offered by FTIR. The molecules that have same functional group will have the peak at the same wavenumber range regardless the rest of the molecules; however differ in wavenumber shift in the wavenumber range due to the whole structure arrangement. Henceforth, the wavenumber shift and the presence of the peak at certain wavenumber region provide the basis for flavonoids structure classification.

(iv) Eight significant regions were assigned in Table for the identification of flavonoids based on their chemical structure. The similarities and differences identified from the PCA were further utilized for development of algorithm for flavonoids identification using nested if else statement as in Figure 6.

Table: Five regions assigned for classification of flavonoids under PCA

Region	Wavenumbers (cm^{-1})	Structural identification	References
1	4000-3250	Presence of hydroxyl group	[22]
2	3140-3000	Presence of di-substitution	[22]
3	1670-1620	Unsaturation bonds	[22]
4	1650-1600	Conjugation of bonds	[22]
5	1600-1500	Aromaticity	[22]

4. Results

Figure 3 shows the FTIR spectrum for flavone, flavanone and flavonol. From the FTIR spectrum shown in Figure 3, each of flavonoids shows different spectrum due to different structure arrangement. Different peak positions, intensities, widths and shape shown in Figure 3 indicate the structure difference of flavonoids subgroups hence used for the band assignments as in Table.

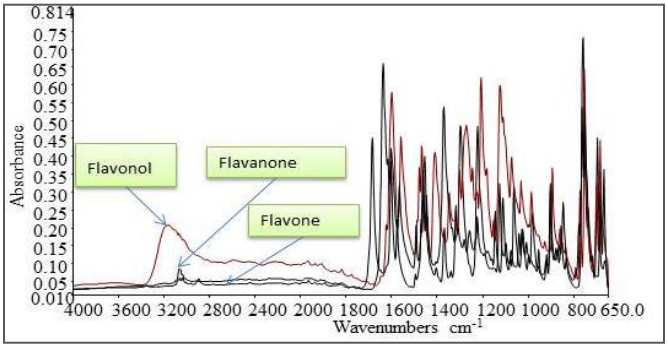

Figure 3: FTIR spectrum in mid IR range for flavonol, flavone and flavanone

As seen in Figure 3, the FTIR spectrum of molecules differs at certain wavenumber range even though the molecules have the same functional groups. The presence of hydroxyl group, compared to the other flavonoids for example, will cause the wavenumber shift at particular wavenumber range. Besides that, the overall structure arrangement such as the presence of different substitution will cause wavenumber shift hence producing different spectrum. That is why, the FTIR is powerful method for identification since no different molecules will have same the spectrum; it is the fingerprint data for the molecule.

Five significant regions have been assigned in Table for their identification based on its structural difference as in Figure 5. Figure 4 shows the results of PCA analysis of flavonoids spectrum based on the assigned regions.

In PCA analysis, the correlation factors that contribute by the PCA analysis provide the pattern of the samples. The sample that is close to each other indicates their similarities meanwhile far to each other indicate their differences. This pattern of analysis provides clear discrimination between samples as a tool of identification.

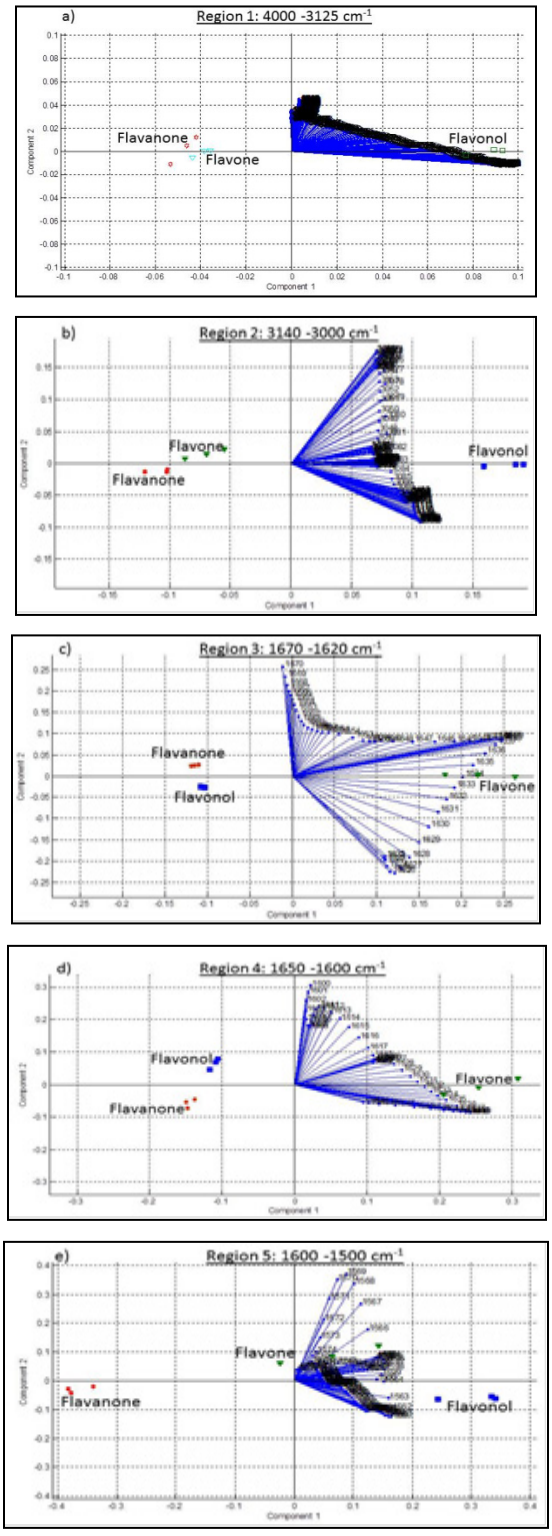

Figure 4. Results of PCA for flavonoids in the region 1 (4a), region 2 (4b), region 3 (4c), region 4 (4d) and region 5 (4e)

5. Discussion

. Flavonoids aglycone can be divided into few subgroups which are flavanone, flavonol, flavone, flavanol, anthocyanidin and isoflavonoid [39]. For flavanone, flavonol and flavone, their variation within the groups is depending upon the presence of OH group at C-3, a saturated single bond between C-2 and C-3, and their conjugation and saturation behavior as in Figure 5 [40].

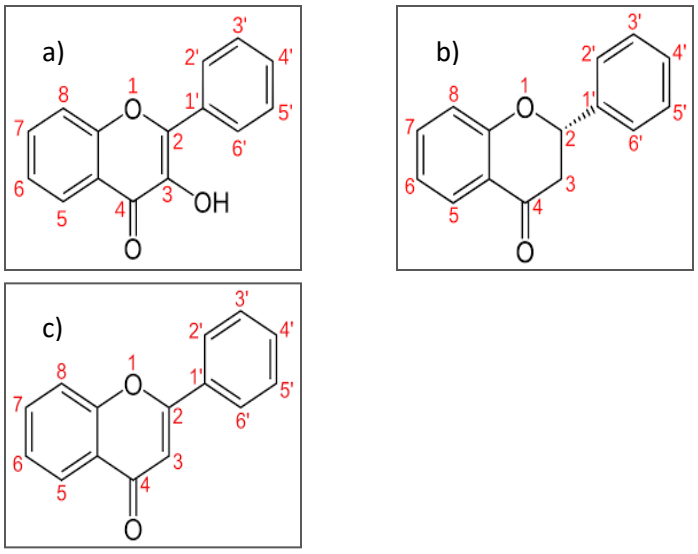

Figure 5. Structure of flavonoids subgroups, a) flavonol b) flavanone c) flavone

The differences exhibit by the flavonoids subgroups structure has lead to different spectrum shown in Figure 3 and results of PCA shown in Figure 5.

Based on Figure 4, the identification of flavone, flavanone and flavonol are focusing on the heterocyclic ring C that represents the major structural difference between the flavonoids. Based on Table, 4000-3125 cm^{-1} has been identified for the presence of hydroxyl group in flavonoids, 3140-3000 cm^{-1} for the presence of di-substitution of heterocyclic ring C, 1670-1620 cm^{-1} and 1650-1600 cm^{-1} for the saturation and conjugation of bonds respectively. Meanwhile, 1600-1500 cm^{-1} indicates the general aromaticity behavior of the flavonoids.

For flavonol, the presence of hydroxyl group at carbon 3 and di-substitution of heterocyclic ring C at carbon 2 and 3 provides the distinct characteristics of structure arrangement as compared to flavanone and flavone. Based on Figure 4 (a) and (b), for region 1 and 2, clear discrimination shown by PCA analysis on flavonol at wavenumbers 4000-3125 cm^{-1} and 3140-3000 cm^{-1}due to the presence of hydroxyl group and di-substitution at carbon 2 and 3 respectively as compared to flavanone and flavone.

Once the flavonol is identified, the flavanone and flavone is identified and distinguish based upon their saturation and conjugation bond as in Figure 5. Based on Figure 5, flavanone contain saturated carbon at 2 and 3 meanwhile, the flavone contain unsaturated carbon at 2 and 3. Besides, compared to flavanone, the conjugation of bond particularly presence in flavone. The arrangement of saturation and conjugation characteristics of flavonol that similar to flavanone provides the discrimination between the flavone as compared to flavonol and flavanone. Based on Figure 4 (c) and (d) in region 3 and 4, clear discrimination is shown by the PCA analysis on flavone at wavenumbers 1670-1620 cm^{-1} and 1650 -1600 cm^{-1} due to unsaturation and conjugation bonds respectively, as compared to flavanone.

The aromaticity characteristics of the flavone, flavonol and flavanone are differs due to their structure arrangement as in Figure 5 that can be an indication of their individual differences. Based on Figure 4(e) in region 5, clear discrimination is shown by PCA analysis on flavanone, flavone and flavonol due to their aromaticity at wavenumbers 1600-1500 cm^{-1} that provides their individual difference.

The significant region based on the structural information of the compounds provides the algorithm for the characterization model as shown in Figure 6. The application of PCA is integrated into the model to provide rapid identification of flavone, flavanone and flavonol.

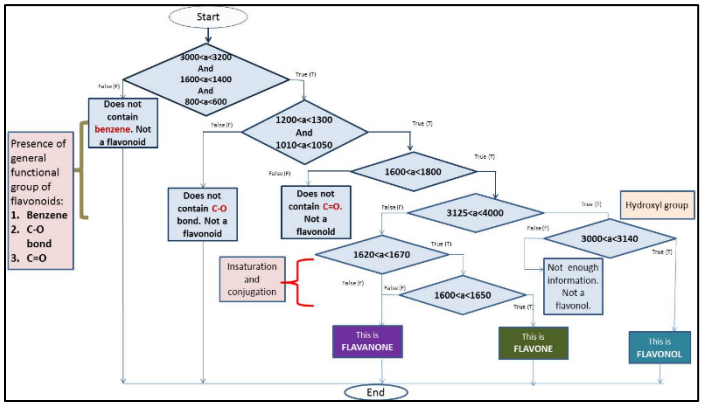

Figure 6. Flow diagram of characterization model algorithm where a is refer to absorbance value

The main contribution in this study is, despite other method which utilized much equipment and statistical method for identification and confirmation, with further exploitation on PCA methodology and the informative spectrum data provided by FTIR which not yet fully utilize, will provides the simple, easier, accurate, less expensive and rapid identification of flavonoids subgroups. The selected region based on PCA will provides significant identification of flavonoids based on its structure arrangement. Henceforth, the isolation procedure for example, will be less time consuming and identification of flavonoids presence in fruits and plants can be optimized.

6. Conclusion and recommendation

Application of PCA into the characterization model for rapid identification of flavonoids based on the FTIR spectrums was presented. The results shown that clear discriminations of flavonoids shown at wavenumbers 4000-3125 cm^{-1} and 3140-3000 cm^{-1} for flavonol, 1670-1620 cm^{-1} and 1650-1600 cm^{-1} for flavone and 1600-1500 cm^{-1} for individual flavonoids.

The research is still in progress where some individual flavonoids subgroups derivatives such as quercetin, myricetin and luteolin to name a few, were tested under the selected regions for flavonoids characterization and identification.

Besides, further exploitation on the advantages offered by PCA methodology will be performed; for example the studies on contribution plot and confidence limit provided by PCA to enhance and validate the results.

It is recommended that further studies to be performed on the identification of other flavonoid subgroups using proposed method to enhance the identification of flavonoids that is widely distributed in plants and fruits.

ABSTRACT

This paper is an extension of the work originally presented at the European Microwave Conference (EuMC) about a reconfigurable hybrid metal-plasma Yagi-Uda antenna operating at 1.55 GHz: this antenna consists of metallic reflector and active element and two plasma directors. The conference work showed through full-wave numerical simulations (CST Microwave Studio) how it is possible to achieve reconfigurability with respect to the gain by turning on/off the plasma discharges. However the model that was used to represent the plasma discharges was quite ideal, so one comment that was provided questioned the actual possibility of achieving reconfigurability in a real system.
Consequently we performed extensive measurements of different plasma discharges and thanks to the collected data, we noticed some important differences between the full-wave numerical model of the plasma that we used in the conference paper and the actual plasma discharges that were generated in the experimental setup: the dielectric vessel and the metallic electrodes used respectively to confine and generate the plasma have an influence on the radiation pattern of the antenna and so they must be included in the design procedure; the cylindrical plasma discharge is much easier to realize when the cylinder diameter is at least 3mm; and finally the collision frequency of the plasma in realistic cases is pretty higher than the one adopted in our previous work.
Therefore this work presents a feasibility study of a more detailed and realistic model of our antenna with respect to the plasma discharges. We will show that reconfigurability can still be achieved through a proper design of the overall antenna, thus paving the way to an actual realization of the proposed reconfigurable Yagi-Uda.

1. Introduction

Traditional antennas exploit metallic components to radiate and/or receive electromagnetic waves. In recent years there has been an increasing interest in another type of antennas, namely Gaseous Plasma Antennas (GPAs), whose radiating properties rely on partially or fully ionized gas rather than on metallic conductors [1-8]. The gas is confined into dielectric vessels such as glass cylinders (but the enclosure can be of any shape, e.g., monopoles and loops, and of any dielectric material) and the plasma can be turned on and off very rapidly (on time scales the order of milliseconds or microseconds) by different excitation means [3]. In the off state, the plasma reverts to a neutral gas that is confined in a dielectric holder, thus being transparent to any electromagnetic (EM) waves; when the plasma is turned on, it behaves as an electrical conductor that is able to transmit and receive EM signals.

1.1. Gaseous Plasma Antennas: Advantages

Plasma antennas have a number of potential advantages over conventional metal antennas since their properties can be electrically (rather than mechanically) controlled. This makes plasma antennas appealing for a number of applications, some of which are briefly discussed in the followings [4].

First of all, when a plasma discharge is unenergized, the gas reverts to its neutral state and so it stops behaving as a conductor. This feature makes plasma antennas difficult to be detected by radars, once the plasma vessel and excitation system are properly designed and if the antenna is energized only when the

[*]Corresponding Author: Giulia Mansutti, Department of Information Engineering, University of Padova, Via G. Gradenigo 6/B, 35131, Padova, Italy | Email: giulia.mansutti@gmail.com

communication takes place. This property leads to a potential interest in plasma antennas for military applications.

Secondly, plasma antennas are transparent to EM waves whose frequency is above the plasma frequency; this feature makes plasma antennas interesting when dealing with appli- cations that need many antennas (or antenna arrays) used for different communication systems that must be stacked together due to space constraints (e.g., shipborne maritime communications) and that operate at different frequencies. In this case plasma elements are an interesting alternative to conventional metallic ones since they can provide significantly lower mutual coupling values among the different arrays; as a matter of fact, unenergized plasma elements do not interfere with active elements, and the coupling among plasma antennas working at different frequencies is significantly lower than the one provided by metallic antennas.

Additionally, plasma elements can be energized and de-energized on time scales of microseconds; as a result, the signal degradation caused by antenna ringing can be greatly reduced by using a plasma antenna transmitting at high rates and that is switched off at the end of each bit.

Finally, the radiation properties of a plasma antenna can be changed by electrically controlling the plasma parameters (e.g., density), which can be achieved by tuning the power delivered to the plasma. Therefore plasma antennas can be rapidly reconfigured with respect to their radiation pattern, input impedance, and working frequency.

1.2. Gaseous Plasma Antennas: Issues

Nevertheless, the usage of plasma discharges as antennas in communication systems can be hindered by several issues such as the noise introduced by the plasma, the complexity of the plasma antenna, and the availability of suitable technology solutions to generate the plasma.

The noise introduced by the plasma is strongly related to the way the plasma is generated, and this fact has been holding back the use of plasma antennas for many years. Different plasma generation techniques are available: laser-initiated atmospheric discharge [5], DC/AC discharge [6], and radio-frequency (RF) surface-wave plasmas [7]. Both DC and low-frequency AC methods introduced a rather high noise level when generating the plasma. RF surface wave generation and the pulsing power technique made it possible to obtain not only lower noise levels, but also higher plasma density and reduced power consumption [3].

Another obstacle to the exploitation of plasma antennas can be identified in the inherent complexity of plasma antennas. Specifically, a plasma antenna comprises not just the plasma, but also the equipment needed to generate it (e.g., the metallic electrodes in the case of a RF surface-wave-generated plasma). Furthermore, the plasma density in an actual plasma discharge is nonuniform, with a nonuniformity that depends on the plasma generation technology; before considering the actual realization of a plasma antenna, it is therefore necessary to develop a representative prototype of the plasma discharge the antenna will be comprised of, and to measure the plasma density therein. As a result, the presence of electrodes, and the nonuniform plasma distribution within the discharge are expected to affect the radiation properties of the actual plasma antenna, and are to be taken into account in the design, and realization of an actual plasma antenna.

Other critical aspects towards the realization of an actual plasma antenna, are the availability of the proper technology to ignite, and sustain the plasma, and the capability of developing customized dielectric vessels whose shape and dimensions must be carefully chosen according to the antenna type (e.g., monopole, dipole) and operating frequency.

1.3. Original Contribution and Paper Organization

In the proof of concept of a hybrid metal-plasma Yagi-Uda antenna presented in [1], two plasma discharges have been used as antenna directors to achieve reconfigurability with respect to the gain; specifically, the gain has been controlled by turning either on or off the plasma directors. In the full-wave numerical preliminary study that was performed in CST Microwave Studio [8], the plasma directors were ideally modeled as two cylinders made of a uniform dispersive Drude material, i.e., neglecting the presence of the dielectric tubes into which the plasma is confined and of the plasma generation equipment, i.e., the metallic electrodes attached at the two edges of the dielectric cylinder. Moreover we have modeled the off state of the plasma directors simply excluding the plasma elements from simulations. Therefore the comment that was made in the review process was related to the actual possibility of our proposed antenna to achieve reconfigurability in a more realistic scenario.

The aim of this work is to present a feasibility study of a realistic version of our hybrid metal-plasma Yagi-Uda antenna with some major differences with respect to the ideal model provided in [1]: (i) the plasma elements comprise the dielectric tubes and the electrodes; (ii) the collision frequency and plasma dimensions have been set now to more realistic values obtained through experimental characterizations of different plasma discharges; (iii) the off-state of the plasma directors is modeled including the dielectric tubes filled with neutral gas (i.e., unenergized plasma) in the simulations; and finally (iv) the overall design of the Yagi-Uda antenna was revised according to the above-mentioned differences.

The rest of the paper is organized as follows. In Section II the model of our new version of the hybrid metal-plasma Yagi-Uda antenna is described in details; Section III is dedicated to the results and related discussion with a particular focus on the comparison with our previous work [1]; finally in Section IV conclusions are reported.

2. Antenna Design

The aim of this work is to investigate the capability of achieving reconfigurability for a realistic metal-plasma Yagi- Uda antenna whose reflector and active element are made of metal while the directors are plasma discharges (as the one depicted in Figure 1). Therefore the substantial difference with respect to the work that was made in [1] involves the modelization of the plasma directors: more realistic values of the discharge diameter and collision frequency have been chosen according to typical values that were obtained from measurements of different implemented plasma discharges prototypes; moreover the dielectric vessels and electrodes used to generate the plasma are present.

The starting point for our analysis was then the modelization of the ideal plasma discharge, i.e. the plasma material that is confined into the glass vessel in the real plasma director. A weakly ionized plasma has been assumed in this work and it has been

represented by means of a cold fluid model [9] by making the following assumptions.

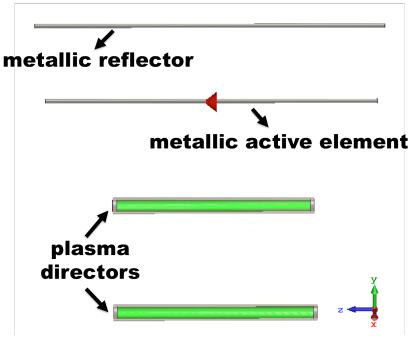

Figure 1. Design of the realistic Yagi-Uda antenna in CST Microwave Studio [8].

The first one is that the thermal motion of the ions inside the gas is negligible. Secondly, we assumed one single collision frequency that accounts for all the dissipation processes, i.e., the charge-to-charge and charge-to-neutral collisions. Finally, we assumed that the electron density and spatial distribution are temporally constant, that is equivalent to assume that the electric field intensity of the incident EM wave is small enough.

The weakly ionized gaseous plasma is modeled as a dispersive material that is suitably represented (both theoretically and in CST) as a Drude material. This provides the expression of the relative permittivity of the plasma ε_r as a function of the plasma parameters and of the operating frequency of the antenna:

$$\epsilon_r = \left(1 - \frac{\omega_p^2}{\omega^2 + \nu^2}\right) - j\frac{\nu}{\omega}\left(\frac{\omega_p^2}{\omega^2 + \nu^2}\right) \qquad (1)$$

where $\omega = 2\pi f$ is the angular frequency of the incident EM wave (i.e., the signal), ν is the momentum-transfer collision frequency of electrons with heavy particles (ions/atoms), $\omega_p=[n_e e^2/m_e\varepsilon_0]^{1/2}$ is the electron plasma frequency, m_e and e are the electron mass, and charge respectively, n_e is the local plasma electron density that is assumed to be uniform within the discharge and ε_0 is the free space permittivity.

Some of these parameters are unchanged with respect to [1]: the operating frequency of the antenna is 1.55 GHz, and the plasma frequency is $\omega_p = 178.4 \cdot 10^9$ rad/s since it has been shown by experimental measurements that this is an easily achievable value in real scenarios.

Regarding the collision frequency that accounts for the dissipation processes inside the plasma, this has been chosen significantly different from [1]: it is $\nu = 2.5067 \cdot 10^9$ s^{-1} instead of $\nu = 0.10328 \cdot 10^9$ s^{-1}, i.e., much higher, since in actual realization of plasma discharges this is a more realistic value.

Therefore the values of ε_r are significantly different with respect to [1] and this can be clearly evinced from Figure 2 in which the real and imaginary parts of the relative permittivity are reported for the two scenarios. At the frequency of interest 1.55 GHz the real and imaginary parts of ε_r are $\mathrm{Re}\{\varepsilon_r\} = -314$ and $\mathrm{Im}\{\varepsilon_r\} = -81$ in this work, while they were $\mathrm{Re}\{\varepsilon_r\} = -334$, $\mathrm{Im}\{\varepsilon_r\} = -4$ in [1]. There is an important difference between the values of $\mathrm{Im}\{\varepsilon_r\}$ in the two cases: the great increase in the imaginary part of the permittivity (that translates in an increase in the losses of the antenna) is caused by the substantial change in the collision frequency that is much higher now and that indeed accounts for the dissipation processes inside the plasma.

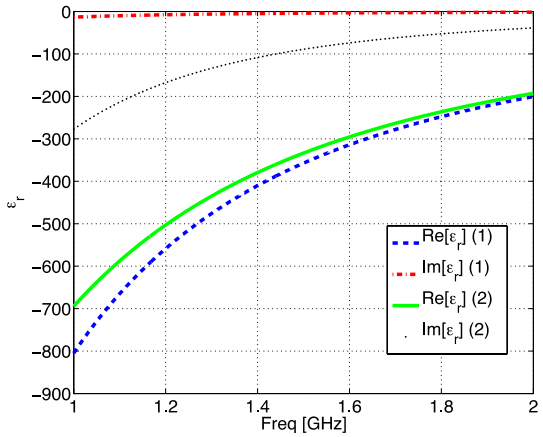

Figure 2. Comparison between the relative dielectric permittivity of the dispersive plasma in this work and in [1] (respectively (2) and (1) in the legend): imaginary part (dotted black line for (2), dash-dotted red for (1)) and real part (solid green for (2), dashed blue for (1)).

Now as far as the plasma directors dimensions are concerned, we chose to change the diameter of the discharge from 2.5 mm to 3 mm since in real cases it is more feasible to confine plasma in vessels with a larger diameter, and since 3 mm has proven to be a feasible dimension as it was proven when by actually realizing such a plasma discharge.

The length of the discharge was set according to a simplified model described in the followings. The cylindrical plasma column behaves as an open waveguide that can sustain surface- wave propagation and that therefore radiates significantly due to the breaking of the translational symmetry: this happens during the antenna operation mode, i.e., when the angular frequency $\omega = 2\pi f$ is much lower than the plasma frequency ω_p. This behaviour of the cylindrical plasma bar has been verified through a simplified analytical model according to which, for an infinitely long column of uniform non-magnetized plasma endowed with relative dielectric permittivity ε_r, the dispersion relation for the surface wave that propagates along the column is given by [7]:

$$\frac{k_{\perp p}}{\epsilon_r}\frac{I_0(k_{\perp p}r_p)}{I_1(k_{\perp p}r_p)} + k_{\perp 0}\frac{K_0(k_{\perp 0}r_p)}{K_1(k_{\perp 0}r_p)} = 0 \qquad (2)$$

where r_p is the plasma radius, $k_{\perp p} = (\beta^2 - \omega^2\varepsilon_r/c^2)^{1/2}$, $k_{\perp 0} = (\beta^2 - \omega^2/c^2)^{1/2}$ are the transverse propagation constants in the plasma and in free space, and β denotes the propagation constant along the plasma column; and finally, I_i , and K_i , $i = 0, 1$, are modified Bessel functions of the first and second kind, respectively.

The solution of (2) yields the so-called dispersion relation $\omega = \omega(\beta)$ of the surface wave. Since the plasma column has finite length, it is expected that suitable combinations of progressive and regressive surface waves along the plasma-air interface can satisfy the boundary conditions at the ends of the column, and thus give rise to standing surface waves or modes of the open cavity resonator.

Exploiting the dispersion relation it is possible to calculate the resonance frequency of a plasma column with given dimensions and therefore it is possible to calculate the length of the plasma column in order to have it resonating at a desired frequency.

According to traditional RF antenna design rules, the column should resonate at a given frequency f when its length is approximately half the wavelength in free space λ_0. But since plasma is a dispersive medium, the plasma column in the UHF band shows an effective wavelength that is shorter than the one in free space, that means that the resonance frequency for a column of length L is downshifted. Therefore, the plasma column is significantly shorter than its metallic counterpart: its length has been ultimately set to 52mm (instead of $\lambda_0/2$ = 96.8mm), a value obtained starting from $\lambda_{eff}/2$ and adjusted in order to optimize the performances of the overall Yagi-Uda antenna.

As far as the Yagi-Uda antenna model is concerned, its dimensioning follows the general rules of RF antenna design [10]: the reflector length is $L_{rfl} = 0.5\lambda_0 = 90.91$ mm and the active dipole is $L_{dpl} = 0.47\lambda_0 = 85.45$ mm. We considered a classic metal Yagi-Uda antenna in order to compare the performance of our solution with those of the standard design: in this case the metal directors length is approximately $L_{dir} = 0.4\lambda_0 = 73.82$ mm. The distance between the reflector and the dipole is $s_1 = 0.25\lambda_0 = 45.45$ mm and the spacing between the dipole and the directors and the two directors is $s_2 = 0.34\lambda_0 = 61.82$ mm. All the elements have the same radius, i.e., $r = 0.003\lambda_0 = 0.54$ mm. In CST Microwave Studio the dipole is fed through a 50 Ω discrete face-port that is placed in a gap g = 1.4 mm.

As far as the simulative model of the plasma directors is concerned, we decided to include the dielectric vessels and the metallic electrodes used to generate the plasma in the CST simulations. The gaseous plasma is confined into a glass cylinder (pyrex material from CST library) of internal radius $r_{int} = r_{plasma} =$ 3 mm and thickness of 0.6 mm: these values have been chosen according to real glass tubes that have been realized to confine the plasma in an experimental setup. Finally the glass cylinder is closed at the two extremities by two metallic electrodes of 1mm thickness that resemble those used to generate the plasma by RF surface wave technique. A detail of the director design in CST Microwave Studio is reported in Figure 3.

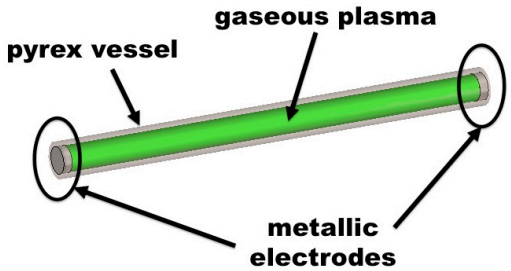

Figure 3: Design of the realistic plasma director in CST Microwave Studio [8].

In order to optimize the properties of the Yagi-Uda antenna when the two discharges are used as directors, we increased of 4 mm the distance between the two directors (this value was obtained performing optimization through a parameter sweep in CST). The last thing to point out about the model of our antenna concerns the off state of the plasma directors: in [1] when one or both the plasma bars were un-energized, they have been simply excluded from the simulations; in this work instead, we included the glass cylinders and metal electrodes in the simulations, replacing the plasma cylinder with vacuum when the plasma is off.

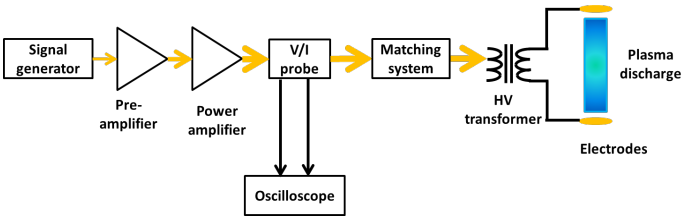

Figure 4. The scheme of the RF plasma generation system.

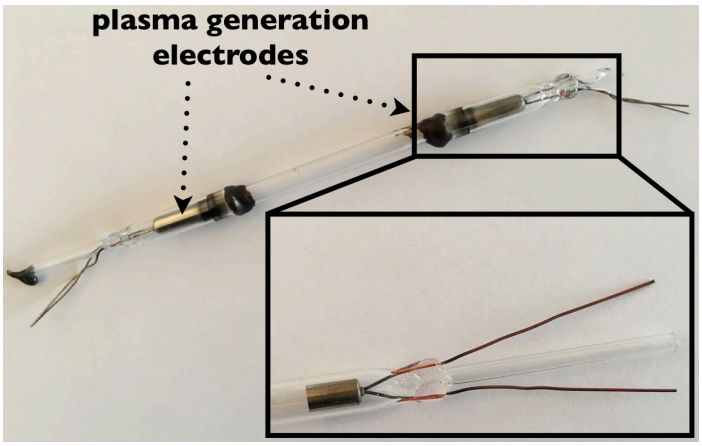

Figure 5. The experimental plasma discharge that has been used as director.

3. The Experimental Setup of the Plasma Director

To realize the plasma directors, we have relied on a ca- pacitive discharge [6] that has been driven by 50 Ω Radio Frequency (RF) power source; the RF power has been fed in the 1.8 ÷ 15 MHz range of frequencies through a matching network for efficient power transfer to the plasma, as illustrated in Figure 4. The signals are carried by means of RG-58 coaxial cables, while RF power is conveyed via RG-214 coaxial cables. The plasma has been generated by a couple of high voltage electrodes (see Figure 5) that have been placed internally at the far ends of the cylindrical pyrex vessel while being sealed with the prescribed argon gas atmosphere of 2 mbar. The pyrex vessel has an inner diameter of 3 mm, and an outer diameter of 4 mm; the two electrodes have been placed at a distance such that it is possible to realize a plasma column like the one identified in the antenna design phase.

To estimate the actual plasma density distribution within the plasma discharge, we have relied on a microwave interferome- ter [11], which is capable of plasma density measurements regardless of the gas type; specifically, the plasma density value is related to the phase shift produced on a microwave signal travelling through the plasma. The instrument works in the $10^{16} \div 7 \cdot 10^{19}$ m^{-3} range of plasma density values, is movable along the plasma source, and measures density in a plasma slab that is extended across the diameter of the source (see Figure 6). The plasma frequency value that was used in this work (see Section II) agrees with the measurements that were performed.

4. Results and Discussion

In this section the main results concerning the realistic metal plasma antenna are reported and compared with those obtained in

[1] for its ideal counterpart. The results were obtained through full-wave numerical simulations by means of CST Microwave Studio Suite [8].

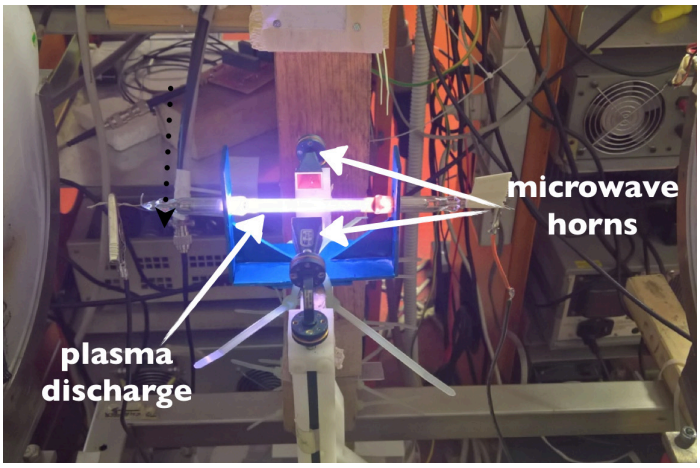

Figure 6. The experimental set-up with the plasma discharge between the two horns of the microwave interferometer for plasma density measurement.

The analysis was carried out in the frequency range 1 ÷ 2 GHz and concern mainly two metrics: (a) the reflection coefficient and the input impedance, (b) the radiation properties of the antenna, i.e., farfield gain and its reconfigurability together with radiation efficiency.

4.1. Reflection Coefficient and Input Impedance

As a first step, Figure 7 reports the absolute value of the reflection coefficient $|S_{11}|$ for the Yagi-Uda antenna with zero and two metal directors, for the hybrid Yagi-Uda with two ideal plasma directors [1] and for the antenna with the two realistic directors (as described in Section II). These three configurations were chosen as representative since they account for the starting condition, i.e., the antenna with no directors that is designed to resonate at f = 1.55 GHz, and the condition of maximum possible detuning for the antenna, i.e., when two directors are present; the other cases involving one director are omitted for ease of read of the graphs but are similar to and in perfect agreement with the results shown in the figure. As it can be seen, the absolute value of the reflection coefficient at the operating frequency is well below −15 dB in all the three cases, thus confirming that the realistic plasma discharges that were conceived in this work do not detune the antenna. In Figures 8-9 the real and imaginary parts of the input impedance Z are reported again for the classic metal antenna, for the ideal hybrid Yagi-Uda and for the realistic hybrid antenna both with two directors. It can be seen how at the operation frequency f = 1.55 GHz, Im{Z} is almost zero for the three antennas, while Re{Z} changes: it is 45 Ω for the classic antenna and for the hybrid ideal one, while it is 43 Ω for the realistic one. It can be noticed however how also in the case in which a realistic discharge is considered the idea of using a metal dipole as the active element of the antenna proves to be a good solution in order to avoid the matching issues caused by the low input impedance of plasma antennas [12].

4.2. Radiation Properties and Reconfigurability

As far as the reconfigurability of the antenna is concerned, Figures 10-11 depict the gain of the hybrid realistic Yagi-Uda antenna with zero, one and two directors in linear scale (for ease of read) in the E-plane (xz-plane) and H-plane (xy-plane) respectively.

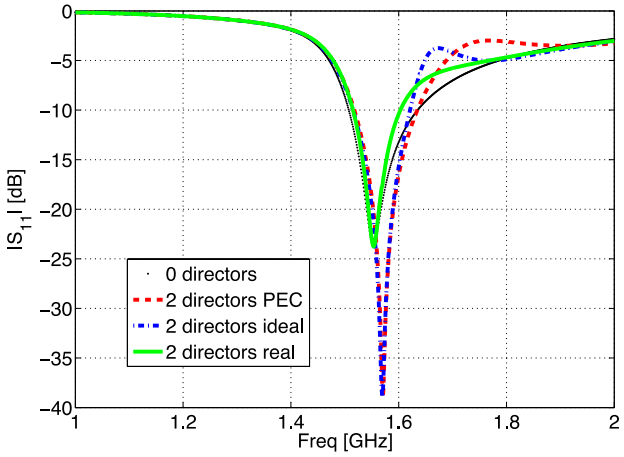

Figure 7. Absolute value of the reflection coefficient $|S_{11}|$ for the Yagi-Uda antenna with: no directors (dotted black line), two PEC directors (dashed red line), two ideal plasma directors (dash-dotted blue line) and two realistic plasma directors (solid green line).

As stated in Section II, when one or two directors are switched off, the vessel and electrodes have been included in the simulations and nonetheless we can see how reconfigurability with respect to the gain can still be achieved: the higher the number of active plasma directors, the higher the gain.

Then we compared the gain of the realistic hybrid antenna both with its ideal counterpart [1] and with the classic metal antenna. Figures 12-13 report the gain for the three antennas with one director switched on, on the E-plane and H-plane respectively: it can be seen how the gain of the antenna with the realistic plasma director is lower than those of the antenna with the ideal plasma director and than the one with the metal director (5.13 vs 6.02 and 6.25). Nonetheless the plot is in linear scale and therefore there is around 1 dB of difference between the maximum achievable gain in the three cases. The fact that the gain with the realistic plasma director is lower than in the case of the ideal one is reasonable considering that the collision frequency that accounts for the dissipation processes is considerably higher in the realistic case.

Figures 14-15 report the same plot but this time with both the plasma directors turned on. Analogous considerations can be made as in the previous case: the gain for the realistic antenna is 5.6 that is lower than that of the ideal one (6.63) and of course lower than the one of the classic Yagi-Uda (7.1); but again, the values are in linear scale so the difference between the gain of the ideal and realistic hybrid antenna is less than 1 dB.

The last case concerns the antenna when both the directors are turned off: in the ideal case, the directors were excluded from simulations, while in the realistic case, the dielectric vessels and electrodes are included. The results are not reported graphically since the two radiation patterns are almost identical. This proves, as it was expected, that the main factor that influences the radiation pattern of the antenna is the plasma collision frequency, i.e., the parameter that accounts for the dissipative processes and that in this work is significantly higher than in [1].

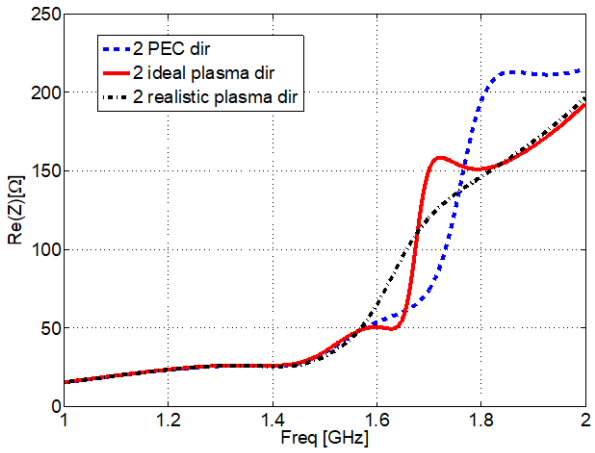

Figure 8. Real part of the input impedance of the Yagi-Uda antenna with: two PEC directors (dashed blue line), two ideal plasma directors (solid red line) and two realistic plasma directors (dash-dotted black line).

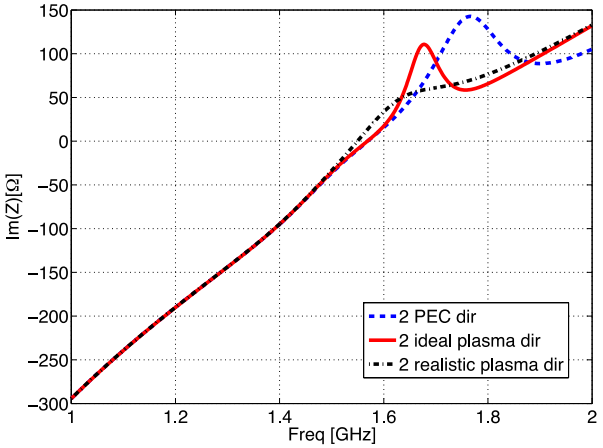

Figure 9. Imaginary part of the input impedance of the Yagi-Uda antenna with: two PEC directors (dashed blue line), two ideal plasma directors (solid red line), and two realistic plasma directors (dash-dotted black line).

As far as the efficiency is concerned, as expected this is lower in the realistic case in which losses are higher (this translates in a greater value of the collision frequency as commented previously): the efficiency is approximately 100 % for the metal Yagi-Uda, 98 % for the ideal hybrid Yagi-Uda and 80 % for the realistic one.

5. Conclusions

In this work the study and design of a reconfigurable metal-plasma Yagi-Uda antenna for microwave applications has been presented: plasma discharges have been suitably designed to be used as directors of the antenna in order to achieve reconfigurability with respect to the gain. These plasma directors were designed starting from [1] and they were modified in order to resemble more realistic plasma discharges: the dielectric vessel and metallic electrodes were included in the model and moreover the dimensions and plasma parameters of the discharges were set according to experimental measurements of real plasma antennas.

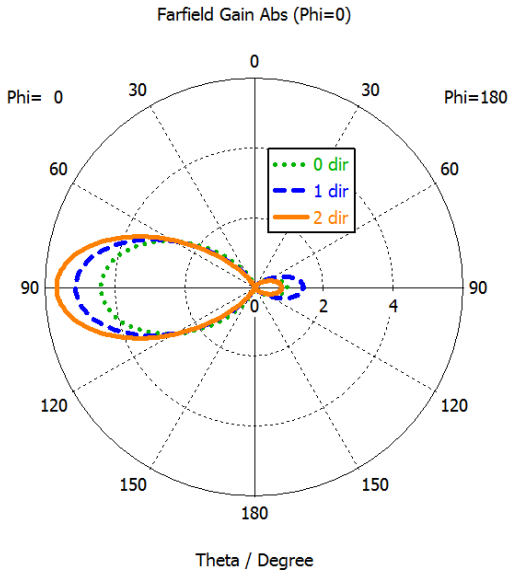

Figure 10. Farfield gain of the realistic hybrid antenna on the E-plane, i.e., xz-plane (see Figure 1) with zero (dotted line), one (dashed line) and two directors (solid line).

It has been shown that the performance of the antenna is very good as compared to [1]. Moreover it is clear from the results that reconfigurability with respect to the gain can still be achieved even with realistic plasma discharges used as directors. Of course, the radiation pattern is affected by the considerably higher value of the collision frequency, i.e., by the fact that dissipative processes are stronger in this case.

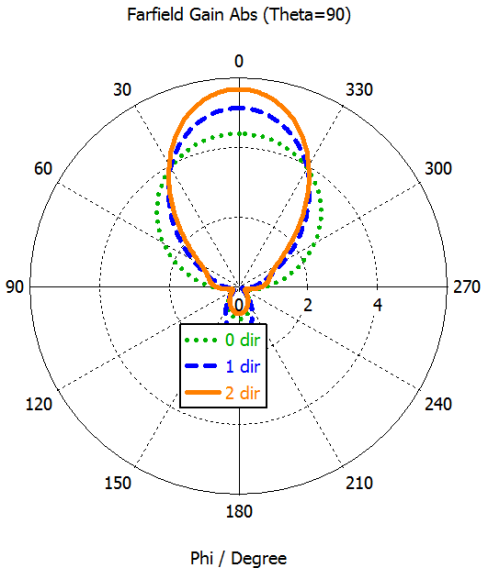

Figure 11. Farfield gain of the realistic hybrid antenna on the H-plane, i.e., xy-plane (see Figure 1) with zero (dotted line), one (dashed line) and two directors (solid line).

As a future step, we aim at considering plasma discharges with a non-uniform density, i.e., a density that changes axially along the cylindrical vessel and that resembles even better the behaviour of a realistic plasma discharge.

Therefore this study paves the way to the actual realization of the conceived hybrid metal-plasma Yagi-Uda antenna. However,

it must be pointed out that, in order to characterize and measure our proposed antenna not only in terms of its reflection coefficient but also in terms of its radiation pattern, there are still some issues to face, mainly related to the rather complicated setup that is needed to ignite and sustain the plasma inside the two directors.

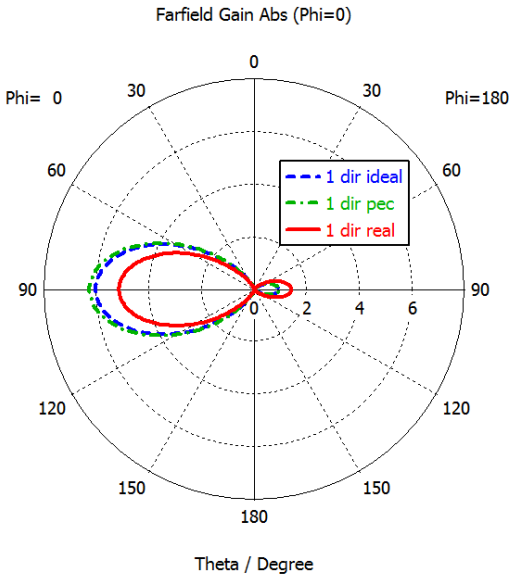

Figure 12. Farfield gain of the Yagi-Uda antenna on the E-plane, i.e., xz-plane (see Figure 1), with: one PEC director (dash-dotted green line), one ideal plasma director (dashed blue line) and one realistic plasma director (solid red line).

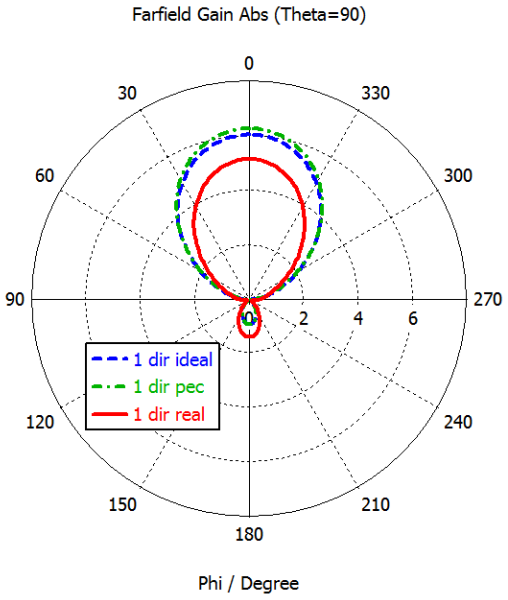

Figure 13. Farfield gain of the Yagi-Uda antenna on the H-plane, i.e., xz-plane (see Figure 1), with: one PEC director (dash-dotted green line), one ideal plasma director (dashed blue line) and one realistic plasma director (solid red line).

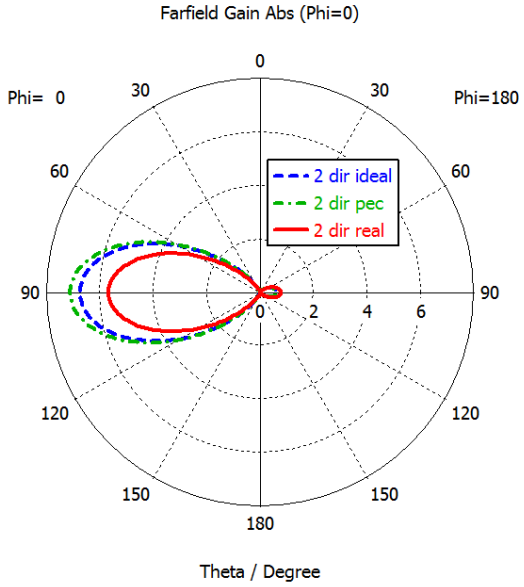

Figure 14. Farfield gain of the Yagi-Uda antenna on the E-plane, i.e., xz-plane (see Figure 1), with: two PEC directors (dash-dotted green line), two ideal plasma directors (dashed blue line) and two realistic plasma directors (solid red line).

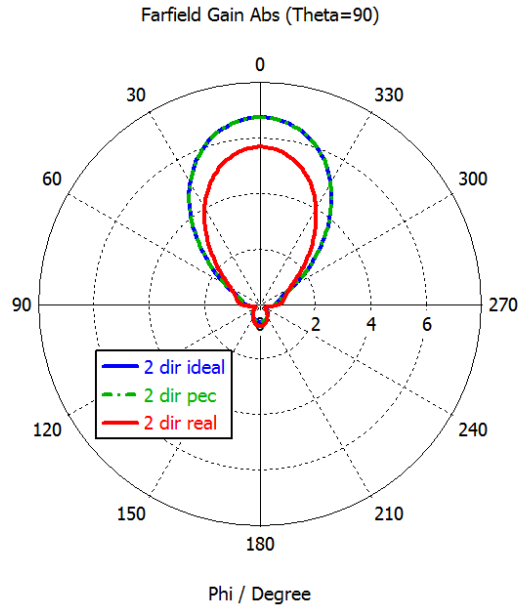

Figure 15: Farfield gain of the Yagi-Uda antenna on the H- plane, i.e., xz-plane (see Fig.(1)), with: two PEC directors (dash-dotted line), two ideal plasma directors (dashed blue line) and two realistic plasma directors (solid red line).

ABSTRACT

A web service impersonation is a class of attacks in which an attacker poses as or assumes the identity of a legitimate service to maliciously utilize that service's privileges. Providing security for interacting cloud services requires more than user authentication with passwords or digital certificates and confidentiality in data transmission. In this paper, we focus on the service cloud model, which facilitates the composition and communication among web services owned by different cloud vendors. We develop a distributed mechanism to detect and mitigate impersonation attacks against web services in the cloud. The detection approach monitors the behavior of each service and identifies anomalies as a potential impersonation attack if it deviates significantly from the expected behavior. To verify the impersonation attack, we deploy a cloud-based verification technique, misleading suspicious services with useless responses. The experimental results show that modeling request behavior reliably detects a significant number of impersonation attempts, with a performance degradation that is a reasonable trade-off.

1. Introduction

A web service impersonation is a class of attacks in which an attacker poses as or assumes the identity of a legitimate service to maliciously utilize that service's privileges. This attack can cause a serious threat to the security of service clouds, i.e. those clouds that allow the provisioning of multiple vendor services to dynamically compose an application to answer a client request. By impersonating a legitimate service, the intruder can maliciously access the victimized a service's resources. For the service cloud, this attack class is a version of identity theft. Such attacks completely undermine traditional security mechanisms due to the trust imparted to service credentials once they have been authenticated. Many attempts have been made at detecting this kind of attack (also called masquerader or identity spoofing attacks) against legitimate users in clouds. In this dissertation, we have developed a distributed mechanism to detect and mitigate impersonation attacks against web services in the cloud [1].

When using the cloud, an end user's credentials to authenticate request messages between web services lacks the verification of the origin of the request (i.e. the requester service). Thus, this vulnerability can be used by the attacker after stealing the credentials to create fake services. Since the credentials represent a long-term authentication tool, the attacker can attack a web service for unlimited time and the owner of the credentials would not discover the problem until the damage is done.

In our proposed architecture (Figure 1) [1], we assume a secure session with a security token issued by a Security Token Service (STS) to mitigate the general vulnerability of spoofing the user credentials. The STS is trusted by both the client and the web service to provide interoperable security tokens. The client sends an authentication request, with accompanying credentials, to the STS. The STS verifies the credentials presented by the client, and then in response, it issues a security context token (SCT) that provides proof that the client has authenticated with the STS. The SCT is built on a SAML standard format for exchanging authentication and authorization data between different parties [1, 2]. The client presents the security token to the service. The service then verifies the token with the STS, which proves that the client has been successfully authenticated. For proper use of the token, it is expected that all composed, trusted services communicate with the STS to perform token delegation and validation at each service request and response, but only client services issue or cancel a token. The SCT holds information to specify its scope, creation, and expiration time to develop the basis for encrypting and signing subsequent message exchanges, which results in efficient and secure communications between services in an application. The cloud services and STS use X.509 certificates to sign and encrypt their messages. The scope of the issued SCT is limited to the designated STS regardless of whether the sender service specified

the scope in the initial request. This prevents the sender from using the SCT to directly access a recipient without communicating first with STS. Therefore, a token's lifetime is limited to its session active time.

The proposed architecture introduces the concept of scoped distributed Security Management Databases (SMDBs) to store audit logs, meta-information about the infrastructure of each scope, history of security incidents, incident reports, related security policies, and SLAs [2]. Scoped detectors use SMDB content to identify security threats exploiting the scoped content. We have shown in [3] how CAPEC attack patterns fit into the evidence collection and evaluation strategy using the proposed architecture.

For the proposed system, we implement our solution using Apache Web Service Security for Java (WSS4J) to secure the deployed cloud services and their messages within a provisioned application given the primary security standards. WSS4J supports the encryption of messages using X.509 certificates of services. Furthermore, it prevents replay attacks that can happen when the attacker sniffs a message and resends it to the same recipient. Apache WSS4J makes all security tools available for developers to secure their services against impersonation attacks by using strict authentication standards. When a service passes the identity authentication it is fully trusted in the application. However, if the service identity has been compromised for any reason, WSS4J cannot detect the impersonation attack or even log its traces in the log file. Consequently, the impersonated service will be authenticated and the attacker can illegally gain access to potentially private information.

The impersonation attack is not only limited to the SOAP messaging protocol in service clouds. Any type of communications between services that requires request authentication is vulnerable to impersonation attacks. Authentication in REST services does not have a standard policy or rules. However, the most common used approaches for REST request authentication are HTTP AUTH and tokens. In HTTP AUTH, the client service needs to compute the Base64 encoding of its credentials and include them in each future HTTP request to the server using the "Authorization" HTTP header. This header can be encrypted using the server public key and the client private key. This approach is very similar to the approach used in the SOAP protocol by using the SOAP header to carry authentication information to the destination. Both HTTP and SOAP headers can be faked by the attackers who illegally obtain a copy of the legitimate client service's identity.

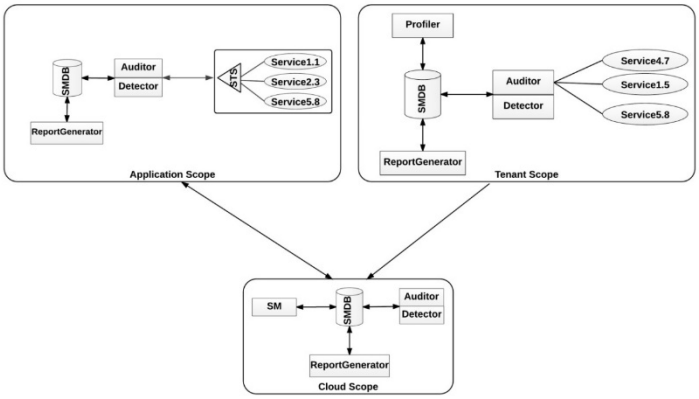
The second authentication approach used in RESTFUL clouds is to create a dedicated login service similar to a STS that accepts credentials and returns a token. This token should then be included, as a URL argument, to each following request. The attacker can also get a valid token by using the stolen credentials. Consequently, regardless of the type of communication messaging used between services, it is possible for an attacker who has a stolen identity to successfully pass the authentication step and get trusted in the target server.

The Amazon REST APIs use a custom HTTP scheme based on a keyed-HMAC (Hash Message Authentication Code) to authenticate REST requests. To authenticate a request, the client needs first to concatenate selected elements of the request to form a string. Then, it must use its AWS secret access key to calculate the HMAC of that string. Informally, this process is called "signing the request," and the output of the HMAC algorithm is called the signature, because it simulates the security properties of a real signature. Finally, the client, either a human user or another service, has to add this signature as a parameter of the request by using the syntax described by the server. The risk stems from the leaked AWS secret access key, which happened recently for many customers of Amazon clouds. Hence, the REST messaging architecture is also vulnerable to impersonation attacks if the authentication identity has been compromised. In this paper, though we will focus on detecting the attack by using SOAP protocol, the solution design can be extended to work with REST services.

In this paper, we hypothesize that the legitimate service can obtain sufficient information from the cloud regarding the successor service classes that it often communicates with when provisioned for certain application. An impersonated service, on the other hand, would likely have a more chaotic and random behavior by communicating more extensively with known successor services and more broadly to services not often communicated with in a manner that is different than the victim service being impersonated [4]. Thus, our detection approach focuses on monitoring a service's behavior in real time to determine whether current service actions are consistent with the service's profiled behavior.

To reduce the false positive rate, which is the main drawback of the anomaly detection systems, we combine the detection of anomalous behaviors with a cloud-based verification technique. The verification technique prevents the risk of revealing private data to impersonators and, at the same time, verifies the identity of the malicious service. When the verification algorithm positively verifies the detection results, it returns a fake response to delude the attacker.

The major contribution of this paper is our distributed framework for auditing and detecting impersonation attacks in service clouds. We design a distributed impersonation detection approach within the framework that is based on profiling each service's request behavior. This behavior reveals that monitoring the general features of the SOAP request messages between web services can achieve a reasonable detection rate with minimal false positive alarms. In order to increase the accuracy of the detection system, we design an aging method to determine when the profiles need to be updated and how to adjust them so they are more heavily influenced by the most recently observed behavior. Moreover, we manifest the false positives and decrease the impersonator live time inside the cloud by re-authenticating the suspicious service using a novel verification technique. Since the credentials of the suspicious service may be spoofed by the impersonator, our verification technique uses a predefined fake response to validate the identity of the suspicious service that exhibits a significant behavior deviation. If the suspicious service accepts the fake response by the suspicious service, then the detection system has correctly detected the impersonator. Otherwise, the suspicious service is considered to be a legitimate service that has been incorrectly classified as an impersonator because it changed its behavior without updating its profile.



Our experimental results show that modeling service behavior reliably detects a high percentage of impersonated services with no false positives. The limited set of statistical values used for service behavior modeling results in an acceptable performance. However, in the case of mimicry attacks where the impersonator fully mimics the victim service's behavior, the detection algorithm cannot detect the malicious requests. Resolving such attacks and improving the algorithm performance are future work.

The paper is organized as follows. The threat model is described in Section 2. The literature review of impersonation detection techniques is presented in Section 3. Section 4 demonstrate the detection approach used in this research. Section 5 discusses the detection results. Section 5 concludes the article with some suggestions.

2. Threat Model

2.1. Vulnerabilities

The standard approaches of identity verification including authentication and encryption have been shown to fail to detect impersonated services for a variety of reasons, including insider attacks, misconfigured services, faulty implementations, buggy code, and the creative construction of effective and sophisticated attacks not envisioned by the implementers of security procedures. Attack methods such as phishing, fraud, and exploitation of system vulnerabilities still achieve results in service clouds. Credentials and passwords are often reused, which amplifies the impact of such attacks.

The Heartbleed bug leaked private information such as encryption keys and credentials from the service's owner server. Leaked secret keys allow an attacker to decrypt any past and future traffic to the protected services and to impersonate the services as well. Therefore, any protection given by the encryption and the signatures in the X.509 certificates can still be bypassed. Mitigating bugs like Heartbleed is out of the service owner and cloud provider control, which means we need to design another line of defense to mitigate the risk of "bleeding" the encryption keys (X.509) and service credentials. In this article, we introduce a preventative approach that distinguishes between requests coming from legitimate services and those coming from fake services with impersonated or spoofed credentials to block them and alert the victim's owner to revoke the stolen keys.

Different incidents happened in Amazon cloud prove that the classical authentication and authorization techniques are not safe enough to fully trust all services holding valid identities. In April 2010, Amazon experienced a Cross-Site Scripting (XSS) bug that allowed attackers to hijack credentials from the site. In 2009, numerous Amazon systems were hijacked to run Zeus botnet nodes. Also, in April 2014, some of AWS clients claimed about very high bills due to their credentials were compromised.

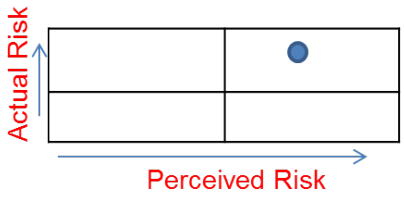
2.2. Target Assets

The expected target of the impersonation attack is the legitimate service's identity.

2.3. Impact

According to the CSA in [5], the risk analysis technique CIANA classifies the impact of service hijacking or impersonating as a combination of authenticity, integrity, confidentiality, non-repudiation, and availability threat. On the other hand, STRIDE risk analysis puts the service impersonation under tampering with Data, repudiation, information disclosure, elevation of privilege, and spoofing identity. Therefore, service impersonation attack causes a very high risk on the cloud from all aspects of security.

According to a survey conducted by CSA the extended CSA Top Threats Working Group [5] , the impersonation threat is still relevant to clouds by 87%. Also, the data leakage was ranked as the third top threat in 2013.The risk matrix for service impersonation is depicted in Figure 2.



2.4. Scenarios

The attacker who exploits a bug similar to Heartbleed and has a copy of the encryption public and private keys and the credentials of the victim service (we use identity to describe these information) can effectively perform a service impersonation attack against the victim service. Then, it can illegitimately use the stolen identity to gain access to other services in the service cloud by following the listed steps:

1. The attacker builds a fake web service by using the stolen identity to impersonate the victim service.
2. During an active session of an application that has the victim service provisioned within it, the attacker uses sniffer software to steal a valid token sent from the STS to the victim service. The intercepted token is encrypted by the public key of the victim service. Since the attacker has the encryption keys of the victim service, he can decrypt the token.
3. The attacker uses the stolen token along with the victim identity to ask the STS to delegate the token to the target service of the attack. The target service must be provisioned within the same application with the victim service.
4. The STS authenticates the impersonated service and replies with a delegated token.
5. The attacker finds the interface of the target web service and its entry points (i.e., methods) by discovering its public WSDL file.
6. The attacker uses the delegated token and the stolen identity to create and encrypt a request to the target service.

7. The target web service validates the token of the impersonated service with the STS.
8. The STS authenticates the token and sends the confirmation to the target service.
9. The target service decrypts and checks the structure of the message.
10. The target service responds to the impersonated service with a valid encrypted response SOAP.
11. The attacker decrypts the received response using the victim private key.

With this scenario, private information can be revealed to illegitimate services by trusting the presented identity without doing a more thorough check. The success of this attack can trigger several attacks, such as DDoS attacks as we have explained in [6], to abuse the availability of the target service and the integrity of the victim service.

3. Related Work

There are two general approaches for intrusion detection: misuse detection and anomaly detection [7]. The misuse detection uses the knowledge accumulated about attacks and checks for signatures of these attacks while the anomaly detection builds a reference model of the usual behavior of the system being monitored and checks for deviations from the observed usage. The false positive rates of misuse detection are lower than that of anomaly detection [8] but anomaly detection has the advantage of detecting previously unknown attacks. In impersonation attack detection, the intrusion detection system cannot get the signatures of attackers until the attackers have been detected by the system. Therefore, the attack model cannot be constructed in advance; hence we prefer to use anomaly detection approach in this context.

In the literature, anomaly detection was implemented in a variety of approaches. These approaches are usually categorized into two groups, i.e. statistical approaches and machine learning approaches [8]. In statistical approaches, anomaly detection systems usually watch behaviors of observed objects to comprise statistical distributions as a set of trained profiles during the training phase. These systems then apply the set of trained profiles by comparing them against a new set of activities of observed objects during runtime. An anomaly is detected if there is a significant deviation resulted from the observation. In general, any incident whose frequency goes beyond a predefined standard deviation from statistical normal ranges raises an intrusion alarm [7].

Machine learning based approaches tend to reduce the supervision costs during the training phase of statistical approaches by enabling detection systems to learn and improve their performance on their own. Neural networks and Hidden Markov Model have been proved to be useful techniques at the network traffic level as shown in in [9] and [10]. However, using ML algorithms in a highly dynamic environment like service clouds have several drawbacks such as increasing performance overhead, storage requirements, and computational expense [11].

In the context of this paper, we focus on statistical approaches for detecting impersonation attacks. In [8,12-15], statistical algorithms are applied to detect anomalous patterns in the system. They use the normal behavioral profiles of the monitored object, which is either a user or system process. Unlike these systems, this research applies anomaly detection at the web service level. Rather than profiling the normal behavior of users or systems, our approach profiles the normal request behavior of web services. Hence, the detection system deals with the web service as an independent object that can be impersonated irrespective of its owner's behavior.

Researchers in [16] provide an intrusion detection framework for cloud systems targeting masquerader attacks. Each user has a profile to model its behavior and make it available across the cloud. To measure the deviation between an activity initiated by a normal user and activity initiated by the masquerader, they use the Data-Driven Semi-Global Smith Waterman alignment algorithm. The objective is to compute the best alignment score, by aligning the active user's session sequence (e.g., mouse movements, system calls, opened windows titles, etc.) to the previous stored sequences for this user. It achieves good results in detecting masqueraders in clouds with detection accuracy of 88.4 % and a low false positive rate of 1.7 %. However, the focus on monitoring human users is insufficient for detecting service impersonations in service clouds. Service clouds are mainly composed of collaborative services from different administrative domains with different security policies. Researchers in [16] do not address attacks that might be triggered by impersonated services with legitimate identities.

The detection approach presented in [17] detects insider masqueraders in file systems. This approach tracks and measures changes in user behavior, alerting on any significant changes. They use one-class support vector machines to develop user behavior models and a set of data features related to the file systems including: the process name, the process path, the parent of the process, and the type of process action, the process command arguments. Their experiments show that modeling search behaviors of genuine users reliably detects all masqueraders with a very low false positive rate of 1.1%. Despite the fact that they do not test this approach on clouds, it may be applicable for only storage clouds. Hence, their detection system is not applicable for the service cloud model we work with. However, our verification technique is inspired by their proposed decoy technique, which launches disinformation attacks against malicious insiders, preventing them from distinguishing the real sensitive data from fake worthless data. They place traps within the file system which are documents downloaded from the Internet including several types of useless documents such as tax return forms, medical records, credit card statements, e-bay receipts, etc. The decoy files are downloaded by the legitimate user who owned the system and placed in highly-conspicuous locations that are not likely to cause any interference with the normal user activities on the system. A masquerader, who is not familiar with the file system and its contents, is likely to access these decoy files, if he or she is in search for sensitive information. Their decoy technology is more suitable for file systems or storage clouds more than service clouds. Hence, we design a service-cloud-based decoy technique as our verification technique to mislead the impersonators with fake information.
