• Closest Point of Approach (CPA) • Speed • Maneuver • Heading • Distance	• Distance • Heading • Deceleration • Speed • Closest Point of Approach (CPA)

TBH cue is removed from the list because of the assumption of conditional independence. This assumption does not allow to fuse evidences that are dependent to each other [22, 23]. Since TBH is dependent to speed cue, there is a need to remove one of them from the list. CPA holds the part of the information that TBH has. However, there is no way to reach speed effect in TBH. Therefore, threat selection algorithm does not accept TBH as evidence.

Scores of threat assessment cues reference multiple evidences in Bayes' rule. These evidences are fused to locate in Bayes' formula together. Therefore, there is a need to redefine (11) according to combination of these evidences. Equation (11) is turned to following form after processing multiple evidences rule:

$$P(T_i|\ \wedge_{j=1}^{n} C_j) = \frac{P(T_{i-1}) \prod_{j=1}^{n} P(C_j \mid T_{i-1})}{P(T_{i-1}) \prod_{j=1}^{n} P(C_j \mid T_{i-1}) + P(N_{i-1}) \prod_{j=1}^{n} P(C_j \mid N_{i-1})}$$

where $P(N) = 1 - P(T)$ and $1 \leq n \leq 5$
n : number of threat assessment cue
N : opposite hypothesis of T (4)

In (12), $P(T)$ denotes the probability of track to be a target Moreover, $P(N)$ stands for the probability of a track to not being a target. After the computation of probability of T hypothesis, decision making process of this process is simply performed as follows:

$$f(t) = \begin{cases} P(T_i \mid \mathbf{C}) \geq \beta, & t \text{ is threat} \\ otherwise, & t \text{ is not a threat} \end{cases} \quad (5)$$

Threshold value is chosen somewhere middle of the scale. Because, Bayesian Inference results tends to get maximum or minimum value when it becomes stable after couple of iteration. This result could be observed in the evaluation section of this paper.

4.4. The Calculation of Threat Assessment Rating

Threat selection algorithm separates the list of suspected objects as target that needs more attention and other tracks that does not have priority to be observed. There is still need of ranking on this list if a scenario includes dozens of objects.

Threat assessment rating of each object is calculated by taking account into scores generated from threat assessment cues. Each threat assessment cue does not affect the final result equally. They influence the result with respect to the importance on threat level against defended asset. While their weight on threat assessment rating is determined, studies done for air and surface warfare are considered as reference. The list of threat assessment cues and weight of them changes depending on category of surrounding objects. Table 3 gives this lists and importance order of cues as follows:

Table III: Threat assessment cues according to the importance in threat assessment

Air Tracks	Surface Tracks
• Time Before Hit (TBH) • Speed • Maneuver • Heading • Distance	• Distance • Heading • Deceleration • Speed • Time Before Hit (TBH)

As explained in section 4.2, each threat assessment cue does not carry same weight in calculations. Therefore, formal definition of the calculation of threat assessment rating can be described as follows:

$$v_1 + v_2 + v_3 + v_4 + v_5 = 1 \quad (6)$$

$$w_1 + w_2 + w_3 + w_4 + w_5 = 1 \quad (7)$$

$$V_a = \sum_{k=1}^{5} w_k C_k,\ \mathbf{C} \rightarrow [0, 1],\ V_a \in \mathbf{V} \quad (8)$$

$$V_i = \begin{cases} air\ track, & vt_i + v_2 s_i + v_3 m_i + v_4 h + w_5 d_i \\ surf.track, & w_1 d_i + w_2 h_i + w_3 a_i + w_4 s_i + w_5 t_i \end{cases} \quad (9)$$

First phase of the threat evaluation model generates the score for each threat assessment cue after the selection of the category. These scores are generated by following methods introduces in section 4.2. In (16), $\mathbf{C} = \{C_1, C_2, C_3, C_4, C_5\}$ denotes scores generated in that phase. Then, threat assessment rating is calculated by adding up these scores with a specified weight. (14) defines weights of air tracks and (15) shows the relation of weights for surface tracks.

Equation (16) defines the calculation of threat assessment rating formally. (17) is more clear version of (16), which gives details of formulas for each category. Threat assessment rating is calculated at each iteration. Whenever kinematics of track or own ship is changed, then threat assessment rating of each track is updated.

5. Evaluation

Threat evaluation model is evaluated with synthetic scenarios. Similar scenarios are formed for both air and surface objects. While playing these scenarios, scores of threat assessment cues and resulting threat selection value and threat assessment rating are recorded in combat management system. These records are visualized by using ordinary charts that show probability of threat assessment cue as y-axis and iteration of each calculations as x-axis.

Synthetic scenarios are generated with the tool that capable of produce track data and own ship data. Objects in simulation tool are able to follow route defined by the user. Moreover, category and speed of objects can be entered to system by the user. While playing scenario, simulation tool directs related data to combat management system.

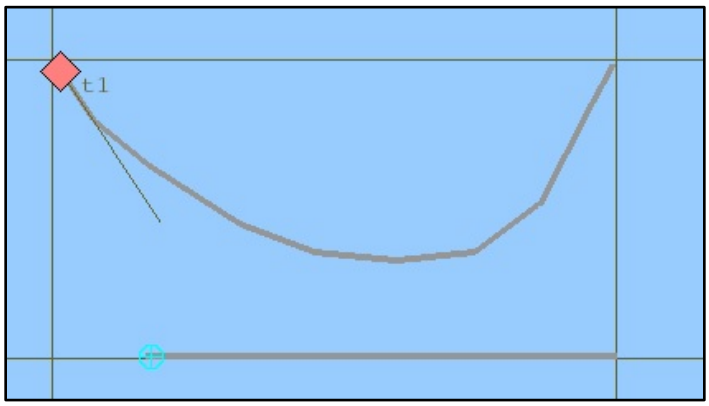

Figure 4 Syntetic Scenario 1

Figure 4 shows the first scenario generated in simulation tool. This scenario is played for both an air object and a surface object. The mentality behind this type of strategy is to see whether category affect algorithms results or not. We expects the difference results since threat assessment cues and their weight are different in categories.

According to first scenario, red object closes to the route of own ship that symbolized with blue mark, then point out its heading away and become distant to own ship as shown in Figure 4. In surface scenario, speed of the red object is convenient to a naval vessel platform.

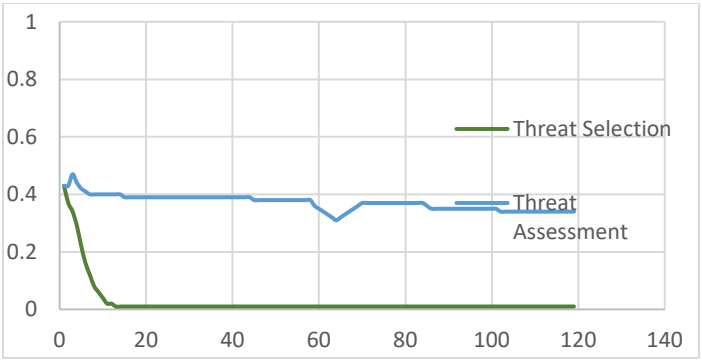

Figure 5 Results of Previous Study for Synthetic Scenario 1 Used for Surface Object

Figure 5 indicates that previous implementation [1] results seems to be very steady. There is no critical change on the threat level even if surface object changes its route significantly. Since common parameters and weights used for both categories in this implementation, kinematics of surface object could not exceed barriers of those parameters. Therefore, result is not a good indication for operator.

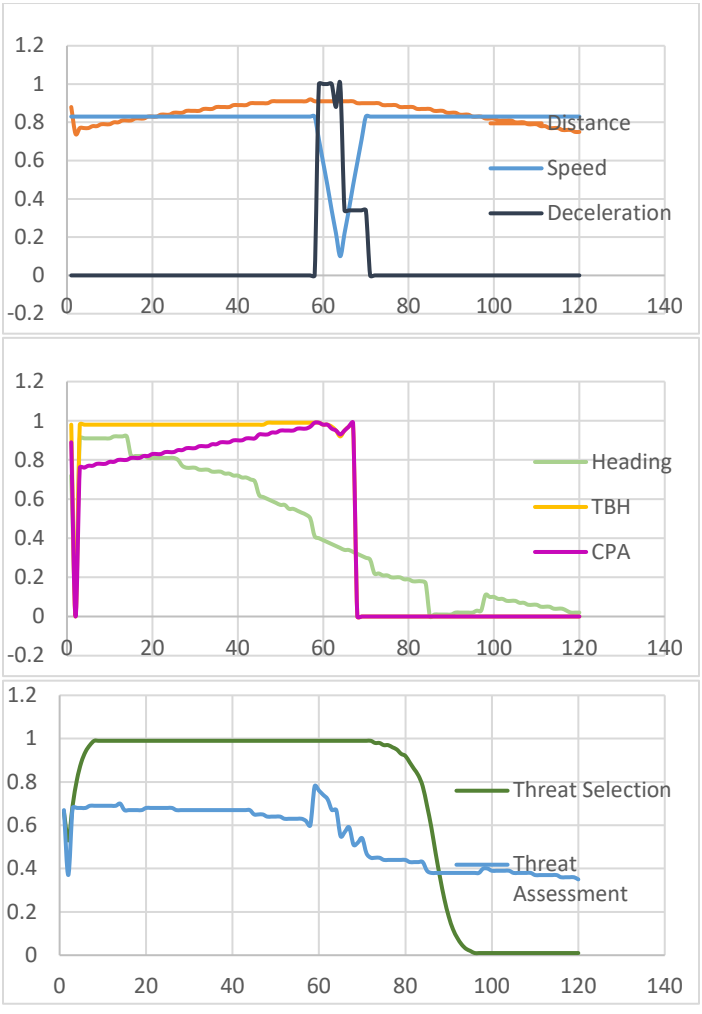

Figure 6 Threat Assessment Parameters Scores and Resulting Threat Selection Probability and Threat Assesment Rating for Synthetic Scenario 1 Used for Surface Object

Figure 6 indicates scores of threat assessment cues and results of algorithms. At the beginning of the scenario, TBH and CPA are very dominant over results. Since orientation of red object is very threatening for own ship, it classified as target by threat selection algorithm and takes around 0.7 threat assessment rating. In the middle of scenario, red object slower down its speed. This behavior causes an increase at deceleration score. Then, threat assessment rating increase as expected. I nth second part of the scenario, red object changes its orientation and give up being threat for own ship. Its threat assessment rating drops with this movement. However, threat selection algorithm does not classify the res object as friendly despite of last movement. This is a reasonable results since there is no guarantee that danger has passed away. Algorithm warns the operator for a while to follow actions of red object. After an enough number of iterations, red object seem to be not dangerous. Threat selection algorithm decrease its total score while it goes away.

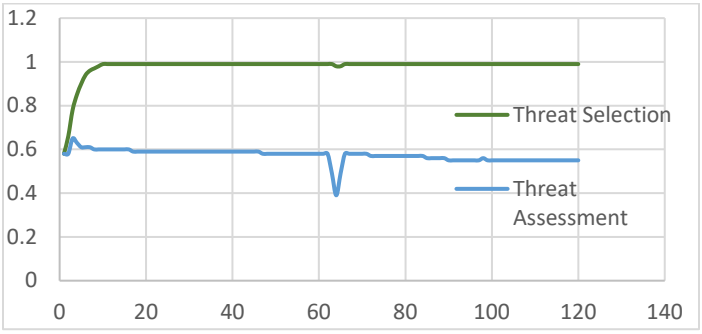

Figure 7 Results of Previous Study for Synthetic Scenario 1 Used for Air Object

Similar to the surface scenario, previous implementation [1] results seems to be very steady again in Figure 7. Air object is selected as a threat all the time and threat assessment rating does not change sharply.

Figure 8 reveals results of similar scenario with an air object. Red object follows again typical scenario shown in Figure 4 with the speed making sense for an air object.

In the beginning of the scenario, red object is categorized as target again by the threat selection algorithm. It takes around 0.8 threat assessment rating. When it turns out its heading way from defended asset, its threat assessment rating begins to drop down. After a while, TBH and CPA becomes low and it drop down the threat assessment rating sharply. Then, threat selection algorithm begin to decrease its threat level. In the middle of the scenario, speed of red object is slower for a while. This situation lead to decrease in threat assessment rating. Since deceleration does not mean anything for an air object, results of algorithm behaves different then what they do in surface scenario.

Through the end of the scenario, red object move away and become distant to friendly asset. As a result, threat assessment rating becomes close to 0.

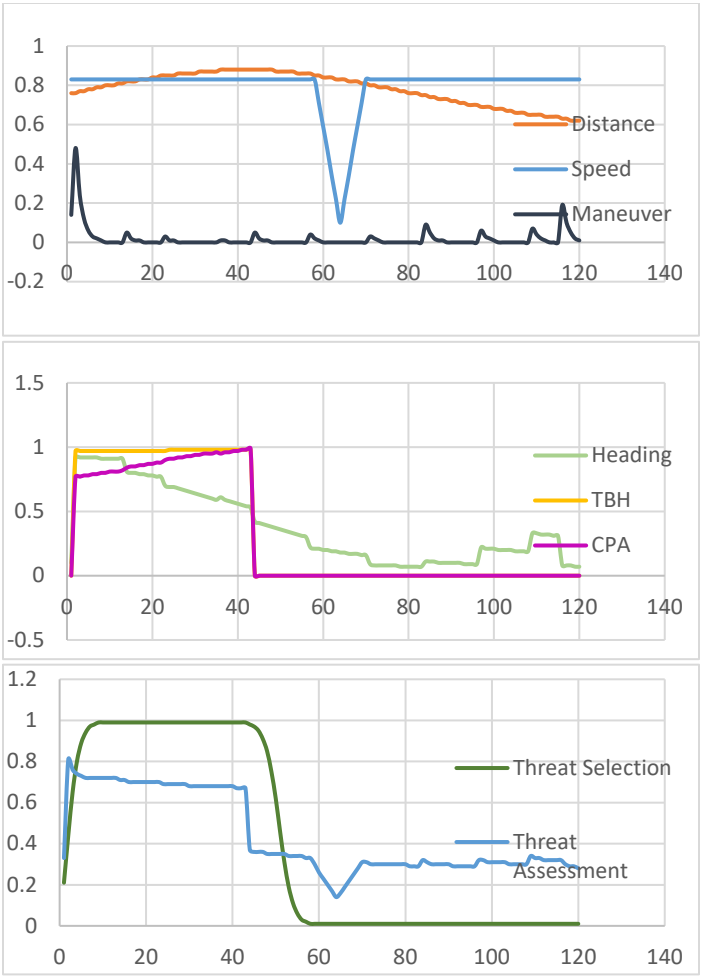

Figure 8 Threat Assessment Parameters Scores and Resulting Threat Selection Probability and Threat Assesment Rating for Synthetic Scenario 1 Used for Air Object

Figure 9 indicates second general scenario by the user in simulation tool. According to scenario, red object moves around defended asset by not changing its distance too much.

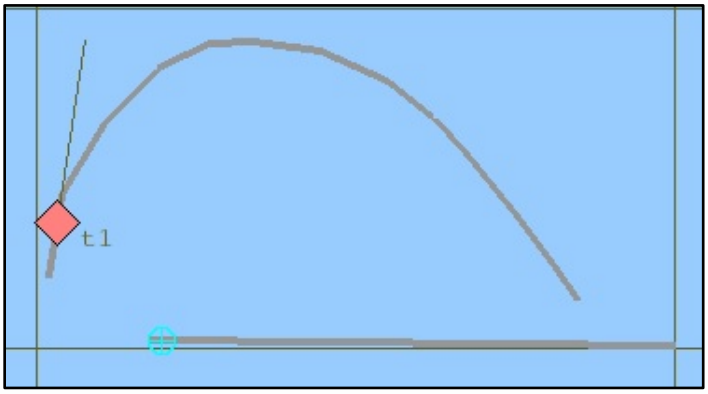

Figure 9 Syntetic Scenario 2

In Figure 10, it is not difficult to observe that previous implementation [1] could not give a valuable feedback about the foreigner entity as shown in figure. The object is classified as safe through the scenario.

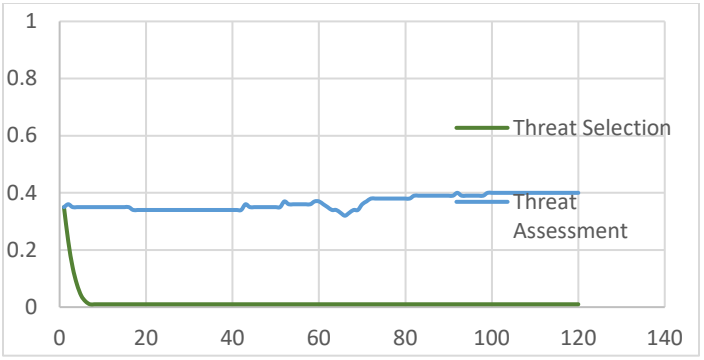

Figure 10 Results of Previous Study for Synthetic Scenario 2 Used for Surface Object

Figure 11 indicated results of second scenario for surface object. Since there is a peek for CPA and TBH in the beginning of the scenario, red object is sensed as threat. When red object sits on its road, threat selection algorithm give up threat classification for red object. In the middle of scenario, CPA and TBH becomes higher again. Threat selection algorithm notice the danger and classifies red object again as threat. However, threat assessment rating of red object does not affected from this change too much.

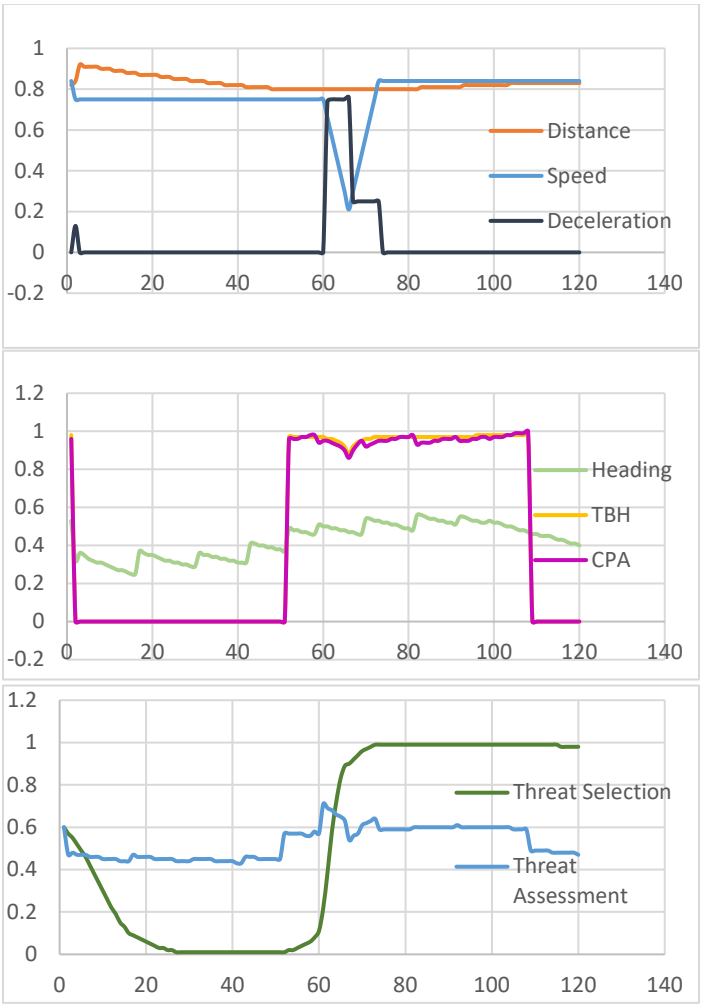

Figure 11 Threat Assessment Parameters Scores and Resulting Threat Selection Probability and Threat Assesment Rating for Synthetic Scenario 2 Used for Surface Object

Because, TBH is bottom of the list according to importance level of threat assessment cue. Threat assessment rating gets its highest value when surface object slows down. This behavior activates deceleration cue and increase threat assessment rating to highest value.

Similarly, previous implementation [1] does not provide beneficial picture to the operator as shown in Figure 12. Results does not affected from kinematics of object very much.

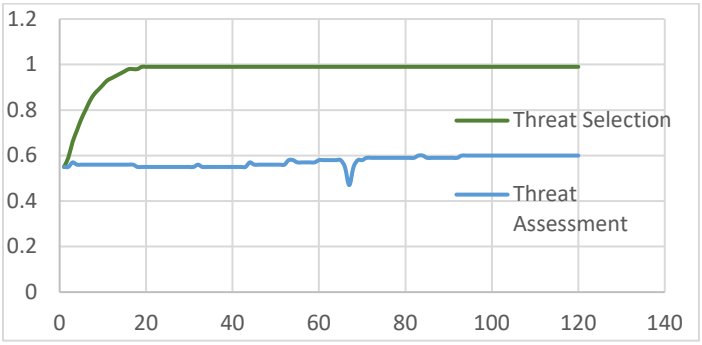

Figure 12 Results of Previous Study for Synthetic Scenario 2 Used for Surface Object

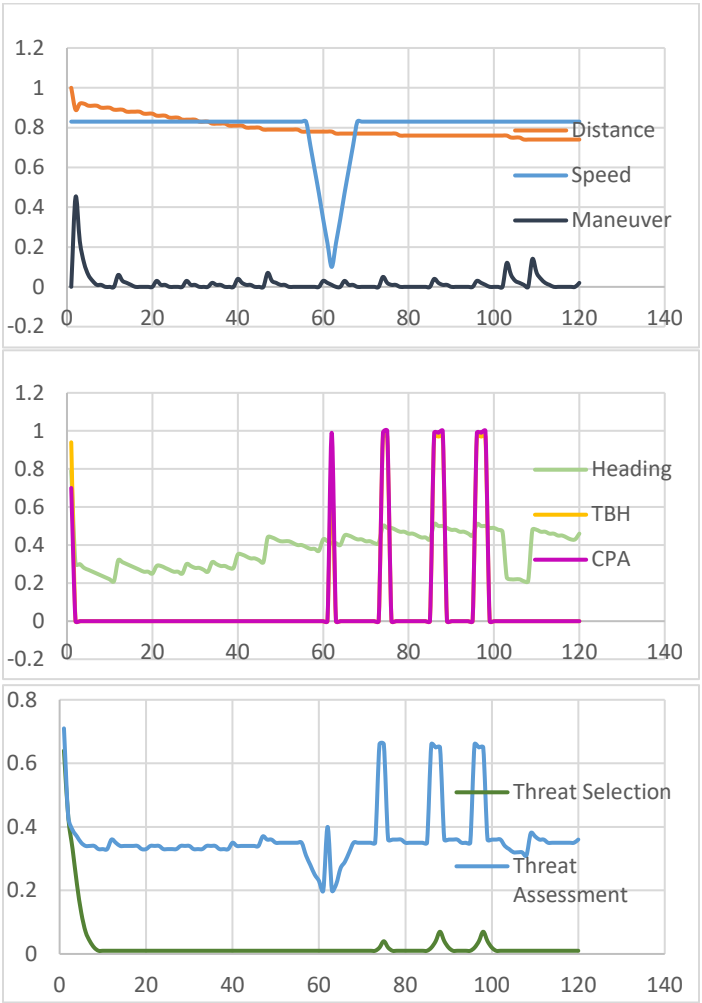

Figure 13 Threat Assessment Parameters Scores and Resulting Threat Selection Probability and Threat Assesment Rating for Synthetic Scenario 2 Used for Air Object

The route in Figure 9 is repeated for air object that has higher speed than surface object normally. As can be seen in Figure 13, red object is classified as threat at the beginning of the scenario. Because, TBH and CPA is effective at that time. Then, threat assessment rating begin to decrease. CPA and TBH shows themselves time to time. While the response of the threat assessment rating is a sharp increase, threat selection algorithm does no affected from this short period movement. Red object end scenario as safe object.

6. Related Work

There are many researches from different perspectives for threat evaluation problem. Mainly, rule based approaches, fuzzy logic methods and Bayes network studies are popular ones in this field as follows.

U.S navy officers have made serious contributions to a rule based study by answering question of survey related with threat evaluation in air defense domain [16]. Moreover, a different survey is conducted with U.S navy officers to contribute study done for threat evaluation in surface warfare [11]. These studies reveals most important threat assessment cues in both air and surface domain. After the extraction of these cues, rule based techniques applied on them to find out threat assessment rating of surrounding entities.

Fuzzy sets theory is used in another study for air threat evaluation process [15]. Range, altitude, CPA, speed, maneuver, weapon envelope, visibility, own support, fire, target support and IFF are used as threat assessment cues in proposed fuzzy inference system. It is claimed that simulation results indicate that proposed method is correct, accurate and reliable and it has minimum error in evaluating threats. By using fuzzy logic, they handle with imperfect situations, also.

Another study use altitude, speed, CPA and range as parameters to compute threat assessment rating of entities in tactical picture. This method is a fuzzy knowledge based reasoning model [24].

Bayesian belief networks takes important place in many threat assessment systems while performing fusion operations. Since Bayesian networks provides flexibility in terms of taxonomy of threats, it is chosen as a fusion method in Beaver's study [25]. Moreover, a security threat assessment model based on Bayesian Network is proposed in order to prevent subjective judgement of the information and bring objective perspective to OWA operators [26].

Another study uses Bayesian network to measure the overall probability of a threat that shows five anomalous ship behaviors. These behaviors are listed as deviation from ordinary routes, abnormal AIS activity, unexpected port arrival, abnormal close approach and zone entry [27]. For each behavior, the method shows whether the specific behavior occurs with a probability value.

In study based on Bayesian Network, target type, weapon range, speed, TBH and distance are taken into account while calculating threat basement rating [9]. Nodes of Bayesian Network is formed from these cues. There is hierarchical relationship between them, which could be examined more in detail at mentioned article.

A Bayesian Network based method is introduced by claiming advantages over other methods such as logical and fuzzy [18]. This study works for air defense scenarios. Moreover, linear Gaussian approximation seems to be necessary for their implementation.

Another threat evaluation system based on Bayesian Network is developed in Johansson's study [9]. Mainly, target type, weapon range, speed, TBH and distance are used as threat assessment cues. These parameters become the nodes of Bayesian Network while constructing the relationship among them.

Dynamics of threat evaluation problem changes depending on capabilities of platform and target's category. Systems that deployed on platforms has effective influence the problem. This situation is main reason behind the selection of threat assessment cues in the combat management system of the platform.

7. Conclusion

In this paper, we extent the work that originally presented in 2016 IEEE Symposium Series on Computational Intelligence (SSCI) [1]. Original paper presents threat evaluation model depending on kinematics of target without any indication about target's classification. Proposed model accepts all targets and produces results for them without checking any capabilities of objects. This paper updates threat evaluation model by adding category information to the model. In this time, model has category information about surrounding objects and there is a chance to benefit from this critical information.

Updated threat evaluation model begins with the category selection step. If an object is an air force, then the model apply air procedure on it; otherwise, surface parameters are taken into account to evaluate the threat level of the object. Basically, threat evaluation model for air and surface objects follows same path within themselves. Firstly, threat assessment cues are extracted from target's kinematics. Then, threat selection algorithm are applied on target by benefiting from scores generated at first phase in both air and surface flow. Finally, threat assessment rating are calculated by fusing threat assessment cues in both flows. However, there are significant differences that affect the resulting values between air and surface flow of the model. Firstly, air objects and surface objects are separated from each other by indication of danger. While maneuver cue is a indication of dangerous target for air objects, it does not have this kind of effect on surface object. Moreover, the deceleration cue has an impact on threat level of surface object, there is no influence of deceleration cue on air objects. Therefore, set of threat assessment cues change according to the category information of the target. Other threat assessment cues are common for both categories. However, their importance ranking are very different. While TBH is very important for air objects, distance dominates cores of surface object. This situation generates critical difference between flows of the model and it could be observed from results of synthetic scenarios. As a result, this study brings more confident results since it takes into account of accurate dynamics of related category while evaluating threat level of objects.

Original work apply same model to all targets without considering target's nature and capabilities. Current model eliminate these deficiencies at certain level. Similar synthetic scenarios are played for different categories. It is observed that behavior of models changes accordingly.

Evaluation section reveals that original work does not make an impact as current one while running on defined synthetic scenarios in this paper. Mostly, results of previous work seems to be steady. Once, a target is classified as threat, it remains at the same classification through the rest of the scenario. However, target moves and changes its direction in all scenarios. It seems to be Common parameters and cues for both air and surface objects does not perform well for these scenario.

Original work results with one common list that includes air and surface objects together by applying same methods on them. In this study, air and surface objects follows different flows with parameters special for them. In the end, threat evaluation model generated two list, one for air objects and one for surface objects. There is no fusion of these two lists. As a future work, threat evaluation model could be updated to produce one common list by combining results coming from different flows. Ranking surface and air objects will require serious investigation to reach confident results.

Conflict of Interest

The authors declare no conflict of interest.

Mobility of knowledge workers
Knowledge spillover, Social network, Tacit knowledge, Star inventor

ABSTRACT

This paper is an extension of work originally presented in 2017 6th International Conference on Industrial Technology and Management (ICITM). This research focuses on the mobilization of human resources in the Asian electrical industry and analyzes the impact of engineers' international mobility on the innovation of enterprises in the host countries. I examine the characteristics of engineers who moved from Japan to China and South Korea to explore which types of engineers successful firms in China and South Korea select from rival companies in Japan. In addition, this study focuses on the role of the inventors' networks to investigate the significance of researcher mobility and knowledge spillover as mechanisms that facilitate the flow of tacit knowledge. This study reveals that during the process of innovation, informal networks play an important role in the mobility of engineers. The findings suggest that successful firms require people with analytical skills and problem-solving capacity, not "star inventors."

1. Introduction

To spur innovation and economic growth, the endowments of knowledge factors, such as research and development and human capital, are a necessary condition to generate new technologies. The greatest source for the generation of new economic knowledge is generally considered to be R&D (Research and Development) [1], [2]. R&D not only generates innovation but also develops firms' ability to identify, cultivate, and exploit knowledge and ideas developed by other firms. In other words, firms are exogenous, whereas their performance in generating technology changes is endogenous [2]. Endogenous growth models suggest that R&D activities undertaken by profit-maximizing firms represent an important investment in obtaining new knowledge, whereas knowledge is an input in the process of generating endogenous growth [3]-[5].

In this sense, knowledge spillover is an important mechanism for endogenous growth. Small and young enterprises can supplement their lack of R&D through knowledge spillover [6]. The mechanisms by which knowledge is transmitted across firms and individuals include, for example, publications; the mobility of employees, scientists and engineers; and reverse engineering. The mobility of knowledge workers in general and new firm start-ups in particular has become an important mechanism of knowledge spillover [7]. Michelacci (2003) implies that a low rate of return on R&D may be attributable to an inability to transform new knowledge into economic opportunities through skills, aptitudes, and insights [8].

Knowledge that can be easily codified can be transmitted and understood over long distances at very low cost [9]. However, tacit knowledge is difficult to communicate, and it therefore relies on face-to-face interaction to be transmitted effectively [10]. Thus, the knowledge spillover resulting from the mobility of knowledge workers is especially important because it facilitates the transfer of tacit knowledge, which is not readily transferable via codified sources. The mobility of knowledge workers, such as scientists, inventors, and engineers, has a significant and positive impact on new firms' output and productivity growth [11], [12]. Knowledge workers from large, established firms may have knowledge and ideas about inventions and ultimately about innovations. The mobility of knowledge workers therefore plays a central role in the spillover of knowledge and ultimately in economic growth. Additionally, informal networks and labor mobility are closely linked with respect to their emergence and re-configuration [13]. Cross et al. (2001) investigate methods of improving employees'

ability to create and share knowledge in social networks [14]. However, the literature identifying the mechanisms underlying the transmission of knowledge spillover by social networks remains underdeveloped.

Engineers' mobility plays an important role in the transfer of knowledge from stable and mature enterprises to high growth and young enterprises, especially in high-technology sectors. Many studies have examined the relationship between the mobility of knowledge workers and innovation; however, the relationship between the characteristics of engineers who move abroad and innovation is a less-researched field. Only a few studies have analyzed the impact of R&D investment and human capital on innovation. Therefore, this study empirically analyzes the impact on innovation of the quality of the talent that migrated from developed countries.

This paper focuses on the link between the mobility of individual engineers and knowledge spillover. The purpose of this study is to identify the influence of engineers' mobility on firm development and innovation. I investigate the role of engineers who migrated from large, established companies to young companies in transmitting knowledge. Engineers from large, established corporations often have new knowledge that they acquired through research and development work in their firms' labs.

I propose a hypothesis to investigate the link between researchers' mobility and R&D performance. The hypothesis is that young, successful firms in China and South Korea are selective in their hiring, overwhelmingly recruiting talent from large, established firms in countries such as Japan with the expectation that the knowledge spillover embedded in their new hires will allow the young firms to catch up technologically. I explore this hypothesis by investigating patent data to estimate the effect of knowledge transfers from Japanese firms to Chinese and South Korean firms. I analyze the mobility of engineers from Japanese firms to Chinese and South Korean firms by drawing on patent data from 1976 to 2013. Young, successful firms in China and South Korea employ many engineers who were formerly employed by Japanese firms. I therefore examine the characteristics of engineers who moved from Japan to China and South Korea to explore what types of engineers Chinese and South Korean firms select from rival companies in Japan. In addition, this study focuses on the role of engineers' networks to investigate the significance of engineer mobility and knowledge spillovers as mechanisms facilitating the flow of tacit knowledge. Thus, I use social network indices to analyze co-invention networks. Additionally, I examine whether these engineers play an essential role in innovation within their new companies.

Next, I examine what types of researchers absorbed technology and knowledge from developed companies and contributed to innovation in young companies such as Chinese and South Korean firms. To this end, I use a knowledge production function model to obtain insights into the process of innovation using the knowledge embedded in new hires. For the specific methods of analysis, the knowledge production function developed by Pakes and Griliches (1984) is used; for the explained variables, patent citation counts are used as a representative index to measure innovation through the number and quality of patents [15]. I use panel data from 5 young, successful firms in China and South Korea over the past two decades.

A few studies have focused on the effect of talent migration on knowledge spillover via informal networks. One of these papers focuses on scientific labor as a measure of spillover [16] and studies the personal characteristics of scientists employed at a biotech company. Here, I extend this framework by examining engineers who moved from developed firms in Japan as the source of knowledge transmission. This study examines the relationship between the characteristics of individual knowledge workers and knowledge spillovers. It also investigates the relations between the mobility of knowledge workers and their informal networks during the process of innovation.

2. Theory and Hypotheses

2.1. Mobility of knowledge workers and innovation

This study conducted an empirical analysis of the effect of knowledge workers' mobility on innovation. In the previous literature, the influence of investment in R&D and human capital has been analyzed [15], [17]-[22]. These studies examine the influence of R&D input on R&D output by using the knowledge production function and considering the patent productivity of R&D using company-level data from North America and Europe. In addition, several models related to innovation have been presented, including some that use a knowledge-production function to analyze the effect on innovation activities produced by human capital and investment in R&D. Those studies focus on the role of human capital and R&D expenditures in obtaining knowledge capital in return.

Unlike those previous analyses of innovation and technological change that focus on the firm, in this paper, I focus on the individual. Some researchers have examined scientist mobility in the context of individual careers. Many of these studies focus on Ph.D. graduates [23], [24]. Zucker et al. (1997) examine the mobility of "star scientists" as a knowledge transfer mechanism [25].

The most prevalent model in the literature on innovation is that of the knowledge production function, which was formalized by Zvi Griliches (1979) [19]. The inputs in the model of the knowledge production function are R&D cost, human capital, skilled labor, and educational levels [19], [26]. The model of the knowledge production function from the literature on innovation and technological change can be represented as

$$IA_i = \alpha RD_i^{\beta} X_i^{\gamma} \varepsilon_i$$

In the equation, IA represents the degree of innovative activity, RD represents R&D input, and X represents human capital inputs.

Conventionally, R&D investment costs have been widely used as surrogate variables for innovation. However, the size of R&D costs is an input index, which cannot be used to measure the output of innovation. In this study, I use the number of patents as an output index of innovation. However, both the quality of patents and the number of patents are important issues. In this regard, patent quality has been studied, and the number of times a patent has been cited has been proposed as a proxy for patent quality. Trajtenberg (1990), Jaffe et al. (2000), Reitzig (2003), Hall et al. (2005) and Carpenter et al. (1981) have found a strong correlation between the number of citations and the quality of patents [27]-[30]. For example, Harhoff et al. analyze American and German patents and find that the number of citations in the patents that were updated before expiration was greater than that for the patents that expired

earlier [31]. For these reasons, I use the number of citations as an index to measure innovation in this study.

2.2. The characteristics of engineers hired by successful firms in China and South Korea

A combination of various types of technologies can be interpreted as an indicator of the increasingly complex nature of innovation [32]. Small enterprises can make up for a lack of innovation through knowledge spillovers from engineers who have experience with the complex nature of an innovation. This study analyzes the impact of the transfer of technology and knowledge on innovation in a corporation caused by the mobility of engineers who previously held positions with mature enterprises and then moved to young, successful firms. For this analysis, the characteristics of the knowledge workers hired by young, successful firms in emerging nations must first be analyzed. In particular, I shed light on the link between engineers' personal characteristics and inventors' attraction to a rapidly growing company. To measure the characteristics of talent, various indices have been considered. From the recruitment perspective, superiority as a researcher and whether the person held a position where in-house technology and knowledge could be accumulated are important factors.

Young, successful firms in China and South Korea must be selective in their hiring when recruiting engineers from Japanese firms. Warren (1997) emphasizes that a person who has produced results in his or her former work will have a positive influence on the new firm's productivity after migration [33]. Thus, successful firms will select engineers who have had excellent results in their former job. A high value for the number of citations received (forward citation) implies that a technology is used in diverse fields of future invention. I hypothesize that successful firms will hire inventors whose patents have been extensively cited. A high score on the number of patents cited (backward citation) means that the patents are based on past inventions drawn from diverse categories. This leads to my first hypothesis:

Hypothesis 1-1. Successful firms employ new hires who have had excellent results in their former jobs and have experience with the complex nature of innovation.

Because recruited talent is expected to lead local inventors in developing technology and knowledge in emerging nations' corporations, their rich experience and knowledge should have a strong impact. Therefore, successful firms will hire engineers who have long-term experience in stable and mature enterprises. Additionally, successful firms will hire engineers who have rich experience in a variety of technical domains. Thus, I propose as follows:

Hypothesis 1-2. Young, successful firms select engineers as new hires who have long-term experience.

Hypothesis 1-3. Young, successful firms select engineers as new hires who have rich experience in a variety of technical domains.

Similar statements can be made about informal networks. Successful firms employ people who occupy central positions in inventor networks. In other words, "star engineers" are selected by Chinese and South Korean companies. Zucker et al. (1996) study the mobility of "star scientists". They emphasize that the very best "star scientists" play central roles in both the development of the science and its successful commercialization [34]. Hence, I propose as follows:

Hypothesis 1-4. Successful firms select "star inventors" as new hires.

Zellner (2003) studies the various elements of knowledge transfer via scientists' migration [35]. He investigates the migration of scientists formerly employed at the Max Planck Society in Germany by using survey data obtained from a sample of scientists who moved from the Max Planck Society into the commercial sector. The main result of this analysis is that knowledge that is specifically related to a certain research question is not the most important issue for the scientists employed by the Max Planck Society who transferred into the private sector. The results suggest that non-specific knowledge was valued more highly than specific knowledge. In other words, broad knowledge and analytical skills are more important than propositional knowledge. It is said that those who are strongly tied to the star people in the network can acquire a wide range of knowledge [36]. Hence, I propose as follows:

Hypothesis 1-5. Successful firms select engineers as new hires who are strongly connected to "star engineers."

2.3. The type of talent contributes to innovation in emerging nations' enterprises

Knowledge workers who have rich experience with inventions will contribute to innovation. Amalya (2004) indicates that scientists who have rich experience with inventions increase the number and citation rate for firm patents and contribute to firms' success [37]. Another study [25] finds that "star" bio-scientists play a central role in their firms' success. Thus, knowledge workers from developed countries are expected to have vast scientific knowledge and communicative competence. This discussion leads to the following hypothesis:

Hypothesis 2-1. "Star engineers" who were formerly employed in a developed country's enterprises contribute to innovations by emerging nations' enterprises.

The ability to exploit external knowledge is a critical component of innovative capabilities, and the ability to evaluate and utilize outside knowledge is related to the level of prior knowledge. The ability to recognize the value of new information, assimilate it, and apply it to innovation is defined as "absorptive capacity" [1]. An inventor must have a strong absorptive capacity or the ability to successfully replicate new knowledge to access the new knowledge developed by other units [38]. A similar statement can be made about firms' absorptive capacity. While encompassing a firm's ability to imitate new process or product innovations, absorptive capacity can also include a firm's ability to exploit outside knowledge. Cohen (1990) suggests that the development of a firm's absorptive capacity will build on its prior investment in R&D [1]. Thus, I hypothesize that engineers who moved from Japanese firms will contribute more to Chinese and South Korean firms' innovation in the growth stage. Hence, I propose as follows:

Hypothesis 2-2. To promote innovation through knowledge spillover, enterprises in emerging nations need an adequate "absorptive capacity."

3. Data and Methodology

3.1. Data

In this study, I examine the characteristics of engineers who moved from Japan to China and South Korea and the characteristics of engineers who contribute to Chinese and South Korean firms' innovation. I used US patent data for filings by Japanese, Chinese and South Korean companies between 1976 and 2013. I calculated the number of years of experience from the year that the inventor first filed for a patent, so it was necessary to use data from as far back as 1976. It is said that a particularly high number of engineers who moved from Japanese companies to Chinese and South Korean companies are in the electrical equipment industries. Therefore, I used patents from the H section of the IPC classes. IPC stands for International Patent Classification and is a universal patent classification that was created based on the "Strasbourg Agreement on International Patent Classification" (effective in 1975). The H section indicates a patent in the electric field. I targeted approximately 270,000 patents from Japanese electrical manufacturers, approximately 50,000 Chinese patents, approximately 70,000 South Korean patents, and approximately 50,000 Taiwanese patents. I extracted all of the inventor names from those patents and confirmed people with the same name as Japanese inventors among the Chinese and South Korean inventors. Because inventors with identical names as inventors in Section H are highly likely to be the same people, the fact that their names appear on patents filed by both Japanese companies and Chinese and South Korean companies means that these people have moved between these companies. However, it cannot be denied that it is possible that the same name might refer to different people. Therefore, I decided to establish a criterion for the degree of similarity between IPC numbers at the IPC main group level, and only in cases in which that criterion was met did I judge the people to be equivalent. In this way, I judged the names of inventors who appeared in both Japanese and Chinese or South Korean patents to be equivalent when they met the requirements for a connection between IPC numbers, and I judged them to have moved between Japanese companies and foreign companies, thus raising the probability that these were actual movements. After identifying the movements of all of the inventors, I judged whether they moved from or to a Japanese company. Moreover, using the last patent application by their former company and the first patent application by their destination company, I calculated the probability of the timing of the movement for all transferees. I checked the patent data for the names of the companies where the inventors previously worked in Japan and the names of the companies to which they moved in China and Korea. I deleted data that conflicted with the period in which they were assigned to one of the countries.

Then, I calculated a network index for all of the inventors that were employed by Japanese companies to check the characteristics of the inventors who were also employed by Chinese or South Korean companies.

I focused on 5 successful companies in China and South Korea: Samsung, LG, Hyundai, Huawei and Hon Hai Precision. Samsung, LG, and Hyundai are South Korean companies. Huawei is a Chinese company. Hon Hai Precision is Taiwanese company.

For Hypothesis 1, the analysis is based on the notion that rapidly growing companies are selectively recruiting engineers from developed countries. The engineers who migrated from corporations in Japan to the 5 successful companies and to other companies in China and South Korea were identified from the patent data filed by the Japanese companies. All of the engineers' names listed as inventors on the patents mentioned above are extracted. Excluding those with identical names, there are approximately 170,000 inventors from Japanese companies and approximately 50,000 inventors from Chinese and South Korean companies. Then, all of the names of the inventors mentioned above who appear in both patents filed by Japanese companies and those filed by non-Japanese companies are extracted. Because engineers with identical names who are mentioned as inventors in Section H are highly likely to be the same people, the fact that their names appear on patents filed by both Japanese companies and Chinese and South Korean companies means that these people have worked in both countries. However, even given identical names, some of the data may refer to different engineers. Therefore, certain conditions were set to eliminate these cases by checking the International Patent Classifications. Next, with regard to patents with inventor names that match those extracted as above, the company that employed them was identified by examining the applications. Then, by considering the order of the years in which the applications were filed, the researchers' career changes could be identified regarding the company they left and the company they then joined.

In Hypothesis 2, to analyze how talent from developed countries contributes to innovation by emerging nations' enterprises, patent data and financial data from a 22-year period (1990–2011) are used to perform an analysis using panel data for a Chinese corporation (Huawei), a Taiwanese corporation (Hon Hai), and three South Korean companies (Samsung, LG, and Hyundai).

3.2. *Explained variable*

Regarding Hypothesis 1, to indicate which type of knowledge workers migrate to emerging nations' enterprises, the explained variable can have two values: 1 for migrating to emerging nations' enterprises and 0 for not migrating.

For Hypothesis 2, the number of patents is used in this study to determine innovations by emerging nations' enterprises when measuring the results for knowledge workers from developed countries' corporations. Other well-known studies have used the knowledge-production function approach [15], [17]-[22]. Thus, the knowledge production function employing the number of patents is used in this study.

Furthermore, from the perspective of measuring the quality of patents, the citation count is also used as an explained variable because the analysis shows that in many cases, the citation count of American patents (forward citation) is strongly correlated with the value of the patent [27]-[30]. For example, Hall et al. (2005) demonstrate that the aggregation of the citation count of a patent owned by a corporation is correlated with the company's share price [30]. In this way, the citation count is an excellent index to verify the impact of the quality of patents.

3.3. *Explanatory variable*

In this study, to analyze the impact caused by the mobility of human resources and inventor networks on innovation by Chinese and South Korean firms, numerous indices representing the quality of talent are established. To analyze the role played by the mobility of knowledge workers and their influences on innovation and growth in Chinese and South Korean companies, I examine the

characteristics of knowledge workers based on the aspects of skills and inventor networks. Specifically, a social network index and some indices to measure the features of the talent are used as explanatory variables based on patent data.

I use social network indices of co-invention by inventor networks using patent data. I calculate the social network indices for each inventor in the company that employs him or her, and I examine the structural positions in the network. Social networks are composed of different nodes of individuals and the social relationships that individually connect them. By observing the centrality index of each node, it is possible to analyze the characteristics and roles of each node in the overall network. I investigate co-inventor networks by using patent data and develop social network indices based on degree centrality, closeness centrality, betweenness centrality (Freeman, 1979), eigenvector centrality (Bonacich, 1972), clustering coefficients, and page ranks. Degree, betweenness, closeness, and eigenvectors are the four main measures of centrality. These centrality measures capture the relative position of an individual within the network. Degree centrality is defined as the number of links incident upon a node—in other words, the number of ties that a node has [40]. Degree centrality is based on a measured focus on the level of communication activity. In contrast, betweenness centrality reflects the intermediary location of a node along the indirect relationships linking other nodes [40]. Betweenness centrality captures stress control and the capacity to interrupt communication. The maximum theoretical value of betweenness centrality is given by (n-1)(n-2)/2 [41]. Closeness centrality measures depend on the geodesic distance, which is the minimal length of an indirect path. Freeman (1979) suggests that measures of centrality based on closeness reflect a node's freedom from the controlling actions of others and their capacity for independent action within the network [40], [42]. Eigenvector centrality reflects the fact that individuals might profit from well-connected friends [43]. I focus on degree centrality and eigenvector centrality.

A node with high degree centrality has many direct connections with other nodes, and people with high degree centricity are central people in communication within the network. [44]. High degree centrality means that the inventor has experience cooperating with many other inventors from his company. As an individual becomes exposed to increased degree centrality, his or her position in the network will attain a higher status [45], providing more opportunity to learn, acquire and utilize knowledge. Thus, an inventor who has high degree centrality is considered a "star inventor."

Eigenvector centrality is a centrality index proposed by Phillip Bonacich; it evaluates not only high-scoring nodes but also all nodes that are connected to high-scoring nodes. In other words, a high score for eigenvector centrality means that the node has connections with high-scoring nodes. This means that eigenvector centrality is a measure of the influence of a node in a network. Being related to a node that has many relationships with other nodes implies an important position within the network. In other words, an inventor who has a high score on eigenvector centrality is a person with whom "star inventors" always want to work. This is because individuals in such positions can obtain a great deal of important information and have both analytical skills and problem-solving capacity. Recently, the strategic importance of patent analysis has been highlighted by high-technology management as the process of innovation has become more complex [46]. Furthermore, patents facilitate analytical work through their relative advantages [48]. In addition, to measure the features of migrating talent, variables such as the number of migrated inventors, the size of the company of origin, the number of years in the inventor's career, the citation count, the forward citation count, the Herfindahl-Hirschman Index of the IPC number, and eigenvector centrality are used.

The patent citation count is used as a representative index to indicate patent quality. This approach has been validated by various studies [49], [31], indicating that the forward citation count is effective for measuring the quality of a patent. In addition, an inventor who has been involved with many high-quality patents can be regarded as excellent. The total citation count of a patent in which the inventor in question has been involved is used as a surrogate index for his/her excellence. Thus, the forward citation number is an important performance indicator to measure the performance of individual inventors. I therefore count all forward citations received by each patent for each inventor.

Furthermore, as an index to measure patent quality, in addition to the citation count, it has been noted that the number of a patent's backward citations correlates with the quality of the patent [31]. The number of backward citations is effective for measuring a patient's originality [50]. A high score on the number of backward citations means that the patent is complex, and a low score means that the patent is highly original. Therefore, the number of times a patent has been cited has been added as a variable to measure the quality of talent. I use the total number of patent citations (backward citations) as a representative index of originality and complexity.

The number of years in the inventor's career is calculated as the number of years elapsed since the year in which the inventor in question filed his/her first patent application.

In addition, the Herfindahl-Hirschman Index of the IPC number can measure whether an inventor has been involved with patents in a specific technical domain or in a variety of technical domains. In other words, a high HHI value indicates that the inventor specializes in a specific technical field, whereas a low HHI value indicates that the inventor has wide knowledge covering a variety of technical fields.

Another factor affecting the quality and quantity of patents is an increase in R&D costs. There have been numerous analyses [15], [17], [18], [21] of the cost of R&D and patent applications. In general, the number of patents increases and their quality improves as R&D cost increases, regardless of inventor quality. Therefore, in this study, R&D cost in the current period is also used as a variable.

3.4. *Control Variables*

Most empirical studies of firm performance include firm size as either a control variable or an independent variable. Following this tradition, I use firm size as a control variable. In terms of the scale of the company of origin, corporations with $100 trillion or greater in sales are classified as large, whereas corporations with less than $100 trillion in sales are classified as small.

3.5. *Estimation technique*

To test the first hypothesis and determine the characteristics of knowledge workers migrating to Chinese and South Korean enterprises from Japanese corporations, a logistic model is built for

the analysis using two-value objective variables. The model formula is as follows:

$$Pi(i=1)=F(C+\sum \alpha ixi)$$

$$Pi=\exp(C+\sum \alpha ixi)/(1+\exp(C+\sum \alpha ixi))$$

Pi represents the probability of mobility of engineer i, taking the value of 1 if the inventor migrated to an emerging nation and the value of 0 if he/she did not. F is the cumulative distribution function, αi is a coefficient, Xi is an explanatory variable, and C is a constant.

To test the second hypothesis and determine the influence of engineer mobility on innovation by Chinese and South Korean firms, the knowledge production function developed by Griliches and Regev (1995) is applied [26]. The knowledge production function measures the effectiveness of R&D investment for increasing knowledge. Griliches and Regev (1995) establish the following formula to compare labor productivity between companies [26].

$$Y = Xb + Zc + lm + \mu$$

Here, Y represents the logarithm of productivity, X is the logarithm of the input variable (intermediate inputs and capital services per person), and Z represents the control variables (e.g., dummy variables for size, age, and location). The authors establish eight variables: 1) intermediate inputs and fixed capital services, 2) R&D capital and labor quality (as a proxy for human capital), 3) size, 4) sector and type of ownership, 5) industry grouping, 6) establishment year, 7) mobility status (entry and withdrawal status), and 8) year dummies.

In this study, the impact of the migration of engineers from corporations in developed countries on innovation in emerging nations' enterprises is examined by entering the variable related to the knowledge worker's characteristics. Here, I extend this framework to examine the link between knowledge workers' characteristics and innovation. The model formula is as follows.

$$Y = Xb + Zc + Wd + lm + \mu$$

Y stands for the degree of innovative activity, X represents R&D inputs, Z represents local human capital inputs, and W represents the characteristics of knowledge workers who migrated from Japan.

In this study, I use the number of patents and the number of citations as a surrogate variable for innovative activity. The number of patents used as an explained variable represents non-negative numeric data. In this study, a fixed-effect model and a random-effect model are used to perform the calculations, following the example of Hausman et al. (1984) [17]. Hall and Mairesse (1995), Mairesse and Hall (1996), and Harhoff (1998) analyze French, American, and German manufacturers using a fixed-effect model to control for the deviation of a company's fixed effect [51]-[53].

4. Results and discussion

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command, and use the naming convention prescribed by your conference for the name of your paper. In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll down window on the left of the MS Word Formatting toolbar.

4.1. Identify the Headings

The main regression results are reported in Table 1. I analyze the characteristics of knowledge workers recruited as new hires by 5 successful firms in China and South Korea. A logistic regression model is used to verify the influence of the basic explanatory variables, such as inventors' individual social network index, the number of years in their career, and the evaluation of their invention. Model 1-6 reports the results for South Korean companies and Model 7-10 reports the results for Chinese companies.

Consistent with Hypothesis 1-1, the results indicate that the coefficient of forward citations is significantly high for South Korean companies; however, it is negative for Chinese companies. Conversely, the results for the number of backward citations are negative for South Korean companies and positive for Chinese companies. These results mean that South Korean firms employ knowledge workers who have had excellent results in their former jobs and have the ability to be original. In contrast, Chinese firms employ knowledge workers who have not had excellent results in their former jobs but who have experience with the complex nature of innovation. These results suggest that there is a high probability that South Korean companies select new talent by considering the number of times that a given patent has been cited, which is the most commonly used index to indicate a patent's importance.

In addition, consistent with Hypothesis 1-2, the variable for years of experience is negative in Model 5 (Hyundai) and Model 7 (Huawei) and positive in Model 1 (Samsung), Model 3 (LG), and Model 9 (Hon Hai).

The coefficient of HHI is negative for all of the companies. This result means that successful firms in China and South Korea select engineers who have experience not in a specified technical domain but in a variety of technical domains with Japanese firms. This result supports Hypothesis 1-3.

Consistent with Hypothesis 1-4, the coefficient for degree centrality is statistically positive in Model 3 and statistically negative in Model 7. Inventors who have high degree centrality tend to have experience cooperating with many other inventors in their company. I define them as "star inventors." This result suggests that LG acquires "star inventors" and Huawei does not. In other words, the specific knowledge that an inventor absorbed while employed at a mature enterprise is not necessarily the most important element transferred into emerging nations' companies.

However, consistent with Hypothesis 1-5, the results show that the coefficient for eigenvector centrality is significantly positive in Model 2, Model 4, and Model 10. This result means that Chinese and South Korean companies prefer talent with high eigenvector centrality. Inventors who have a high score on eigenvector centrality are inventors with whom the "star inventors" always want to work. In other words, young, successful firms acquire knowledge workers who connect strongly with the "star inventors." This result supports Hypothesis 1-5.

Table 2 shows the results analyzing the link between the quality of human capital inputs and innovation using a fixed- effect model and a random-effect model. Model 1-4 reports the results for 1990-2011. The null hypothesis can be dismissed based on the Hausman test regarding the selection of the two calculation methods. Therefore, the fixed-effect model is preferable.

Consistent with Hypothesis 2-1, regarding knowledge workers employed by Japanese firms, the coefficient for eigenvector centrality is positive in Model 1 and Model 3 in Table 3. Additionally, the coefficient for degree centrality is positive in Model 1 and Model 3. However, only the coefficient for eigenvector centrality in Model 1 is positive. The results showing a positive coefficient for eigenvector centrality mean that inventors who strongly connect with "star inventors" contribute to innovation in emerging nations' companies. In other words, the inventors who connect strongly with "star inventors" contribute more to young companies' innovation as measured by the number of patents than do "star inventors" who were formerly employed by mature companies. Thus, Hypothesis 2-1 is not supported.

Table 3 shows the results of analyzing the link between the quality of human capital inputs and innovation using a fixed effects model and a random effect model. Model 5-8 reports the results for 2001-2011. The null hypothesis can be dismissed based on the Hausman test regarding the selection of the two calculation methods. As a result, the fixed-effect model is preferable.

Consistent with Hypothesis 2-2, the coefficient for the number of Japanese inventors is statistically positive in Model 5. This result shows the impact on innovation by emerging nations' enterprises as measured by the number of patents won by Japanese researchers employed at these companies from 2001-2011. Similarly, the coefficient for the number of Japanese inventors is statistically positive in Model 1. However, the level of statistical significance is different. The coefficient for the number of Japanese inventors in Model 5 is significant at the 5% level; however, the coefficient for the number of Japanese inventors in Model 1 is significant at the 10% level. These results mean that inventors with experience in a developed country contributed more to quantity of innovation after 2001 than in the period from 1990-2001. This tendency is not similar in quality of innovation (see Model 3 and Model 7). The results suggest that after emerging nations' enterprises strengthened their "absorptive capacity," there was a high possibility that new hires who had formerly been employed in developed countries would contribute to innovation, as measured by the quality of patents. Thus, Hypothesis 2-1 is partially supported.

5. Conclusion

In this study, I identify the influence of engineers' mobility on firms' development and innovation. In particular, this study focuses on knowledge spillover and transnational networks between companies in developing and developed countries from the perspective of inter-organizational labor mobility. I investigate the role of engineers who migrated from Japan to China and South Korea in transmitting knowledge from large, established companies to young companies.

This analysis has yielded important insights into how knowledge workers' characteristics condition their transnational mobility and engagement in international knowledge development. First, this analysis of the characteristics of inventors who migrate from Japanese corporations to China and South Korea indicates that rapid growth companies recruit knowledge workers from Japanese companies based on differences in priority characteristics such as skills, the length of their careers, and their experience in technical fields. Interestingly, top firms, such as Samsung and LG, are more selective in their hiring than other firms in that they overwhelmingly recruit talent from Japan. Successful companies in China and South Korea select engineers who do not have experience cooperating with many other inventors but who do have analytical skills and problem-solving capacity. In other words, successful firms require people with analytical skills and problem-solving capacity, not "star inventors." This result means that for successful companies, non-specific knowledge is more important than specific knowledge. These findings dovetail reasonably well with the findings from Zellner's study (2003) [35].

Second, the knowledge production function is applied to analyze what types of knowledge workers contribute to innovation in emerging nations using panel data. With respect to innovation, inventors who connect strongly with "star inventors" from developed companies play an important role, as do the "star inventors" themselves.

Based on the above results, it can be argued that at the time of hiring, it is most important to select people with the applicable skills, which suggests that corporate growth requires not only "star inventors" but also inventors who connect strongly with the "star inventors."

My study has notable limitations. At this time, only analyses of Chinese and South Korean enterprises were conducted. However, in terms of the relationship between innovation and talent migration, it would be worthwhile to expand the scope of analysis to all emerging nations. Additionally, this research focused on the electronics industry. However, the effect of inventor mobility may differ considerably from industry to industry. Therefore, further research is needed on other industrial sectors.

Nevertheless, the theoretical framework developed and applied herein draws on a broad range of academic literature. The empirical findings are well aligned with the framework regarding the link between the mobility of knowledge workers and knowledge spillover. The approach developed herein will hopefully inspire future empirical studies to analyze the role of migrating knowledge workers.

Conflict of Interest

The author declare no conflict of interest.

Communication failure
Wireless control networks

A B S T R A C T

Sensor network protocol stacks require the addition or adjustment of functions based on customer requirements. Sensor network protocols that require low delay and low packet error rate (PER), such as wireless control networks, often adopt time division multiple access (TDMA). However, it is difficult to add or adjust functions in protocol stacks that use TDMA methods. Therefore, to add or adjust functions easily, we propose NES-SOURCE, a compact wireless control network protocol with a fast path-switching function. NES-SOURCE is implemented using carrier sense multiple access/collision avoidance (CSMA/CA) rather than TDMA. Wireless control networks that use TDMA prevent communication failure by duplicating the communication path. If CSMA/CA networks use duplicate paths, collisions occur frequently, and communication will fail. NES-SOURCE switches paths quickly when communication fails, which reduces the effect of communication failures. Since NES-SOURCE is implemented using CSMA/CA rather than TDMA, the implementation scale is less than one-half that of existing network stacks. Furthermore, since NES-SOURCE's code complexity is low, functions can be added or adjusted easily and quickly. Communication failures occur owing to changes in the communication environment and collisions. Experimental results demonstrate that the proposed NES-SOURCE's path-switching function reduces the amount of communication failures when the communication environment changes owing to human movement and others. Furthermore, we clarify the relationships among the probability of a changing communication environment, the collision occurrence rate, and the PER of NES-SOURCE.

1. Introduction

This paper is an extension of a work originally presented at the 2016 TRON Symposium [1].

Recently, sensor network technology has been applied to smart networks and Internet of Things networks, such as wireless control networks (WCN) for factory and plant automation. Such practical applications require a low delay, a low packet error rate (PER), and delay guarantees [2, 3].

In general sensor network protocols, e.g., the ZigBee PRO specification [4], nodes in the network determine the communication path autonomously. Therefore, it is difficult to consider communication delay when designing a system because the communication route is unknown. Therefore, many WCN protocols that require delay guarantees adopt a fixed routing system, i.e., external routing information is the input.

Some WCN protocols employ multiple routes simultaneously during data transmission to eliminate the delay caused by packet loss. For example, WirelessHART [5] increases communication reachability by duplicating all communication paths from each node to the base station. However, duplicating communication paths can cause collisions.

Thus, most existing WCN protocols adopt TDMA [5–9] because it is contention-free.

However, TDMA has the following problems.

(1) Handling difficulty

TDMA requires high synchronization accuracy. Generally, it is difficult to implement programs that can maintain synchronization accuracy in less than 10 ms because, in embedded software environments, unexpected delays of several milliseconds occur randomly, such as OS task switches and interrupts.

For example, the flooding time synchronization protocol [10], which is a general time synchronization technology, handles such random delays by including time information in the send frame under the RFLSI driver sequence. Software that crosses network layers is difficult to develop without errors. The WCN stack must operate with various types of hardware wherein processing capacity and how connected sensors are handled vary. In addition, customer requirements must be considered for each application. When using a stack with TDMA, we must adjust the stack each time the hardware changes. In particular, when using sensors that generate various interrupts or require time-consuming operations, it is difficult to maintain accurate TDMA synchronization.

As described above, TDMA systems are difficult to implement, i.e., it is difficult to add or modify functions to such systems.

(2) High procurement cost

Note that rigid hardware specifications must be satisfied to maintain high TDMA synchronization accuracy.

For example, Linear Technology's WirelessHART module maintains high synchronization accuracy by measuring temperature changes and clock error changes during the manufacturing process and writing this information to memory.

However, fabricating such hardware is difficult, and procurement costs are high.

Some WCN studies have employed CSMA/CA protocols [11, 12]. However, CSMA/CA protocols are designed for large networks and are ineffective in typical WCNs (approximately 25 nodes) [3, 5].

In this paper, we propose the NES-SOURCE protocol stack for a WCN of practical size.

NES-SOURCE has compact implementation. Its code size is approximately one-quarter that of a general sensor network protocol stack and approximately one-half that of the TDMA-based WCN protocol stack. The cyclomatic complexity, which is a measure of source code complexity, of NES-SOURCE's functions is at most 10, which is less than other WSN [19] and WCN [20] protocol stacks. This indicates that NES-SOURCE stacks can be customized and adjusted quickly.

NES-SOURCE has a high-speed path-switching function, i.e., paths are switched quickly when communication failures are detected. With this function, NES-SOURCE achieves a low delay and a low PER without duplicating the communication path, which is the case with TDMA-based technology. Compared to a simple fixed-path protocol, NES-SOURCE has the following features that allow routes to be changed quickly.

(1) Reduced back-off time

Sensor data and commands used in a WCN are at most several dozen bytes. By limiting the frame size to approximately 100 bytes, the random back-off time with CSMA/CA can be reduced from a maximum of approximately 15 ms to a maximum of 2.8 ms, as specified in IEEE 802.15.4g.

(2) ACK omission

If the communication path comprises a single hop, when NES-SOURCE detects packet loss in the MAC layer, it resends the frame using a backup route without waiting for the network layer ACK timeout.

With the above features, NES-SOURCE's communication delay can be reduced to approximately 60 ms for a communication path using a normal single-hop route and a backup two-hop route, which has been confirmed experimentally.

Packet loss occurs owing to packet collision or changes in the communication environment. We demonstrate experimentally that the PER and communication delay can be improved by implementing NES-SOURCE's route change function in a changing communication environment, e.g., in a factory environment where people and equipment interfere with wireless communications. Furthermore, we clarify the relationships between the probability of interference from obstacles in a communication environment and the collision occurrence rate and the PER of NES-SOURCE. The NES-SOURCE path-switching method can be considered an optimal method during system design.

2. Problems with Standardized Technologies and Related Work

2.1. Standardized Technologies

Several technologies have been standardized for WCNs.

IEEE 802.15.4 compliant technologies [8] are most frequently used in short-range wireless sensor networks (WSN), e.g., IEEE 802.15.4 is used as the MAC layer protocol in ZigBee IP [13].

IEEE 802.15.4 has two operational modes, i.e., non-beacon and beacon modes. The non-beacon mode is a CSMA/CA-based communication mode, and the beacon mode is a hybrid of TDMA and CSMA/CA. If nodes are in beacon mode, they send packets during a contention-free period (CFP). During the CFP, nodes communicate using TDMA. If the delay request for packets is short, nodes send packets during a contention access period (CAP). Note that nodes communicate using CSMA/CA during the CAP. IEEE 802.15.4's beacon mode is a well-thought-out protocol; however, it has not been implemented broadly because the specification is complicated and difficult to implement.

Time Slotted Channel Hopping (TSCH) is a TDMA-based protocol standardized in IEEE 802.15.4e [15]. TSCH nodes change communication channels each time the nodes change their TDMA timeslot. TSCH network systems are highly noise resistant. Owing to these characteristics, TSCH is used in WirelessHART [5]. TSCH is a suitable MAC layer protocol for WCNs. However, it requires improved clock accuracy, which is expensive. For example, in WirelessHART, clock correction information for

nodes is measured and written during the manufacturing process; however, such processes cannot be performed in all factories.

WirelessHART [5] uses TSCH to enhance communication reliability by incorporating a redundant communication path. However, this protocol control network information resides on the base station side; therefore, the system will fail if nodes cannot communicate with the base station. In addition, these protocols use TDMA, and it is difficult to guarantee delay on the order of 50–100 ms [3].

Sub-GHz bands are suitable for WCNs because they allow communication over greater distances compared to the 2.4-GHz band, which is used in IEEE 802.15.4 [8]. For example, IEEE 802.15.4g [14] is a wireless communication standard that uses a sub-GHz band. The theoretical communication distance of IEEE 802.15.4g is greater than 1 km at 20 mW. This is greater than the IEEE 802.15.4 communication distance (approximately 250 m at best). In addition, compared to 2.4-GHz bands, which are very noisy ISM bands, sub-GHz bands are not noisy.

The maximum frame size of IEEE 802.15.4g is 2048 bytes. Therefore, back-off time during CSMA/CA communication is approximately 15 ms at maximum. This back-off time is too large for a WCN, which requires a communication delay of less than approximately 50–100 ms.

2.2. Related Work

Researchers have improved the reliability of and delays in WCNs. WCN protocols can be classified as TDMA contention-free and CSMA/CA contention-based methods.

WirelessHART [5], PEDAMACS [7], and GinMAC [6] are representative contention-free schemes.

In WirelessHART [5], the base station regularly updates the routing and channel information for the network nodes. Therefore, the system does not function if nodes cannot communicate with the base station [15].

PEDAMACS [7] solves this problem by increasing the base station's transmission power to implement single-hop transmission from the base station. However, single-hop transmission often cannot be implemented in a WCN application environment.

GinMAC [6] avoids this problem by pre-installing node routing information. However, GinMAC uses TDMA and is difficult to implement.

MMSPEED [11] and Dwarf [12] are representative contention-based schemes.

MMSPEED [11] guarantees delay by controlling data stream QoS attributes, and this method is effective for large-scale data streams and networks. The network scale in [11] is approximately 150 nodes, which is greater than a typical WCN (approximately 25 nodes)

Dwarf [12] improves reliability by utilizing unicast-based flooding. This is effective when node density is high in a large-scale network. Therefore, Dwarf is unsuitable for WCNs.

Table 1 Practical WCN requirements

Network size	Up to 25 nodes
Packet occurrence frequency	0.1-1.0Hz (for monitoring) 3×10^{-3}Hz (for FA or PA)
Packet loss rate	10^{-4}order
Delay guarantees	1s (for monitoring) 50-100msec(for FA or PA)
Network topology	Most nodes will be located 1 hop from the station node and at most a distance of 3 hops will be observed.

3. NES-SOURCE Design

3.1. WCN Requirements

According to Zandra et al. [3], control applications can be categorized into three levels depending on the importance of message timing. Wired network communication is reasonable for applications with high-level requirements (e.g., control of life-threatening emergency stop devices). On the other hand, applications with low-level requirements (e.g., applications that safely allow manual intervention and/or monitoring) can use general WSNs.

WCNs can be used for applications with medium-level requirements. Table 1 lists the requirements generally assumed for WCNs. Note that the information given in Table 1 is based on the requirements provided by Samarasinghe et al. [6] and Kumar et al. [2]. The main application of a WCN that satisfies the requirements in Table 1 is assumed to be "a network for automatic control requiring responsiveness on the order of one second from measurement to response." [2, 15]. Note that "automated valve control at the factory" is often given as an example [15].

NES-SOURCE is assumed for use in environments wherein people and equipment move frequently, such as manufacturing plants. When a person or piece of equipment enters the communication path, the communication environment changes, and packet loss can occur. A WCN node cannot use an obstructed path until the obstruction is removed. Therefore, a WCN protocol requires a route-changing function.

As mentioned previously, in the general sensor network protocol, each node changes the communication path autonomously. In contrast, in the general WCN protocol, nodes do not construct routes autonomously. For example, in WirelessHART, nodes use duplicate communication paths simultaneously to transmit packets rather than changing routes.

In WirelessHART and comparable technologies that adopt TDMA, collisions do not occur even if the communication path is duplicated because TDMA is collision-free. However, when using CSMA/CA, collisions tend to occur if communication paths are duplicated because packets are transmitted to the same destination at essentially the same time. In this case, transmission and ACK packet collisions cause contention.

Therefore, when considering a WCN stack using CSMA, we must also consider a method to detect communication failure and switch communication paths quickly.

3.2. NES-SOURCE Features

We designed and developed NES-SOURCE to satisfy the conditions listed in Table 1 [16]. NES-SOURCE has the following features.

- PHY and MAC layers

  The PHY/MAC layer of NES-SOURCE is based on IEEE 802.15.4g. The usable frequency band is the 920-MHz band, the modulation method is GFSK, and the output power is 20 mW.

  Generally, if the single-hop communication distance is long, the number of hops in a multi-hop network decreases, and as a result, communication delay decreases. The communication distance of IEEE 802.15.4g is four times that of IEEE 802.15.4 at 2.4 GHz. Therefore, with IEEE 802.15.4g, it is highly probable that the effective communication delay will be less than that of IEEE 802.15.4. Furthermore, the diffraction characteristic of the 920-MHz band is better than that of the 2.4-GHz band. Therefore, IEEE 802.15.4g is suitable for the application environment assumed by NES-SOURCE (e.g., a factory with complicated piping).

  The CSMA random back-off time of IEEE 802.15.4g is up to approximately 60 ms, which is greater than the maximum random back-off time of IEEE 802.15.4d [17] (11.2 ms) because the maximum frame size of IEEE 802.15.4g is 2048 bytes. This maximum frame size is larger than the maximum frame size of IEEE 802.15.4d (128 bytes). Note that a WCN does not need to communicate large volumes of data; thus, 128 bytes is a suitable maximum frame size.

  Therefore, NES-SOURCE adopts the random back-off time of IEEE 802.15.4d. Our experimental results demonstrate that communication delay is improved by 6.5 ms (an average improvement of 27%) when transmitting 20 bytes by reducing the random back-off time [18].

- Network layer

  Similar to GinMAC, NES-SOURCE routing is a source routing method that uses an input fixed route. With NES-SOURCE routing, it is possible to set multiple paths to a single destination node, and these paths can have predetermined priorities.

  When NES-SOURCE receives transmission requests from the upper layer, it first transmits the packet using the highest priority path. When a packet transmission failure is detected at the network layer, NES-SOURCE retransmits the packet using the next priority path.

  NES-SOURCE uses ACK communication in the MAC and network layers to improve communication reliability. ACK communication in the network layer is required to implement path switching in the network layer. However, when an ACK from the network layer is used in a single-hop route, two transmissions (i.e., network layer data and ACK communications) are performed to confirm the transmission. However, such communication is useless, and reducing the frequency of such useless communication benefits the system.

  NES-SOURCE only uses ACK communications from the MAC layer, i.e., it does not use ACK communications from the network layer when the communication path to the destination node is a single hop. In this case, NES-SOURCE retransmits using the next priority path when the ACK communication of the MAC layer fails. As a result, an average communication delay improvement of approximately 9 ms is confirmed for a single-hop communication path [16].

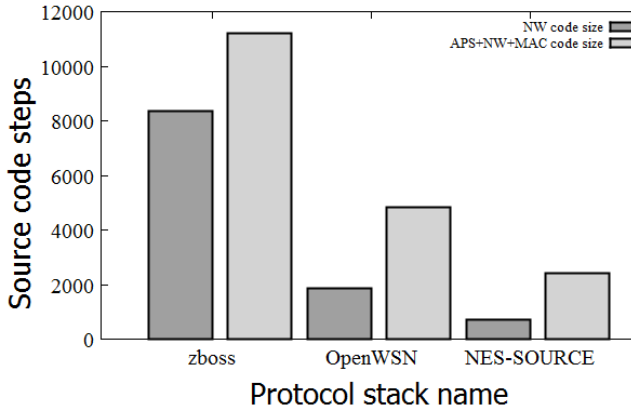

Figure 1 Protocol stack code size comparison

- Software

  The NES-SOURCE source code is more compact compared to the protocol stacks for WSNs and WCNs. A source code size comparison is shown in Figure 1.

  As an implementation of a general sensor network protocol, we refer to zboss [19], which is an open-source implementation of ZigBee PRO. The zboss code size (excluding the PHY driver) is 11217 steps in total (the NW layer code is 8366 steps).

  As an implementation of the control radio protocol stack, we refer to OpenWSN [20], which is an open-source implementation of TSCH. The OpenWSN code size (excluding the PHY driver) is 4833 steps (the NW layer code is 1859 steps).

  For NES-SOURCE, the total code size (excluding the PHY driver) is 2403 steps (the NW layer code is 727 steps). Even if only the number of code steps is compared, NES-SOURCE is a very compact implementation compared to other implementations.

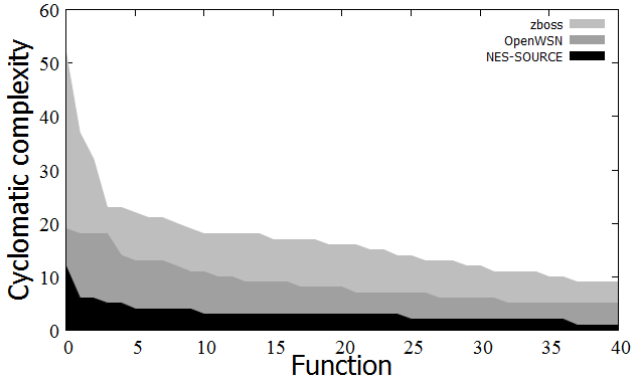

Figure 2 Program complexity

Figure 2 compares the function complexity of each protocol stack. The complexity of a function can be measured by its cyclomatic complexity [21]. Note that adding new code to a function is difficult if the cyclomatic complexity is large. Generally, there is no problem if the cyclomatic complexity is 10 or less. Figure 2 compares the cyclomatic complexity of the top 40 functions in the source code of each protocol stack. For example, zboss has 35 complex functions (the cyclomatic complexity is greater than or equal to 10), and OpenWSN has 10 complex functions. In contrast, NES-SOURCE has only one complex function. Thus, we consider that NES-SOURCE stacks can be customized and adjusted faster than general WSN and WCN protocol stacks.

A size comparison of the highly complex functions in each protocol stack is shown in Figure 3. Generally, fewer steps per function result in better code readability, which makes the code easier to maintain. As can be seen, NES-SOURCE has fewer steps per function than the other stacks; thus, NES-SOURCE is easy to maintain.

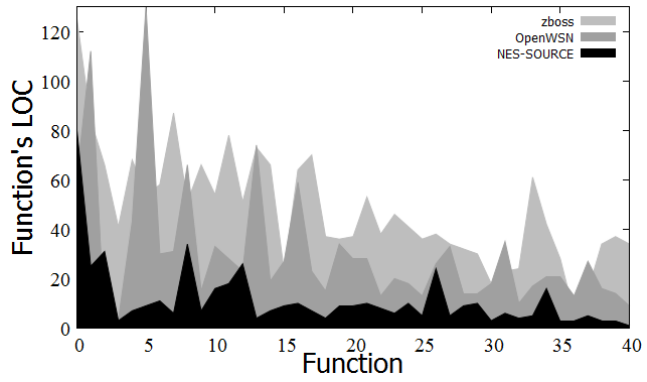

Figure 3 Size comparisons of complex functions

4. Evaluation on Actual Machine

To evaluate and verify NES-SOURCE, we implemented it on an OKI MH 920-Node-232. The MH 920-Node-232 is a sensor node that supports IEEE 802.15.4g and is equipped with a Cortex-M3 processor. Here we adopted FreeRTOS [22] as the embedded OS, and we developed the stack using the C programming language. The other experimental variables are shown in Table 3.

In this experiment, receiving nodes were arranged to form a hexagon, and the transmitting node was installed at the center of the hexagon. The transmission packet was 53 bytes (including overhead), the distance between nodes was 2 m on average, the communication system's transmission frequency was 1 Hz, the number of people in the room was always approximately 10 people, and the number of trials was 10000 for each node (approximately 16 hours).

The experiment evaluated the following packet loss management methods.

- Method 1: Retransmission by the same route

  The transmission node retransmits using the same single-hop route if communication fails. Here, the maximum number of retransmissions is four (Figure 4).

- Method 2: Retransmission by another route
  The transmission node retransmits using a two-hop route if single-hop communication fails. Here, the maximum number of retransmissions is one (Figure 5).

- Method 3: Retransmission by the same and another route

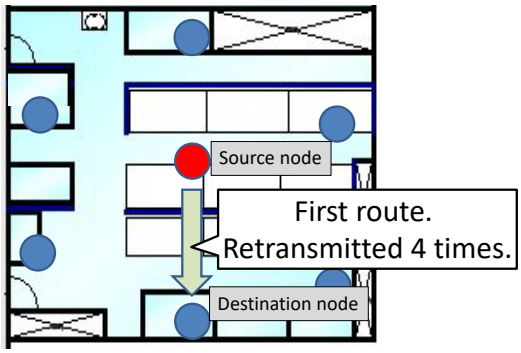

Figure 4 Method 1: first route only

The transmission node retransmits using a two-hop route if single-hop communication fails five times. Here, the maximum number of retransmissions for two-hop communication is one (Figure 6).

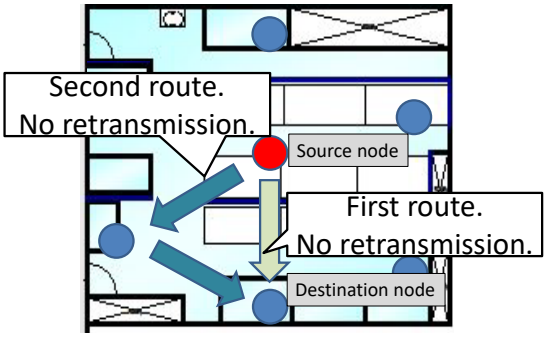

Figure 5 Method 2: two routes without retransition

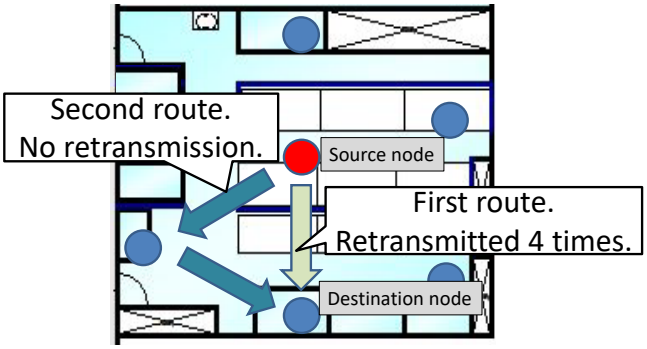

Figure 6 Method 3: two routes with retransition

Figures 7 and 8 show the experimental results. Figure 7 shows the maximum communication delay for each method (i.e., 55.37, 51.84, and 95.93 ms for Methods 1, 2, and 3, respectively). Figure 8 shows the PER for each method (8.71×10^{-3}, 5.83×10^{-4}, and 5.33×10^{-4} for Methods 1, 2, and 3, respectively).

The number of single- and two-hop communication routes for Method 2 was 58138 and 1827, respectively. The number of single- and two-hop communication routes for Method 3 was 59422 and 546, respectively.

5. Discussion

The experimental results indicate that the route change function in the proposed NES-SOURCE stack works effectively.

Table 3 Variable for calculating the PER

Number of successful communications method 1 by 1 hop	N_{m1_1hop}
Number of failed communications method 1	N_{m1_failed}
Number of successful communications method 2 by 1 hop	N_{m2_1hop}
Number of successful communications method 2 by 2 hops	N_{m2_2hop}
Number of failed communications method 2	N_{m2_failed}
Number of successful communications method 3 by 1 hop	N_{m3_1hop}
Number of successful communications method 3 by 2 hops	N_{m3_2hop}
Number of successful communications method 3 by 2 hops	N_{m3_failed}
Number of trials	N_{trial}
PER of 1 hop without retransmission under the WCN traffic	$PER_{1hop_noretry_c}$
PER of 2 hops without retransmission under the WCN traffic	PER_{2hop_c}
PER of 1 hop with 4 retransmissions under the WCN traffic	$PER_{1hop_4retry_nc}$

In the experimental environment, Method 2 was more advantageous relative to PER (Figure 5) than Method 1 as a measure against packet loss.

Furthermore, Method 2 was clearly superior to Method 3 relative to maximum delay (Figure 4). However, when compared relative to PER (Figure 5), the difference between Methods 2 and 3 is small.

These results demonstrate that the effect of link retransmission on packet loss was low in our experimental environment.

Thus, in a changing communication environment (e.g., a person enters the communication path), changing the path is more

effective relative to PER and maximum delay compared to link retransmission.

As stated previously, changes in a communication environment cause packet loss and collision. Note that our experiment did not consider packet collisions. Thus, to calculate a more realistic PER, the collision occurrence rate in WCN traffic was calculated in a simulation.

The simulation was created based on the communication frequency assumed by a WCN (Table 1) and the communication device settings given in Section 4. The simulation parameters are shown in Table 2.

The simulation results show that, for 25 nodes in the vicinity and a packet transmission frequency of 1 Hz for each node (i.e., a WCN general data transmission environment; Table 1), the PER of one-to-one communication without retransmission ($PER_{1\text{hop_noretry_c}}$) was 0.8%. In addition, if four retransmissions were allowed ($PER_{1\text{hop_4retry_c}}$), the PER was 0%, and the PER of two-hop communication without retransmission ($PER_{2\text{hop_noretry_c}}$) was 1.59%.

On the basis of the simulation and experimental results given in Section 4 and Table 3, respectively, we can calculate the PER of NES-SOURCE in WCN traffic. The relationships among the values shown in Table 3 are expressed as follows.

$$N_{trial} = N_{m1_1hop} + N_{m1_failed} \quad (1)$$

$$N_{trial} = N_{m2_1hop} + N_{m2_2hop} + N_{m2_failed} \quad (2)$$

$$N_{trial} = N_{m3_1hop} + N_{m3_2hop} + N_{m1_failed}\,. \quad (3)$$

The PER of each method in a collision-free environment ($\text{PER}_{\text{m1_nc}}$, $\text{PER}_{\text{m2_nc}}$, $\text{PER}_{\text{m3_nc}}$) can be expressed as follows.

$$PER_{m1_nc} = N_{m1_failed} / N_{trial} \quad (4)$$

$$PER_{m2_nc} = N_{m2_failed} / N_{trial} \quad (5)$$

$$PER_{m3_nc} = N_{m3_failed} / N_{trial}\,. \quad (6)$$

On the basis of Equations 4–6, the PER of NES-SOURCE under WCN traffic conditions can be expressed as follows.

$$PER_{m1_nc} = \frac{N_{m1_failed} + N_{m1_1hop} \times PER_{1hop_4retry_c}}{N_{trial}} \quad (7)$$

$$PER_{m2_nc} = \frac{N_{m2_failed} + (N_{m2_1hop} \times PER_{1hop_4retry_c} + N_{m2_2hop} \times PER_{2hop_noretry_c})}{N_{trial}} \quad (8)$$

$$PER_{m3_nc} = \frac{N_{m3_failed} + (N_{m3_1hop} \times PER_{1hop_4retry_c} + N_{m3_2hop} \times PER_{2hop_noretry_c})}{N_{trial}} \quad (9)$$

On the basis of the measurement results (Section 4), simulation results, and Equations 7–9, the PER values of NES-SOURCE under WCN traffic conditions for Methods 1 to 3 were 8.71×10^{-3}, 1.16×10^{-3}, and 8.05×10^{-4}, respectively (Figure 9).

According to Zandra et al. [3], the PER request of a WCN is on the order of 10^{-4}, and the delay request is on the order of 50–100 ms. Therefore, NES-SOURCE can be used in an experimental environment if the given WCN application has a slightly lower PER requirement.

When we construct WCN systems, we cannot predetermine traffic conditions or the frequency of communication problems. To mitigate this uncertainty, NES-SOURCE can flexibly change the packet loss countermeasure depending on the application's requests and the environment. For example, if the network traffic is assumed to be high, Method 1 is reasonable. On the other hand, when the network is constructed in an environment where people frequently enter the communication path, Method 2 is reasonable. Method 3 is appropriate if the goal is to increase the PER, even at the expense of the maximum delay.

"When a person enters the communication path, packet loss occurs."

"Packet loss due to a person can always be avoided by changing the communication path."

Assuming the above points are correct, the relationship between the probability that a person is within the communication path (P_{ps}) and the PER of each method can be expressed as follows.

$$PER_{Method1} = (1 - P_{ps}) \times PER_{1hop_4retry_c} \quad (10)$$

$$PER_{Method2} = (1 - P_{ps}) \times PER_{1hop_noretry_c} + P_{ps} \times PER_{2hop_noretry_c} \quad (11)$$

$$PER_{Method3} = (1 - P_{ps}) \times PER_{1hop_4retry_c} + P_{ps} \times PER_{2hop_noretry_c}\,. \quad (12)$$

For example, Figure 10 shows the relationship between P_{ps} and PER when $PER_{Method1} = 0.8 \times 10^{-3}$, $PER_{Method2} = 1.59 \times 10^{-3}$, and $PER_{Method3} = 0$ (this is the same as the simulation results). In this case, when a person's appearance rate in the communication path exceeds 0.8%, it is better to adopt Method 2 relative to PER.

6. Conclusions

In this paper, we have proposed, implemented, and clarified the effectiveness of NES-SOURCE as a WCN protocol that adopts CSMA/CA, which is easy to handle.

WSN protocol stacks must be customized and adjusted for each application, and the same is true for a WCN protocol stack, which is a WSN protocol stack with strict delay and PER requirements.

Many WCN stacks are implemented using TDMA. However, TDMA is difficult to handle; thus, customization and adjustment are difficult.

Therefore, we have developed the compact NES-SOURCE WCN protocol stack. The proposed NES-SOURCE employs the CSMA/CA method rather than the TDMA method. As a result, NES-SOURCE's code size is approximately 2700 steps, which is less than one-half the size of the TDMA-based WCN stack. In addition, NES-SOURCE has a lower code complexity than conventional WCN stacks and can be customized and adjusted quickly.

The WCN protocol with TDMA ensures communication reliability by duplicating the communication path. In contrast, the proposed NES-SOURCE ensures communication reliability by fast path switching when communication fails.

We conducted experiments in an environment where people entered and exited the communication path, and we confirmed that NES-SOURCE's fast path-switching function works effectively. The experimental results demonstrate that NES-SOURCE's communication failure detection and path-switching mechanism are fast and that communication delay was within general WCN requirements.

We have also clarified the relationships between the probability of a person entering the communication path and the PER due to the occurrence of collisions relative to each of the PER of the path-switching methods that the proposed NES-SOURCE employs. Thus, when designing systems that use NES-SOURCE, it will be possible to predetermine the optimum path-switching method relative to communication frequency and the varying degrees of obstructions in the physical environment.

Conventionally, TDMA must be adopted in WCN systems; however, this is difficult to customize and incurs high costs. In contrast, according to our experimental and simulation results, we can construct less expensive CSMA/CA-based WCN systems that can be customized quickly.

Meta-analysis
Content-based
Integrated learning

ABSTRACT

The purpose of this study is to investigate the effects of integrated content and English education. To fulfill this, 30 studies conducted in elementary school setting matching the meta-analysis criteria, such as being quantitative, experimental, or having affective statistical results after searching for the key words of "content-based", "theme-based" and "integrated learning" on the accessible databases such as RISS and Google scholar were selected. The results of meta-analysis are as follows: 1) Content-based integrated English education is more effective in improving English skills than improving affective factors. 2) There is no discernable difference in effect sizes among different grades. 3) Integrating with knowledge-based subjects were more effective than integrating with all the subjects.

1. Introduction

This paper is an extension of work [1] originally presented at the 2017 International Conference on Platform Technology and Service (PlatCon).

The main goal of learning a target language is to facilitate students' ability to communicate well. In countries that use English as a second language, the goal is to find effective English language learning in a limited period of time. While Korea is known as a country with a high level of education, many students in Korea who get high scores in reading and grammar lack the ability for authentic communication. Therefore, what could be a solution to solve this problem? Integrated English learning may be a solution.

Integrated English learning is an effort to learn English in an English class mixed with other subjects. Learning English at the same time as learning a subject saves time and brings meaningful language learning to learners.

Studies collected and analyzed had some weaknesses. For example, it was hard to identify whether the studies were integrated by the contents or the themes, which is a collection of common points of contents; as such, it can be said that theme-based integration is content-based integration. Furthermore, some of the studies analyzed were difficult to classify as theme-based integration. Therefore, in order to complement weaknesses, the title was changed to "A meta-analysis of content and language integrated learning in English."

Content-based integrated English education (CBIEE) refers to a method of teaching a foreign language whose main theme is extracted from a regular curriculum or curriculum area. Studies about CBIEE were conducted a few times [2, 3, 4] but analyzation of what part was effective for learning language was not conducted. Thus, it is needed to collect and analyze studies about CBIEE and propose directions to investigate via research on CBIEE that have been combined and sorted, and where the effects of CBIEE are found through meta-analysis.

2. Background

2.1. Content-based Integrated English education

The biggest positive effect of content learning through language instruction or language is that they can learn concepts and language in a natural environment; thus, learners can acquire language at the same time as general knowledge. For example, if they learn about other country's environment in class, they will be able to learn about the environment and its related language naturally while communicating through it. The learners who have this meaningful communication are instinctively stimulated to acquire a high level of language. It is, therefore, highly effective for learners' language learning to learn language and learn content knowledge naturally while participating in meaningful, purposeful life activities. The language learned through content has merits not only in terms of words, but also in integrating with higher dimensional thinking because learners' thoughts are reflected in communication [5].

2.2. Meta-analysis

Meta-analysis is an analytical method that synthesizes variouss

articles and derives them as a single result. It draws a standard on papers of similar themes and derives the overall result. In short, it is a way to reanalyze the results so far to derive general results. In order to achieve the main goal of this paper, CBIEE related papers needed to be effectively analyzed and integrated through meta-analysis.

There are five steps for meta-study before analyzing statistics: 1) Problem specification, 2) Study identification, retrieval and eligibility criteria, 3) Study features coding book, 4) Coding, and 5) Analysis and interpretation [6].

3. Method

3.1. Subject of study

1) Primary target classification for meta-analysis

In this research studies related to CBIEE domestic and overseas papers about foreign language education were collected. Key words or phrases for searching studies were content-based, integrated learning, or theme-based. Among the research, the ones that matched the condition were studies that published between the years 2000 to 2015, with 15 were domestic papers, 7 were from overseas papers, and 14 were domestic master's theses and doctoral dissertations. These 36 research papers were where meta-analysis was gleaned.

The number of studies for finding effect sizes in meta-analysis was 51 and the number of effect size for detail factors was 110 each, excluding cases that overlapped. Among these studies, studies that were directly related to searching the effect size for improving English skills and affective factors were chosen. The number of studies that suits the condition was 35 and the number of effect size is 110, excluding the cases which overlapped.

Table 1. Number of cases and number of effect sizes on detail case

Domain	Factor (Sub-domains)	Number of case	Detail case	Number of effect size
Cognitive	English skills	26	Listening	18
			Speaking	15
			Reading	14
			Writing	10
			Vocabulary	2
Affective	affective factors	25	Confidence	16
			Interest	22
			Attitude	13
Total (excluding overlapped)		35		110

2) Secondary target for meta-analysis

After classifying primary targets for meta-analysis, a Q-value test for homogeneity was taken and a random-effects model was chosen for meta-analysis. To raise the reliability and conduct a more valid meta-analysis, studies that were conducted only for elementary school students were only included, with studies that had different variables or a small number of cases were removed. Also, the studies that showed relatively large effect sizes without persuasive reasoning were dismissed. In the end, 13 research formats from domestic papers, 5 from overseas papers, 12 from master's theses for a total of 30 studies with 107 effect sizes were chosen as secondary targets for meta-analysis. Most of the research tried to find the effect of improving language skills and affective factors through CBIEE and the results show that it is both effective in improving language skills and affective factors.

3.2. Research design

1) Setting up variables of analysis

To conduct a meta-analysis related to CBIEE results, variables of analysis were explored and divided into two categories of variables: moderator variable and dependent variable. Moderator variables are integrated subjects, method of learning, and grade.

Table 2. Variables and coding value Conflict of Interest

Variable	Coding value
1. Integrated subject	(1) Knowledge-based subject (2) Skill-based subject (3) Both
2. Learning method	(1) Lecture (2) Group work (3) Storytelling (4) Game (5) Singing
3. Grade	(1) 4^{th} (2) 5^{th} (3) 6^{th}
4. Dependent variable	(1) Language skills (2) Affective factors

Dependent variables are divided into language skills and affective factors. A meta-analysis to investigate the effects of the dependent variables on the detailed variables was conducted. The effects of language skills and affective factors were measured from the results of post-tests of experimental groups and control groups.

The term confidence, which is a detail factor in affective factors, included anxiety in learning foreign language and confidence in learning foreign language as the same factor, and the term attitude included attitude in foreign language lessons and attitude for learning a foreign language as the same factor. Similarly, interest included interest in foreign language and Interest in subject.

Table 3. Detail variable in dependent variable

Dependent variable	Detail variable
1. Language skills	(1) Listening (2) Speaking (3) Reading (4) Writing
2. Affective factors	(1) Confidence (2) Attitude (3) Interest

2) Instrument for meta-analysis

With the criteria of variables and detail variables mentioned earlier, coding is produced for meta-analysis in Excel. The coding of each quantitative data and variable is inserted and based on this CMA program is used to obtain the result from meta-analysis.

3) Data analysis and interpretation

Research for the meta-analysis of CBIEE was searched and

collected for this study. From 2000 to 2015 a total of 30 research papers form annals and graduate-level theses were chosen. By the criteria, moderator and dependent variables are organized, coded, and then analysis performed.

The number of students participating in each study and the experiment method were different. In order to compensate for the errors in each of the different methods weight (*w*) was utilized. For each effect size, an average effect size for moderator was calculated. *Thus, Hedge's g* was used to fix the standard difference in means (*Cohen's d*). After the analysis, the results with some implications were interpreted.

4. Analysis

4.1. Coding for variables and adjusting weights

Based on the coding criteria, the collected studies were divided into certain categories, such as grade, learning method, and the classification of integrated subject. Thirty studies were represented as experimental and control groups, and individual effect sizes were presented. Each effect size was measured for detailed factors of language skill and affective factors.

(N=number of students, ES = effect size)

To compensate any error that was made from the different number of students and quality of study, weight (*w*) was added to offset error. As such, each effect size was measured again with weight. The effect sizes of each study with adjusted weight are shown in Table 5.

4.2. Comparing effect of factors in CBIEE

1) Overall CBIEE effect on English skills versus affective factors

Overall average CBIEE effect sizes on language skills and affective factors are 0.68 and 0.48, respectively where the difference is statistically significant. CBIEE has larger effect size on language skills than affective factors which means CBIEE has more effects on improving listening, speaking, reading, and writing than improving students' interests, confidence, and attitude in learning a foreign language.

Table 6. Overall CBIEE effects on language skills versus affective factors

	n	k	*Q*	*p*	*ES*	*Z*	95 percent CIs	
							Lower	Upper
Cog	24	57	187.67	0.05	0.68	24.33	0.62	0.73
Aff	24	50	227.67	0.05	0.48	14.56	0.41	0.54

(Cog = Cognitive skills, Aff = Affective factors, *n* = number of studies, *k* = number of detail case, *Q* = *Q-value*, *p* = *p-value*, *Z* = *Z-value*)

2) CBIEE effects on different grades

Table 7. CBIEE effects on different grades

G	Var	*n*	*k*	*Q*	*p*	*ES*	*Z*	95 percent CIs	
								Lower	Upper
4th	Cog	8	26	124.43	0.05	0.80	22.59	0.73	0.80
	Aff	9	20	87.40	0.05	0.40	8.10	0.31	0.50
5th	Cog	6	16	11.90	0.05	0.38	22.59	0.26	0.51
	Aff	5	10	9.22	0.05	0.53	6.57	0.37	0.68
6th	Cog	6	12	7.96	0.05	0.67	9.27	0.53	0.81
	Aff	7	15	121.46	0.05	0.52	8.90	0.40	0.63

(G = Grades)

Students in 4th grade had an average effect size on language skills (0.80) which were larger than that on affective factors (0.40), but the difference was not statistically significant. Conversely, 5th and 6th grade students (0.53, 0.52) had larger effect size on affective factors compared to 4th grade learners (0.40). As the grade progressed, the gap between minimum and maximum effect sizes grew, which means the effect of CBIEE matters on the choice of content and a teacher's method of teaching.

3) CBIEE effects on language skills

Table 8. CBIEE effects on language skills

Skills	*n*	*k*	*Q*	*p*	*ES*	*Z*	95 percent CIs	
							Lower	Upper
Listening	18	18	63.73	0.05	0.66	12.86	0.56	0.75
Speaking	15	15	55.75	0.05	0.65	11.82	0.54	0.75
Reading	14	14	43.50	0.05	0.70	12.23	0.59	0.81
Writing	10	10	20.03	0.05	0.76	11.91	0.64	0.89

There was no difference in effect sizes among language skills. CBIEE's effect on students' reading and writing skills was minutely larger than that of listening and speaking skills. Since most activities take place within similar content or themes, they focus on output activities such as reading and writing.

This results show that effect sizes in improving written language is slightly larger than spoken language, although the difference was not statistically significant.

4) CBIEE effects on affective factors

Table 9. CBIEE effects on affective factors

	n	*k*	*Q*	*p*	*ES*	*Z*	95 percent CIs	
							Lower	Upper
Confidence	16	16	91.33	0.05	0.44	7.84	0.33	0.55
Attitude	12	12	60.84	0.05	0.54	8.06	0.41	0.67
Interest	22	22	74.21	0.05	0.47	9.32	0.37	0.57

There was no difference in effect sizes among affective factors. Improving attitude was the largest effect (0.54) where CBIEE helped to give a positive influence on attitude by removing cognitive burden while learning a foreign language.

By analyzing the statistics, CBIEE proved to have positive effects on affective factor development; especially, CBIEE helped students to raise their concentration better by eliminating cognitive pressure. When integrating different subjects, teachers should know that integrating can raise students' affective factors when students face difficult tasks.

5) Knowledge-based subjects vs skill-based subjects

Table 10. Knowledge-based versus skill-based integration

Subjects	*n*	*k*	*Q*	*p*	*ES*	*Z*	95 percent CIs	
							Lower	Upper
Skill-based	13	45	184.79	0.000	0.67	10.44	0.55	0.80
Knowledge-based	9	30	112.31	0.000	0.52	6.01	0.35	0.68
All subjects	8	38	99.94	0.000	0.41	6.32	0.29	0.54

Integrating with knowledge-based subjects (0.67) shows larger effect than that of skill-based subjects (0.52), but the difference was not statistically significant. However, integrating with knowledge-based subjects (0.67) is more effective than integrating all subjects (0.41), which the difference is statistically significant. Integrating with only knowledge-based subjects (i.e., mathematics, science, and social studies) is the most effective way for content integration.

6) Teaching method in CBIEE

Table 11. Effect sizes by different teaching methods in CBIEE

Method	*n*	*k*	*Q*	*p*	*ES*	*Z*	95 percent CIs	
							Lower	Upper
Lecture	11	45	292.96	0.000	0.48	8.22	0.38	0.78
Group work	5	15	3.37	0.001	0.49	3.37	0.20	0.78
Game	4	16	47.42	0.000	0.69	5.86	0.46	0.92
Singing	2	4	0.99	0.002	0.34	3.10	0.13	0.56
Storytelling	8	30	39.76	0.000	0.42	7.91	0.31	0.52

Using games (0.69) shows the largest effect compared to the rest of the learning methods, although the difference was not statistically significant. Students can enjoy their learning while playing games and they are able to release the stress of learning foreign language. It is, however, challenging to see the effect of using singing in CBIEE, because there are only few cases.

7) Overall results of meta-analysis

CBIEE shows larger effects on improving language skills than improving affective factors. We think that most of the experiments are focused on English courses, not regular courses, and these results seem to have resulted. There are no effect size differences among different methods. Integrating specifically with knowledge-based subjects is more effective than integrating with all subjects in improving language skills, which means in order to develop the English language skills, it is important to emphasize the importance of the mixture of subjects rather than the way of teaching.

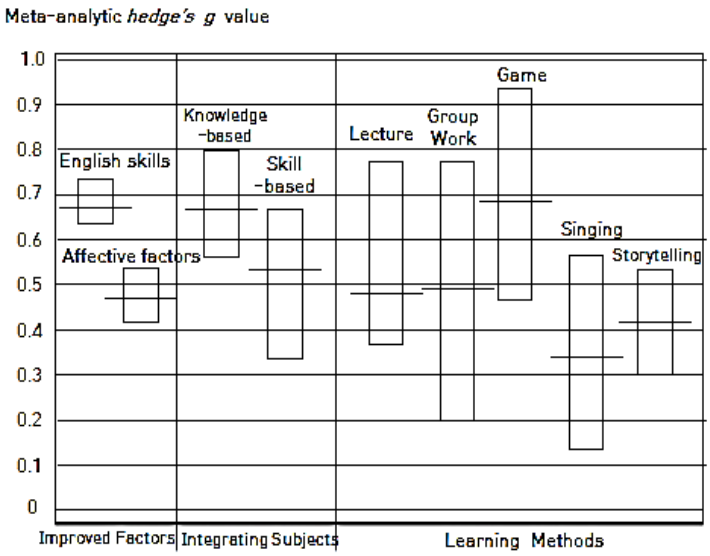

Figure 1 Overall/Meta-analytic effects of CBIEE across sub-domains.

5. Conclusions

It was explored in this study the effect of CBIEE by meta-analysis. Through the meta-analysis, it was found that CBIEE is more effective in improving skills than affective factors and it depicts different effect size across sub-domains.

Compared to a previous meta-study of integrated language learning [7], different results were found in this study. After integrated learning, two studies have different results on the improved factors, such as language skills versus affective factors, and spoken language versus written language. Two studies also have opposite effects on integrating knowledge-based subjects versus skill-based subjects.

Due to this it means that integrating with other courses can have different effects depending on whether the teacher focuses on content or language when the language is taught. This meta-analysis displays not only the findings of the effects of CBIEE itself, but also it may be gleaned that different kind of integration with language, for example, task-based or experience-based integration could give different effects to language learners.

In future studies, it will be necessary for the researchers and teachers to pay much attention and effort to examine the effects of applying various types of integrated foreign language classes and to find appropriate education methods for each country's educational environment.

Intercropping in rubber plantation
Decision Support System

A B S T R A C T

The problem of multi-criteria or multi-objective intercropping crop planning makes it vital to consider all related factors under the constraints that will produce the highest revenue and minimum cost. Principles of intercropping elements including soil type, plant area, plant diseases, planting and harvesting time and economics factors (e.g. price, cost) are some of the factors in making decisions. Intercropping is important in the situation such as during inability to harvest main crops, co-cultivation to increase productivity, or even to increase extra revenue. Therefore, the decision-making system requires a wise decision support system, which can advise farmers on economics matters. In this article, we present the decision support system (DSS) model framework for planting rubber with intercropping by a hybrid approach using ontology-based knowledge consuming rule concepts and relationships for intercropping with integrated multi-objectives optimization to recommend the crop to be planted and the suitable proportion of planting areas or planting co-suited to the rubber plantation of farmers. This approach could be applied as a guideline for another field, such as production problems or other resource allocation issues.

1. Introduction

This paper is an extension of the original work which was presented in 2016 at the International Computer Science and Engineering Conference (ICSEC) [1]. This article explains in more detail about the Research Framework and Research Methodology.

The agriculture in Thailand comprises of 45.84 million acres or 35.7% of area of the country where 25.9% of households are farmers with an average 7.76 acres per person. These farmers are divided into 79.1% monoculture farmers and another 19.9% integrated farming. Other main agricultural activities in Thailand are livestock production, fish or other important aquatic animal raising or salt ponds [2].

Recently, the weather uncertainty and low price of the agricultural products especially hits the monoculture farmer severely. This can be seen in rubber planting (rubber is a major Thailand economic crops), where the rubber price affected the farmers. In 2015, the rubber prices dropped 20.1% as compared to the previous year which made export of rubber drop by THB 52,000 million (21.4% decrease) [3].

Southern Thailand is the main producer of rubber in Thailand, and 70% of the labor in this region are rubber farmers in monoculture. The farmers have been impacted from this terrible situation where their income in 2015 has declined THB 33,000 million (or 17.7 %) as compared to on the previous year. As a result, this decline has raised the household's average debt from THB 134,893 per household in 2013 to THB 153,144 in the first half of 2015. Findings from the Bank for Agriculture and Cooperative shows that the farmers were giving some signal that their income is unsustainable for them to pay the bills normally due to the fluctuation of rubber's price since 2014 and many of them decided to uproot their rubber trees and preferred to plant other more profitable crops. In this condition, monoculture farming might not be the possible answer although the economic return was high, at the same time, the risk is still there when the price fluctuates by the market [4].

https://dx.doi.org/10.25046/aj0203172

Due to that, it is unwise to stay in the type of farming approach which only concentrates on one single type of crop. One solution is to introduce or convert single monoculture into poly or intercropping farming system. In a general sense, intercropping is a planting system that uses a multiple cropping system with at least two or more crops planted in the same field/plot during a growing season [5]. In this regard, intercropping is a potential alternative for a sustainable way for the farmers to overcome the above-mentioned problem by reducing risks of product price fluctuation, pathogens or insect attacks [6]. At the same time, the Thailand government have made a lot of effort to support this idea of intercropping system.

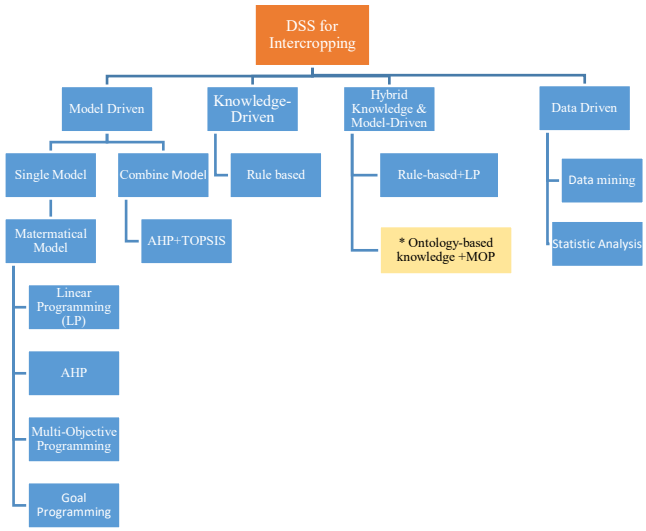
To clarify this idea, we have organized the information in figure 1 to make understandable our proposed concept to assist the farmer in this specific region or it might be applied or adopted in many other area. The interconnectedness of this model is based on the previous works that are discussed fully in Section 2. The proposed concept of integrating the overall concept framework and evaluation is discussed precisely in Sections 3 and 4 and we conclude our idea in Section 5.

2. Related Work

2.1. DSS for Intercropping

Many DSS for intercropping planning used mathematical models or are model-driven to solve this problem such as Linear Programming (LP) [7], Analytic Hierarchy process (AHP), Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) or Simple additive weighting (SAW) [8] , or hybrid technique e.g. AHP and TOPSIS[9]. Nevertheless, that approach will provide just an answer to a priority of alternatives and does not answer about living space to grow. For example, the proportion of main crop and secondary crops and the calculations in this area, considering the distance between the plants and the second plants as well as the principles of the intercrop. After the system recommends a suitable priority for particular co-planting of plants, the farmers need to determine the specific area of use in order to figure out a maximum overall return. Such types of calculation may not result in an answer with maximum income under their restricted resources, and hence their opportunity of profit making is lost with not including the extraction of knowledge from experts to optimize knowledge management and decision-making.

[10] presented an integrated DSS for intercropping by using a rule-based expert system as a model. This method can be extended to cover more decision criteria to cost the cropping. The objective of the work is to manage cropping activities for improved crop production. However, approaches ignore important features due to the paper not offering price statistics for the decision. This factor is necessary for planning crops. [11] showed the model-based support by using evolutionary algorithms to solve multi-objective optimization and design of mixed farming systems aimed to maximize the operating profit and organic matter balance, and to minimize the labor requirement and soil nitrogen losses. [12] presented the goal programming for rubber plantation intercropping with tea trees. The purpose of this work is management of rubber plantation yield before getting a return for seven years.



Note: * New guideline in DSS for intercropping

Figure 1 Summary of approach for DSS-Intercropping

However, literature reviews to analyze approaches in the DSS cannot ignore the knowledge-driven decisions, sometimes generically called expert systems or recommender systems because knowledge-driven DSSs might use artificial intelligence and/or some of the statistical inference technologies to suggest or recommend actions to managers. These systems have knowledge codified to provide specialized problem-solving assistance [13]. Especially in agriculture, the farmers who succeed in farming collect long-standing experiences. The knowledge has been tested through experimentation and theory and then becomes tacit knowledge which is necessary to be maintained and adopted in a knowledge-base for a decision [14, 15].

Therefore, the challenge is to design an ontology in the field of mixed intercropping which refers to the practice handbook of planting and a rule base from domain experts. The system can suggest the plants that grow well together in the suitable areas in a format that can be processed by a computer program. It focuses on knowledge sharing and reuse and sends related parameters about plants that suggest related plants from the recommender engine to calculate multi-objective optimization programming in order to give the answers which can support the intercropping decision supporting system for an individual agriculture.

2.2 Ontology-knowledge base for DSS

Ontology is a structured establishment and knowledge representation in knowledge management system or acts as a tool similar to that system whose indices were used to manage and access the subject of the question using controlled vocabularies comprising vocabularies, terms, syntax and certain rules based on making use of appropriate word patterns [16]. The results of using an ontology-based illustration of the important data structure of a DSS are the distinguishable state from what happened in the past with DSS as closed systems, the primary ontologies' objective are to determine proportionated domain models and knowledge from a variety of sources. Also, some of the inference stages of the DSS can be carried out using state-of-the-art logical reasoning performance, as rule logic providers or justification providers [17].

Advantages of ontologies include seeming well suited to an evolutionary approach to domain knowledge and requirements specification [18] in contrast to traditional knowledge-based approaches, e.g. formal specification languages. Requirements management and traceability can be supported by ontologies. Semi-formal or informal approaches provide no logical formalism or model theory compared to automated validation and consistency checking which are considered as a potential benefit. Finally, the formal specification may be a prerequisite to realizing model-driven design and implementation approaches [19].

Deciding to intercrop does not focus on finding answers to the income or economics alone but it must be based on the principles of integrated crop plants to reduce disease risk and the suitability of the area under the constraints of farmers. Therefore, this research uses ontology-based knowledge for driving DSS and providing the type of plant and design optimization model for calculating the answer for maximum income. This phase uses knowledge acquisition and ontology modeling for ontology design and experiments for economic design modeling.

Ontology-based knowledge representation that allows information sharing, reuse and collaboration on design and obsolescence issues across different organizations provides the basis for decision-making in an intercropping selection and presents concepts, relationships, and instances. To establish a comprehensive knowledge representation scheme, an ontology that can serve as the backbone of the needed information model is required [20].

Ontologies technology can be applied in the work of various systems by considering the purpose of the deployment: (1) information retrieval; (2) systems that require integration of knowledge for a basic understanding of the knowledge domain; (3) systems that have the need for knowledge reuse and such systems may be defined ontologies technology to use allowing another system to be used again by the system later. This may define semantic information that does not have contrary information of semantic ontologies taken back to another system and there is no need to explain that there is no change, such as static domain knowledge or knowledge-based system. In particular; ontology has recently been adopted in DSS in various application domains [21].

Currently, ontologies are semantic knowledge management which have been successfully implemented in DSS in various application domains, and to determine the tasks and parameters of some system modules [17], applied in knowledge management [22]. However, an ontology applies in knowledge management through the web service system, question answering [23] or DSS [24] in planting trees. Nevertheless, that answer or knowledge is about planting monoculture crops only and lacks a decision to plant mixed or intercropping to maximize income while minimizing cost in a limited farmer's resources.

2.3 Multi-Objective Optimization Methods

This section and figure 2 presents a summary approach for Multi-Objective Optimization. There are classical methods and Evolutionary Multi-Objective Optimization (EMO) Method [25].

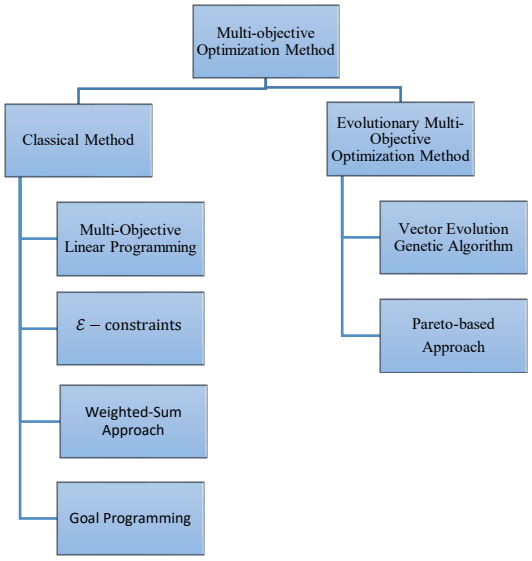


Figure 2 Some approaches for Multi-Objective Optimization

- Multi-objective is a vector of constraints, objective functions, and variables and is considered by Multi-objective Programming Model. A reduced subset of the feasible set exceeds all of the aspiration levels of each objective contains a satisfactory solution a set of which has acceptable alternatives that do not need to be non-dominated. A final choice of a non-dominated solution selected through decision makers' involvement in the information processing stage is a preferred solution [26].
- Ɛ-constraint methods are those of a posteriori using scalarization. By these methods, a multi-objective problem will be converted into a single-objective method and can solve the problem and obtain its solution as a Pareto-optimal single solution.
- Weighted Sum Approach is an easy method to apply to weighted specific functionalities and then combine the weight and objective functions to build a single objective but the problem of using this method is if there is not enough information, it will result in difficulty in defining the objective weight as can be seen from the research of [27].
- Goal Programming Approach is a method that rank evaluates a set of results which uses the stage of Multi-Objective Goal Programming (MOGP), as can be seen from the research of [28] which presents that this method is well known in methodology and development of the proposal which has efficiency in defining goals (Multiple Goal Linear Programming-MGLP) that are trying to deviate between various objectives. The lowest formula is used in calculating outputs from various goals and compares those values until it gets the best results suitable for an allocation problem such as limited resources management [29].
- Vector Evaluation Approach is a method that defines Fitness Assignment which is the first method that expands the steps of Genetic Algorithms, which results

in finding the most appropriate results for various objectives. [30] explained the process consists of 1) Initialization Population 2) Evaluation Objective Function 3) Define Fitness Assignment 4) Selection of the results from the Fitness Assignment of strings: each result during this process will crossover. This is a process where a right string answer which comes paired to exchange to get the new string result and mutation to evaluate new strength until the calculation reaches the maximum number of answers looked for [31].

- Pareto-based Approach: This method is used to rank the Pareto to build relationships between the function, purpose, and strength by using the Pareto principle to calculate the strength. For how to configure the strength to make this the best result, it will have more than one possible result that could be the best answer and it will be in the format of set, or group of the best answers [32].

3. Conceptual Framework

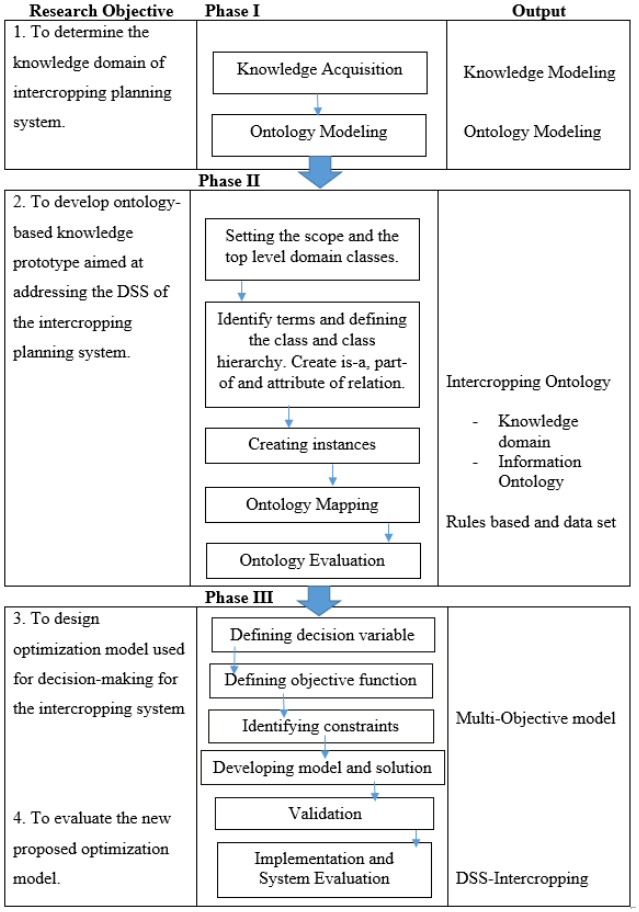

Figure 3 Research Conceptual Framework of DSS-Intercropping

The DSS for growing rubber plants is a hybrid method which works together in two parts. The knowledge-based part uses the process of knowledge management with ontology to obtain a rubber plantation model and to develop an intercropping ontology and rule base that will lead to a more intelligent recommender system which is mixed with a multi-objective optimization model part. It will helps to calculate and allocate each crop area to yield maximum yield and the lowest cost that the system will help farmers or users make decisions as a guideline or primary recommendations before making a decision on plantation operation as indicated by soil, time, season, area, cost, and market price or other critical parameters.

4. Research Methodology

The method of this work is divided into three main phases namely, Phase I knowledge acquisition and ontology modeling, Phase II ontology development, and Phase III optimization modeling and system implementation. This is shown in Figure 3 and details in each phase are presented in Sections 4.1, 4.2 and 4.3, respectively.

4.1. Phase I: Knowledge Acquisition and Ontology Modeling

This research is information to extract knowledge and expert knowledge for decision making and decision criteria and a variety of organizations. The Ministry of Agriculture and Cooperatives of Thailand is the main organization for promoting agriculture. It was split into several entities with different responsibilities. In addition, certain information is required from other ministries. These are summarized as the sources of data for research purposes to support farmers for intercropping shown in Table 1.

Table 1 Summarized the sources of data to support decision making for intercropping

Organization	Type of information
Department of Agricultural Extention	providing: - Knowledge and media for cropping - Disease and pets
Office of Agricultural Economic	- Sale Price Statistic per kg (THB) - Cost per square meters (THB) - Productivity per square meters (kg.)
Royal Irrigation Department	The water situation and rainfall statistics.
Land Development Department	Soil information each province
Provincial Agriculture Office	Advising agriculture in each province for intercropping.
Farmer who are success in intercropping	The information about intercropping from experience.

Knowledge Acquisition

In this section, the knowledge acquisition approach was a combination of text analysis and expert interview approach [33]. The study included three steps:

- Concept and domain knowledge. Identified using secondary resource document analysis e.g. electronic resources, journal, or book. Based on intercropping system principles, in this research merely three factors: spacing, cultivation period, plant disease will be employed as important factors. Selection of factors are also consistent with research that had been performed by a summary of factors from previous research and from the selection of sub rubber plantations booking to pursue an

alternative career at the Department of Agricultural Extension, Ministry of Agriculture and Cooperatives, Thailand which recommended considering the use of tree age criteria. In addition, due to time constraints of performing this research data some important related factors are already sufficiently provided and the high cost of extension of the research to other less important or less prioritized topics and the selection is based on recommendations provided by plant production experts. The selected factors are soil, spacing, time, and diseases. Spacing is important as individual plants require a different area for growth of root, and size of branching. These factors are expected to produce a significant impact on light, water and mineral resource use of plants. Time is a critical factor as well, and a proper arrangement or organization of short-term and long-term co-planted plants will cause an increased use and rate of light, and mineral resource for plants compared to single cropping that is usually suitable for some particular seasons and period of harvesting so as to generate constant revenue throughout the year. Even though mixing or intercropping may not produce complete immunity to related plants, as some diseases can destroy more than one type of plant in one single invasion, a selection of proper but different plants that usually can't be destroyed by the same diseases will much reduce a destruction rate of disease destruction. However, economic factors including price and cost need to be involved because the decisions affect production rates[8].

- Interview with experts who are in the areas of intercropping. Two groups classify the population and sample: (1) government agency officials obliged to provide agriculture information, and (2) farmers successful in intercropping. Purposive sampling from the population is used because they have to choose from the expertise of experienced farmers in the agricultural field and the knowledge and experience of rubber farmers in the province. So the experts came from two groups, the first group were five state employees from five agencies of the Ministry of Agriculture and Cooperatives. As depicted in Table 1, this is an agency that provides information related to agricultural extension which has a direct duty to provide advice on cropping for local farmers, and Group 2 are three farmers who have specialized and succeeded in intercropping in rubber plantations. After that drafting knowledge classification was categorized by evaluating the data types and characteristics of the data using a hierarchical clustering of intercropping system terms. Questions to ask are open-ended questions to extract knowledge of intercropping cultivation. The criterion for selecting a plant to plant with rubber are the age range of tree and plants suitable for growing any plant with the same plant disease, the risk of damage to the main crops or rubber trees. Then the draft knowledge domain is summarized to be verified in the next step.
- Knowledge domain and concept is summarized and results reconfirmed with the experts. Consider the appropriateness of the criteria and concepts that are included in the manual and from expert interviews. Then reconfirm from experts by the focus group method.

Ontology Modeling

Identifying terms of related information is required for the design of ontologies for intercropping which starts from defining the scope of knowledge about intercropping. A combination method is then used for the system to classify the terms into classes and hierarchy of class levels of ontology. Important concepts are sequenced first e.g. the selecting crops principle. For instance, requirements of co-planting plants in terms of disease and insect, soil, and these co-planting plants harvesting time should be overlapped to help farmers have a continuous or relatively constant revenue throughout a year. Then each class qualification is identified including heritage of classes consideration and defining conditions for qualification of a class. For example, classes types of qualifications are identified. The tool to build knowledge modeling is CmapTools. CmapTools collaboration and publishing features are used widely for sharing and representing all knowledge domains including organizing information, brainstorming and knowledge management.

4.2. Phase II: Ontology Development and the Evaluation

Ontology Development

The ontology life cycle has seven steps [34] but: "there is no one way or methodology for developing ontologies and ontology development is necessarily an iterative process." Ontology development should be based on application objectives, data characteristic, information system rules and context and future reuse feasibility [35]. The intercropping ontology will be developed using a top-down approach. This is a way to start with the concept of a generic domain which starts with the most common definitions based on concepts in the domain and take that expertise to be guidelines and define a specific concept. For example, starting by creating a class for the general idea of cropping. Then, create a subclass in that class and go to the bottom of the ontology structure which are instances or data, followed by the modeling:

- Setting the scope and the top level domain classes. To define scope and the top level domain classes it is defined in the field of intercropping and this ontology is used to make decisions in intercropping. It helps answer questions such as "What are characteristic of plants that can grow with rubber plantation?", "Which season is an appropriate season to plant?", "What is the cost and output per square meter?", and "What is the total revenue and cost?" Knowledge-based ontology development uses the ontology editor. Several software platforms and application interfaces (APIs) have been developed to support the Semantic Web vision of making machine-readable content available on the web to permit automatic creation and use of OWL and RDF. Currently there are many tools for ontologies editors such as Protégé, OntoEdit, OILDd, Hozo. However, Protégé is an open-source platform developed by Stanford University and is a kind of popular tool for ontology editor. Protégé is plug-in architecture that can

be adapted to build both simple and complex ontology-based applications. Developers can integrate to output of Protégé with rule systems or other problem solvers to construct a wide range of intelligent systems [36].

- Identify terms or concept and defining the class and class hierarchy. Create *Is-a*, *Part-of* and *attribute-of* relation. Examples of important terms or concepts in this work are such as economic crops, soil, water, plant diseases, seasons, etc. Define relationship between concept types *Is-A* such as rubber is an economic plant. For *Part-of* relationship, for example, the address of the farmer consists of district, etc. Then define the properties of Concept (Term) such as rubber is a species, type of soil suitable for planting, plant diseases, yield per rai (3000 m^2), price etc. There are two types of intrinsic property such as variation, appropriate soil type, planting period, plant disease, and 2 extrinsic properties such as cost and price.
- Creating data instances and ontology mapping. Recommender engine requires a rule engine to construct and additional criterion [37] applied JENA and SPARQL for developing the backend of this component [38].

Ontology evaluation

Assessment of ontology in this work is through clarity, completeness, consistency, and correctness criteria by ontology development experts. Based on an ontology evaluation by an expert also known as assessment by humans it can evaluate all 6 levels including lexical, taxonomy, semantic relations, application, syntactic, and design. When compared to Gold Standard, application-based, and data-driven evaluation [39] and the number of experts to use for validity, [40] advised a minimum of three experts, on the other hand indicated that more than ten was probably unnecessary [41]. Therefore, in evaluating the ontology in this research, it employs three developers with three to five years ontology experience. This step provided evaluation in terms of the concepts, and relationships related to the intercropping system and includes an accuracy evaluation of rules, a concept of result calculation, screening of cultivated plants suitable for a particular area as farmer requests and screening of co-planting plants are assessed by three experts by a comparison between system results and results obtained by experts' presented recommendation. Then it is improved before using an optimization model to calculate economic factor in the next step.

4.3. Phase III: Optimization Modeling and Implementation

Optimization Modeling

After creating the ontology-based knowledge to introduce crops that can be planted with major crops suited to an area by intercropping we will get parameters for design models and import data into the model including data from the database in the recommender system such as the type of crop, prices, and cost and input data from users consisting of: name, address, size of area, cost, and start of planting.

Because this problem is one of resource allocation which are land and cost the mathematical model used to solve this limited resource allocation problem, decision variables are objective functions or the limitations of the model. Each decision variable is often multiplied by a constant and then added as a function, objective or equation or inequality of constraints. These variables have a linear relationship. The models in this characteristic are called Linear models such as x_1 and x_2 instead of the 1st and 2nd crop where z represents the profit or revenue from the sale of both crops. There are three main components: Decision variable, Objectives, and Constraints. A detailed explanation of the objective function and the constraints of the proposed model are given in the following sections.

- **Decision Variables**

From the problem, it is found that the farmers have to choose intercrop plants that fit their own space and resources. Therefore, the decision variable is what economic crops are suitable to grow with rubber trees and how much of the planted area will produce the highest yield and lowest cost. The calculation model contains two parts: Part 1 Data is added to the user's planting area of intercropping, identifying the district to determine the type of soil from the Land Development Department, the size of the area measured in square meters. Secondly one must determine which information is stored in the data set. This includes production per square meter, price (THB / kg.), cost per square meter, and the number of days it takes to grow. The result of this calculation, a multi-objective optimization model, is shown in the background of each type of crop, illustrating the potential highest income and lowest total cost.

- **Create the Objectives and Constraints**

Intercropping has several objectives to prevent pests, adding nutrients to increase productivity, mulch, help increase revenue before harvesting main crops, etc. [42]. However, [43] has studied factors of decision making for multiple crops or new theory farming practices of farmers in north-eastern, Thailand. It was found that the main factors that affected the changing behavior of decision making or the selection of crop system was the price or income and that most farmers' problems are capital, plant diseases and lacking irrigation. This is in line with the study by [44] which presented the factors affecting the decision to change the use of land or change the crops of farmers Thailand were revenue and costs. The problem is caused by the risk of price of output and the problems caused by the monoculture as mentioned above. Helping farmers get the highest annual income with lowest cost was the objective of this research through focusing on the allocation of space to grow various crops to increase revenue. Maximizing plant cultivation income and minimizing cost is the purpose of the model.

Many variables are used to calculate incomes for listed types of plantings as follows: particular productivity per square meter (m^2), sale price / kilogram (calculated as local currency as Thai currency), planting period starting from initial cultivation until harvested and cultivation period (month), area (m^2), related expenditure or production cost is calculated as sum of cost the individual productivity types (kilogram) multiplied by cultivation area (m^2). Constraints include size of the total area of the farm, where the number of plants will be not be equal to one. The

prototype consists of Decision Variable, Objective Function, and Constraints.

- **Developing Model and Validation Solution**

Multi-Objective Programming (MOP) is formulated with the objective of maximizing economic values obtained from an intercropping system as well as minimizing its cost. The optimal levels for various decisions regarding seeding and harvesting time periods and cultivation areas are determined by solving the MOP. The tool used in the test model is MATLAB.

MATLAB is a proprietary fourth-generation programming language developed by MathWorks and MATLAB provides a multi-paradigm numerical computing environment allowing C, C++, Java, Fortran and Python interfacing, user interface creation, algorithms implementation, data and function plotting and manipulations of matrices and offers tools for application development, visualization capabilities, data analysis and high-performance numerical computation [45].

The solution allows one to find an answer within the set area of the possible answers, to find a minimum or maximum of each function simultaneously. The result or best answer consists of m objectives and decision variables as you can see in Equation 1 written as general equations as:

$$Minimize\ (or\ maximize): \{f_1(x), f_2(x), \dots, f_m(x)\} \quad (1)$$

where x is a vector of decision variables

f_i (x) is objective function, where i=1,2, …, m

Therefore, patterns of solving multi-objective optimization function is finding x vector solutions within m constraints as shown in Inequality 2 or within m constraints as shown in Equation 3 that determines the possible solution area. This defines a set of possible solutions.

$$g_i(x) \leq 0, i = 1,2, \dots, m \quad (2)$$

$$h_i(x) = 0, i = 1,2, \dots, m \quad (3)$$

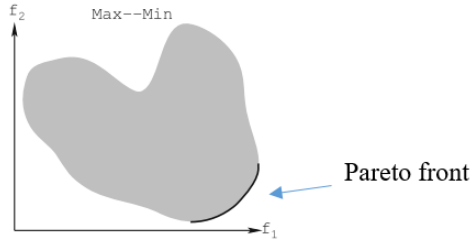

Figure 4 Pareto front of multi-objective functions f_1 (Max) and $f2$ (Min)

[46] define the term Pareto Dominance and appropriate answer Pareto Optimality as seen below:

Definition 1: Pareto dominance: A given vector $u=(u_1, \dots, u_m)$ if and only if u is partially less than v. As can be seen in Equation 4:

$$\forall_i \in \{1, \dots, m\}, u_i \leq v_i \wedge \exists_i \in \{1, \dots, m\}: u_i < v_i \quad (4)$$

Where in the above equation u and v are defined.

Subsequently, there will also be some instances where u is greater than v.

"Definition 2: Pareto optimality: A solution $x_u \in [a, b]$ is said to be Pareto-optimal if and only if there is no $x_v \in u$ for which $v=f(x_v)=(v_1, \dots, v_m)$ dominates $u=f(x_u)=(u_1, \dots, u_m)$.

Pareto-optimal solutions are also called efficient, non-dominate, and non-inferior solutions. The corresponding objective vectors are simply called non-dominated. The set of all non-dominate vectors is known as the non-dominated set, or the tradeoff surface of the problem."

Implementation and System Evaluation

This stage includes coding and testing, installation and training and the final step is system evaluation. Knowledge-driven DSS uses a knowledge base extracted from the tacit knowledge of expert domain which makes the knowledge base available for interaction with decision makers by the structure of the Multi-Objective Optimization model and the overall evaluation system. It is rule based to integrate with the data found in the system database and the decision maker's input to get the answer in planning rubber plantations.

- Checking to confirm the accuracy of recommender engine the introduction of intercropping planted with rubber. Using Ontology-based knowledge includes validation of agricultural information, agricultural economics, and the accuracy of the rule base. According to the principle of rubber plantation, using ontology-based knowledge in intercropping the ontology of the rubber plantation created consists of two parts: part 1 , the agricultural and agricultural economics data is the data of each economic crop such as harvesting season, harvesting Planting Period Planting Cost from data obtained from the public sector with reliable data storage and statistics and the experts in cropping are evaluating the validity of the criteria and parameters used in the model and rule based trust and knowledge validation mappings [47] by ontology development experts and intercropping experts. The validation solution by Mean Absolute Error (MAE) is used to calculate the rating difference between the actual and the predicted ratings.

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| = \frac{1}{n}\sum_{i=1}^{n}|e_i| \quad (5)$$

where:

$$AE = |e_i| = |y_i - \hat{y}_i|$$
$$Actual = y_i$$
$$Predicted = \hat{y}_i$$

- The data collection using a triangulation method was conducted by literature review, expert validation and

review, and user evaluation. The user evaluation focused on decision makers or users focused on decision makers' satisfaction. In order to evaluate overall satisfaction of DSS, the users were officers at various levels of the agricultural extension office such as provincial or district level from 23 districts. Thus, sampling of choice was multi-stage mixed random sampling and selection and the sampling was conducted by division of the sample into district level and purposive selection was made by officers who are responsible for giving related advice and recommendation. Statistics used in this case are mean $\bar{x}$ and standard deviation ($s.d.$).

5. Conclusion and Future Work

Ontology-based knowledge and multi-objective optimization programming to drive a decision support system for intercropping is based on constraint factors from an individual farmer for illustrating maximum income. The research methodology is divided into three phases as follows: (1) knowledge acquisition and ontology modeling. This methodology is based on knowledge's extraction from experts or specialists due to the fact of long experience based knowledge; (2) ontology development and recommender system is a creation of ontology as it is designed as well as a preparation of instance and ontology mapping as rules governing intercropping and evaluation and assessment of ontology; and the last stage is (3) design of multi-objective programming in order to obtain the answers of what types of plants should be planted, the proportion of each co-planting plants, overall generated revenue and production cost. The future work is knowledge acquisition and ontology modeling which is an important step to collect knowledge from experts and published papers issued by Department of Agriculture Extension, Ministry of Agriculture and Agricultural Co-operatives before being used for developing ontology at Phase II.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

Many thanks to Rajamangala University of Technology Srivijaya who sponsored the research grants and, also thanks to Nakhon Si Thammarat Agricultural Extension Office for the information and their time to explain about the problems of farmers.

ABSTRACT

Listening to auditory stimuli during study can give positive and negative influence on human cognitive processing. Thus, it has attracted researchers to conduct studies using various types of auditory stimuli. Some researchers believe that Mozart music and white noise are able to give positive influence on cognitive performance. However, most of the past studies gave more attention towards spatial task. Very little studies have been made on the effect of Mozart music and white noise towards memorizing task. Besides, the effect of these auditory stimuli on task difficulty has also not been studied deeply. Hence, the aims of this study were to investigate the effect of Mozart music and white noise on memory performance with different task difficulty levels; and to propose an effective background stimuli condition for memorization. Experiments have been conducted involving 60 healthy adults that required them to memorize the visual memory task with two difficulty levels; i.e. easy and difficult. Brain signal was recorded during memorization duration using 10-20 electrode placement system of electroencephalography (EEG) machine. EEG is a neurological test for measuring and recording the electrical activity of the brain. The effect of sound stimuli on memory performance was evaluated based on memorization test score and brain activity. The wavelet approach was used in processing the EEG data. Based on the memorizing test score result, the subjects are able to memorize better when listening to white noise compared to Mozart music at different difficulty levels. Listening to auditory stimuli can influence the electroencephalography pattern and brain activity. The level of sensory processing and attention increases when listening to white noise which cause the increase of relative gamma (easy level: p-value = 0.005; difficult level: p-value = 0.007) and beta power (easy level: p-value = 0.001; difficult level: p-value = 0.003). Thus, in this study, it is found that listening to white noise is far more effective in memorizing process compared to Mozart music.

1. Introduction

This paper is an extension of work originally presented in 2016 IEEE EMBS Conference on Biomedical Engineering and Sciences [1]. Listening to background music/sound during performing cognitive tasks can improve the brain functions, develop creative thinking, make people relaxed, relieve mental stress, and increase work efficiency [2]. Working and studying in silence condition for a long time make people easily to feel sleepy, bored, stress, and lost attention. This condition may affect their performance in solving the tasks. Hence, one of the alternatives to make people enjoyable and effective during doing their activities is by listening to auditory stimuli. Auditory stimuli can be defined as events and things that evoke a specific functional reaction in a tissue or organ i.e., the sound that affects our auditory sensations. The auditory stimuli are stimulated when sound cause pressure changes in air or other elastic medium. Usually, the loudness of sound is measured in decibels and travel to the ears as waves. Human ears can detect any sounds within the range of 20 to 20 000 Hz. Then, the detected sounds are converted into neural impulses as a result from transduction process. Deafness and hearing loss can occur if the disruptions happen during transduction process. The sounds can be categorized into many types either comes from man-made or natural. The examples of sounds are birdsong, bell sounds, musical sounds, water sounds, and nightlife sounds. Some of the sounds have a beneficial influence on human emotion, psychology, and

*Corresponding Author: Rubita Sudirman, Faculty of Electrical Engineering, Universiti Teknologi Malaysia, 81310 UTM Johor Bahru, Johor, Malaysia
Email: rubita@fke.utm.my

congenital. Thus, many research has been carried out to investigate the effect of sound on human cognition either for children or adult [2-5]. Besides, the development of the biomedical equipment especially the brain modalities i.e. electroencephalography (EEG), magnetic resonance imaging (MRI), computed tomography (CT), magnetoencephalography (MEG), and positron emission tomography (PET) have facilitated the study.

In this globalization era, an education plays the important role for produce a better, independent, successful and knowledgeable people. The knowledge are important and powerful part of human life. Knowledge is an understanding, awareness or information that has been obtained by study or experience by learning, discovering or perceiving, and that is either in a person's mind or possessed by people [6]. Focusing on students life, every day they are learning and expose too much of new knowledge, such as information, facts, descriptions or skills. Examples of student learning activities are memorized the formula, facts, structure of the design, reading, and drawing. All of this requires them to have a better and good memory in order to process the input information. As we know, education system enforced the students to undergo the test, quiz, and examination to identify and evaluate their level of the learning process. The performance of the students in answering the task has depended on their memory ability to interpret the information and knowledge that they have learned and obtained before.

Attention on the student's problem which is some of them is able to recall the required information during the examination, while, some of them are unable to retrieve what they had learned. This situation has relation with their memory capacity to store the information. One of the suspected factors that resulted in this condition is due to wrong chose of study environment. Usually, the students are interested to study in silent or listening to auditory stimuli condition. Thus, this present study aims to help the students by proposing an effective study environment especially for memorizing purpose. The effective study environment is the condition that can give the positive influence on student performance. According to Soderlund et al., 2010 the human cognitive performance can be influenced by the auditory stimuli but depends on the human population, types of auditory stimuli and cognitive task involved [7]. They had done a study to investigate the effect of white noise on inattentive and attentive children when performing episodic verbal free recall test. The test assessment was done in two different conditions: (1) low noise: no noise, and (2) high noise: 78 dB of white noise. Difference influence has been found between these two children groups which are the performance of inattentive children was improved when listened to white noise but not for attentive children. Based on the Soderlund et al., 2010 [7] findings, we are inspired to discover the effect of environmental factors on memory performance for the normal adult population. Knowing from the previous research that the Mozart music and white noise are able to give the positive influence on people's performance, thus, it's were chosen as auditory stimuli in this present study.

Mozart music is a popular auditory stimulus among the researcher because of its highly structured organization which has potential to excite the same cortical firing patterns that used for cognitive processing [8]. It was considered as a highly structured for three different reasons. First, its harmony has approximately 8-bar phrases that separated by definitive cadence points which are easy to distinguish the differences of each section. Besides, the beats were divided equally at a constant tempo. The last reason is it used various types of equipment or voices but often combined into a single. Shaw et al., 1985 reported that the effect of music can be represented by Trion Model [9]. This model suggests that the music has the ability to alter the synaptic weights of neurons in specific patterns due to Hebbian learning principles [8]. In this principle, the brain regions that involve for learning process was explained. They believe that when listening to Mozart music or any music, the neuron firing becomes stronger and each time the new information coming to the memories it's able to process the information actively and decrease the losing of information. White noise can be recognized by 'sh' sound. Some of the researchers reported that listening to it during performing the task able to give a positive influence on cognitive processing [10]. The explanation on how the white noise, improves the cognitive processing represented by the stochastic resonance concept [7]. The simple example to describe this concept is when the weak signal (e.g. visual stimulus) enters the sensory memory it becomes detectable when white noise is added to the signal [7]. The white noise was interacting with the weak stimulus and pushing it or in simple word, it gives motivation to people to give more attention to the required task. Thus, their performance is increase. Stochastic resonance improves the touch, auditory, and visual sensory. The previous works showed that the white noise has improved the human performance in the verbal task, arithmetic task and the spatial task [11-12].

Generally, the human memory can be categorized into three types that are the sensory memory, working memory/short-term memory and long-term memory [13]. The information or stimuli were caught-up by sensory responsiveness and will be stored either in working memory or long-term memory. The human memory easily to be disturbed by external and internal factors such as interference, storage failure, environmental condition, task difficulty, and emotional factors [13-14]. These factors can lead to losing of information. Discovering the effect of sound on memory performance is an interesting work, thus has attracted some researchers to conduct the study [2, 15-16]. The different style of music/sound gives different influence on memory performance as reported by them. In Boyle and Colheart, and Fu and Kuan, study, the subject required to memorize the task under three different condition; no music, listening to gentle music and heavy music. They had found that the gentle music able to give a positive influence on memory performance compare to the others two conditions. The study by Zhang *et al.* in 2009 was purposely to investigate the effect of music familiarity on memorizing task under different difficulty level [2]. Their study used visual working memory task with two difficulty level (easy and difficult) with four different types of background condition (no music, Chinese,

English, and French). The memorizing test score result revealed that the subject had better performance under no noise/silence condition compare to the others. In this present study, the same task assessment as Zhang *et al*., with some modification was used. A visual memory task that consisted image and number is used in order to avoid the effect of language on subject's performance. The number of items that need to remember is reduce from 15 to 10 items only. The memorizing task was involved in the experiment because it is one of the techniques that used during the learning process. This present study preferred to use Mozart music and white noise as auditory background stimuli because limited of the study had investigate its effect on memory performance.

2. Review on Past Studies

This section discuss on the past research that investigate the effect of Mozart music and white noise on human psychology and cognitive performance.

2.1. Mozart music

Mozart music was introduced by Wolfgang Amadeus Mozart in 18 centuries. It is classified as a classical music that played using pianos as the major instrument. Although this music was famous long time ago among the musicians and public, it did not attract the researchers until this 20th century. Rausher is the first person who interested to conduct an experiment to investigate the effect of Mozart music on spatial tasks [17]. They reported that listening to Mozart music for 10 minutes had enhanced the spatial reasoning skills. Due to that, many researchers had conducted the study to prove the findings. However, it's become a controversial issue when some of the researchers unable to prove Rausher et al., findings [17-21]. Nevertheless, the others confirmed that there was a significant difference was found in spatial-temporal performance, such as in pencil-and-paper maze tasks and paper-cutting and folding procedures compare to other environmental condition [22-24]. Up to now, the study on the Mozart effect is still being conducted by researchers as summarized in Table 1. Some of the researchers used the Mozart music as background music for solving or performing certain tasks, whereas some of them used the music alone without any task. Background music can be defined as a condition which the music is played while the listener's primary attention is focused on another task [12] White noise.

Generally, when we talk about the noisy condition, people will imagine the irritating, distracting and uncomfortable sound. The past research has reported that noise attenuates performance on cognitive tasks involving memory, reasoning, vigilance, decision making and vigilance [34-37]. They examine the effect of noise on cognitive performance by using a high volume of noise (85 dB and above). According to Broadbent's listening to the high volume (above 90 dB) of noise can lead to over-arousal, which causes an increase in stress level [34]. They claimed that listening to high-intensity background noise can irritate, disturbs and attenuates vigilance performance [34].

Smith et al., 2003, stated that the effect of noise on cognitive performance is based on three major factors, which is the type of noise, duration, and intensity (loudness) [38]. As an example, when people listening to moderate intensity of white noise (55 dB) during performing a task, there is only a small effect on performance, however, when the moderate intensity of irrelevant speech is used, it disrupted the person's performance [35-36]. Generally, noise can be divided into several types such as ambient noise, pink noise, and white noise. In this study, the white noise is selected as auditory background stimuli for memorizing the task. White noise can be defined as a sound that is artificially created by combining all audible frequencies in equal amounts [40]. According to new research, listening to the 'sh' sound or white noise consistently could boost the memory [41]. The changes in midbrain activity are examined when the people listening to white noise. This brain part is linked to the learning process and reward pathways. Table 2 shows the past research that uses white noise as stimuli.

The gap of knowledge from previous study and contribution of the present study is focused on three major criteria that are:

(i) Selection of auditory background stimuli

Most of the study focused on either one of the sounds, whether using the Mozart music or white noise on experiment except study by Bottiroli et al. that has been discussed before [12]. The intensity of white noise selected in previous research mostly around 70 dB and above. Based on Zhang et al., (2009), they state that the volume greater than 70 dB will increase the heart rate, blood pressure and cause other responses, thus, it does not suitable to listen for a long duration at this intensity level.

Table 1: Past research of Mozart effect on human

Study	Condition and intensity level	Task	Analysis
[25]	Silent and listen to Mozart, 60 dB	Visual oddball	EEG signal
[26]	Listen to Mozart music and Brahms Hungarian, 60-70 dB	Spatio-temporal rotation task	EEG signal and test scores
[27]	Silent and listen to Mozart music (played normally and reversely)	Attentional blink task	Test scores
[28]	Experiment 1: Silent and listening to Mozart Experiment 2: Silent and Chromatic scales	Visual oddball	EEG signal
[29]	Silent and listen to Mozart music	Trigonometry tests	Test scores
[30]	Mozart music	Psychological stress test, tinnitus handicap inventory and visual analog scale	Test scores
[31]	Listening to Mozart music and Koto music, 55 dB	Science quiz	Test scores and hedonicity of music
[32]	Silent and listen to Mozart music, 60-70 dB	-	EEG signal
[32]	Listen to Mozart (pre-music, during music, Post-music), 60-70 dB	-	EEG signal and heart rate variability
[33]	Silent, listening to Mozart music and Beethoven music	-	EEG signal

Table 2: Past research of white noise effect on human

Study	Condition and intensity level	Task	Analysis
[42]	Baseline, recorded ICU noise exposure, ICU noise and mixed-frequency white noise exposure	-	Measures of sleep architecture, total numbers of arousals, arousal indices, noise parameters and sleep quality
[43]	Silent and listen to white noise	Compound remote associates task, Hopkins verbal learning test and Rey-Osterrieth complex figure test	Test scores
[44]	Listen to white noise, novel sound and high frequency tone	Pitch difference between the target and standard stimuli (Easy and hard)	EEG signal
[45]	Silent and listen to white noise	Easy task: verbal task Difficult task: self-performed mini tasks	Test scores
[10]	Experiment 1: Silent and listen to white noise Experiment 2: Silent and listen to white noise at the left, right and both ear sides	Experiment 1: Dichotic listening Experiment 2: Visuospatial working memory task	Test scores

Contribution 1: The effectiveness between of Mozart music and white noise on memory cognitive task are investigated in this study. The sound intensity is control at medium level (40 to 55 dB) which is safer for long-term exposing to sound especially for study activity.

(ii) Type and difficulty of assessment task

Effect of listening to Mozart music and white noise on task difficulty level (i.e. easy and difficult) does not extremely discover by researchers. Furthermore, the previous research mostly focused on the spatial task ability compares to memorizing process.

Contribution 2: Different difficulty levels (i.e. easy and difficult) of memory task are used in this present study. Thus, the effect of sounds on subject's performance can be investigated either it gives same influence or not for different difficulty level. The memory task is used instead of spatial task because to help the student to find the suitable sound to be listened during memorizing. As we know, memorizing technique is always apply in the study.

(iii) Measurement of memory performance

The effect of sound on memory performance mostly based on cognitive test score. Less of research focused on the effect of the brain activity. Besides, the relation between the score results and activity of the brain was not further discussed and explored.

Contribution 3: The findings of this study are discussed based on two measurements that are memorizing score result and pattern of EEG signal. The EEG machine was used to record the electrical signal of the brain. The activation of the brain rhythm during task-performing are taken account for explaining on how it gives influence on memory ability to store the input information.

3. Theoretical

3.1. Human Brain

Brain is one of the largest, unique and complex organ in the human body that located in the head. The shape of the brain is like a walnut and compose of blood vessels, glial cell and millions of the neuron [49]. It is protected by the cranial bones and the cranial meninges. The weight of the adult brain is approximately three pounds or about 2% of total human's body weight [49]. It is responsible for processing the information, control our behavior, the seat of intelligence and initiator body movement. When receiving input information from the sensory organ, the brain will process the information and then sends the output to muscle. The five sensory responsiveness (touch, smell, visual, auditory, and taste) catch up the stimuli from surrounding and send to the brain to be interpreted before sending to the body for action. The brain can be divided into four main regions that are cerebrum, diencephalon, cerebellum, and brainstem [50]. Each of the regions plays their own roles. The cerebellum can be found behind and below the cerebrum. It is attached to the brain stem. It is responsible for controls motor functions, maintain the body in balance state and interpret the input information from sensory organs [50].

The brain stem is important for basic vital life functions such as controlling and regulation of respiration, cranial nerves, blood pressure, heart rate, breathing, and consciousness in the human body [49]. Besides that, it also functions as a pathway for relaying the information between the brain and the body. It consists of three smaller areas; midbrain, medulla oblongata, and pons. It connects the brain to the spinal cord. Small damage in brain stem areas can cause death. The diencephalon can be found inside the cerebrum. It consists of the thalamus and hypothalamus. It is responsible for maintaining homeostatic balance, sleep cycle, and controlling the motor activities, memories, and arousal. Other than that, it also acts as a relay station for sensory impulses that reach the cerebral cortex, which coming from the brainstem, spinal cord and parts of the cerebral hemisphere. Lastly, the largest region of the brain is

cerebrum or cerebral hemispheres that make up 85 % of human brain weight [49]. The cerebrum separated into the left and right hemisphere by longitudinal fissure. It can be divided into four lobes that are frontal, parietal, temporal and occipital. Each of the lobes represents their own roles. Table 3 describes the function of each brain lobe.

Table 3: Brain lobe functions [49]

Region	Descriptions
Frontal	Controls voluntary muscular functions, aggression, moods, motivation and smell reception
Parietal	Evaluate sensory information of pain, touch, taste, temperature and balance
Temporal	Center for abstract thoughts and judgment decisions, involve in memory processes and evaluates hearing input and smell
Occipital	Receiving and interpreting visual input

In this present study, the cerebral region is interested in evaluating the effect of mental task and sound stimuli on it. The study of the brain has started a long time ago among the scientist and philosophers in order to know deeply how does it work, factors affecting and it functions. Due to the lack of advance and modern modalities/equipment had limited the research. In 19 to 20 centuries, the brain imaging modalities are started introducing by scientists. Thus, it attracts many researchers to conduct the study of the brain.

3.2. Electroencephalography

Electroencephalography has been introduced by Hans Berger in 1920. The scientist believes that human brain generates electrical signal starting between the 17th and 23rd week of prenatal development and throughout life [51]. When the central nervous system is complete and functional there are approximately 10^{11} neurons developing at birth. This assumption has motivated the researchers to apply various type of brain modality in order to know deeply about the brain. Electroencephalography recorded the brain activities by reading the signal that picks up using metal electrode and conductive gel of the scalp. The electrical potential (EEG signal) is generated by the nerve cell of the brain in the cerebral cortex region.

The EEG comes from a combination of three words, which is electro (referring to the registration of brain electrical activity), encephalon (referring to emitting of signals from head) and gram/graphy (referring to writing or drawing) [51]. In research works, the electroencephalography is widely used by researchers compare to other brain modalities due to its ability to record the signal in a short time (milliseconds), low cost, non-invasive technique, not harmless and painful to research subjects.

4. Experimental

The experiment has been conducted at the laboratory with controlled temperature, lighting and auditory intensity level. All equipment and materials such as Neurofax 9200 of EEG acquisition machine, ECI electrode-cap, body harness, ear electrodes, ECI electrode-gel, EEG electrode paste, blunted needle, wet tissue, speaker, laptop, pen and answer sheets were prepared and provided before the experiment started. When the subject entered the laboratory room, they were asked to sit on the chair and took a rested for 5 minutes. The instruction and flow of the experiment was displayed on the laptop screen. Then, the subject was required to fill-up the consent form and survey questionnaire. Subject was prepared with all the EEG equipment and material for recording their brain signal. The simulation program was started when the subject ready to take the experiment. Subject need to undergo three different conditions while memorizing the visual working memory task. The subjects were divided equally into two groups to counterbalance the effect of environmental condition on subject performance [2, 12, 26]. Groups 1 were memorized under silence, listened to Mozart music and listened to white noise condition, whereas group 2 undergo silence, listened to white noise and listened to Mozart music condition. The sound intensity level was controlled at 40 to 55 dB to reduce the effect of loudness on them [52]. Sixty healthy (40 females, 20 males) subjects from Universiti Teknologi Malaysia at the age between 19 to 26 years old with no musical talents were involved in this study. They were selected based on mini-mental state examination (MMSE) to determine their mental conditions. Only subjects that passed the MMSE test were undergo the experiment. The flow of task require to be followed by subjects were as stated below:

Condition 1: Silent

- Memorize easy level task for 2 minutes and brain signals are record at this time.
- Rest for 30 seconds.
- Recall the task for 2 minutes.
- Rest for 1 minutes.
- Memorize difficult level task for 2 minutes and brain signals are record at this time.
- Rest for 30 seconds.
- Recall the task for 2 minutes.
- Rest while look up the scenery pictures for 3 minutes before proceed to next environmental condition.

Condition 2 and 3: Listen to auditory stimuli

- Same flows as condition 1 are used for condition 2 and 3 except during the memorizing time the subjects require to listen to the auditory stimuli.

5. Data Processing and Analysis

The brain signals were recorded during the memorizing period using EEG machine. The raw EEG signals were saved in ASCII format before processed via Matlab software. Usually, the raw EEG signals were composed of the noise signals that come from the muscle movement (high-frequency noise) and eyes blinking noise (low-frequency noise). Thus, the raw EEG signal needs to be pre-processed for filter the unwanted signal. This present study preferred to use the stationary wavelet transform (SWT) method to remove the high frequency and low frequency of noise. The db3 mother wavelet with 5 decomposition level was chosen to remove the high-frequency noise and low-frequency noise from EEG signals [53-55]. Before filtered the noises, there were 10 out of 20 EEG channels was selected to determine the effect of auditory stimuli on visual memory. The selected channels were frontal: Fp1, Fz, F8; temporal: T3, T4, T5, T6; parietal: Pz and occipital: O1; O2. The clean EEG signals were process again using db4 mother

wavelet with 7 decomposition level of discrete wavelet transform (DWT) method for obtained alpha, beta, theta, and gamma rhythm. The relative power of each frequency band was calculated.

6. Result and Discussion

This part is discuss on the results obtain from the assessment test and EEG pattern. The test scores are determine based on the correct response that answer by the subject. Meanwhile, the EEG features are extract using wavelet transform as mentioned earlier. Statistical analysis of sign test and paired samples *t*-test are used to determine the significant difference between control condition and test condition. The results has been tabulated and graphed in the following section.

6.1. Assessment test score

The answered from assessment test were only considered as correct when the filled numbers on figure was same as those were presented. The sign test with 0.05 of alpha (α) level was used to compare the median differences of correct responded between auditory stimuli condition relative to control condition. Two hypothesis has been set as below:

Null hypothesis, H_0: *p*-value > α; the median value of test score does not shows a significant different between the test condition and control condition.

Alternative hypothesis, H_1: *p*-value < α; the median value of test score shows a significant different between the test condition and control condition.

According to Table 4 and Figure 1, the subjects were able to memorize better when the white noise played for easy (mean: 8.561) and difficult (mean: 4.228) level of the task. A significant difference have been found for median test score of white noise (*p*-value: easy level = 0.009; difficult level = 0.01) relative to control condition. Although listening to Mozart music also can improve subject visual memory but it does not give bigger influence on their test score when comparing with the control condition, since no significant difference (p-value: easy level = 0.203; difficult level = 0.061) was found from the sign-test analysis. Looking at these three conditions it revealed that the subjects' memory ability was improved when listening to auditory stimuli compared to silence condition. This happened because of the positive effect of auditory stimuli on subject's mood, arousal, attention and alertness level, and sensory input processing. Bottiroli et al., 2014, has reported that listening to white noise and Mozart music during performing the mental task will affect the arousal (degree of physiological activation), mood (long lasting emotions), and listener's enjoyment which in turn influence the memory performance [12].

Table 4: Mean and *p*-value of test score result

	Easy Level		Difficult Level	
Condition	**Mean**	***p*-value**	**Mean**	***p*-value**
Control	7.281		2.912	
White Noise	8.561	0.009*	4.228	0.010*
Mozart Music	8.070	0.203	3.632	0.061

Considering the effect of task difficulty level on subjects performance, it showed that the increasing of items need to be remember had degraded the ability to memorize. The easy level of visual memory task gave better result compared to difficult task. Subjects were able to memorize better in easy level compared to the difficult level due to the number of items that need to be remembered were different for each level. In easy levels, the subjects were required to remember 2 digits number with pictures only, but for difficult task, they need to memorize the pictures with 4 digits number. In the control condition, the percentage decreased of test score for easy level relative to difficult level was about 60%. Meanwhile, 50.6% and 54.6% were found for white noise and Mozart music. The higher percentage decreased was showed by control condition compared to auditory stimuli condition. From here, it indicated that the auditory stimuli were also improved the memory performance when the difficulty level was increased, especially the white noise.

6.2. Electroencephalography pattern

The frequency domain features were extracted from the EEG signal to determine its characteristics when induced by auditory stimuli during memorizing test. The paired samples *t*-test analysis with α = 0.05 was used to identify the significant different of the relative rhythm power of auditory stimuli condition relative to control condition. Besides, the increasing and decreasing trend of the relative rhythm power of auditory stimuli condition toward control condition also discussed. The hypothesis of paired samples *t*-test is set as below:

Null hypothesis, H_0: *p*-value > α; the mean value of relative rhythm power does not shows a significant different between the test condition and control condition.

Alternative hypothesis, H_1: *p*-value < α; the mean value of relative rhythm power shows a significant different between the test condition and control condition.

Relative gamma power

Gamma rhythm (< 30 Hz) is associated with the movement, sensory processing or solving high mental task [51]. In this case study, we are focused on the role of gamma rhythm in activating sensory processing in order to fulfill the study objectives. Sensory processing is an ability of the brain to receive and response to the coming information from sense organ. The sense organs are connected to the human brain via the peripheral nervous system which allowing us to process the input information. Generally, human have five dominant sense organs which are eyes, ears, nose, tongue and skin that use for see, hear, smell, taste and touch. This sense organs contain receptor that transport the input information through the sensory neurons to the nervous system. The ability of the brain in processing the input information can be observed through the relative gamma power value.

Based on Table 5 and Table 6, the white noise (easy level: 67.522 and 65.925) had the highest relative gamma power with significance difference of easy level: *p*-value = 0.005; and difficult level: *p*-value = 0.007) compared to Mozart music and control condition. However, the Mozart music also showed

significant difference on relative gamma power for difficult task (p-value: 0.003). The relative gamma power was increased for auditory stimuli condition because of the brain need to process information that caught up by the eyes and ears. When listening to Mozart music and white noise, the brain is not only process the upcoming information from the visual but also the auditory stimuli. Different from control condition which is no sound is provided, thus the brain only need to process the information from the visual only. That is the reason why the control condition had lower relative gamma power compared to auditory stimuli conditions.

Next, comparing on difficulty level, it showed that the relative gamma power of control and white noise condition was decreased for difficult task relative to control condition. Meanwhile, the Mozart music showed the highest relative gamma power for a difficult task (64.282) compared to easy task (63.628). So, it indicated that the increases of task difficulty level for Mozart music condition will increase the sensory processing. But, for control and white noise condition, the sensory processing was decreased when the task difficulty level increased.

Relative beta power

Beta rhythm (13-30 Hz) is associated with the attention/concentration level, active thinking, focus on the outside world or solving concrete problems [51]. This study focused on the relative beta power for determining the attention/concentration and active thinking level of subjects during memorizing. Based on Table 5, it shows that the relative beta power was the highest in white noise condition for easy (117.318) and difficult (121.218) level of the task. It means that the subjects attention/concentration and active thinking level were significant improved when listening to the white noise during remembering the items as indicated in Table 6 by paired samples t-test analysis relative to control condition (easy level: p-value = 0.001; difficult level: p-value = 0.003). However, the attention/concentration and thinking level was significantly improve for the easy level (p-value = 0.004) but not for the difficult task (p-value = 0.141) when listening to Mozart music relative to control condition. Among these conditions, the findings showed that listening to Mozart music and white noise able to increase the attention/concentration and thinking level compared to silence condition.

The higher and good attention/concentration level plays an important role when working memory task was involved [56]. In this case study, the subject was only given 2 minutes to memorize all the items, so they need to give full attention on the task in order to memorize it. If they unable to focus on the task during the memorizing time, they will have problem to retrieve back the information later. That is why it is really important to have high beta rhythm during the memorizing process for getting a good test score result. As seen from the result that listening to auditory stimuli makes the subject more attentive and concentrate on the task compared to the silent condition.

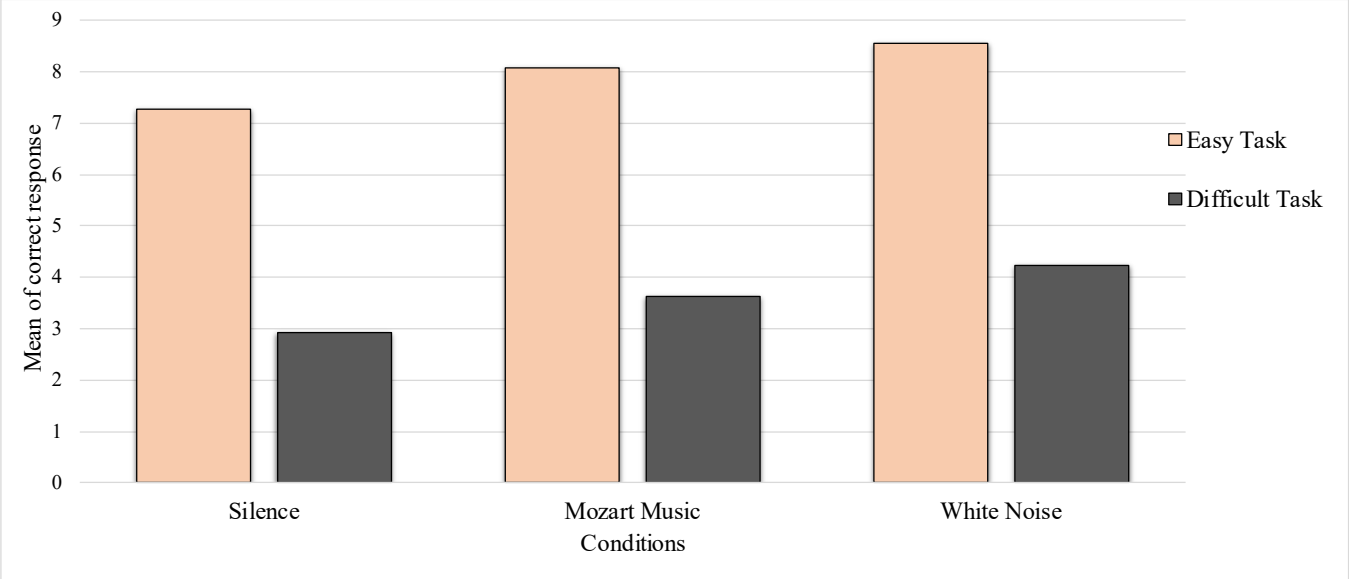

Figure 1: Graph of mean test score at silence, Mozart music and white noise condition

Table 5: Relative power of rhythms for easy and difficult task at silence, listen to Mozart music and white noise condition

	Easy Level			Difficult Level		
	Silence	**Mozart music**	**White noise**	**Silence**	**Mozart music**	**White noise**
Gamma	60.449	63.628	67.522	59.193	64.282	65.925
Beta	111.032	115.640	117.318	113.166	115.842	121.218
Alpha	165.469	167.464	166.372	168.520	169.526	165.092
Theta	225.215	222.400	224.511	227.440	224.280	226.487

Table 6: The *p*-value of paired sample t-test analysis for relative rhythm power of auditory stimuli condition relative to control condition

	Easy level		Difficult level	
	Mozart music	**White noise**	**Mozart music**	**White noise**
Gamma	0.124	0.005*	0.014*	0.007*
Beta	0.004*	0.001*	0.141	0.003*
Alpha	0.257	0.607	0.597	0.068
Theta	0.385	0.820	0.371	0.738

The relative beta power was higher for difficult task compared to easy task for all conditions. The reason was due to subject require giving more attention/concentration level during memorizing the difficult task which will increase the relative beta power. It can be concluded that the more items need to remember, the more attention/concentration level was required.

Relative alpha and theta power

Alpha and theta rhythm associated with the human emotion, mood and arousal state [51]. The frequency of 8-13 Hz (alpha rhythm) represents the relaxed awareness without attention and concentration level. Meanwhile the frequency of 13-30 Hz (beta rhythm) represents the deep meditation, access to unconscious material, and creative inspiration. According to the paired samples *t*-test result in Table 6, there was no significant difference found for relative alpha and theta conditions of auditory stimuli condition relative to control condition. It showed that no significant influence was found on alpha and theta rhythm when listening to white noise and Mozart music. However, the relative alpha power was the highest when in Mozart music condition for easy level (167.464) and difficult level (169.526) of task compared to others (see Table 5). Listening to Mozart music gave a little influence on subject relaxation state but does not give bigger impact on them since the relative alpha rhythm does not have much difference relative to control condition. The relative theta power showed highest value for control condition for all levels. It means that a little influence was found on theta rhythm roles but not too much when compared to auditory stimuli conditions. From the findings, it revealed that listening to the white noise and Mozart music during memorizing does not makes the subject to feel stress and distract.

7. Conclusion

The Mozart music and white noise has different influence on memory performance due to the different types of harmony and beats of the auditory stimuli. White noise has approximately constant harmony and beat, whereas Mozart music has slow, fast, low and high of harmony and beat. Listening to the auditory background stimuli during memorizing the task is able to increase the attention, concentration and thinking level due to the activation of the brain neuron when exposed to it. Before selecting the auditory stimuli to be listened during the learning process, the volume intensity level, type of auditory stimuli, duration, and type of cognitive task should be considered to get positive influence on memory performance. Therefore, in conclusion, this study suggested that the student should listen to white noise at a moderate intensity (40 to 55 dB) of volume during the memorizing time. The limitation of the previous study has been overcome in this present works in terms of types of task and selection of sound. It has been found that the white noise is more effective to be listened, compared to Mozart music for memory and recall ability of visual task. Therefore, the findings in this study same as the expected outcome and set in the objectives of the study.

a) The auditory background stimuli and task difficulty give different influence on the ability of subject in memorizing the visual task and electroencephalography pattern.
b) The increases of relative gamma and relative beta power has increase the level of attention, thinking, and sensory processing. No significant influence was found for relative alpha and theta rhythm for auditory stimuli condition relative to control condition.
c) White noise is effective to listen during memorizing visual working memory task due to it able to improve the memory performance.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to express their appreciation to University Teknologi Malaysia for providing the facilities and funding for this study under vot Q.J130000.2523.13H25.

Thermal transient measurement
Switched capacitor
Simulation model calibration

ABSTRACT

With the increasing integration level of electronic circuits management of the generated heat became one of the most important design aspects. Beside the semiconductor components capacitors are also affected by the elevated temperature. In this paper a new thermal characterization method is proposed adopting the thermal transient measurement technique for capacitors utilizing the capacitance itself as temperature dependent parameter. The proposed switched capacitor based circuit generates a signal proportional to the capacitance of the component and hence the temperature. The measurement method is demonstrated on self and transfer resistance measurement setups and also verified using CFD simulations. It is shown that the captured thermal transient curve can even be used to fine tune the inaccurate simulation model parameters achieving a more accurate calibrated 3D simulation model.

1. Introduction

The thermal design of electronic systems received high focus in the last decades as the increasing level of integration increases also the power densities that the designers need to face with. The primary sources of heat are often the semiconductor components, and hence there is extensive research and development on how to construct new components with lower thermal resistance, how to arrange the components appropriately in the system and how to find new cooling solutions in order to avoid overheating.

However, not only the semiconductor components suffer from the increased power densities but also the discrete components like capacitors. The elevated temperature can have an immediate effect on their electric parameters. Changing capacitance and dissipation factor values and increased leakage current usually affect negatively the performance of the overall system. In addition there are also long term consequences of the elevated operation temperature, namely the reliability of the component usually decreases as a consequence.

The operating temperature of the capacitors, just like that of other components depends on the environment, i.e. on one hand on the heating of the surrounding components, on the other hand on the internal heat generation of the device itself. If there is a significant power loss on the capacitor then its internal core temperature can even be significantly higher than the circuit board that is hosting it. For this reason there is an increasingly growing demand towards developing a methodology to measure the thermal behavior and the thermal properties of capacitors.

In order to be able to take these effects into account the thermal resistance between the surrounding components and the capacitor (the transfer resistances) and the thermal resistance between the region of the capacitor where the heat is generated and the environment (the self-resistance) should all be characterized

For thermal engineering of discrete capacitors simulation is the primary method of investigation and characterization [1] although analytical calculations based on simplified models are sometimes also provided in application notes [2-4]. Experimental results are only rarely mentioned in relevant papers or datasheets, although the numerical results should always be verified using experiments.

Key problem is that the core temperature of the capacitors is hard to accurately measure in-situ. Most of the published measurement solutions utilize embedded thermocouples [5] or use infrared temperature sensors focused on a hole drilled in the casing of the component. But all these methods do modifications in the device structure. The published nondestructive methods simply measure the surface temperature only and use approximate calculations to guess the internal temperature of the capacitor. The common issue of all these measurement solutions is the high uncertainty and low reproducibility because of the badly defined sensor placement.

This paper is an extension of the work originally presented in EPTC 2016 [6].

2. Electrical test method

In case of semiconductor components the characterization of the thermal impedance may occur either by using some steady state solutions or more commonly by using the thermal transient measurement [7] method. Although in some cases the junction temperature can be measured using infrared imaging as well, the most commonly used solution is the electrical test method for its simplicity and accuracy.

In case of the electrical test method the inner temperature of the component is measured by utilizing a temperature dependent electrical parameter of the chip itself, like the forward voltage of a constant current biased p-n junction or the threshold voltage of a MOSFET device. This makes the thermal characterization of these components quick and nondestructive and also enables the measurement of the transient response in order to characterize the time domain behavior of the device besides the thermal resistance.

A thermal transient measurement gives information not only about the thermal resistance of the components, but as the time constants of the cooling depends on the building materials and the geometry of the device, it can also reveal structural information.

The output of the thermal transient measurement is usually a cooling curve, showing the inside temperature of the device, continuously from a hot steady state temperature to a cool steady state temperature. Some basic thermal parameters can be calculated from this curve directly. As the heating power is known (P) the junction to ambient thermal resistance can easily be calculated from the peak temperature read at the beginning of the cooling curve (T_J) and the environment temperature that is practically equal to the junction temperature after it has cooled down (T_{Env}):

$$R_{th} = \frac{T_J - T_{Env}}{P} \quad (1)$$

Utilizing the whole captured thermal transient data more sophisticated measurements can be implemented using the transient dual interface method as it is described by the JEDEC JESD51-14 measurement standard.

Finally with appropriate mathematical transformations [8] the time constants of the cooling curve can be identified and a one dimensional equivalent RC network can be constructed, where the thermal resistances and thermal capacitances can be associated to the different physical features in the structure.

In order to do thermal transient measurement three mandatory criteria has to be fulfilled:

- An appropriate temperature sensitive electric parameter (TSP) must be found.
- A known heating power must be applied on the component to elevate its temperature.
- The heating power must be switched off abruptly and the transient response of the TSP has to be captured.

If a measurement setup can be constructed that fulfills the above three criteria, the same methodology could be applied for the thermal characterization of discrete capacitor components. In the following sections a possible implementation of the thermal transient measurement for capacitor components will be discussed.

2.1. Temperature measurement

The capacitor temperature can also be measured with an electrical measurement but it needs to be considered that selecting the appropriate temperature dependent electric parameter is a key for the good measurement results. Most of the electric parameters of the capacitors are typically temperature dependent e.g. capacitance, dissipation factor (tanδ) and leakage current.

Any of the electric parameters of a capacitor could be selected for temperature sensing, but it always needs to be considered that unlike in the case of semiconductor chips, where both the dissipation and the temperature dependent electric parameter are well localized, in case of capacitors some parameters might depend on the temperature of several different sections of the structure that not necessarily have the same temperature. In such cases a weighted average temperature is perceived that may or may not be representative to the real device temperature.

The construction of the various capacitor types (electrolytic, tantalum, ceramic and foil capacitors) are different and accordingly not only the electrical, but their thermal behavior is also different.

Due to the significant temperature dependence of the electrochemical properties of the electrolytes, the electrolytic capacitors are the most affected by the temperature [9]. The increasing component temperature decreases the viscosity of the fluid leading to higher charge transfer capability. As a result the equivalent serial resistance (ESR) the impedance and the dissipation factor all decrease. The leakage current however shows significant increase with the temperature. Manufacturer datasheets reported even an order of magnitude change in the leakage current for 100°C temperature change. The capacitance also shows high temperature dependence, but the breakdown voltage and the serial inductance are not significantly affected by the temperature.

The tantalum electrolytic capacitors show similar thermal behavior, but the temperature dependence of the capacitance is lower. The ESR also decreases with the temperature; this dependence is reverse proportional to the ion concentration in the electrolyte. As a result tantalum capacitors with higher ESR show also higher temperature dependence. The leakage current is significantly dependent on the temperature.

The temperature dependence of ceramic and foil capacitors are both primarily defined by the type of dielectric material, i. e. the polymer and ceramics type. The higher permittivity materials show higher temperature dependence. The Calss-1 ($\varepsilon<200$), capacitors show limited or no temperature dependence, while Class-2 ($\varepsilon \approx$ 200 to 10000) devices show high temperature dependence, often not linear or not even monotonous.

Finally the capacitance of the foil capacitors show either positive (Polyester) or negative (Polystyrene and Polypropylene) temperature dependence.

2.2. Capacitance as a temperature dependent parameter

It is visible that there are numerous options for the selection of the temperature dependent parameter, but we wanted to select one that can be used for various capacitor types. We selected the most obvious parameter that almost always shows significant temperature dependence, this is the capacitance.

The temperature dependence of the capacitance is mainly based on the temperature dependence of the dielectric material

used in the structure, hence its location is well defined in the component. It has to be noted however that due to the relatively low thermal conductivity of the materials in the capacitor relatively high temperature gradients can arise inside the device, thus the measured temperature is an average value.

As a demonstration of the concept a couple of different capacitors have been selected with different capacitance values and voltage ratings and were calibrated. For the calibration the capacitors were put in a climate chamber, the temperature was increased from 10 to 90°C in 10°C steps. At each temperature level the capacitance value was measured with a simple multimeter repeatedly until we did not see further change in its value. When the capacitance value stabilized we could assume that the component stabilized at the environmental temperature and the capacitance value was registered. This low accuracy measurement method was already sufficient to give a rough picture on the temperature dependence of the selected components. In *Figure 1* and *Figure 2* the relative change of the capacitance is plotted as the function of temperature.

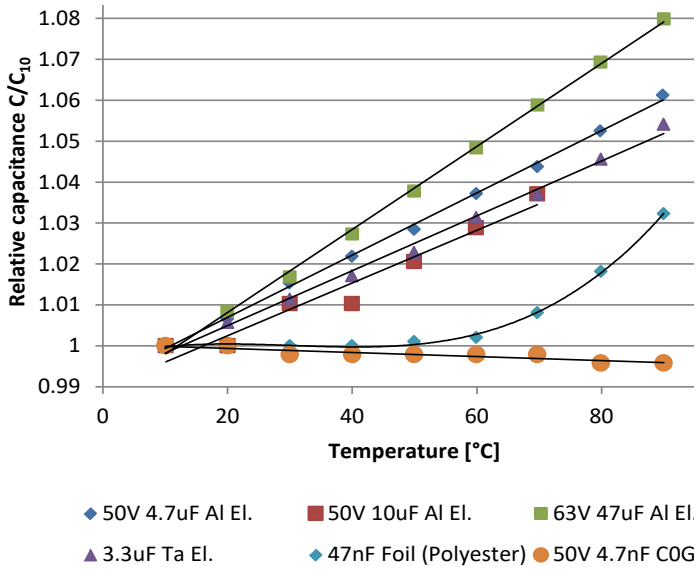

Figure 1 Temperature dependence of various capacitors measured with a simple multimeter, low dependence

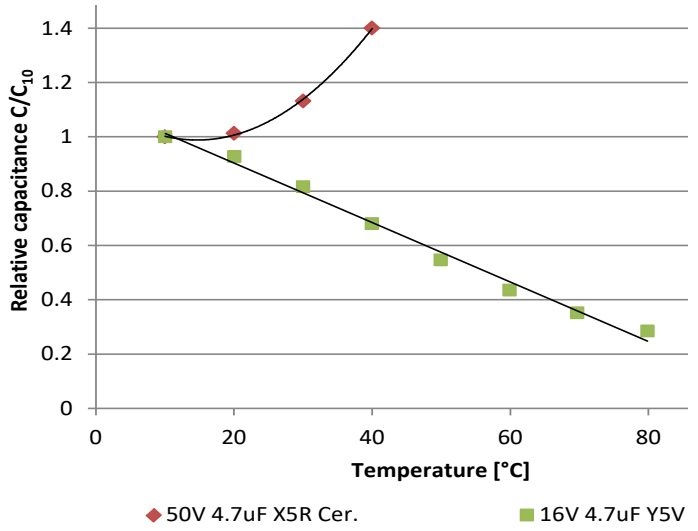

Figure 2 Temperature dependence of various capacitors measured with a simple multimeter, high dependence

The different electrolytic capacitors, both the Aluminum and the Tantalum types had similar magnitude of temperature dependence, the capacitance increased linearly by 5-8% in the 10-90°C range.

The ceramic capacitors showed very different temperature dependence depending on their classification, while the polyester film capacitor showed strong nonlinearity.

2.3. Applying heating power

After the temperature dependent electrical parameter has been selected one must find a way to heat up the component. The heating power is either generated in the component itself (self-heating) by the ripple current, or by an external component (cross-heating). Both cases can be examined with appropriately selected electrical and mechanical setups.

3. Experimental setup

Although the accuracy of a simple multimeter was sufficient for the demonstration of the temperature dependence; in precise measurements a more sophisticated instrumentation is needed. Moreover, in order to be able to measure the thermal transient of the component, the temperature needs to be measured with a relatively high frequency.

On the other hand measuring the absolute value of the capacitance is not required. For our application it is enough to produce a voltage signal that is proportional to the change of the capacitance, hence the change of the device temperature. It has to be noted however that for accurate self-resistance measurement the heating and sensing points must be at the same geometrical location otherwise the results will be distorted. For optimal interfacing to our existing thermal transient measurement system the optimal transient signal has to be in the 0...5 V voltage range.

After considering the available options we found that a switched capacitor system can be used to generate the required signal with high flexibility to adjust to various capacitance values.

The high level block diagram of the measurement circuit is shown in *Figure 3*.

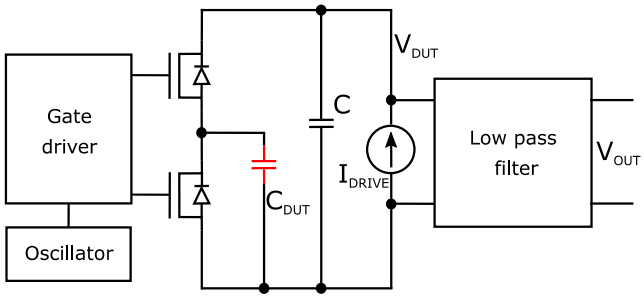

Figure 3 Block diagram of the experimental measurement setup

By driving the MOSFETs with non-overlapping clock signals the tested capacitor (C_{DUT}) is being periodically charged and discharged. The average current transferred towards the measurement ground is proportional to the DUT (Device Under Test) capacitance (C_{DUT}), the switching frequency (f) and the applied voltage drop (V_{DUT}). The switched capacitor can be represented by an equivalent resistance:

$$R_C = \frac{1}{fC_{DUT}} \quad (2)$$

In the arrangement presented in *Figure 3*the capacitor C is charged with a constant current I_{drive}, and discharged by the switched capacitor circuit. In equilibrium state the average charging current is equal to the discharging current:

$$I_{drive} = \frac{V_{DUT}}{R_C} . \quad (3)$$

Hence the voltage drop is inverse proportional to C_{DUT} capacitance:

$$I_{drive} = \frac{V_{DUT}}{f C_{DUT}} . \quad (4)$$

It has to be noted that the pulsating discharge current causes periodic voltage variation on capacitance C. For optimal operation capacitance C must be significantly higher than C_{DUT}, in order to minimize the voltage drop when the charge sharing happens between the two capacitors. Nevertheless it also limits the settling speed of the circuit, so it's appropriate sizing is critical. In the current experiments the value of capacitor C was selected to be 10x C_{DUT}, and an appropriately sized filter has been utilized to provide an acceptable noise level at the output. Finally the output signal V_{out} is proportional to the C_{DUT} capacitance and to measure its temperature dependent value it is connected to one of the measurement channels of a thermal transient tester (T3Ster) equipment.

The circuit parameters can be adjusted to be used with various capacitor values. The actual measurement setup was optimized for capacitances in the 0.1 nF… 1 µF range. The oscillator frequency is freely adjustable in the 10 kHz..1 MHz range and the cut off frequency of the filter was selected to be 5 kHz hence the useful thermal transient should start after 1 ms.

The measurement circuit can be easily adjusted to smaller capacitances, but for higher capacitance values the switching frequency would be too low and the useful bandwidth of the transient signal would be insufficient. For higher capacitances a different measurement approach should be selected.

In this paper the measurement method is presented with three slightly different measurement arrangements, providing examples for transfer and self-resistance measurements, and demonstrating that the measurement of both the heating or cooling transient is possible.

The first measurement setup demonstrates the transfer R_{th} measurement. A 33 nF foil capacitor was selected as DUT that was fixed to a 5 W ceramic power resistor as a heat source. The measurement arrangement is shown in *Figure 4*. In this setup the transfer effect is expected to last long. In order to cancel the effect of the air movement the test structure was put in a still air chamber (a one square feet size standard measurement environment). 10mA current was applied on the capacitor and the switching frequency was adjusted to achieve about 1 V voltage drop at room temperature. At t=0 s 1.5 A heating current was applied on the resistor generating approximately 3 W of heat. In order to be able to calculate the thermal resistance of the structure the thermal transient curve needs to be captured from one steady state to another. In the current measurement setup 1800 seconds were required to achieve complete steady state after the heating switched on.

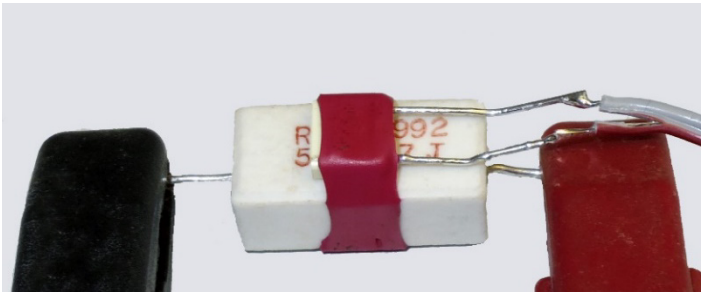

Figure 4 Transfer resistance measurement setup

For the second experiment a 100 nF ceramic capacitor was selected with X7R dielectric material. The leaded capacitor was soldered to a test PCB panel with different pin lengths and the effect of the pin length on the cooling transient was investigated. A photo of the measurement setups is shown in *Figure 5*. For the measurement similar sensing parameters were selected as for the foil capacitor: 10 mA sensing current was applied and the switching frequency was adjusted to obtain a voltage drop of about 1 V. In this case the device was heated up by applying a higher current across the switched capacitor. The higher average current caused a power loss on the ESR of the capacitor and hence heated it up. By applying 60 mA heating current the voltage increased significantly and the dissipation on the capacitor was about 0.5 W. The heating current was applied on the component for 100 seconds, then the heating was switched off and the transient measurement was immediately started and a 120 s cooling transient captured.

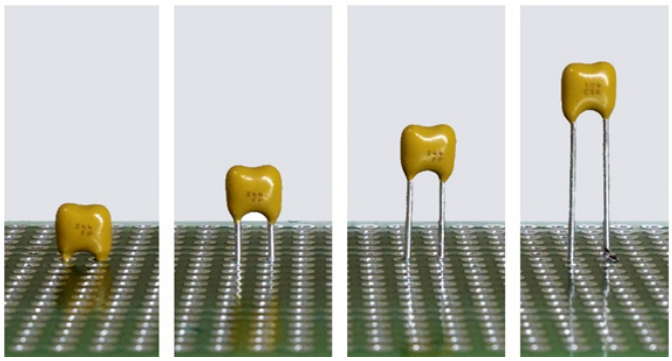

Figure 5 Thermal impedance measurement setups with different pin lengths

In the final experiment the same mechanical arrangement was used as shown in *Figure 5*, but only with the shortest and longest pin configuration. In this case the heating transient was captured instead of the cooling one. 70 mA heating current was selected and the switching frequency was adjusted to set the voltage drop to about 4 V. After switching on the heating a 200 s heating transient was captured. This time was sufficient for the structure to achieve steady state.

Before presenting the results of the experiments we show how the measured voltage values will be converted into temperature values.

3.1. Temperature sensitivity calibration

In order to transform the captured voltage transient into temperature transient the temperature sensitivity of the measured

signal needs to be calibrated. The temperature sensitivity calibration was straightforward in case of the first two experimental setups. The transient change of the capacitances were captured in a low power state, when the applied dissipation was practically negligible; only about 10 mW. In this state the temperature difference between the core of the capacitor and its environment is negligible, hence in steady state we can assume that the core temperature equals to the environment temperature.

For the calibration the capacitors were placed in a climate chamber and the electrical parameters of the driving circuit were set exactly the same as during the measurement. The chamber temperature was adjusted between 15°C and 85°C in 10°C (5°C for the ceramic capacitor) steps, and the output signal was registered at each steps after both the temperature and the output signal have stabilized.

The resulting calibration curves are shown in *Figure 6*. The data points corresponding to the foil capacitor (red dots) fit well on a linear curve (red dashed line) with a slope of 2.16 mV/°C. The temperature dependence of the ceramic capacitor however shows significant nonlinearity. In the measured temperature range this temperature dependence could be fairly approximated with a fourth order polynomial, but this does not guarantee that outside of the characterized range it is still a valid approximation. It also has to be noted that the temperature dependence is monotonous in the measured range in both of the cases. The monotony of the calibration curve is a primary requirement to be able to use the curve for voltage-temperature transformation.

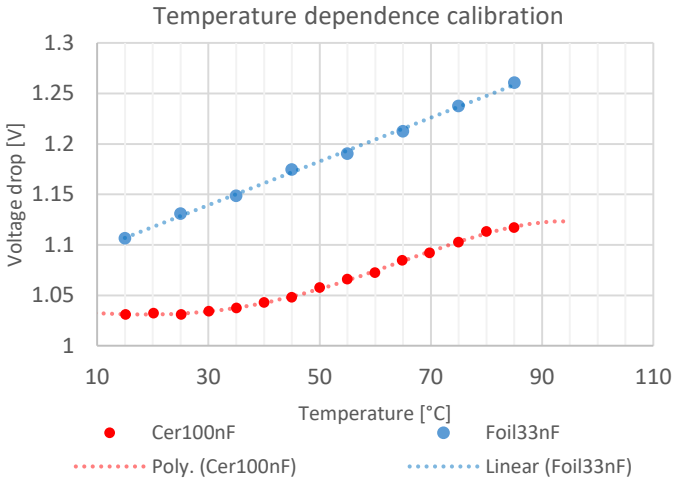

Figure 6 Temperature sensitivity calibration curves of the two capacitors at low power level

The TSP calibration for the third experiment is more challenging. In this case the heating transient of the component was captured, when the applied dissipation was high (0.28 W). Due to the significant junction to environment thermal resistance of the component there is a considerable temperature difference between the core temperature of the component and the regulated environmental temperature. In order to overcome this issue the device was also put in the environmental chamber, but now in unpowered state.

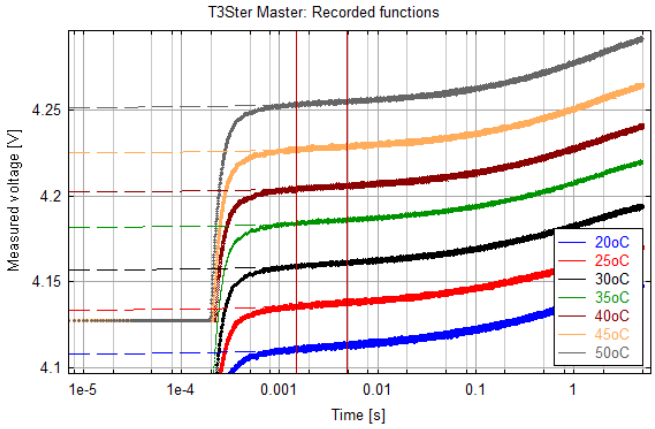

Figure 7 Measured short switch on transients of the ceramic capacitor at several environment temperatures

At each temperature level after the temperature has stabilized the powering of the capacitor was switched on and a short heating transient was captured. Just after switching on, the capacitor temperature is still equal to the chamber temperature, but immediately starts to increase. The captured transient responses are shown in *Figure 7* at a few environment temperature levels. In the initial section an electric transient can be observed, which is not related to the component temperature, only caused by the change of the electrical operating conditions. After about 1 ms the signal value is proportional to the temperature. In order to approximate the voltage drop just after turning on the heating, a square root function was fitted on each transient responses between 1.5 ms and 5 ms. and the voltage extrapolated to t=0 s time. The square root fitting is a widely used initial electric transient compensation method in case of semiconductor devices, where the heat generation is localized to the surface of the semiconductor chip. In case of the capacitor component where the heat is mostly generated in the core volume the validity of this approximation is questionable, but it has only a minor effect on the final results.

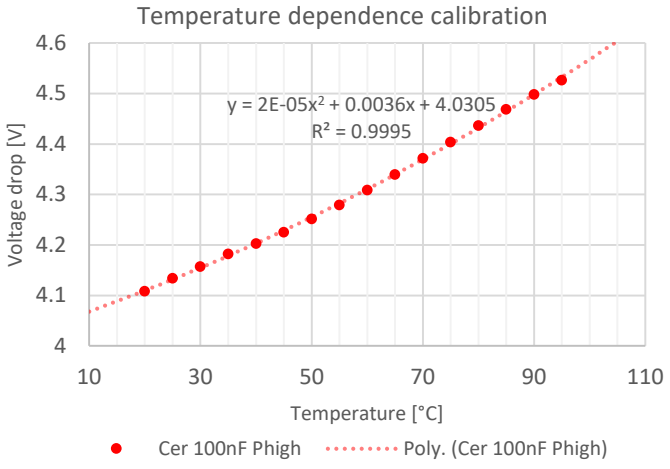

Figure 8 Temperature sensitivity calibration curve of the ceramic capacitor at high dissipation

The calibration was done between 20°C and 95°C in 5°C steps. The resulting calibration points are shown in *Figure 8*. The experienced nonlinearity was small, a second order curve fit well on the measured data points.

The overall time required for the thermal transient measurement of a single capacitor is mainly defined by the calibration time. The measurement time depends on the time constants of the test structure, but in case of good cooling it can be as low as a few tens of seconds. Meanwhile the calibration is a rather time consuming task as the environment temperature needs to be changed, waiting until the device temperature also stabilizes and then the corresponding voltage registered. This process often takes more than an hour for a single calibration. However, the calibration task can be done in parallel on high number of devices achieving a good overall throughput.

4. Measurement results

Another experiment is also presented in this paper in order to demonstrate the transfer resistance measurement, where the heating is coming from external heat source, and the capacitor core temperature is captured using the switched capacitor circuit. After the temperature sensitivity calibration the captured raw data could be transformed into temperature response as it is shown in *Figure 9*. Despite the switching mode operation of the circuit the noise level of the measured signal is reasonably good. The noise RMS (Root Mean Square) was about 0.2°C in all measurements.

As it is expected the initial section of the curve is completely flat, there is no temperature change measurable until 3 seconds. The heat generated by the resistor needs this time to propagate to the capacitor. As the thermal coupling in the experimental setup was much stronger than in normal applications, normally an even longer propagation time can be expected. Consequently if the goal is to measure only the transfer resistances the switching frequency can be significantly reduced to allow the measurement of much larger capacitance values, or the filter frequency can be reduced to achieve lower noise and more accurate temperature reading.

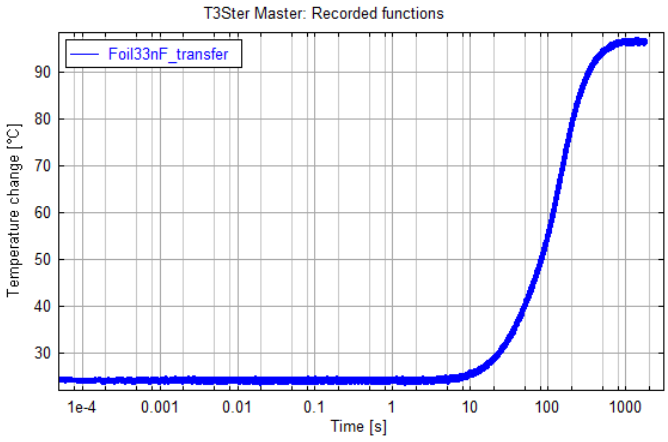

Figure 9 Temperature transient curve for transfer heating of the foil capacitor sample

The goal of the second experiment was to prove that the measured signal is in fact temperature transient and hence it is dependent on the thermal resistance of the structure. The different pin lengths were representing different thermal resistances between the capacitor and the hosting PCB. *Figure 10* shows the measured temperature transient responses. It is clearly visible that the longer the pin was the higher temperature change was measured. This also proves that one of the main heat flow paths in such arrangements is the conduction through the pins to the PCB. It has to be noted that in case of the red curve the calculated temperature was above 90°C, which is beyond the calibration range. As a consequence the calculated temperature in this range is expected to be inaccurate.

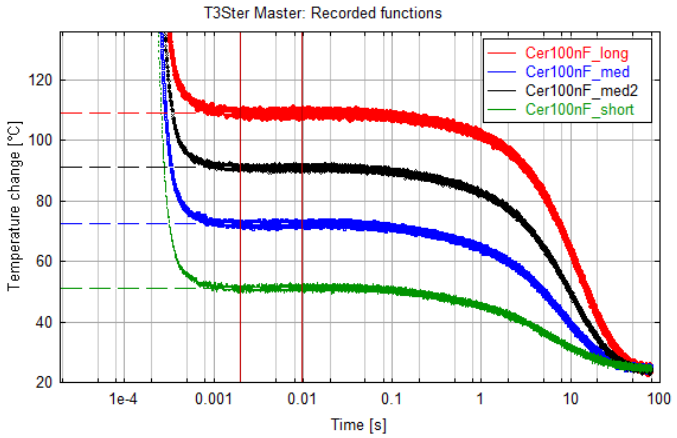

Figure 10 Cooling transient curves measured on the ceramic capacitor with different pin lengths

As opposed to the transfer heating measurement the temperature change starts much earlier in case of self-heating. The end of the electric transient is about 1 ms, and the valuable thermal signal starts soon after it. This shows that if the heated and measured points overlap, then the response speed of the measurement circuit becomes more important. How much information we lose that depends only on the internal thermal resistance and capacitance of the capacitor structure.

In order to obtain a more accurate thermal transient curve, good enough for further post-processing the parameters of the measurement setup were further optimized in the third experiment. We found that instead of the cooling curve that is most commonly used in case of testing semiconductor components, the heating curve provides a better signal. The temperature sensitivity is higher with lower nonlinearities, ensuring better signal to noise ratio.

The captured heating curves for the short and long pin scenarios are shown in *Figure 11*. It can be observed that the initial section of the two curves overlap perfectly, and split up only after about 2 seconds. In the initial section the heat experiences the same physical structure. The difference appears when the heat arrives to the PCB in case of the short pin arrangement but it needs to pass through longer pins representing higher thermal resistance when the pin is long.

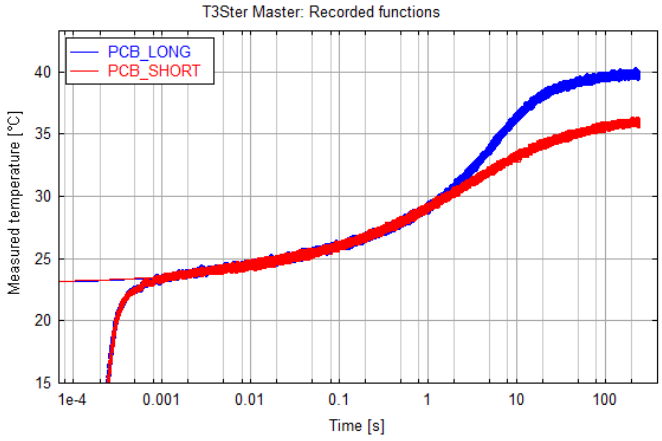

Figure 11 Measured heating transient curves of the ceramic capacitor with long and short legs

With the evaluation of the thermal transient measurements a one dimensional Cauer RC model can be constructed that in case of semiconductor components not only provide a good behavioral model, but structural information can also be extracted from it [8]. The structure function [10] is a graphical representation of the identified equivalent Cauer RC network. It plots the sum of the thermal capacitances in the function of the sum of the thermal resistances from the source of the heat towards the ambient, in cases of one dimensional heat flow that is a very good approximation in most of the practical cases. The resulting curve helps in interpreting the larger data sets. The steep sections in the structure function represent a physical layer with high added thermal capacitance but low thermal resistance that corresponds to a good thermal conductor material. On the other hand the flat sections of the curve represent high resistance with low added capacitance, hence a thermal insulator. In case of real one dimensional heat flow path the subsequent layers can be identified based on the corresponding slope on the curve and hence the structure can be analyzed.

4.1. Verification with simulation

The thermal transient measurement of the capacitor provided realistic transient curves, and the effect of the change of pin length could also be clearly identified. However the validity of the curve still needs to be proven. We decided to build up the detailed 3D model of the capacitor and compare the simulated and the measured thermal transient responses.

As we did not have detailed structural information from the manufacturer we cross sectioned the capacitor to identify the important features and measure their sizes. A cross section picture of the capacitor and the built simulation model can be seen in *Figure 12*.

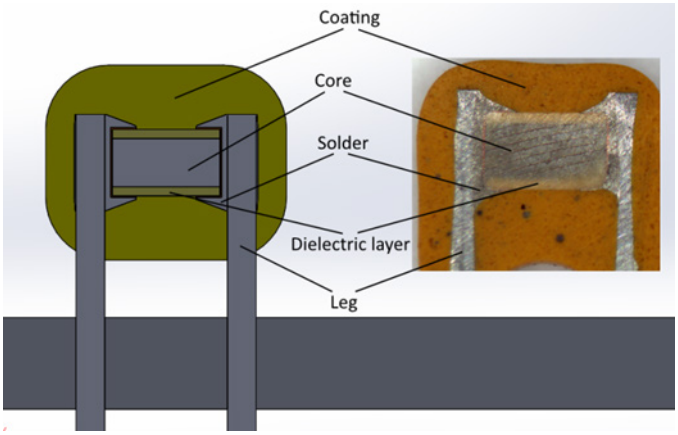

Figure 12 Simulation model of the measured ceramic capacitor

The most important structural elements are the capacitor core, where the electrodes and the X7R dielectric material are providing the layered structure, a dielectric cover layer, where no electrodes are visible, the solder, the copper legs and the coating ceramics.

According to the information found in the literature [4] the BaTiO3 is a commonly used ceramics to create X7R grade ceramic capacitors. As a base approximation we supposed that this material was used as dielectric layer and used the material properties suggested by the referenced paper. In order to simplify the simulation model the layered core has not been modeled in detail, but the weighted average thermal parameters of the BaTiO3 and the chromium electrodes have been used. As the layer thicknesses were unknown we used an arbitrary 8:2 volume ratio as the first approximation. The coating material was also unknown; hence as a first approximation we used the same thermal parameters as for the dielectric material. The solder was assumed to be SAC (Tin-silver-copper) solder. The initial guess material parameters can be read in Table 1.

Table 1. Material parameters, initial guess

Component	Material	λ [W/mK]	C_p [J/kg K]	ρ [g/cm^3]
core	custom	20.5	412	6.16
Dielectric	$BaTiO_3$	2.7	400	5.9
Coating	custom	2.7	400	5.9
Solder	SAC	78.4	306	7.4
Leg	Al	230	1037	2.69
PCB	FR4	0.3	880	1.2

The transient response of the structure was simulated with time steps identical to the sampling rate of the measurement. The time domain curve of the transient response provides much less information than its transformed version the structure function. The simulated and measured curves can be better compared using the structure function as it is shown in *Figure 13*.

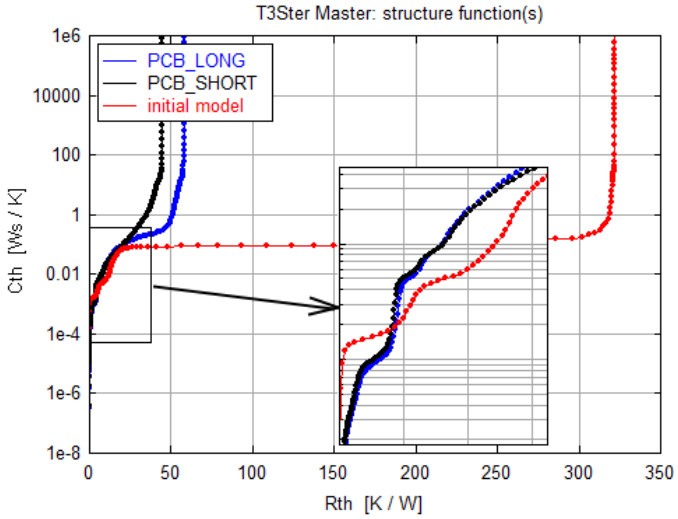

Figure 13 Structure function generated from the simulated transient of the initial "best guess" model compared with the measured curves

The black and blue color curves were generated from the measured transients with short and long pin lengths and the red curve was generated from the simulated transient. At the large scale plot the initial section of all the curves seem very similar, but after the initial section a large excess resistance can be observed in the simulation model. If we take a closer look at the initial part of the curves it becomes apparent that while the two measured curves are identical despite the differences in the pin length the simulated structure functions already show slight differences. In order to understand the differences between the simulation model and the modeled component the structure function has to be analyzed.

4.2. Using the structure function to fine-tune the simulation model

For semiconductor packages a detailed thermal model can be step by step calibrated based on the measured transient curve starting from the chip and moving towards the more remote features [11]. This can be done because there is typically a

dominant heat flow path that can be well described with the one dimensional spreading model and the time constants corresponding to the different elements of the heat flow path are increasing gradually as we are receding from the junction. However in case of the capacitor component the one dimensional spreading from the core is not a good assumption. As an example from the core of the capacitor the heat also spreads towards the pins through the solder contact, and the coating. In such situations what we see in the structure function is the parallel sum of the two thermal resistances (and capacitances).

As a result the same section of the structure function can be affected by more than one model parameters. As it is shown in *Figure 14* the conductivity of the core material (green and blue curve) and the surrounding dielectric layer (red and orange) are also affecting the length of the first flat section of the curve. Other sections are more dependent on one single material parameter and can be more clearly identified on the structure function.

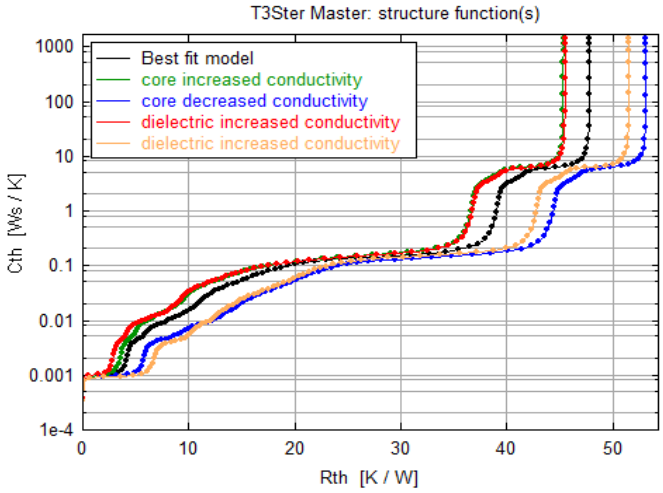

Figure 14 Effect on the structure function of the increased and decreased conductivity of the core (green and blue) and the dielectric layer (red and orange)

The large resistance at the end of the structure function corresponding to the initial model (*Figure 13*) was caused by the low conductivity of the PCB by neglecting the effect of the copper traces. *Figure 15* shows a simplified summary about which sections of the structure function are affected by the various model parameters.

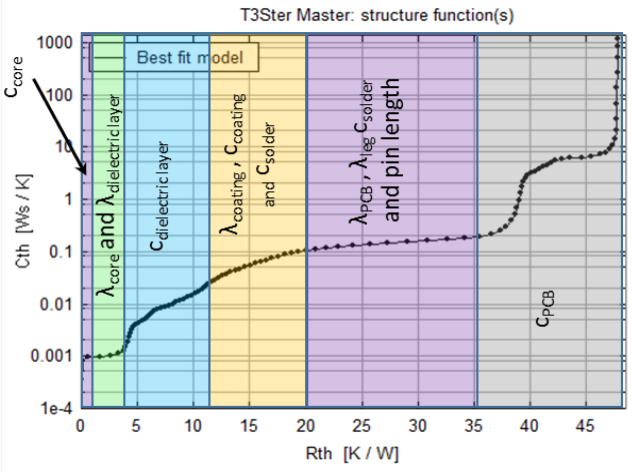

Figure 15 Different areas of the structure function and the various simulation model parameters affecting their shape

Having this information we know which parameters to adjust in order to have the simulated transient fit the measured one. After iterative adjustment of the appropriate thermal parameters of the PCB, capacitor core material, dielectric material, and coating material a very good match between the simulated and the measured transients could be achieved in the important domain up to about 35 K/W. Above this thermal resistance the thermal response is no more dependent of the thermal parameters of the capacitor model, hence it was out of our scope. With further work the whole simulation model could be matched to the experimental results.

Figure 16 shows the structure function of the measured transients and the one simulated after the model calibration, demonstrating very good agreement. The final model parameters are listed in Table 2. Almost perfect match can be achieved until 35 K/W.

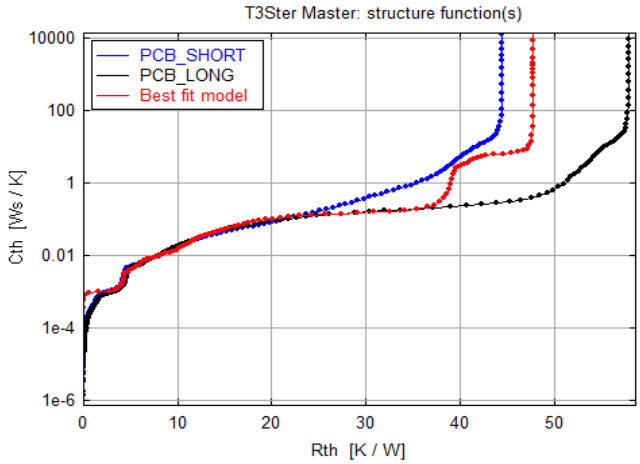

Figure 16 Structure function corresponding to the simulated (red) and measured structure (blue and black) after the calibration

Table 2. Material parameters after calibration

Component	Material	λ [W/mK]	C_p [J/kg K]	ρ [g/cm³]
core	custom	25	300	5
Dielectric	$BaTiO_3$	2.6	1000	5.9
Coating	custom	3	500	6
Solder	Custom	78	2500*	7.4
Leg	Cu	380	416	8.96
PCB	Custom	30	880	4

*The specific heat of the solder was increased to unrealistic levels to avoid geometrical changes (the volume in the model was lower than in the actual capacitor)

Nevertheless a small difference still remains after the calibration in the very early section of the structure function, below 2.5 K/W, where the simulation result and the measured transient do not match. In this section the structure function could not be affected by the adjustment of the model parameters. The simulated structure function shows stepwise capacitance change at practically 0 K/W, as the heat generation was assumed to be evenly distributed in the core of the capacitor. But the lower slope section of the structure function corresponding to the measured transient denotes that the heat generation is more localized to a smaller volume and the heat has to spread in the core to fill its volume.

5. Conclusions

In this paper a new measurement setup for the thermal characterization of capacitors was proposed. This method adopts the thermal transient measurement technology that is widely used for the characterization of semiconductor packages and structures.

The measurement method uses no external temperature sensors, but utilizes a temperature dependent electric parameter of the measured component itself to measure its temperature. The various temperature dependent parameters were reviewed and the capacitance was selected as it shows significant temperature dependence in case of most capacitor constructions.

In order to measure the change of the capacitance with sufficiently high temporal resolution a switched capacitor based measurement solution is proposed. The presented measurement circuit can be adjusted to measure capacitances in a wide range with approximately 1 kHz bandwidth.

The measurement method was demonstrated with three measurement setups. The first setup demonstrated the transfer R_{th} measurement, capturing the heating curve of the capacitor after a closely attached heat source turned on. It is shown that due to the long time required for the heat to reach the capacitor even a strong thermal coupling enables us to significantly reduce the switching speed of the switched capacitor and hence measure significantly higher capacitances.

The second setup demonstrated the self-resistance measurement, heating up the capacitor by its own losses at high ripple current and then measuring the cooling transient. The measurement was repeated with different pin lengths and the effect of the pin length on the thermal resistance of the component could be identified.

In this third setup also the self-resistance was measured, but capturing the heating curve of the capacitor. This setup provided better signal to noise ratio than the cooling measurement.

The detailed 3D simulation model of the capacitor and the PCB to which it was soldered to were built and the heating transient was measured and simulated. The first simulation and measurement results showed acceptable match in the initial section of the transient and the generated structure functions, but further from the heat source the difference was large.

By comparing the structure functions generated from the measured transient and the simulated one, the inaccurate model parameters could be iteratively fine-tuned to achieve an almost perfect match between the measured and simulated structure functions. This demonstrates that the thermal transient measurement can not only be used to measure the thermal resistance of the component, but also helps in calibrating the simulation model.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Abstract— The process of mapping large numbers of markers is computationally complex, as the increase of numbers of markers results in an exponential increase in the mapping runtime. Also, having unreliable markers in the dataset adds more complexity to the mapping process. In this research, we have addressed these two issues and proposed our solution. The proposed approach builds solid maps in two phases: Phase 1 builds an initial map following these steps: 1) Resample the original dataset to generate variant datasets, then cluster all resampled datasets into groups of markers. 2) Merge all groups of markers to filter out unreliable markers. 3) Generate a Map for each group of markers. 4) Concatenate all groups' maps to form the final map. Phase 2, Adds more markers to the initial framework to build a high resolution map as follows: 1) Use Kmeans algorithm to filter out unreliable markers and cluster the remaining markers. 2) Insert the remaining markers in their best positions in the initial framework. To evaluate the performance of the proposed approach, we compare our constructed maps on the human genome with the physical maps. Moreover, we compare our constructed maps with a state-of-the-art tool for building maps. Experiment results show that the proposed approach has a very low computational complexity and produces solid maps with high agreement with the physical maps.

1. Introduction

This paper is an extension of work originally presented in The 15th IEEE International Conference on Machine Learning and Applications [1]. Genome mapping [2] is the process of finding the order of markers within chromosomes; where markers are short fragments of Deoxyribo Nucleic Acid (DNA) sequence most often located in noncoding regions of the genome (regions that do not encode protein sequences). Markers orders can provide researchers with essential information for localizing disease-causing genes in the genome. Radiation Hybrid (RH) Mapping [3] is a statistical mapping technique to order markers along a chromosome, and estimate the physical distances between markers. RH mapping is widely used in many mapping projects, and has several advantages over alternative mapping techniques [4]. In RH Mapping, chromosomes are separated from one another, then high doses of X-rays are used to break the chromosome into several fragments. The main principle of RH mapping is that the probability of separation of two adjacent markers due to radiation breakage increases with the increase in physical distance [4]. The order of markers on a chromosome can be calculated by estimating the frequency of breakage and retention between the markers.

An RH population can be seen as a m X n Boolean matrix, where m is the number of markers, and n is the number of individual organisms in the mapping population. A single RH vector represents one marker across all individuals/Panels. All markers in each panel is assigned a value of 1 or 0, where the value 1 indicates the presence of that marker in that panel, and the value 0 indicates the absence of that marker. Once all markers in all panels are screened and saved, the RH population will be used for the mapping process. Figure 1 shows a sample RH population of 3 markers on 6 panels.

After preparing the RH population, the RH mapping process starts. The Obligate Chromosome Breaks (OCB) is used to indicate the similarity and estimate the distance between two markers in RH population [5]. The basic mapping step is to estimate the OCB between all pairs of markers, where a 1 is followed by 0 or vice versa in the same panel, and place the closest (similar) markers together. For example to map the simple population in Figure 1, we need to find the similarity between these three RH vectors

[*]Corresponding Author: Raed Seetan, Computer Science Department, Slippery Rock University, 16057, Tel: 724-738-2940, USA | Email: raed.seetan@sru.edu

(markers), and then place the similar markers close together in the constructed map. First calculate the OCB for all possible markers permutations (the number of times a 1 is followed by 0 or vice versa in the same panel), and second select the permutation with the minimum number of OCB; the best map of these three markers is {M1, M2, M3} with five breaks. Any other permutation will have more than five breaks.

The toy example in Figure 1 is used just to explain the process of mapping a RH population. Typically, the number of markers in chromosomes range between a hundred to thousands. Thus, calculating the OCB for all markers permutations is unfeasible solution for such large numbers of markers; where for n markers, there are n!/2 permutations to evaluate. In this study, we are going to map a RH dataset of the human genome with hundreds of markers. Heuristic approaches [6-8] have been used to map such larger datasets of markers in a reasonable time. Although the heuristic approaches are relatively fast, they scale exponentially with the number of markers. Figure 2 shows the typical pattern of mapping different datasets of markers using some heuristic algorithms that have been used to map RH populations in many researches [9-12].

The main goal of this study is to propose an alternative approach to map large numbers of markers in a short time. The proposed approach works in two phases. Phase 1, has been originally published in [1], constructs maps as follows: 1) Uses Jackknife resampling method on the original RH population to create slightly variant RH samples. Then, all the generated samples are grouped into clusters based on their LOD (logarithms of odds -base 10) scores. The LOD score [14] was developed as a probabilistic measure for linkage, and has been used consistently throughout the RH literature [9-11]. 2) Merges all RH samples clusters into consensus clusters, and filters out the unreliable markers. 3) Constructs a map for each consensus cluster. 4) Connects all consensus clusters maps into one single map. Phase 2, uses the output map of Phase 1 as a skeleton to map additional markers and improve the resolution of the initial map. Phase 2 works as follows: 1) Uses Kmeans clustering to find the candidate markers to be added to the map. 2) Finds the best position of each candidate marker in the initial map in order to add them to improve the final constructed map.

To demonstrate the effectiveness of our approach, three metrics are going to be used: 1) Accuracy, which indicates the agreement of the constructed maps with the published maps. 2) The number of mapped markers in the constructed maps. 3) The running time to construct the maps. We will compare our constructed maps with the maps we published in our original work in [1]. Also, we will compare our results with a state-of-the-art tool for building radiation hybrid maps. In our approach, we use the Clustering technique to reduce the mapping computational complexity, thus, mapping large datasets of markers in a short time. Also, our approach considers the problem of noisy markers and can filter out unreliable markers to increase the accuracy of the constructed maps.

The rest of this paper is structured as follows: Section 2 presents the related work. In Section 3, our proposed approach is discussed in detail. Section 4 presents the experimental results of the proposed approach, and Section 5 concludes this research.

2. Related Work

Conventional techniques [15, 16] for filtering out unreliable markers depend mainly on resampling [17]. Thus, these techniques are not recommended for filtering out unreliable markers from a large dataset due to their high computational complexity. The filtering process can be summarized in three sequential steps: 1) Resample the original dataset. 2) Use mapping techniques to map each resampled dataset. 3) Construct a matrix to show the reliability of all markers and filter out the most unreliable marker. These three steps are repeated to filter out unreliable markers one at a time. This iterative process is too time consuming for a large dataset, as to filter out only one unreliable marker, there is a need to resample the dataset and map all resampled datasets. The computational complexity of mapping a single resampled dataset scales exponentially with the number of markers to be mapped, as shown in Figure 2. Thus, repeating this complex mapping process for every single resampled dataset to filter out one unreliable marker is not a feasible solution for large datasets. As we discuss our proposed solution in Section 3, we will show that how our approach resampled the dataset and filtered out the unreliable markers without the need of mapping the resampled datasets. Thus, the proposed approach reduces the computational complexity of the whole mapping/filtering process.

RHMapper tool [12] provides another approach to build solid maps with only the reliable subset of markers. The mapping process is divided into two steps: 1) use *find_triples* command to search the data set for well-ordered triples, and save them. 2) Use *assemble_framework1* or *assemble_framework2* commands to assemble the saved well-ordered triples into a final map. The assembly process uses the overlapping between the well-ordered triplets of markers to combine them into a final map, where the *assemble_framework1* command seeks for overlapping with two consecutive markers in each triplet, for example: triplets (A-B-C) and (B-C-D) will be assembled into (A-B-C-D). *assemble_framework2* command can add gaps to assemble triplets, for example: triplets (A-B-C) and (A-C-D) will be assembled into (A-B-C-D). Although, this mapping strategy can build solid maps, mapping a hundred markers takes several hours to finish [13], so this approach does not scale well with the number of markers.

Multimap [13] is another tool to build maps with reliable markers. The mapping process starts with searching for the strongest pair of markers, then iteratively adds one marker at a time to extend the initial map. Apparently, this mapping process does not scale well with large datasets of markers.

Carthagene tool [11] is another well-known package that has been used in many studies to construct solid maps [24, 25]. The *Buildfw* command implements an incremental insertion procedure to build maps with only reliable markers; and it works as follows: first, search for the triplet of markers that maximizes the difference between the likelihood of the best map, and the second best map using only this triplet of markers. Once the best triplet of markers is found, save it as an initial framework map. Second, for each marker not mapped in the framework, try to insert it into its best interval. In order to insert a marker into its best interval in the framework map, two thresholds are evaluated: 1) AddThres and 2) KeepThres. AddThres is used to determine if a marker can be placed in its best interval or not; where if the loglikelihood difference between the best two insertion intervals is greater than the AddThres, then the marker can be inserted in its first best interval in the map. If that marker can be inserted in its best interval in the map, the KeepThres is evaluated, which is used to determine if the new inserted marker can be saved in the framework map or not. If the loglikelihood difference between the best two maps is greater than the KeepThres, then the new inserted marker will be saved in its best interval and will be used to map other markers in the following iterations. Otherwise, the new inserted marker will be removed from the current framework map.

One of the limitations of the incremental insertion procedure in Carthagene is that only a few markers are mapped at the final map, if the recommended values of the AddThres and KeepThres are used [11]. Another limitation is that the mapping process starts with only three markers as an initial map. Thus, adding one marker at a time to the initial map makes the mapping process not suitable for large numbers of markers. Moreover, the incremental insertion procedure cannot be parallelized.

In this research, we compare our proposed approach with the Carthagene incremental insertion approach. Our proposed approach can take advantage of the parallel computing to reduce the computation complexity of the mapping process; where markers are grouped into smaller clusters, and these groups of markers can be mapped in parallel. We expect to outperform the Carthagene approach in terms of the mapping runtime. Also, in terms of mapping accuracy, our proposed approach uses the grouping process over all resampled data to filter out the unreliable markers, and thus uses only the reliable markers to build solid final maps. We expect our approach to build solid maps, as the grouping process will help in reducing the effect of unreliable markers to the local clusters maps, not to the entire map.

3. Proposed Approach

The proposed approach divides the mapping process into two phases, where each phase consists of several steps. The first phase builds an initial map with the most reliable set of markers, Figure 3 shows the systematic workflow of the first phase. The second phase uses the initial map constructed in phase 1 as a framework to map more markers to the initial framework, which results in building a high resolution map (mapping larger numbers of markers), Figure 4 shows the systematic workflow of the second phase

3.1. Phase 1: Building Initial Framework Map

1) Resampling and grouping: The Jackknife resampling technique is used to generate N variant RH samples of the original RH dataset, where each resampled RH dataset will have N-1 individuals (leave-one-individual-out).f After generating the resampled datasets, the Single Linkage Agglomerative Hierarchical clustering technique [18] is used to group each dataset into different clusters of markers. The *group* command is implemented in the Carthagene tool can be used to create these clusters of markers. The idea of the grouping is to create small groups of markers with low intra-cluster distances and high inter-cluster distances.

Groups aggregation and filtering: The first step generates N variant RH sampled datasets, and with each resampled dataset many clusters of markers. The goal of this step is to use all clusters of markers of all resampled datasets to filter out unreliable markers and aggregate the clusters of markers to generate solid consensus clusters. A matrix of size *m x m* is used to show the stability of linkage relationship between all pairs of markers, where m is the number of markers in the RH population. The matrix is created and initialized to Zero. Then, we trace all the clusters in all RH sampled datasets to update the values of the elements of the matrix. For each paired ordered markers (Mi, Mj), we increment both indexes (i, j) and (j, i) in the cluster matrix by 1 each time the pair (Mi, Mj) appear in one cluster in all sampled datasets.

....

After that, we start filtering out unreliable markers; two factors are defined for each marker: 1) the Stability-Factor (SF), which indicates the stability of neighbors markers throughout all sampled datasets clusters. For example, the Stability-Factor value of 80 for markers (Mi, Mj) means that over all resampled RH datasets, markers (Mi, Mj) appear 80 times together in the same cluster. 2) The Reliability-Ratio (RR), which is calculated by the count of relationships above the Stability-Factor divided by the total number of relationships for that marker. Figure 5 shows a simple example to illustrate the filtering process. All markers with Reliability-Ratio less than a threshold are considered unreliable markers and can be filtered out. In our experiments, we used RH population of 93 individuals and filtered out markers with SF values less than 80, and RR less than 50%. After filtering out the unreliable markers from all clusters, the remaining markers will be considered reliable markers and will form the consensus clusters.

2) Mapping clusters' markers: In this step, we build a map for each consensus cluster of markers. Several heuristics algorithms can be used to build the maps, in this study, we follow the mapping strategy published in [4, 9, 10] to build a map for each cluster, using the heuristics algorithms implemented in the Carthagene tool [11]. The following steps present the mapping strategy: 1) *Mrkdouble* command to identify and merge identical markers by a single marker. 2) *Build* command to build an initial nice map, where the command finds the best pair of markers, with the strongest linkage, and incrementally tries to add the remaining markers if they satisfy the insertion criteria. 3) *Greedy* and *Annealing* commands are used as improvement steps to find a better map in case a local improvement exists. 4) *Flips* and *Polish* commands are used to apply all possible permutations in a sliding window to check if a better map can be achieved. Running all these commands in that sequence will build a map for each cluster.

3) Connect maps and polish: Building a map for each consensus cluster shows the local order of the markers in each cluster. However, all these small maps need to be concatenated to form a whole chromosome map. In this step, we concatenate the clusters' maps generated in the previous step to form one map for a whole chromosome. This process can be done in an iterative manner. First, we extract the boundaries, the first and the last marker, of each cluster map. Second, we group all boundaries into clusters, the *group* command in Carthagene can be used to make these clusters; we start with a high LOD score T, i.e. T= 18. Boundaries from different maps that fall into one cluster are connected using the closest boundaries to form a bigger map. This step is repeated, where at each iteration the LOD score T needs to be lowered by a factor of x, i.e. x= 3, to let the far away boundaries to be connected to form one single map. A polishing step is used at the end of this step to improve the constructed map by trimming marker at the edges of the final map with LOD score less than 3, which generally indicates that there is no linkage between two markers.

	M1	M2	M3	M4	M5	SF >= 80	RR >=50%	Reliable
M1	--	**90**	**90**	**60**	**26**	**2**	**2/4**	**Yes**
M2	90	--	10	15	2	1	1/4	No

M4	60	15	80	--	0	1	1/3	No
M5	26	2	80	0	--	1	1/3	No

3.2. Phase 2: Improving Framework Map

1) Loose markers extraction and grouping: After building a framework map with only the most reliable subset of markers, our goal is to use the framework map as an initial map to construct a high resolution map by mapping more markers from the remaining left out markers (Loose Markers) to the initial framework map. In this step, we use the initial constructed framework map as a skeleton to map the loose markers, where loose markers will be placed into the intervals of the initial framework map. This process works as follows: 1) Extract the loose markers from the original dataset. 2) Group the loose markers into clusters; the Kmeans algorithm is used to make the clusters of the loose markers. Kmeans algorithm works well for large datasets. To run the Kmeans algorithm, we need to set the number of clusters (K). In this study, we set the value of K

to the number of markers in the initial framework map plus 1. Assuming that all loose markers are going to be placed in between framework's markers, so if the number of markers in the framework map is n, that means we have n+1 number of intervals to place the loose markers in. Thus, the number of clusters K can be set as n+1, if the number of loose markers is less than the number of markers in the initial framework map, then we consider each loose marker as a single cluster.

2) Insert loose markers in their best positions: The kmeans algorithm will group the loose markers into clusters, where markers within clusters are too close to each other and far away from other clusters' markers. Generally, for large datasets singleton clusters, clusters with only one marker, are considered unreliable clusters and will be filtered out, as they are not attached to any other loose markers. After we group the loose markers into clusters, we choose randomly a loose marker from each cluster and try to place that loose marker into its best position in the initial framework map. To find the best position of that loose marker, the *Buildfw* command in Carthagene is used to report the best position for each loose marker, where the loose marker is inserted in all possible positions in the framework map, and then reports the best position based on the linkage of the loose marker with its immediate neighbors (left and right markers, if possible). After we find the best position of each loose marker, we add them to their best positions. In case there are more than one loose marker in one position, we randomly pick one marker and keep it in that position. Step 1 and Step 2, in Phase 2, can be repeated to include more markers in the framework map, where the final map of each iteration is used as an input for the next iteration to map as many loose markers as needed. Figure 4 shows the systematic workflow of Phase 2.

4. Experimental Results

4.1. Datasets

The three common used human genome radiation hybrid panels are: 1) The G3 [19] and 2) TNG [20] panels produced by Stanford University and 3) The Genebridge 4 [21] panel by the Sanger Center. In this study, we use the Genebridge 4 panel where the number of individuals is 93. We have selected 8 different chromosomes with varying number of markers to show the scalability of our proposed approach over the increasing number of markers. Table 1 shows the selected chromosomes with their numbers of markers. The choice of these chromosomes is determined by the availability of markers in both radiation hybrid data set and physical marker locations. The physical marker locations are extracted from the Ensemble website [22], and the RH dataset are downloaded from the EMBL-EBI website [23].

4.2. Evaluation of the approach

The proposed mapping approach builds maps in two phases: In Phase 1, we construct initial map with the most reliable markers. Once the initial map is constructed, Phase 2 extends the initial map to include more markers in the final map. In this section, we are going to refer to Phase 1 as Clustering Method; and Phase 1 and Phase 2 together as Extended Clustering Method. The Clustering Method has been evaluated in [1], where the reported results show that the constructed maps have high agreement with the corresponding physical maps. To evaluate the Extended Clustering Method, we use the same dataset we have used in [1], the constructed maps reported in [1] will be used as an input to Phase 2 in the Extended Clustering Method.

The running time for the Clustering Method has been reported in [1] and can be seen in Figure 6. The big improvement in the mapping runtime of our Clustering Method over the Carthagene Method can be explained by the grouping of the large numbers of markers into small groups, and taking advantage of parallel processing to map all these groups of markers simultaneously in a short time. The hieratical clustering in the Clustering Method and the Kmeans clustering in the Extended Clustering Method only take a few seconds to complete. On the other hand, the Carthagene Method, uses only three markers as an initial map and then incrementally adds more markers to that initial map one marker at a time to construct the maps. Figure 6 shows the mapping running time for both Carthagene Method and the Clustering Method using the same dataset. The Extended Clustering Method running time depends on two factors; first, the numbers of markers in the initial map, and second, the number of iterations; where the more markers there are in an initial map, the less time it takes to map the remaining markers. Table 1 shows that the Clustering Method can generate initial maps with large numbers of markers compared to the number of markers in the maps constructed using the Carthagene Method.

The accuracy of the constructed maps is measured by Pearson Correlation, where the closer the value is to 1, the stronger the linear correlation (agreement) between the markers positions in the constructed maps, and the markers positions in the corresponding physical maps. Table 1 shows the Pearson Correlation between the physical maps and the constructed maps using 1) Carthagene tool; 2) The Clustering Method; and 3) The Extended Clustering Method. The results show that maps generated using the Clustering Method have higher correlations with the physical maps than the maps generated using the Carthagene tool. Out of 10 chromosomes, the Carthagene tool outperforms the Clustering Method for only one chromosome, Chromosome 21, with a slight difference. While, the Clustering Method outperforms the

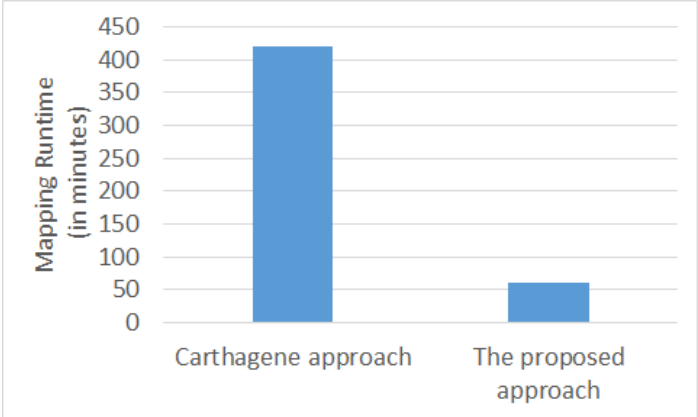

Figure 6. The proposed approach mapping runtime vs the traditional Carthagene approach.

remaining 9 chromosomes. For some chromosomes the improvement is huge, for example, Chromosome 3, the accuracy of the Carthagene Method is 0.45 while the accuracy of the Clustering Method is 0.99. Another example is Chromosome 12, where the accuracy of Carthagene Method is 0.10, while the accuracy of Clustering method is 0.73. For some other chromosomes, the difference in accuracy between the Carthagene Method and Clustering Method is small, for example: Chromosome 10, the accuracy of Carthagene Method is 0.98, while the accuracy of the Clustering method is 0.99. Also in Chromosome 21, the accuracy of Carthagene Method is 0.98, while the accuracy of Clustering method is 0.97.

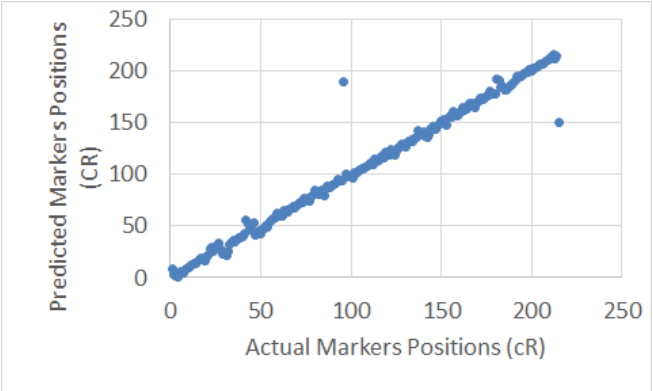
Moreover, Table 1 shows the number of mapped markers in each chromosome using all three methods. The results show that for most chromosomes the constructed maps using the Clustering Method have more markers than the constructed maps using the Carthagene Method. One of the limitation of the Carthagene Method is that the constructed maps have only a few numbers of markers, and this can be seen in Chromosomes 10 and 12. For Chromosome 10, Carthagene maps only 16 markers, where the Clustering Method maps 46 markers. For Chromosome 12, Carthagene maps 42 markers, while the Clustering Method maps 71 markers. For other chromosomes the numbers of mapped markers between the Carthagene Method and The Clustering Methods are similar and this can be seen in Chromosome 16, 21 and 22 where the difference in mapped markers is small. In some cases, Carthagene tool maps more markers than the Clustering Method, for example Chromosome 3 and 7. However, the correlations between the constructed maps and the physical maps for these chromosomes are not as strong as our proposed approach maps for the same corresponding chromosomes.

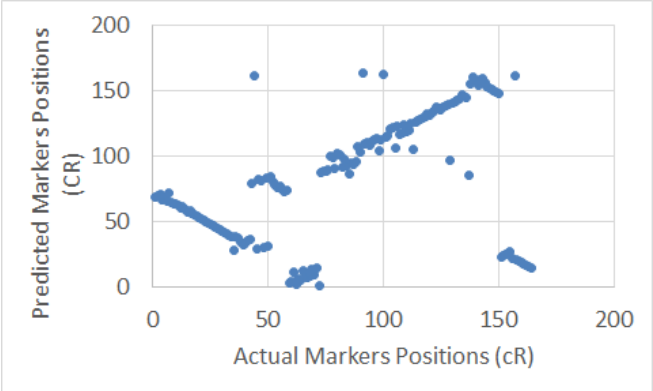
Table 1- Comparison Of The Number Of Mapped Markers And Correlation Between The Constructed Maps And The Physical Maps For Carthagene Method, Clustering Method, Extended Clustering Method.

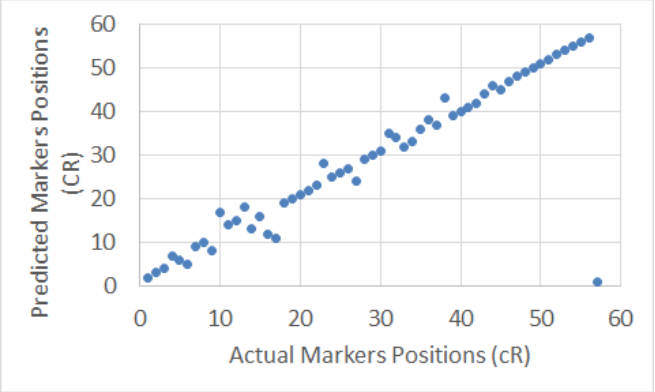
	Input Markers	Carthagene	Clustering	Extended Clustering
Chromosome 3 No. Of Markers In Map Pearson Correlation	1038 -	164 0.45	153 0.99	215 0.99
Chromosome 5 No. Of Markers In Map Pearson Correlation	1071 -	49 0.84	84 0.94	115 0.88
Chromosome 7 No. Of Markers In Map Pearson Correlation	1026 -	165 0.71	78 0.88	100 0.82
Chromosome 10 No. Of Markers In Map Pearson Correlation	846 -	16 0.98	46 0.99	57 0.88
Chromosome 12 No. Of Markers In Map Pearson Correlation	1028 -	42 0.10	71 0.73	81 0.68
Chromosome 15 No. Of Markers In Map Pearson Correlation	619 -	83 0.88	77 0.99	110 0.80
Chromosome 16 No. Of Markers In Map Pearson Correlation	677 -	70 0.53	69 0.95	87 0.89
Chromosome 18 No. Of Markers In Map Pearson Correlation	407 -	65 0.95	84 0.99	103 0.99
Chromosome 21 No. Of Markers In Map Pearson Correlation	173 -	33 0.98	34 0.97	46 0.95
Chromosome 22 No. Of Markers In Map Pearson Correlation	314 -	41 0.64	36 0.71	41 0.59

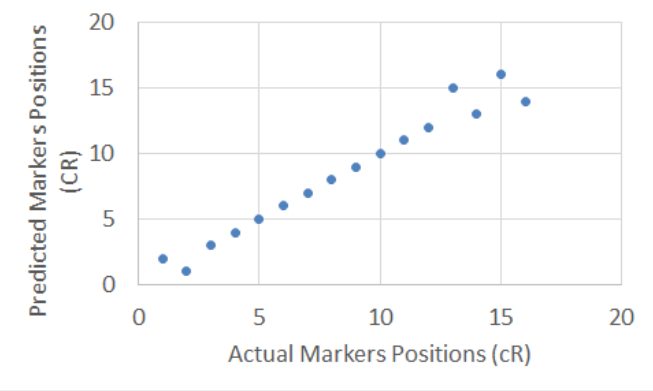
The main goal of the Extended Clustering Method is to map more markers to build high resolution maps. The Extended Clustering Method is an iterative process, where in each iteration some markers are added to the current map to form a new map, and that new map will be used in the next iteration to map more markers, and so on. Table 1 shows the number of mapped markers for each chromosome using the Extended Clustering Method for one iteration. For Chromosome 3, the Extended Clustering Method mapped 215 markers, while the Clustering Method mapped 153 markers. Although, the number of mapped markers is increased in the Extended Clustering Method map, the accuracy of the constructed map remains high 0.99. The same pattern is shown for Chromosome 18. For other chromosomes, Chromosomes 5 and 7, the number of mapped markers is increased and the accuracy of the final maps is decreased slightly. In other cases, for example Chromosome 12, The Extended Clustering Method mapped more markers, but the accuracy dropped from 0.73 to 0.68. Although the accuracy of Chromosome 12 was dropped to 0.68, it is still higher than the accuracy of the Carthagene map, 0.10.

To show graphical representations of the alignment of the constructed maps for some chromosomes using both the Carthagene Method and the Extended Clustering Method, we plot the known markers positions along the x-axis, and the predicted markers position along the y-axis. The plots show how well the constructed maps agree with the corresponding physical maps. The diagonal line in each plot shows the perfect alignment between the predicted markers positions and the actual markers positions. Figures 7 to 22 show the maps for all 10 chromosomes. Our approach is designed to build robust maps. The resampling and clustering techniques are intended to filter our unreliable markers and map only reliable markers. Moreover, mapping markers inside a cluster does not affect the mapping of the other markers outside that cluster. Thus, if there is a noisy marker in a cluster, the effect of that noisy marker will be limited to only the markers inside that cluster, other markers outside that cluster will not be affected; and that can been seen through the local flipping markers' positions errors in our proposed approach constructed maps.









5. Conclusion

In this research, we have proposed a scalable approach for building high resolution maps. The proposed approach can take advantage of the parallel computing to map large numbers of markers in a short time, thus reduce the computational complexity of the mapping process. The proposed approach can be summarized in two phases: Phase 1, generates resampled datasets, then group all datasets into small clusters to filter out unreliable markers and construct consensus clusters. These clusters are mapped in parallel. Once the initial map is constructed, Phase 2 can be used to iteratively add more markers to the initial map and build high resolution maps. Experiment results on the human genome show that the proposed approach has a very low computational complexity and produces solid maps with high agreement with the physical maps. Also, the results show that our approach outperforms a state-of-the-art tool for building radiation hybrid maps in terms of accuracy of the constructed maps and mapping runtime.

ABSTRACT

Energy efficiency is a salient design consideration for stabilization mechanisms when assembled on a battery-powered vehicle. In this paper we study the implementation of a two-axis gimbal with passive revolute joints for motion isolation of an inertially stabilized platform (ISP) mounted on a host vehicle. The objective is for the ISP to maintain a steady line of sight (LOS) of a payload placed in an arbitrary position on the ISP workspace by performing mass stabilization. The proposed method eliminates the need to operate gimbal motors throughout the operation of the host vehicle, stabilizing the platform LOS by relying on the gimbal passive joints acting as suspension to isolate the ISP from disturbances imparted by the host vehicle. We describe the principle of operation and a prototype of the proposed stabilizing mechanism is presented.

1. Introduction

An inertially stabilized platform consists of a gimballed electromechanical system that maintains a steady line of sight (LOS) of a payload (imaging instrument, communication instrument, sensor, etc.) with respect to an inertial reference frame. The control system adjusts the gimbal orientation angle to compensate for the changes in orientation of the host vehicle on which it is mounted. The angular motion of the host vehicle is measured with an inertial measurement unit (IMU). The stabilizing algorithm calculates the necessary coordinate frame transformations in order to derive the target orientation of the gimbal in inertial space for the platform to hold its line of sight.

For the payload to maintain its line of sight, the stabilizing system must have a quick response time. Moreover, in conventional applications of gimballed stabilization, the system must actively drive the gimbal actuators throughout the operation of the host vehicle to compensate its changes in orientation and to reject other disturbances. This turns out to be computationally expensive, since the required kinematic calculations and the calculations of target angular velocities of the gimbal motors have to be performed fast enough not to impose a lag in response time of the system. Perhaps more importantly, the active gimbal compensation throughout the operation of the vehicle demands a high consumption of power.

In this research, we study the implementation of a two-axis gimbal with unactuated freely rotating joints for disturbance isolation of an inertially stabilized platform (ISP). A payload is placed by a user in an arbitrary position within the ISP workspace, and the line of sight stabilization of the payload is achieved by displacing a counterweight horizontally and vertically to adjust the center of gravity (COG) of the payload-counterweight system to be at the crossing point of the passive gimbal rotation axes. As a result, undesired moments of inertia applied to the platform by external disturbances are eliminated. The passive gimbal joints act as a suspension that decouples the host vehicle chassis from the ISP, isolating it from disturbances and keeping the payload's orientation stationary in inertial space.

The work presented in this paper is an extension of the stabilization method originally presented in IEEE SII2016 [1]. In the present work, we first discuss the method of elimination of moments of inertia to isolate the payload from external disturbance. We next discuss a method to calculate the position of the payload COG on the surface of the platform and present a theoretical framework to calculate the height of the payload COG by measuring the roll and pitch inclination angles of the passive gimbal. Finally, we present the results of fundamental experiments with the second prototype to evaluate the mechanism.

2. Balancing Principle

The aim of the stabilizing mechanism discussed in this paper is to keep a steady line of sight of a payload of arbitrary weight within the load capacity specifications of the mechanism, and with arbitrary mass distribution, placed in an arbitrary position on the stabilized platform's workspace. To accomplish this by performing mass stabilization it is therefore necessary to measure the payload weight, and to calculate the position of the center of gravity of the payload [2, 3]. With this information about the payload, the three-dimensional target position of the counterweight is calculated to perform mass-stabilization.

Due to the freely rotating joints of the gimbal, placing a payload on the platform in a position offset from the vertical axis of symmetry of the ISP induces a torque on the passive gimbal's axes; this results in the inclination of the platform about the gimbal axes. The stabilizing mechanism aligns the orientation of a payload with respect to the inertial reference frame by adjusting the horizontal and vertical position of a counterweight. An XY Stage mechanism displaces the counterweight center of gravity horizontally on the *x-y* plane and a Z Stage displaces the counterweight vertically along the *z* axis. The position of counterweight is adjusted to locate the center of gravity of the payload-counterweight system at the crossing point of the gimbal rotation axes.

2.1. Static Balance: Gravity

Balance on roll axis: the offset position r_1 of the payload with respect to the platform's vertical axis of symmetry on the *y-z* plane induces a torque on the passive roll axis of the gimbal due to gravity, resulting in an inclination angle σ of the gimbal about its roll axis of rotation, as illustrated in Figure 1. To compensate the torque induced by the payload, the horizontal position of the counterweight is displaced along the *y* axis with the Y Stage up to position r_2 to induce a torque with the same magnitude and opposite direction. For static balance on the roll axis of a payload with weight w_1 and counterweight with weight w_2, the position r_2 of the counterweight on the *y* axis must satisfy (1). This places the center of gravity of the payload-counterweight system on the vertical axis of symmetry of the inertially stabilized platform on the *y-z* plane as illustrated in Figure 2.

$$r_2 = \frac{w_1 r_1}{w_2} \tag{1}$$

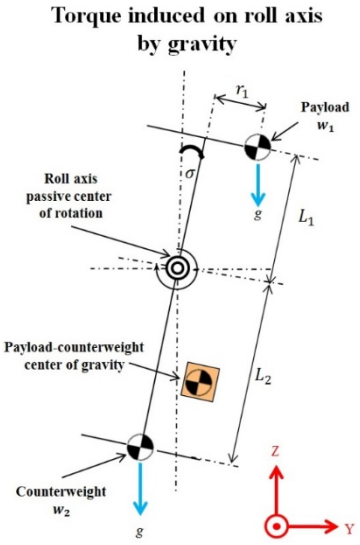

Figure 1. Inclination of the passive gimbal about the roll axis due to load unbalance against gravity on the *y* axis.

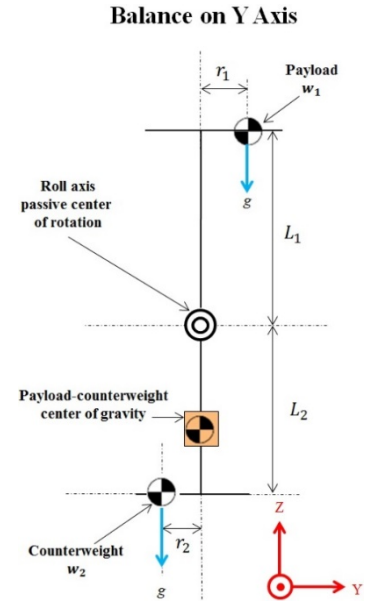

Figure 2. Static balance on the *y* axis against gravity provided by the displacement of the counterweight with the Y Stage.

Balance on pitch axis: the offset position r_3 of the payload with respect to the platform's vertical axis of symmetry on the *x-z* plane induces a torque on the passive pitch axis of the passive gimbal due to gravity, resulting in an inclination angle θ of the gimbal about its pitch axis of rotation, as illustrated in Figure 3. The horizontal position of the counterweight is displaced along the *x* axis with the X Stage to position r_4, which for static balance must satisfy (2). This places the center of gravity of the payload-counterweight system on the vertical axis of symmetry of the inertially stabilized platform on the *x-z* plane, as illustrated in Figure 4.

$$r_4 = \frac{w_1 r_3}{w_2} \tag{2}$$

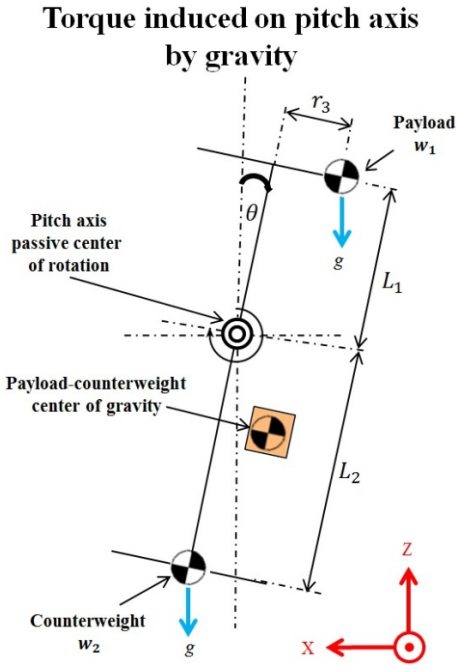

Figure 3. Inclination of the passive gimbal about the pitch axis due to load unbalance against gravity on the *x* axis.

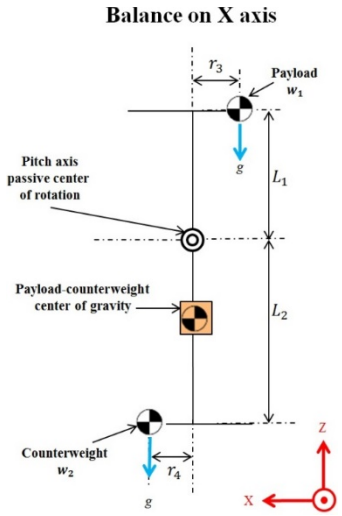

Figure 4. Static balance on the *x* axis against gravity provided by the displacement of the counterweight by the X Stage.

2.2. Static Balance: Disturbances by Host Vehicle

Accelerations of the host vehicle also induce torque on the passive gimbal. Depending on the direction of motion of the host vehicle, this torque is induced on either the pitch axis of the gimbal, the roll axis of the gimbal, or both. Figure 5 illustrates the inclination of the passive gimbal due to a horizontal acceleration a of the host vehicle along the x axis of the stabilizing mechanism, inducing a toque on the pitch axis of the gimbal.

To eliminate the torque induced on the passive gimbal due to accelerations of the host vehicle, the vertical position of the counterweight is displaced along the z axis with the Z Stage. For static balance the along the z axis of a payload with weight w_1 and counterweight with weight w_2 , the distance L_2 from the gimbal axis of rotation to the counterweight must satisfy (3)

$$L_2 = \frac{w_1 L_1}{w_2} \tag{3}$$

where L_1 is the distance from the gimbal axis of rotation to the ISP. After the center of gravity of the payload-counterweight system is displaced horizontally by the XY Stage to place it on the vertical axis of symmetry of the gimbal, the vertical displacement along the z axis places the center of gravity of the payload-counterweight system on the crossing point of the passive gimbal rotation axes, as illustrated in Figure 6.

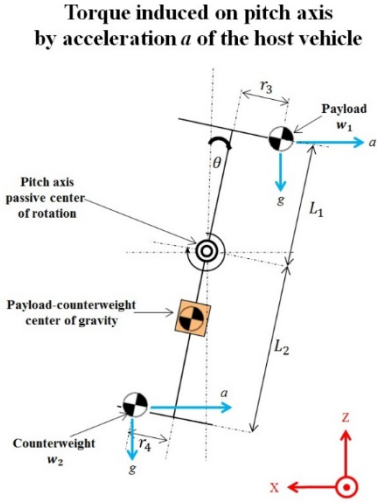

Figure 5. Inclination of the passive gimbal about the pitch axis due to load unbalance against the acceleration of the host vehicle.

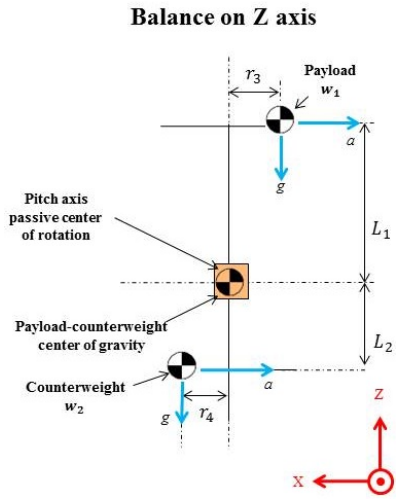

Figure 6. Static balance on *z* axis against host vehicle acceleration provided by the displacement of the Z Stage.

3. Components of the Stabilizing Mechanism

Figure 7 illustrates the components of the proposed stabilizing mechanism. The stabilizing mechanism consists of an XY Stage mechanism with omnidirectional driving gear [4] located below the centers of rotation of the two-axis passive gimbal. The XY Stage acts as counterweight, with adjustable position along the x and y axes. The XY Stage/Counterweight is mounted onto the Z Stage that adjusts its vertical position along the z axis. The stabilized platform is located above the centers of rotation of the passive gimbal roll and pitch axes.

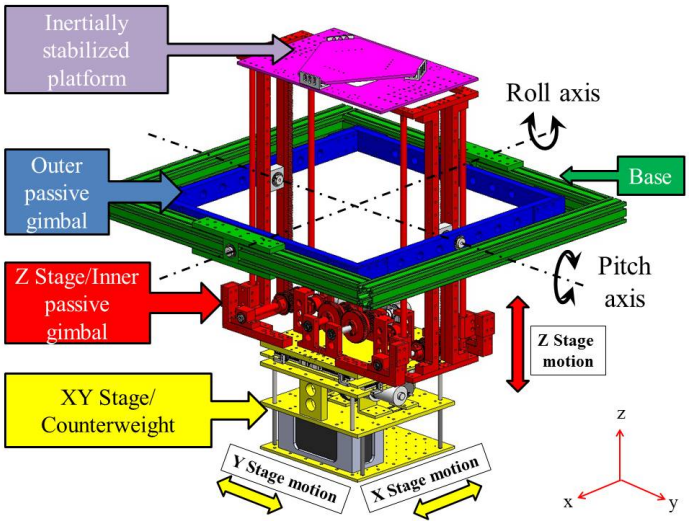

Figure 7. Stabilizing mechanism with passive two-axis gimbal.

The payload weight and the position of its COG on the surface of the ISP are measured with three CZL204E strain gauge load cells located on the platform. We propose the calculation of the height of the payload COG by measuring the roll and pitch inclination angles of the passive gimbal caused by the placement of the payload on the ISP. The passive gimbal's roll and pitch inclination angles are measured with a SEN-10736 inertial measurement unit onboard the inner gimbal of the stabilizing mechanism [5]. The proposed method for calculating the three dimensional position of the payload COG is discussed in chapter 4. Figure 8 illustrates the stabilizing mechanism mounted on the omnidirectional host vehicle.

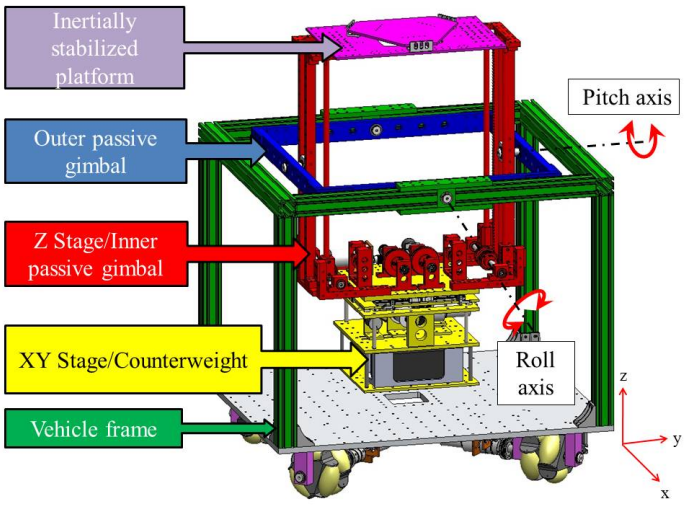

Figure 8. Stabilizing mechanism on the omnidirectional host vehicle.

4. Calculation of the Position of the Payload Center of Gravity on the Inertially Stabilized Platform

In this chapter we discuss the method of calculating the position of the payload's center of gravity (COG) in three dimensions once it has been placed on the inertially stabilized platform. We first describe the coordinate frame assignments to the system, we next describe the method to calculate the position of the payload COG on the surface of the platform ((*x,y*) coordinates of the payload COG on the surface of the platform) employing the multiple-point weighing method [6]. Finally, we propose a method to calculate the height of the payload COG from the platform surface (*z* coordinate of the payload COG from the surface of the platform) by exploiting the passive nature of the two-axis gimbal.

The algorithm to calculate the position of the payload center of gravity in three dimensions is the following:

1. Assign three coordinate frames on the stabilizing mechanism. A coordinate frame Σ_0 as the reference frame, a coordinate frame Σ_1 on the surface of the ISP, and a coordinate frame Σ_2 on the counterweight.
2. Measure the weight of the payload and calculate the horizontal position of its COG on the platform's surface (on ISP coordinate frame Σ_1) after the payload has been placed on the platform by the user.
3. Measure the roll and pitch inclination angles of the passive gimbal caused by the placement of the payload on the ISP surface. Then describe the position of the inclined ISP and the payload COG with respect to the reference frame Σ_0.
4. Define a cross-sectional plane in which both the pitch and roll inclination angles of the ISP are implicit.
5. Describe the position of the inclined ISP and payload COG with respect to the cross-sectional plane.
6. Perform a statics analysis of moments on the cross-sectional plane to calculate the height of the payload COG from the surface of the ISP.

4.1. Coordinate Frame Assignments

The stabilizing mechanism's vertical axis of symmetry lies orthogonal to the plane of intersection of the passive gimbal's roll and pitch axes as shown in Figure 9. Three coordinate frames are assigned to the stabilizing mechanism, illustrated in Figure 10.

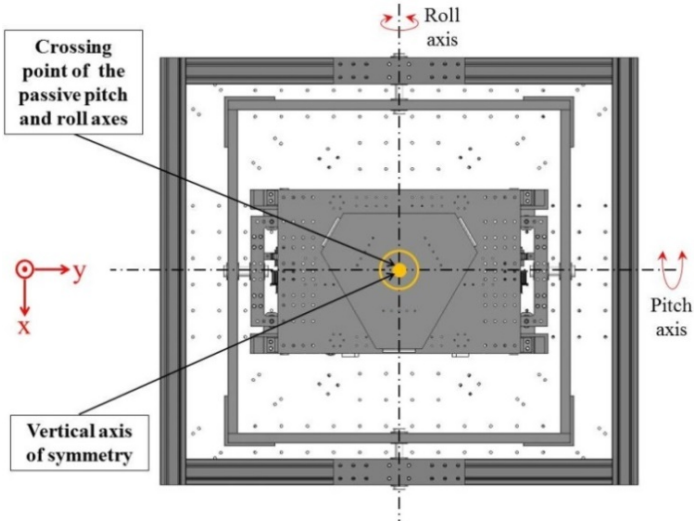

Figure 9. Top view of the stabilizing mechanism on the host vehicle.

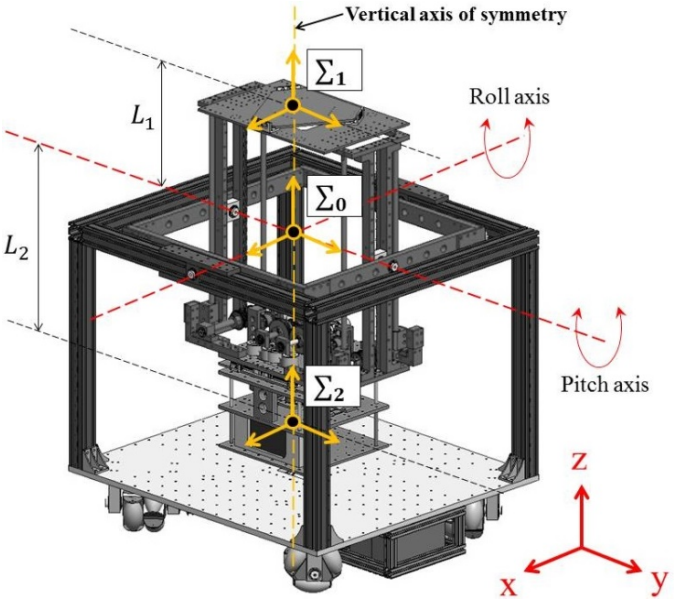

Figure 10. Coordinate frame assignment on the stabilizing mechanism.

A fixed reference coordinate frame Σ_0 is assigned with its origin at the intersection of the passive gimbal's roll and pitch rotation axes and its vertical axis collinear with the stabilizing mechanism's vertical axis of symmetry. Positions and rotations of the ISP and the counterweight are defined with respect to this reference frame.

A coordinate frame Σ_1 is assigned to the surface of the inertially stabilized platform with its vertical axis collinear with the mechanism's vertical axis of symmetry and with its origin at a vertical distance L_1 from the origin of the reference frame Σ_0, above the passive gimbal's pitch and roll rotation axes.

A coordinate frame Σ_2 is assigned to the counterweight with its vertical axis collinear with the balancing mechanism's vertical axis of symmetry and with its origin at a vertical distance L_2 from the origin of the reference frame Σ_0, beneath the passive gimbal's pitch and roll rotation axes.

4.2. Calculation of the Horizontal Coordinates of the Payload Center of Gravity on the Surface of the Inertially Stabilized Platform

In the proposed stabilizing mechanism, the inertially stabilized platform's effective workspace is a tray resting on top of three CZL204E strain gauge load cells, with which the weight of the payload placed on the tray is measured. The layout of the load cells is shown in Figure 11.

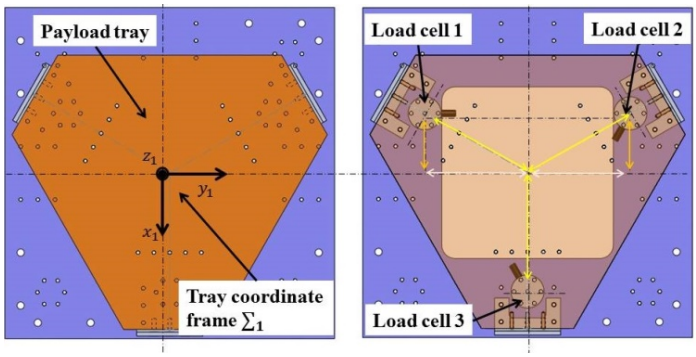

Figure 11. Load cell layout for weight measurement of the payload on the inertially stabilized platform.

The position of the COG of the payload placed on the tray is calculated from the relationship between force measurements of the three CZL204E strain gauge load cells using the multiple-point weighing method. The position coordinates of the payload COG are described with respect to the platform coordinate frame Σ_1, where r_1 is the y coordinate of the position of the payload COG on the platform and r_3 is the x coordinate of the position of the payload COG on the platform, as shown in Figure 12.

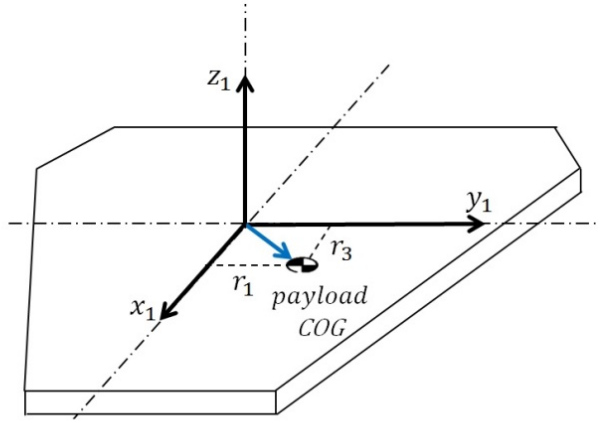

Figure 12. Illustration of the position coordinates r_1 and r_3 of the payload center of gravity on the surface of the inertially stabilized platform.

Figure 13 illustrates the multiple-point weighing method for calculating the position of the payload center of gravity on the surface of the ISP. The weight w_1 of the payload is the sum of the force readings A, B, C of load cell 1, load cell 2, and load cell 3, respectively, described with (4).

$$w_1 = A + B + C \tag{4}$$

The distance r_1 corresponding to the y coordinate of the payload COG on the ISP coordinate frame is calculated with (5).

$$r_1 = \frac{(B)77.942 - (A)77.942}{w_1} \tag{5}$$

The distance r_3 corresponding to the x coordinate of the payload COG on the ISP coordinate frame is calculated with (6).

$$r_3 = 90 - \left[\frac{(A+B)135}{w_1}\right] \tag{6}$$

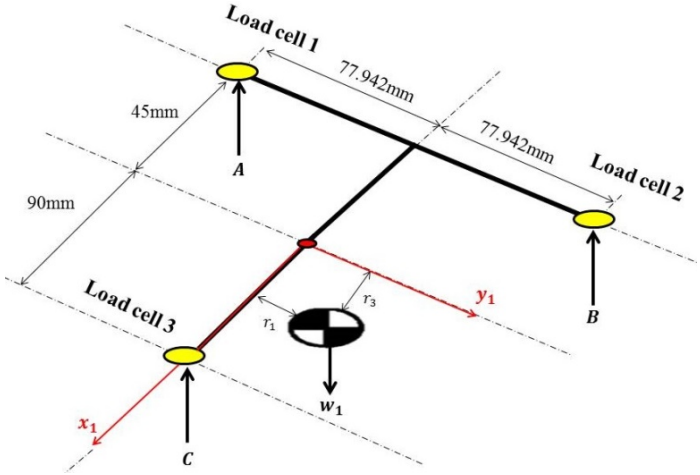

Figure 13. Multiple-point weighing method for calculating the position coordinates of the center of gravity of a payload on the surface of the inertially stabilized platform.

The position coordinates of the payload COG on the surface of the platform are defined with respect to platform coordinate frame Σ_1 with vector ${}^1P_{COG}$ (7).

$${}^1P_{COG} = \begin{bmatrix} r_3 \\ r_1 \\ 0 \end{bmatrix} \tag{7}$$

4.3. Calculation of the Vertical Coordinate of the Payload Center of Gravity from the Surface of the Inertially Stabilized Platform

After calculating the horizontal position coordinates of the payload COG on the surface of the platform as described in the previous section, the next step is to calculate the height h of the payload COG with respect to the platform surface, namely its z position coordinate, as seen on Figure 14.

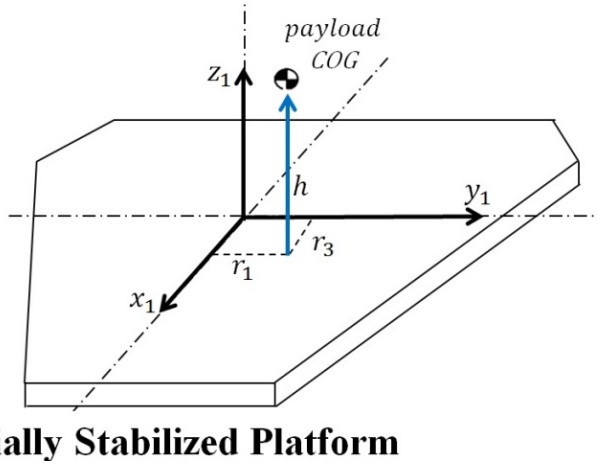

Figure 14. Illustration of the vertical position h of the payload center of gravity from the surface of the inertially stabilized platform.

A payload with weight w_1 initially placed on the platform workspace offset from the stabilizing mechanism's vertical axis of symmetry by distances r_1 and r_3 will cause the passive gimbal to incline along the roll axis by an angle σ and along the pitch axis by an angle θ, as illustrated in Figure 15. After placing the payload on the surface of the ISP, we describe the positions of all the coordinate frames with respect to the reference frame Σ_0. We proceed to calculate the height of the payload COG from the surface of the ISP by analyzing the roll and pitch inclination angles of the passive gimbal.

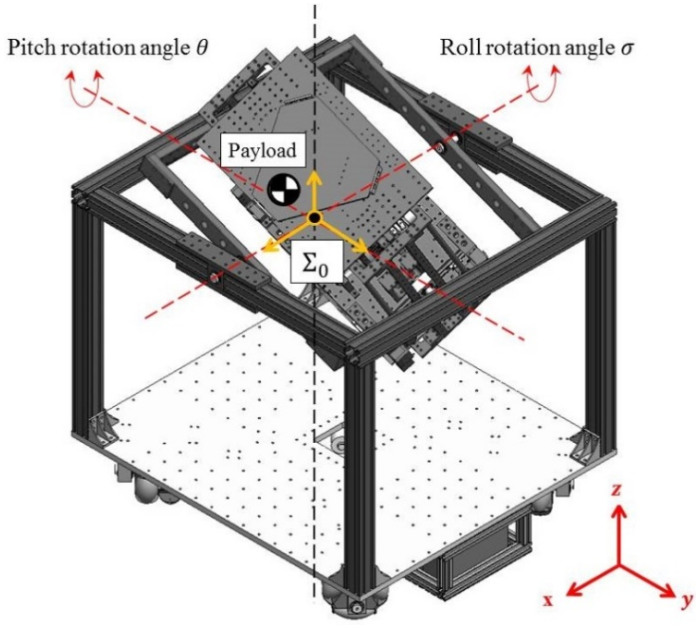

Figure 15. Inclination of the passive gimbal caused by initial placement of a payload on the inertially stabilized platform.

The position coordinates $({}^0P_{origin1x}, {}^0P_{origin1y}, {}^0P_{origin1z})$ represent the position of the origin of ISP coordinate frame Σ_1 with respect to the fixed reference frame Σ_0 resulting after the pitch and roll rotation of the passive gimbal caused by the placement of the payload on the ISP. These coordinates are described by vector ${}^0P_{origin1}$ (8).

$$ {}^0P_{origin1} = \begin{bmatrix} \cos\theta & \sin\sigma\sin\theta & \cos\sigma\sin\theta \\ 0 & \cos\sigma & -\sin\sigma \\ -\sin\theta & \sin\sigma\cos\theta & \cos\sigma\cos\theta \end{bmatrix} * \begin{bmatrix} 0 \\ 0 \\ L_1 \end{bmatrix} = \begin{bmatrix} {}^0P_{origin1x} \\ {}^0P_{origin1y} \\ {}^0P_{origin1z} \end{bmatrix} \quad (8) $$

The position coordinates $({}^0P_{origin2x}, {}^0P_{origin2y}, {}^0P_{origin2z})$ represent the position of the origin of the counterweight coordinate frame Σ_2 with respect to the fixed reference frame Σ_0 resulting after pitch and roll rotation of the gimbal. These coordinates are described by vector ${}^0P_{origin2}$ (9).

$$ {}^0P_{origin2} = \begin{bmatrix} \cos\theta & \sin\sigma\sin\theta & \cos\sigma\sin\theta \\ 0 & \cos\sigma & -\sin\sigma \\ -\sin\theta & \sin\sigma\cos\theta & \cos\sigma\cos\theta \end{bmatrix} * \begin{bmatrix} 0 \\ 0 \\ L_2 \end{bmatrix} = \begin{bmatrix} {}^0P_{origin2x} \\ {}^0P_{origin2y} \\ {}^0P_{origin2z} \end{bmatrix} \quad (9) $$

We now perform a transformation of the position of the payload COG on the surface of the ISP from its description with respect to the ISP local frame (7) to a description with respect to the reference frame Σ_0. The coordinates $({}^0P_{COGx}, {}^0P_{COGy}, {}^0P_{COGz})$ represent the position of the payload COG with respect to the reference frame Σ_0 resulting after pitch and roll rotation of the passive gimbal. They are described by vector ${}^0P_{COG}$ (10).

$$ {}^0P_{COG} = \begin{bmatrix} \cos\theta & \sin\sigma\sin\theta & \cos\sigma\sin\theta & {}^0P_{origin1x} \\ 0 & \cos\sigma & -\sin\sigma & {}^0P_{origin1y} \\ -\sin\theta & \sin\sigma\cos\theta & \cos\sigma\cos\theta & {}^0P_{origin1z} \\ 0 & 0 & 0 & 1 \end{bmatrix} * \begin{bmatrix} r_3 \\ r_1 \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} {}^0P_{COGx} \\ {}^0P_{COGy} \\ {}^0P_{COGz} \\ 1 \end{bmatrix} (10) $$

To perform the calculation of the height h of the payload COG from the surface of the ISP, we carry out a statics analysis of the inclined stabilizing mechanism. For this purpose we derive the spherical coordinates (r, β, α) of the ISP coordinate frame Σ_1 with respect to the reference frame Σ_0. The spherical coordinates describe the ISP's radial distance, azimuth angle and elevation angle with respect to the reference frame Σ_0. The spherical coordinates are used to select a cross-sectional plane in which both the pitch and roll inclination of the ISP are simultaneously accounted for. The inclination of the ISP in roll and pitch is simultaneously described by the elevation angle α of the spherical coordinates of the ISP coordinate frame.

The ISP spherical coordinates r, β, and α are defined by (11), (12), and (13) respectively; they are derived from the ISP Cartesian coordinates described by (8) and are all described with respect to the reference coordinate frame Σ_0

$$ r = \sqrt{\left({}^0P_{origin1x}\right)^2 + \left({}^0P_{origin1y}\right)^2 + \left({}^0P_{origin1z}\right)^2} \quad (11) $$

$$ \beta = \tan^{-1} \frac{{}^0P_{origin1y}}{{}^0P_{origin1x}} \quad (12) $$

$$ \alpha = \sin^{-1} \frac{{}^0P_{origin1z}}{r} \quad (13) $$

where:

r = radial distance from the origin of the reference frame Σ_0 to the origin of the ISP coordinate frame Σ_1.

β = azimuth angle of the point ${}^0P_{origin1}$ (origin of the ISP coordinate frame Σ_1).

α = elevation angle of the point ${}^0P_{origin1}$ (origin of the ISP coordinate frame Σ_1).

We proceed to select a cross sectional plane using the description of the position of the ISP in spherical coordinates derived above. A coordinate frame Σ_3 is assigned to the cross-sectional plane, with its origin coincident with the origin of reference frame Σ_0, its x_3 axis collinear with the projection of radial distance r on the x_0, y_0 plane, its z_3 axis collinear with the z_0 axis of the reference frame Σ_0, and with its $y_3$axis orthogonal to axes x_3 and z_3 as illustrated in Figure 16.

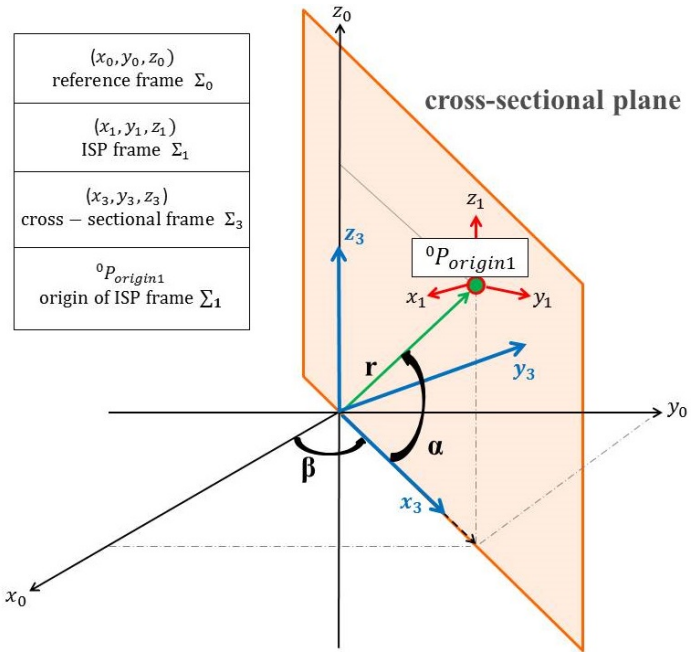

Figure 16. Image of the cross-sectional plane selected from the inertially stabilized platform's spherical coordinates, and the corresponding coordinate frame assignment Σ_3.

We now proceed to describe the position of the origin of the ISP coordinate frame Σ_1, the counterweight coordinate frame Σ_2, and the position ${}^0P_{COG}$ of the payload COG all with respect to the cross-sectional plane frame Σ_3.

The transformation of the position of the origin of the ISP coordinate frame Σ_1 from its description with respect to reference frame Σ_0 (8) to its description with respect to the cross-sectional plane Σ_3 is defined by vector ${}^3P_{origin1}$ (14).

$$ {}^3P_{origin1} = \begin{bmatrix} \cos\beta & \sin\beta & 0 \\ -\sin\beta & \cos\beta & 0 \\ 0 & 0 & 1 \end{bmatrix} * \begin{bmatrix} {}^0P_{origin1x} \\ {}^0P_{origin1y} \\ {}^0P_{origin1z} \end{bmatrix} = \begin{bmatrix} {}^3P_{origin1x} \\ {}^3P_{origin1y} \\ {}^3P_{origin1z} \end{bmatrix} \quad (14) $$

The transformation of the position of the origin of the counterweight coordinate frame Σ_2 from its description with respect to reference frame Σ_0 (9) to its description with respect to the cross-sectional plane Σ_3 is defined by vector ${}^3P_{origin2}$ (15)

$$ {}^3P_{origin2} = \begin{bmatrix} \cos\beta & \sin\beta & 0 \\ -\sin\beta & \cos\beta & 0 \\ 0 & 0 & 1 \end{bmatrix} * \begin{bmatrix} {}^0P_{origin2x} \\ {}^0P_{origin2y} \\ {}^0P_{origin2z} \end{bmatrix} = \begin{bmatrix} {}^3P_{origin2x} \\ {}^3P_{origin2y} \\ {}^3P_{origin2z} \end{bmatrix} \quad (15) $$

The transformation of the position of the payload COG from its description with respect to reference frame Σ_0 (10) to its description with respect to the cross-sectional plane Σ_3 is defined by vector ${}^3P_{COG}$ (16).

$$ {}^3P_{COG} = \begin{bmatrix} \cos\beta & \sin\beta & 0 \\ -\sin\beta & \cos\beta & 0 \\ 0 & 0 & 1 \end{bmatrix} * \begin{bmatrix} {}^0P_{COGx} \\ {}^0P_{COGy} \\ {}^0P_{COGz} \end{bmatrix} = \begin{bmatrix} {}^3P_{COGx} \\ {}^3P_{COGy} \\ {}^3P_{COGz} \end{bmatrix} \quad (16) $$

We now proceed to describe on the cross-sectional plane the distance ρ from the ISP's coordinate frame origin to the position of the payload COG. The position of the ISP coordinate frame described with respect to the cross-sectional plane Σ_3(14) and the position of the payload COG described with respect to the cross-sectional frame Σ_3 (16) shown in Figure 17. Here α is the elevation angle of the ISP and ρ is the distance from the ISP coordinate frame origin to the position of the payload COG.

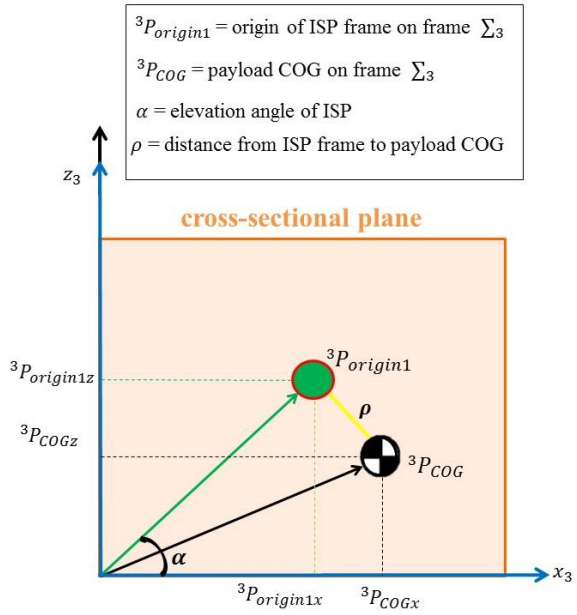

Figure 17. View normal to the cross-sectional plane with the location of the inertially stabilized platform frame and the payload center of gravity.

From the view normal to the cross sectional plane and the coordinate descriptions of the position of the ISP (14) and the payload COG (16) , distance ρ is defined by (17).

$$ \rho = \sqrt{({}^3P_{COGx} - {}^3P_{origin1x})^2 + ({}^3P_{COGz} - {}^3P_{origin1z})^2} \quad (17) $$

Finally, we proceed to take moments under static condition about the crossing point of the gimbal pitch and roll rotation axes (coincident with the origin of the cross-sectional frame Σ_3) to calculate the height h of the payload COG as per Figure 18

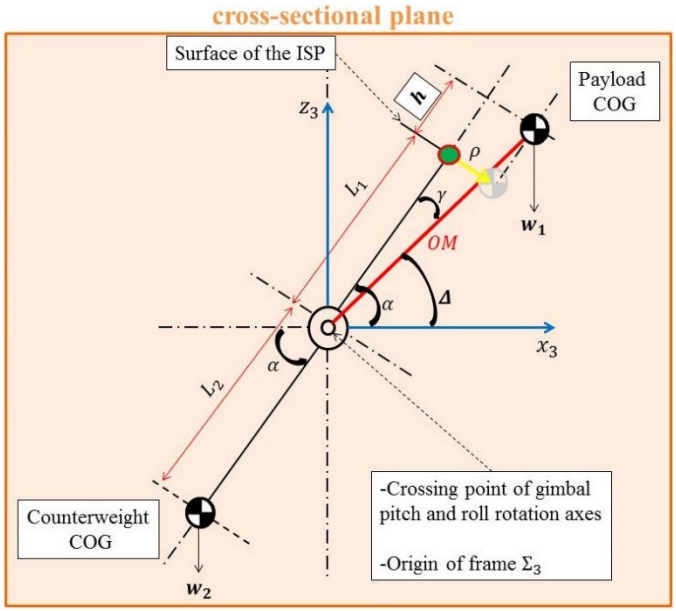

Figure 18. View normal to the cross-sectional plane for the calculation of the height h of the payload center of gravity.

where:

L_1= distance from crossing point of the gimbal rotation axes to the ISP coordinate frame Σ_1.

L_2= distance from the crossing point of the gimbal rotation axes to the counterweight coordinate frame Σ_2.

w_1= weight of the payload.

w_2= weight of the counterweight .

OM = distance from the crossing point of the gimbal rotation axes to the payload COG.

α = elevation angle of the ISP.

h = height of the payload COG from the ISP surface.

$$\gamma = \tan^{-1}\frac{\rho}{L_1} \quad (17)$$

$$\Delta = \alpha - \gamma \quad (18)$$

$$\mathrm{OM} = \sqrt{(L_1 + h)^2 + \rho^2} \quad (19)$$

As illustrated in Figure 18, we use the view of the cross-sectional plane to take moments about the crossing point of the gimbal pitch and roll axes under static condition (20). From this equation the height *h* of the payload COG from the surface of the ISP is calculated with (21).

$$\sum \tau = \sqrt{(L_1 + h)^2 + \rho^2} * cos\,\Delta * w_1 - L_2 * \cos\alpha = 0 \quad (20)$$

$$h = \frac{\sqrt{(\cos\alpha)^2 * {L_2}^2 * {w_2}^2 - (\cos\Delta)^2 * \rho^2 * {w_1}^2} - (\cos\Delta) * L_1 * w_1}{w_1 * \cos\Delta} \quad (21)$$

5. Control

The pitch and roll inclination angles of the passive gimbal are measured by the onboard SEN-10736 inertial measurement unit. The pitch angle measured is used as feedback in a PID control scheme to actuate the X Stage, displacing the counterweight along the *x* axis until the passive gimbal reaches a setpoint angle of zero degrees of inclination about the pitch axis [7]. The roll angle measured is used as feedback in a PID control scheme to actuate the Y Stage, displacing the counterweight along the *y* axis until the passive gimbal reaches a setpoint angle of zero degrees of inclination about the roll axis [7]. As a result, the payload line of sight is oriented to a horizontal position with respect to the inertial reference frame Σ_0.

Both the X Stage and the Y Stage are each equipped with a Copal RE30E500-213 incremental optical encoder for position feedback. Figure 19 shows the block diagram for the X Stage control and Figure 20 shows the block diagram for the Y Stage control.

For the control of the Z Stage, the control system calculates the target vertical position L_2 of the counterweight that satisfies (3) using the weight of the payload measured by the CZL204E strain gauge load cells located on the platform. Once the calculation according to (3) is done, the control system displaces the Z Stage vertically to reach this setpoint. Figure 21 shows the block diagram for the Z Stage control.

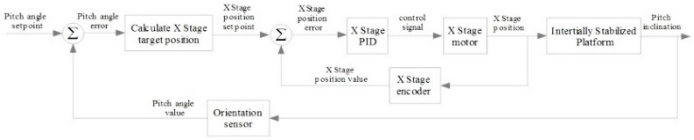

Figure 19. Block diagram for X Stage control.

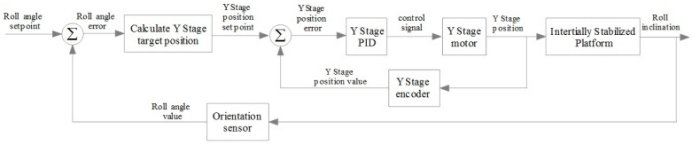

Figure 20. Block diagram for Y Stage control.

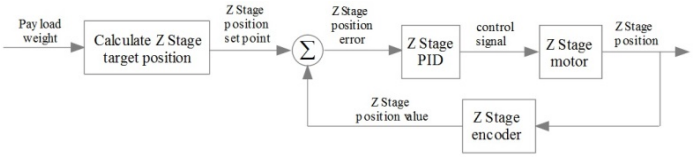

Figure 21. Block diagram for Z Stage control.

6. Experimental setup

The second prototype of the inertially stabilized platform with passive gimbal as well as the host vehicle are here presented. Fundamental experiments were conducted to measure the linear speed of the X Stage, Y Stage, and Z stage. Moreover, a fundamental experiment was conducted to test the accuracy of the calculation of the position of the payload COG on the surface of the inertially stabilized platform.

The stabilizing mechanism mounted on the omnidirectional host vehicle is shown in Figure 22 and its dimensions are shown in Figure 23.

A close-up of the stabilizing mechanism's counterweight comprised of the XY Stage and the Z Stage is shown in Figure 24.

Figure 25 shows an overview of the motions of the XY Stage and Z Stage of the stabilizing mechanism.

An overhead view of the inertially stabilized platform is shown in Figure 26, and a bottom view of the vehicle's omnidirectional mobile base is shown in Figure 27.

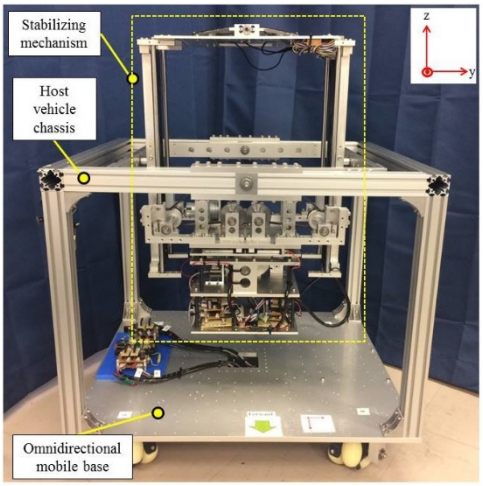

Figure 22. Second prototype of the stabilizing mechanism on the host vehicle.

Z Stage encoder	Copal RE30E500-213 incremental optical encoder Resolution: 500 pulse/rev

6.1. Linear Speed of the XY Stage

Fundamental experiments were performed to measure the linear speed of the X Stage as it is displaced along its motion range, and the linear speed of the Y Stage as it is displaced along its motion range. The tests to measure the linear speed of each stage were performed by driving the corresponding stage motor at full capacity from the start of its motion range to the end of its motion range, repeating the motion 5 times for each stage.

Figure 28 shows the velocity profile of the X Stage as it is displaced from rest at 0mm to its maximum motion range of 81mm. The X Stage had an average linear speed of 200.3 mm/s, taking 0.35 seconds to move along its motion range.

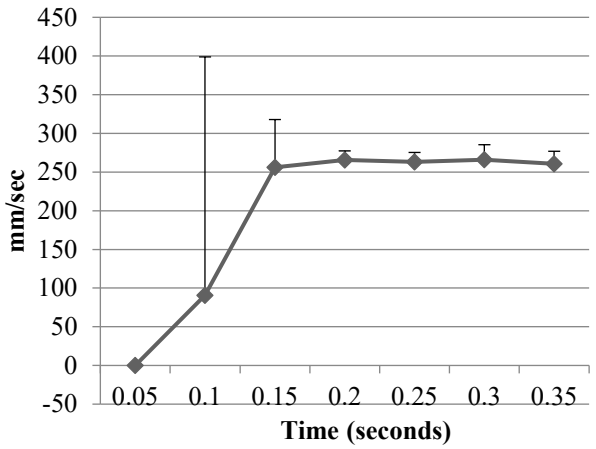

Figure 28. Linear velocity of the X Stage.

Figure 29 shows the velocity profile of the Y Stage as it is displaced from rest at 0mm to its maximum motion range of 115mm. The Y Stage had an average linear speed of 210.2 mm/s, taking 0.5 seconds to move along its motion range.

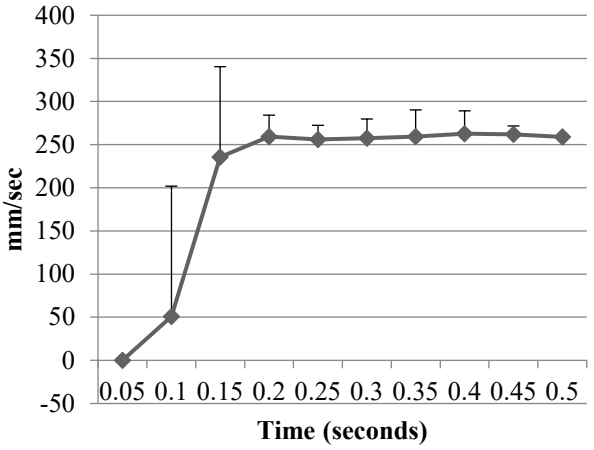

Figure 29. Linear velocity of the Y Stage.

6.2. Linear Speed of the Z Stage

Initially, the deployment of the Z Stage driving motor on the second prototype actuated the Z Stage via a direct attachment of the motor shaft to the driving gear shaft. Experiments revealed that the motor driving the Z Stage lacked enough braking power

to maintain the Z stage at a fixed position (setpoint position) on the Z axis. When the Z stage reached its vertical target position and the motor was braked, the downward weight of the XY Stage/Counterweight produced a torque on the motor shaft higher than its braking torque, and as a result, the Z Stage moved down. This caused the control system to drive the Z Stage upward again trying to maintain the target position, resulting in large oscillations of the Z Stage during operation time. Figure 30 shows the previous deployment of the Z Stage motor.

To tackle this problem, we modified the method to drive the Z Stage to a worm gear drive with a reduction ratio of 20:1 This modification improves the lifting torque of the Z Stage to elevate the XY Stage/Counterweight and takes advantage of the non-backdrivability of the worm gear to provide a mechanical break that prevents the Z Stage from moving down once it has reached its vertical target position. Figure 31 shows the modified deployment with worm gear drive to improve lifting torque and provide a mechanical break to prevent a descent of the Z Stage due to gravity.

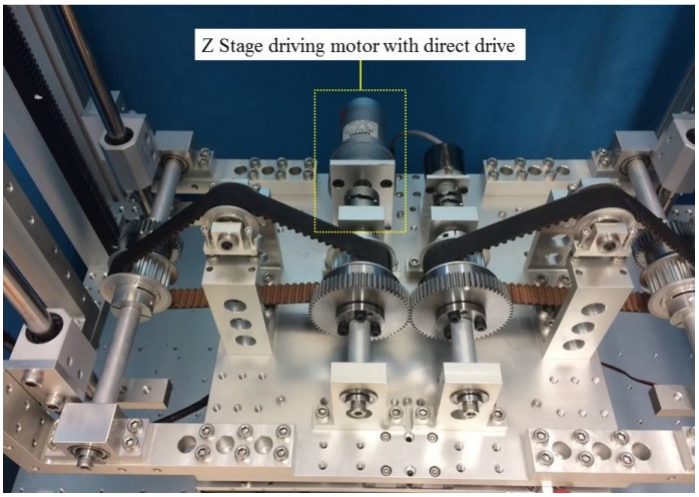

Figure 30. Previous deployment of the Z Stage driving motor.

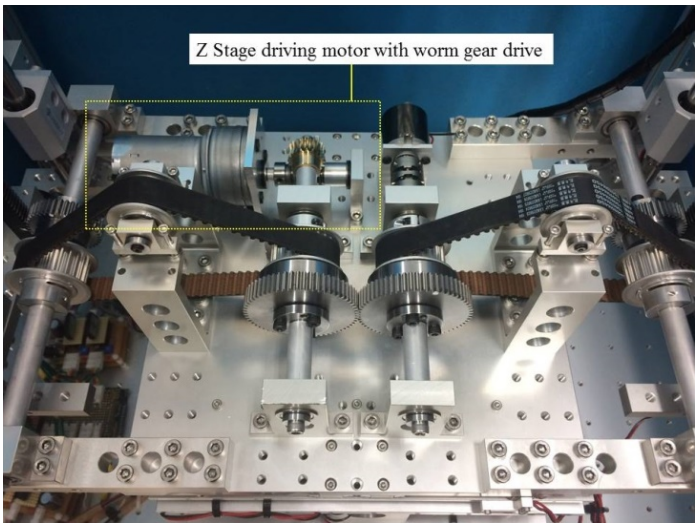

Figure 31. Current deployment of the Z Stage driving motor with worm gear.

With the current deployment of the Z Stage driving motor with worm gear drive, a fundamental experiment was performed to measure the linear speed of the Z Stage as it is displaced along its motion range. The tests to measure the linear speed were performed by driving Z Stage motor at full capacity from the start of its motion range, to the end of its motion range, repeating the motion 5 times.

Figure 32 shows the velocity profile of the Z Stage as it is displaced from rest at 0mm to its maximum motion range of 390mm. The Z Stage had an average linear speed of 5.75 mm/s, taking 67.9 seconds to move along its motion range.

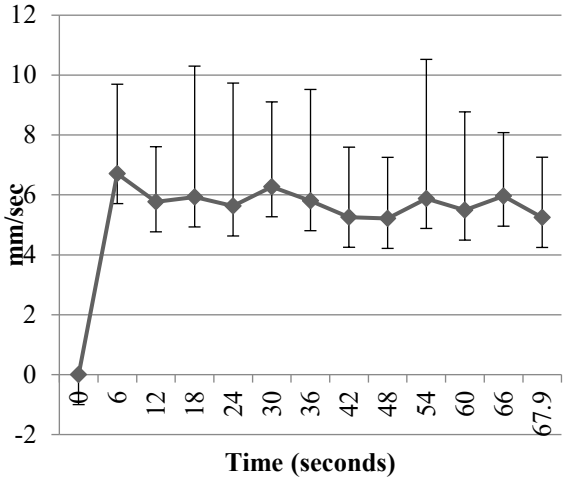

Figure 32. Linear velocity of the Z Stage.

6.3. Calculation of the Position of the Payload Center of Gravity on the Surface of the Inertially Stabilized Platform

For this experiment, a grid with 5mm markers was aligned with the axes of the ISP coordinate frame Σ_1 (Figure 33), and a 1.5 kg calibration weight was placed on eight different positions on the surface of the ISP as payload, corresponding to eight (x,y) coordinates on the ISP coordinate frame Σ_1. The coordinate position of the payload on the surface of the platform was measured with the multiple-point weighing method discussed in Chapter 4, section 4.2.

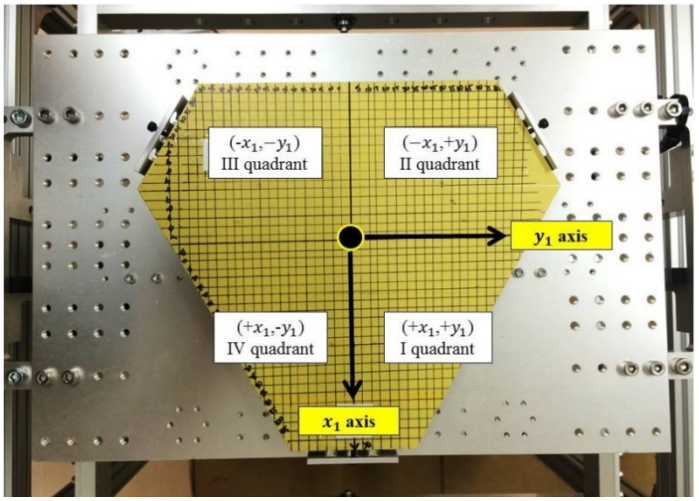

Figure 33. The inertially stabilized platform with a grid for the experiment to calculate the horizontal position of a payload's center of gravity.

Table 4 shows the results of the measurements of the horizontal position of the payload COG corresponding to its physical position coordinates on the ISP surface. Figure 34 illustrates the results shown in Table 4.

Table 4. Results of the measurements for the positions of the payload center of gravity.

Location	Physical COG Coordinates in millimeters	Measured COG Coordinates in millimeters	Standard Error in Measured COG Coordinates	
	(x,y)	*(x,y)*	*x*	*y*
1	(-50.0, 0.0)	(-51.16, 0.57)	0.19	0.09

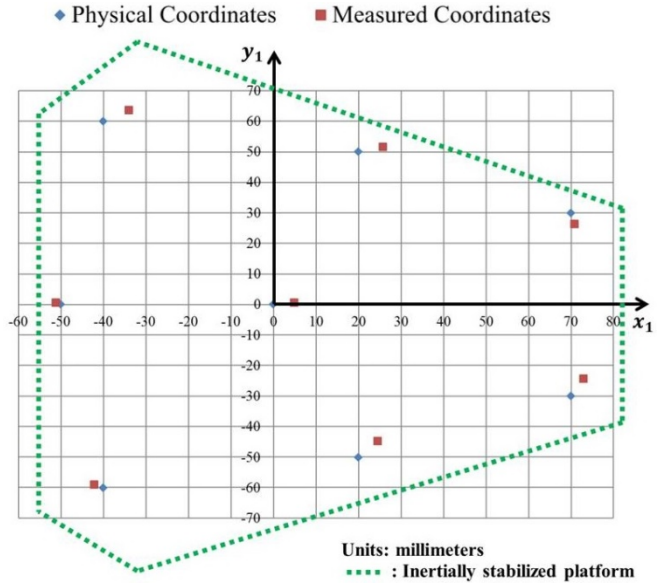

Figure 34. Physical positions of the payload center of gravity on the surface of the ISP and the corresponding measured values.

Future steps

The next step in this research is to experimentally test the proposed theoretical framework for the calculation of the height of the payload center of gravity presented in Chapter 4, section 4.3.

Applications

The stabilizing strategy and motion isolation method with passive gimbal axes discussed in this paper rely on adjusting the mass properties of the system. Since the calculations and motor actuations to accomplish payload stabilization are performed at startup, once the system is balanced no motor output or computational calculations are required during the rest of operation time of the system. These feature reduces the power requirements and the computational resources needed during the operation time of the stabilizing system, making it suitable for battery powered-applications and applications where computational capability is restricted.

Furthermore, the ability of the proposed stabilizing mechanism of having a payload placed in an arbitrary position on the platform and stabilizing its LOS makes its use intuitive and simple, suitable for applications involving human interaction without requiring skill or assembly.

Conclusion

In this paper, a method for disturbance isolation of an inertially stabilized platform using a passive gimbal was described. In the method discussed, the inertially stabilized platform is attached to a gimbal suspended on the host vehicle chassis by freely rotating (passive) joints, with no torque coupling between the gimbal and the host vehicle chassis. As a result, the gimbal is isolated from the vehicle chassis angular motion.

A consequence of the use of a passive gimbal is that in order to stabilize the line of sight of a payload, the payload's weight and the position of its center of gravity are required to be known. A method of calculating the three-dimensional position of the center of gravity of a payload once it is placed on the inertially stabilized platform was presented. The calculation of the (*x,y*) coordinates of the payload COG was tested experimentally and demonstrated to be adequate.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Cooperative Intelligent Transportation Systems (C-ITS) are gaining ground and currently are almost part of our everyday life. A C-ITS environment can provide numerous services that soon will become essential to roads' users. The latter resides in improvement of road safety, entertainment, and commercial services. However, in order to provide such services, the C-ITS environment needs an advertisement and dissemination service for them. Indeed, users have to be aware of the available services in order to request them if needed. Current standards of service announcement show their limits, especially regarding the interoperability between communication profiles. For this reason, in this paper, we describes our new service advertisement solution called CAM-Infrastructure. The latter is compliant with ETSI standards and is deployed in SCOOP@F, a nationwide scale project.

1 Introduction

In the few last years, automobile manufacturers gave more interest into Collaborative Intelligent Transportation Systems (C-ITS). Indeed, they provided numerous prototypes of vehicles equipped with sensors, dedicated computing hardware and dedicated short-range radio (DSRC) for communication with other nearby ITS Station Vehicles (ITSS-V) or with road side infrastructure (ITS Station Road side unit (ITSS-R)). Furthermore, numerous deployment project were achieved like SCMS [1], SEVECOM [2], PRESERVE [3] [4], CORRIDOR [5], Eco-AT [6] and SCOOP@F [7].

Within an ITS environment, numerous services such as improvement of road safety, driver assistance, entertainment and commercial services are provided. In order to achieve these services, their advertisement and dissemination are mandatory. In a classical scenario, a service provider which can be an application provider or even a commercial advertisement provider sends out the service advertisement message through an ITSS-R, and nearby receiving, ITSS-Vs start to disseminate those advertisement messages by forwarding them to other vehicles in their neighborhood [8].

Numerous works and studies were proposed and conducted in the goal of providing efficient and secure service advertisement protocols. However, beyond the different organisms' architectures and requirements, only ISO and IEEE proposed standards: Fast service advertisement protocol (FSAP) described by ISO 24102-5 standard [9]; and Wave Service Advertisement (WSA) defined in IEEE 1609.3 standard [10]. Nonetheless, the latter are compatible only with architectures proposed by their respective organisms. ETSI proposes Service Announcement Message (SAM) and Extended SAM (ESAM), which is -while writing this paper- not yet standardized [11] [12]. In addition, SAM is suitable only for systems using Geonetworking protocol on G5. We recall that using Geonetworking protocol for information carrying have the shortcoming of huge time delays, since the packets go by each hop.

Our work is part of SCOOP@F project. The latter is a french Cooperative ITS pilot deployment project (extended to Europe) that aims at deploying C-ITS in a nationwide scale. 2000 kms of road are to be equipped with Road Side Units (ITSS-R) and 3,000

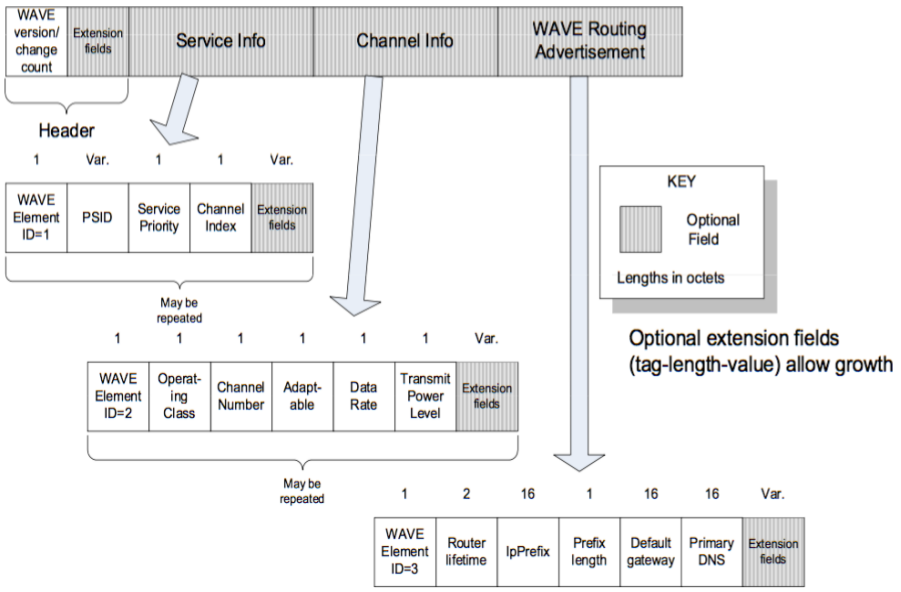

Figure 1: WSA message format [13]

ITSS-V with On-Board Units to enable communication between the infrastructure (the road operator) and the user (the driver). Ile de France, Bordeaux and its ring, Bretagne and Isere counties, in addition to Paris-Strasbourg highway represent the fields of the first deployments . SCOOP@F architecture relies on ETSI published standards. Thus, WSA is not compatible with our needs. Furthermore, SAM does not cover all our needs and requirements. Indeed, in multiple scenarios, we use one hop (face-to-face) advertisement, which is not compatible with SAM.

In order to remedy SAM limits, we implemented a new advertisement solution called Cooperative Awareness Message Infrastructure (CAM-I). Its main advantage is that CAM-I is compliant with the Cooperative Awareness Message (CAM) existing standard [14]. We describe the details of CAM-I structure and functioning in this work which represent an extension of [15].

The rest of the paper is organized as follows: Section 2 gives an overview of the existing advertisement standards and explain our motivation for this work. Section 3 details our CAM-I solution. Section 4 describes a comparison of the proposed solution CAM-I with existing solutions. Finally, Section 5 concludes this paper and introduce our future works.

2 Related Works and motivation

Numerous research proposals and studies on services advertisement were conducted. However, since our project concerns a real nationwide deployment project, we will discuss only standardization working groups and consortia works.

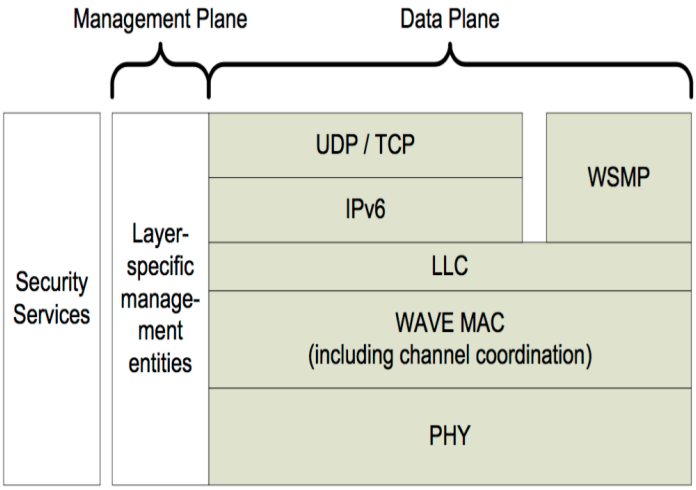

Figure 2: IEEE communication stack [16]

2.1 IEEE WAVE Service Announcement (WSA)

IEEE proposes WAVE Service Announcement (WSA), described in IEEE 1609.3 [10]. In a system implementing it, all stations are required to monitor the multi-channel radio Control Channel (CCH). In 1609.3 provider mode, the station transmits a WSA message on the CCH during the CCH interval. Consequently, since all ITSS are monitoring this channel at that time, they all receive the WSA. The WSA contains a list of the services that the provider will provide during the Service Channel (SCH) interval. It also provides the SCH channel number that they will be using. The services are identified by a code number known as a Provider Service Identifier (PSID). If an ITSS in user mode receives a WSA that contains a PSID of interest, it will switch to the appropriate SCH

during the SCH interval and will make use of that service [17]. Figure 1 describes the structure of a WSA message.

WSA is only compatible with architectures that deploy IEEE WAVE communication stack described by Figure 2. Thus, this solution does not fit needs of SCOOP@F project and more generally european projects which rely on ETSI-based architecture.

2.2 ISO Fast Service Announcement Protocol (FSAP)

ISO proposes Fast Service Announcement Protocol (FSAP) [9] [18] in order to inform peer stations about available services by means of Fast Service Announcement Messages (FSAM). FSAM structure is very similar to WSA messages. This service advertisement distinguishes at least the following roles: (1) Service Advertisement Manager which contains a Server manager that transmits FSAMs and a Client manager, responsible for FSAMs' reception; (2) Service Provider which ensure provision of ITS services; and (3) Service User which consumes ITS services. FSAM messages are encoded according to UPER encoding rules [19].

FSAP relies on two types of unique identifiers in its functioning:

- **ITS Application IDentifier (ITS-AID):** specified in ISO 17419 [20] as an unsigned integer which have the same function as the IEEE PSID. It also shares a common number space with PSID. According to [20] the ITS-AID of FSAP is equal to 2.113.664.
- **ITS Port Number (ITS-PN):** also specified in ISO 17419 [20]. It is used at the OSI transport layer in order to identify source and destination port numbers of advertised application and services.

[18] introduces Harmonized Service Advertisement Message (HSAM), a hypothetical service advertisement message, having almost the same structure as FSAM and that can be extended to different forms. Figure 3 describes its structure details.

2.3 ETSI Service Announcement Message

ETSI proposes Services Announcement Message (SAM), which represents an ITS message that advertises available services. SAM is broadcasted from an ITSS-R on G5 on channel CCH using the Geonetworking protocol. Within a SAM, an ITSS-R must provide some specific information such as the list of the available services, the type of target for each services and the communication profile. More specifically, the available services are a list of Service-IDs. The target of the service has the value (All) or a Community-ID (CID) which associates a specific group of ITSS to an ID. The communication profile is identified by a Communication Profile Identifier (CPID).

SAMs can be sent simultaneously until a maximum threshold of sent messages which depends on the risk of congestion of CCH. At reception, SAMs are received in transport level packets. The Network & Transport layer will send the SAMs to the Facilities Layer. At this level, a first function called "Messages Management" decodes the SAMs and sends the list of services and other data to a second function called "Services Announcement" which will provide several checks. For each service, the Service Announcement function will check if the ITSS is part of "All" or a "community" thanks to its CID. If yes, it will need to verify if the service has been subscribed or not. If the community or ITSS did not subscribed for the announced service then it should not be considered. The ITSS will create a list with all the relevant services checked from the list of the advertised services proposed in the SAM. The service announcement function will select one or several relevant services from the list depending on the channel capability so the service can be executed.

2.4 ETSI Extended Service Announcement Message

Recently, ETSI proposed an extended version of SAM called Extended SAM (ESAM) [12]. It defines three roles: (1) a Service Provider whose role is to register, update or deregister the provided services. (2) Service Announcer which announces the services provided by the Service Provider. The service provider and the service announcer can be the same ITSS or two distinct ITSSs. (3) Service User which represent ITSS-Vs that use the service.

The communication between each role is defined following the communication stack in Figure 4. At the application layer, the type of service, the requested actions regarding this service and other fields depending on the previously mentioned roles are defined to the management entity through the MA-SAP interface. At facility layer, ESAM needs to be encoded or decoded then managed by the management entity for each message transmission where UPER encoding rules are applied. One principal function of the management entity is to define the ITSS Communication Profile (ITS-SCP) used for the message transmission through the MA-SAP interface. Security processes between the Facility Layer and the Security Entity are achieved through the interface SF-SAP. At Networking and Transport (NT) Layer, the ESAM is delivered as a payload to the facility layer through the NF-SAP interface.

One novelty of the ESAM is the inclusion of ExtendedChannelInfos field and other needed extensions in its definition. For instance, the ExtendedChannelInfos is used in order to define new communication technologies which can be used to announce the ESAM such as IPv6. This feature was missing from the previous SAM definition which supported only G5 communication as discussed in [15]. However, no

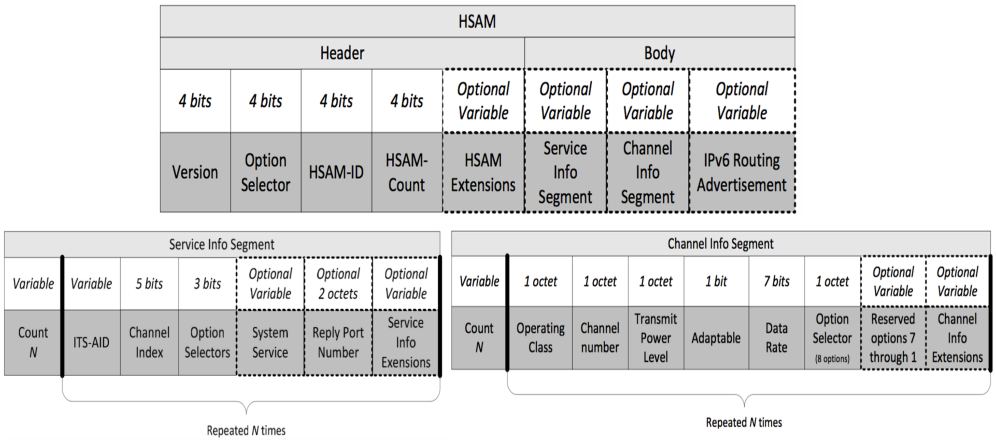

Figure 3: HSAM structure [18]

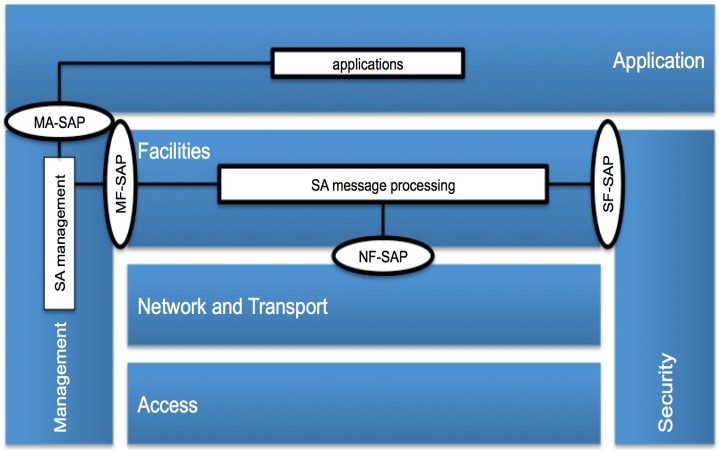

Figure 4: SA in the context of the ETSI ITSS reference architecture [21]

clear definition on the use of new protocol type different than GN is defined yet.

SAM and ESAM solutions are suitable only for systems using Geonetworking protocol on G5 (plus IPv6 for ESAM), which relies on broadcast of messages. The latter does not suits to SCOOP@F needs, in which it does exist multiple scenarios where ITSSs communicate in face-to-face way (one hop) using IP protocol. In addition SAM and ESAM still being drafts from years and are not considered as standards yet.

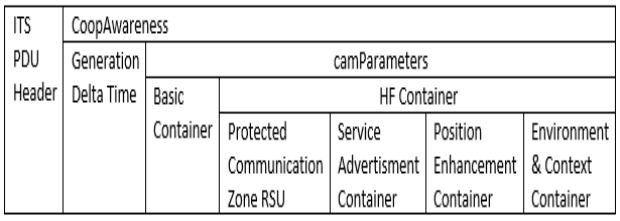

Figure 5: CAM-I structure

To remedy these limits and to achieve SCOOP@F needs, we propose a new solution for service advertisement called CAM-I, a solution compliant with ETSI CAM standard [14].

3 New solution for services advertisement: CAM-I

In this section we describe the details of the advertisement solution that we propose.

3.1 Global structure

In ETSI architecture, periodic messages called CAM are diffused continuously. In our solution, the available services are advertised via the periodic broadcasting of a specific CAM message by the ITSS-R, called CAM-Infrastructure (CAM-I) message. The latter has almost the same structure as a CAM message sent by an ITSS-V.

As described in [14], a CAM is composed of one common ITS PDU header and multiple containers. The ITS PDU header is a common header that includes the information of the protocol version, the message type and the ITSS ID of the originating ITSS.

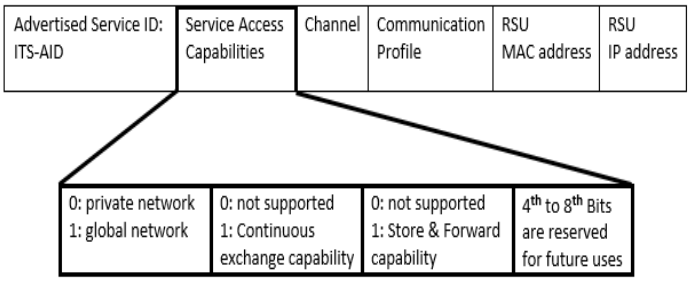

Figure 6: Service Advertisement Container structure

For an ITSS-V a CAM shall comprise one basic container and one high frequency container, and may also include one low frequency container and one or more other special containers:

- Basic container: includes basic information related to the originating ITSS.
- High frequency container: contains highly dynamic information of the originating ITSS.
- Low frequency container: contains static and not highly dynamic information of the originating ITSS.
- Special vehicle container: contains information specific to the vehicle role of the originating vehicle ITSS.

As indicated in the CAM standard [14], all CAMs generated by an ITSS-R shall include a basic container and optionally more containers. Consequently, the proposed CAM-I is composed of an ITS PDU Header, a basic container and a High Frequency container, which in turn, is composed of 4 containers. Described by Figure 5, CAM-I structure is similar to the one of CAM. Its header (ITS PDU Header) and Basic Container are compliant with the standard ETSI EN 302 637-2 [14]. The ITS PDU header includes the protocol version, the message type, the ITSS-R identifier of the originating ITSS-R. In addition, a generation delta time of the message is included. The Basic Container includes the following fields: (1) The type of the emitting station (ITSS-R): 15; (2) The geographic position of the ITSS-R. While the PDU header and the low frequency are the same as in CAM, we modified the High Frequency (HF) container. More specifically, we defined a HF Container composed of the following containers:
(1) Service Advertisement Container;
(2) Position Enhancement Container;
(3) Environment & Context Container;
(4) Protected Communication Zone RSU Container.

Table 1 describes the structure of the three last containers. Service Advertisement container is detailed in next section.

3.2 Service Advertisement Container

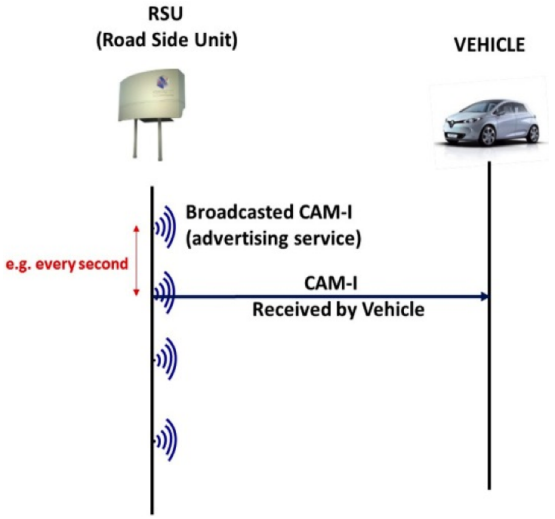

Figure 7: CAM-I Service Advertisement scenario

As described by Figure 6, Service Advertisement Container includes the following fields:
(1) Advertisement Service ID: this byte provides the ID of the advertised service.
(2) Service Access Capabilities (SAC): The second byte details access capabilities to (1) a private network such as a network of the road operator that offers an access reserved to its staff, or (2) to a global network like Internet. The choice of access policy for SCOOP@F vehicles depends on the global access policy selected by each road operator. In SAC:

- The first bit indicates if a private access or a global access is available. If it is equal to 1, then the ITSS-R provides access to a private network and if it is equal to 0 ITSS-R provides access to a global one.
- The second bit, when having the value 1, it indicates the capacity of the ITSS-R to establish a continuous exchange with a remote server via the private/ global network. If this it has the value 0, then the ITSS-R does not possess this capacity.
- The third bit, when it is equal to 1, it indicates

Container	Data Elements	Type	Size in Bytes	Description
ITS PDU Header	Protocol version	same as in [14]		Version 1
	Message ID	same as in [14]		CAM
	Station ID	same as in [14]		ITSS-R identifier
Generation Delta Time	Generation Delta Time	same as in [14]		
Basic Container	Station Type	same as in [14]		ITSS-R
	Reference Position	same as in [14]		Accurate position of the ITSS-R established at installation time
Protected Communication Zone RSU Container	Data elements for Toll collect protection	same as in [14]		for tolling collection
Position Enhancement Container	GPS Position Delta Latitude	same as in [14]		Optional, enable to correct positioning error by comparing the RSU accurate position with the given RSU GPS position
	GPS Position Delta Longitude	same as in [14]		Same as for GPS Latitude
	GPS Position Delta altitude	same as in [14]		Same as for GPS Latitude
	Satellite constellation locally available	Integer	1 byte	Enable the use of correction if the vehicle detects the same satellite constellation
	Trace leading to the ITSS-R	same as in [14]		Enable the improvement of the vehicle position and the computation of the time window for RSU exchange
Environment and context container	local meteorological data	Binary	1 byte	Provide local meteorological data for environmental characterization
	Road environment	Integer	byte	Provide the road environment type in which the RSU is positioned
	Traffic condition	Integer	1 byte	Provide the current traffic condition

Table 1: Global Structure of the proposed CAM-I

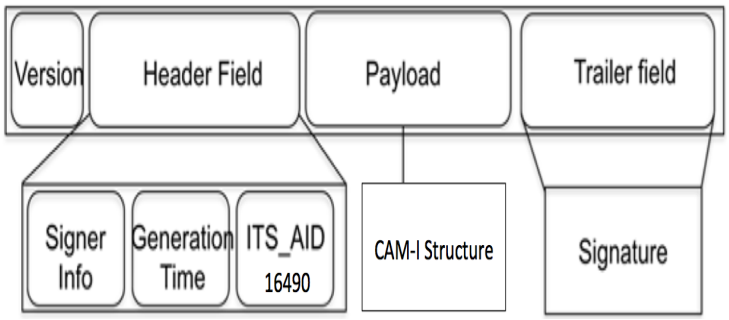

Figure 8: Secured Message transporting CAM-I structure

Octet	Description
0	SSP version control
1 to 2	Service-specific parameter
3 to 30	Reserved for future usage

Table 2: Octet Scheme for CAM-I SSPs

the capacity of the ITSS-R to store locally a message and to transmit it as soon as possible towards a remote server (store and forward) via the private/ global network, as soon as this one is available. If this bit has the value 0, the ITSS-R does not possess this capacity.

- The bits N° 4, 5, 6, 7 and 8 are reserved for a future usage.

(3) Channel: This field contains the channel used for communication
(4) Communication Profile (CP): The fourth byte indicates the communication profile.
(5) RSU MAC Address (RM): This field indicates the MAC address of the ITSS-R.
(6) RSU IP Address (RIP): This field indicates the IP address of the ITSS-R. If IPv4 is supported the field contains the IPv4 address of the RSU. If IPv6 is supported the field contains the IPv6 address of the RSU. If both IPv4 and Ipv6 are supported, the field contains both addresses.

Figure 7 describes a typical scenario where an ITSS-R broadcasts a CAM-I, an ITSS-V receives the message and requests a needed service.

CAM-I messages are encoded in ASN.1 UPER encoding and integrated as the payload of a secured message compliant with the structure described in the standard ETSI TS 103097 [22] as described by Figure 8. For security purposes, the secured message is signed using the private key of the sender through Elliptic Curve Digital Signature Algorithm (ECDSA). The secured message contains also a field named ITS Application ID (AID). The latter describes the type of message transported by the secured message and its value should belongs to a standardized list defined by ISO organism. For example the ITS AID value of CAM is 36, of DENM is 37. A request to ISO was sent to provide an ITS AID for CAM-I. Consequently, pending a response, we use 16490 value, which belongs to test range values. CAM-I is broadcasted via CCH channel with a frequency f as follows: $1\ hertz \leq f \leq 10\ hertz$. this frequency is chosen according to the environment and context needs. As for CAM messages and in compliance with ETSI 103097 standard, for each second, the first sent message contains the sender's certificate. For the rest, just the digest of the certificate, computed using SHA 256 algorithm is sent. Detailed ASN.1 structure of the advertisement container is described by Listing 1.

3.3 Security material for CAM-I users

in order to use CAM-I service, the ITSS-R should have the authorization for. The latter is provided within its certificate. Indeed, ETSI certificates contains (1) a field called ITS AID, which includes the list of the services that the station is authorized to access and use; and (2) a field called ITS AID Service Specific Permissions (SSP), which indicates specific sets of permissions within the overall permissions indicated by the ITS-AID. In other words the SSP is a field that includes the different authorized options for each ITS AID. For example, if an ITSS-R can have authorization to use CAM-I service but not authorized to use PKI requests sub-service.

SSPs for CAM message are defined using 3 byte as described in ETSI EN 302 637-2 v1.3.2 [14]. SSPs for DENM message are defined using 4 bytes as presented in ETSI EN 302 637-3 v1.2.2 [23]. For CAM-I, we choose to use the octet scheme for CAM-I SSPs described by Table 2.

In Table 3 we give the SSPs adopted in SCOOP@F project for CAM-I usage.

4 Comparison of CAM-I with existing standards

In this section we produce, through Table 4, a comparison of the proposed CAM-I with WSA and SAM . One can note that CAM-I represents the advantage of using face-to-face communication instead of Geonetworking, which can performs enormous time savings. Furthermore, it is compliant with all standards, thus, CAM-I can be used in other deployment projects, even

[1]CAM-I uses a proprietary access control protocol named NACS. Once the advertisement message CAM-I is intercepted by ITSS-Vs

if they are not based on ETSI standards.

5 Conclusion and future work

In this paper we have proposed a new solution for service advertisement in Intelligent Transportation Systems' environments called CAM-I. The latter is compliant with existing ETSI standards. Furthermore, it remedies SAM and ESAM limits for interoperability with communication protocols. CAM-I is deployed in SCOOP@F project, which represents a french deployment project that intends to implement a full ITS environment in a nationwide scale. Till the day we are writing this paper, three advertised services are deployed: (1) ITSSs' provisioning with certificates from PKI; (2) upload of logs generated by ITSSs; and (3) Data Exchange with specific applications.

For our future works, at short term we plan to study the impact of this solution on the network's overhead and the study of its evolution regarding the infrastructure scalability. For long term perspectives, we plan to submit CAM-I proposal to ETSI organism in the goal to standardize it.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

This paper is an extended version of the paper originally presented at the International Conference on Machine Learning and Applications (ICMLA 2016), which proposes the construction of classifiers, based on the application of machine learning techniques, to identify defaulting clients with credit recovery potential. The study was carried out in 3 segments of a Bank's operations and achieved excellent results. Generalized linear modeling algorithms (GLM), distributed random forest algorithms (DRF), deep learning (DL) and gradient expansion algorithms (GBM) implemented on the H2O.ai platform were used.

1 Introduction

This paper is an extension of the work originally presented at the International Conference on Machine Learning and Application (ICMLA 2016) [1], which presented the first results of a Brazilian bank research to reduce its losses with defaulting clients. That study covered only a sample of 22.764 transactions, representing a homogeneous group of bank customers. We extend our previous work by adding all operations from individual costumers which were in arrears in July 2016.

The Figure 1 shows that there was a slight decrease in the number of debtors in June 2016, but increased again in the following months.

The Bank had nearly 54 million active credit agreements with individuals at the end of July 2016. Of this amount, approximately 8.6 million were delayed for 15 days or more, accounting for 15.9% of the contracts. These delinquent contracts amounted to more than R$20.8 billion (US$6.4 billion in July 2016), accounting for approximately 5.8% of the Bank's individuals loan portfolio, an increase of 1.2 percentage points over December 2014. That is, in 21 months the financial volume of overdue loans contracted by individuals increased by 26%.

The Brazilian Central Bank (BACEN) regulation requires financial institutions to classify their credit operations and perform a Provision for Doubtful Accounts (PDA), according to a risk classification. The main criteria for the classification is the number of days in arrears of each individual credit agreement. The Table 1 shows the days-in-delay ranges considered to determine a risk classification and therefore the minimum percentage PDA that financial institutions must reserve. As an operation increases the number of days in arrears, there is a non-linear increase of PDA, which may allocate 100% of the outstanding balance of the contract. For example, an operation with a debit balance of R$ 1,000, with 15 days in arrears, must reserve a minimum provision of R$ 10. The amount of the provision may reach R$ 1,000 if the arrear reach 180 days.

Table 1: Days in arrears x Provision

Days in arrears	Minimum Risk	PDA %
15-30	B	1
31-60	C	3
61-90	D	10
91-120	E	30
121-150	F	50
151-180	G	70
over 180	H	100

At the time of the credit granting, financial institutions assume the credit risk and make the corresponding provisions in accordance with the current Central Bank regulation. Acting in this way, in a possible default of the customer, the financial institution and the stability of the financial system will be protected. However, as a customer delays its operations, the natural reaction of financial institutions is to restrict credit to them, increasing the chances of these

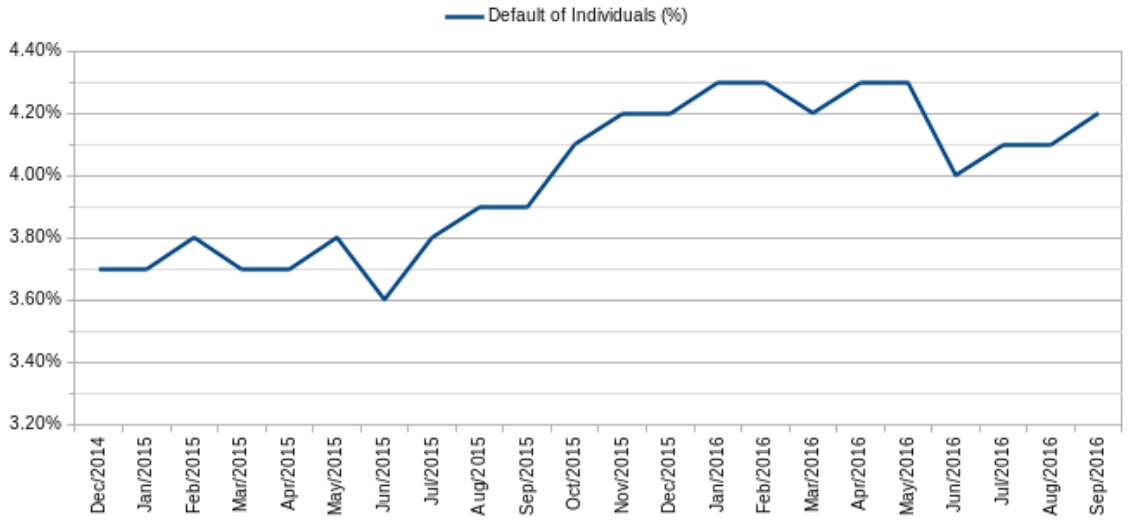

Figure 1: Default of individuals.

customer's evasion to other institutions, since they will not be able to carry out new credit operations with the original institution.

With the increase in delinquency, a mobilization of account managers of the bank began in order to mitigate the evasion of its clients by approaching the customer in arrear and proposing alternatives that could fix the delayed payments. Hence, solving the default situation and the possible loss of the customer of its portfolio, as well as reducing the financial amount allocated to (PDA).

Provided that the selection of the clients is a time and resource consuming task, the main objective of this study was to apply machine learning techniques to predict the recovery probability of credit transactions, providing a list of delinquent clients with the greatest potential for regularization of their operations.

Models were developed using Generalized Linear Models (GLM), Gradient Boosted Methods (GBM), Distributed Random Forest (DRF) and Deep Learning (DL)[1] . The models were compared using the recall indicator, which will be explained on section 3. The models were developed using the R language and H2O machine learning platform, considering its parallel processing capabilities. Further details on section 3. [2]

This paper is organized as follows: Section 2 presents the credit scoring state of the art. Section 3 presents the methodology used in this study. Section 4 presents the modeling and evaluation of the generated models for each method. Section 5 presents the conclusion and future works.

2 State of the Art

The default numbers observed in Brazil, from December 2014 to September 2016, indicate that financial institutions need a tool to support their credit granting decisions. Although there are several studies to identify the customer credit risk, qualifying them as good or bad payers, helping to make a decision to grant credit, there is few research studying the credit recovery, when the delinquency occurs. [2]

In [3], the author conducted a study evaluating 41 publications on the award of credit since 2006, all of them using classifiers to categorize customers as good or bad payers. Those works were organized into three categories of classifiers: individuals; homogeneous ensemble; and heterogeneous ensemble classifiers. Most of the algorithms used were implemented through logistic regression and decision trees, with their use of boosting, bagging and forest variants.

The Table 2 lists the eight datasets that were used in [3] to verify the performance of each of the 41 models proposed, evaluating them from the standpoint of 6 indicators: Area Under the Receiver Operating Curve (AUC), percentage correctly classified (PCC), partial Gini index, H-measure, Brier Score (BS) and Kolmogorov-Smirnov (KS).

Table 2: Datasets used in [3].

Name	Samples	Features	Debtors %
AC	690	14	44.5
GC	1000	20	30.0
Th02	1225	17	26.4
Bene 1	3123	27	66.7
Bene 2	7190	28	30.0
UK	30000	14	4.0
PAK	50000	37	26.1
GMC	150000	12	6.7

[1] Documentation available at http://docs.h2o.ai/h2o/latest-stable/index.html
[2] H2O is an open source machine learning platform, available at www.h2o.ai

In [4], the author presents AUC as an indicator that represent how well classified were the data, independent of its distribution or misclassification costs. PCC is an overall accuracy measure that indicates the percentage of outcomes that were correctly classified.[5]

A score was assigned to each algorithm, referring to the classification received in the comparison between them within the same performance measure . For example, the algorithm K-means was in 12th place considering the AUC indicator, while the KNN was in 29th place. Thus, the scores attributed to them were 12 and 29, respectively. Then, the algorithms were ordered by the average of all metrics, where the 1st place were the algorithm that obtained the lowest score.

The heterogeneous multi-classifiers presented a better performance, although the performance between the three categories was very similar.

The Table 3 presents the results of the benchmark, indicating that the HCES-Bag algorithm obtained the highest AUC result, while the AVG-W and Gasen algorithms reached 80.7% of the PCC.

Table 3: State of Art - Models Comparison - Adapted from [3]

	Algorithm	AUC	PCC
Heterogeneous Ensemble	HCES-Bag	0.932	80.2
	AVG W	0.931	80.7
	GASEN	0.931	80.7
Homogeneous Ensemble	RF	0.931	78.9
	BagNN	0.927	80.2
	Boost	0.93	77.2
Individual	LR	0.931	70.84
	LDA	0.929	78.4
	SVM-Rbf	0.925	79.9

3 Methodology and Infrastructure Setup

This section presents the methodology used in this study, which was segmented in stages according to the phases proposed by CRISP-DM [6]. The result of each phase is described in the next Section.

Training model environment - The models were trained on the H2O.ai platform, in a cluster formed by 5 virtual machines on the same subnet and with the same configuration. Their operating system was Red Hat Enterprise Linux 6.8 64 bits, with 34 cores and 80 GB of RAM. It were used H2O.ai version 3.10.4.5 and R version 3.3.0. It were allocated 44 GB of RAM and all cores of each machine, reaching a total of 170 cores and 220 GB of RAM.

The training dataset consisted of about 40 million copies, requiring a robust platform to be made available for the processing of this data.

The Figure 2 shows the CPU meter of the H2O.ai cluster in action at the moment of the training models. It shows the percentage of use of the processors of each machine, identified by the final number of its IP address (174 to 178) and the port number where the service was running (54321). The intensive use of the 170 available cores shown in the Figure 2 reinforces the need for a robust platform.

Each vertical bar represents 1 core and the colors represent the type of process executed: idle time (blue), user time (green) and system time (red).

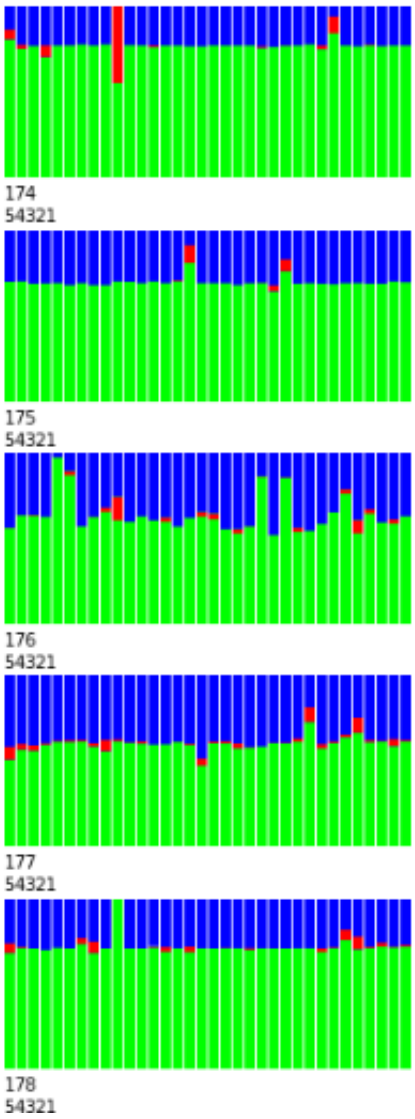

Figure 2: Cluster H2O in action

4 Results

In this sections, the results of the CRISP-DM phases are detailed: Data Understanding, Data preparation, Modeling, Evaluation and Implementation.

4.1 Data Understanding

The dataset was obtained by the extraction of information from legacy systems and customers relationship data marts. It has information about customers accounting,demographic and financial data. The dataset had 28 features and 1 label that indicates the recovery of the respective credit operation. The

Tables 4 and 5 present these 28 characteristics organized by categorical and numerical features.

Table 4: Numeric features

Features	Description
V1	Number of days of delinquency.
V2	Number of days remaining for the end of the contract.
V3	Contract value.
V4	Amount of the outstanding balance.
V5	Amount PDA provisioned for the contract.
V6	Percentage loss expected for the contract.
V7	Quantity of products owned by the customer.
V8	Time of customer relationship with the Bank.
V9	Customer age.
V10	Customer income.
V11	Customer total contribution margin amount.
V12	Value of Gross Domestic Product per capita

Table 5: Categorical features

Features	Description
VC1	Customer portfolio type.
VC2	Customer behavioral segment.
VC3	Product.
VC4	Product modality.
VC5	Structured operation indicator.
VC6	Management level that approved the operation.
VC7	Transaction risk credit.
VC8	Range of past delays.
VC9	PDA lock indicator.
VC10	Customer relationship with the bank.
VC11	Client instruction level.
VC12	Customer gender.
VC13	Nature of customer occupation.
VC14	Customer registration status.
VC15	Customer's age group.
VC16	Age group of relationship time.

For the data understanding, the analysis began in July 2016 containing all credit operations contracts, regardless of the contracted product, with more than 14 days in arrears. In addition, transactions with the highest risk were considered as already lost contracts by our business specialists and removed from our dataset.

For definition of the label, the delay reduction indicator, the following operation was performed, considering that the data of the delayed operations were used in July 2016:

- Delay Reduction Indicator = 1, for all transactions that showed a reduction in the number of days overdue in the subsequent month, that is, in August 2016, or that their debit balances have been reduced.

- Delay Reduction Indicator = 0, otherwise, that is, presenting a delay or debit balance in August 2016 equivalent to or greater than that observed in July 2016.

The Table 6 presents the summary of transactions in the month of July 2016, which resulted in a base with 4,514,029 contracts. Of this total, only 271,193 (6.01%) were recovered.

Table 6: Dataset July 2016

Not recovered	Recovered
4,242,836	271,193
93.99%	6.01%
Samples	4,514,029

The bank has several strategies for credit recovery, according to the customer profile and the category of the credit operation, grouping them with distinct trading rules. Existing segments are divided into massive and individual strategies. Massive strategies are implemented for segments that have a known behavior pattern, whereas individual strategies cover operations that have atypical or special characteristics which require a case-by-case analysis to perform a collection and recovery.

Based on this information, the dataset was splitted into segments compatible with the institution's recovery strategies, grouping similar products and customer segments with characteristics in common removing from the study the segments that have an individualized trading strategy. The Table 7 lists the 11 segments that will be worked on in this study, in addition to the Individualized Strategy segment, which was removed from the study.

4.2 Data Preparation

In this study, the analysis were performed only in the first 3 segments, Mortgage Loan I, II and III. The remaining segments are in the final analysis phase and will be presented at a later time.

Then, the data preparation was started, analyzing each one of the segments, preparing the data sets for the modeling phase.

The Tables 8, 10 and 12 present the summary of descriptive analysis of the numerical features of segments Mortgage Loan I, II and III, respectively. In these tables the data of quartiles and Kendall's Tau [7] of each feature are presented.

The Tables 9, 11 and 13 present the summary of the descriptive analysis of the categorical variables, listing the Kendall's Tau and the number of levels of each feature.

Table 7: Credit Operations Segments

Segment	Credit Recovered				Samples
	No		Yes		
	Qty	%	Qty	%

4.3 Modeling

For each dataset, 4 predictive models were elaborated, using the H2O platform integrated to the R, using the algorithms Generalized Linear Models (GLM), Gradient Boosting Method (GBM), Random Forest (DRF) and Deep Learning (DL). The first three algorithms were chosen because they represent the techniques most used in the calculation of credit risk, which performs a classification task very similar in [8]. The algorithm DL was used to verify its behavior in a knowledge area not yet explored, but with expectation of good suitability due to the use of a great amount of variables. [9]

The datasets of the Mortgage Loan I and III segments were splitted into 3 parts: 70% for training, 20% for validation and 10% for testing. Due to the small number of observations in the Mortgage Loan II, this dataset was splitted only in training and validation in a proportion of 80% and 20%, respectively. The next subsections present the evaluation results for each segment.

4.3.1 Mortgage Loan I

- GLM - This algorithm obtained an AUC = 0.7774755 and a PCC of 66.53%, as shown in the Figure 3 and in the Table 14

5 Conclusion

The main objective of this study was to apply machine learning techniques to predict the probability of recovery of credit transactions, providing a list of defaulting clients with greater potential for regularization of their operations.

Studies were carried out on 3 segments of credit operations, which have different recovery strategies, the Mortgage Loan segments I, II and III. With the machine learning, it was possible to elaborate predictive models with great contribution to assist the Managers in the approach to their clients with operations in arrears.

Mortgage Loan I - The model with the highest recall was obtained with the GBM algorithm. In a total of 11,342 contracts in default, there were 3,424 contracts recovered. The model was able to correctly predict 3,141 contracts, reaching a recall of 92.86%. Using the prioritization list generated by the model, the work of Bank Managers would be more assertive. In addition, the model correctly predicted 7,770 (97.02%) contracts, out of 8,008 contracts that would not be recovered.

Mortgage Loan II - The model with the highest recall was obtained with the DL algorithm. In a total of 421 delinquent contracts, there were 116 contracts recovered. The model was able to correctly predict 106 contracts, reaching a recall of 94.38%. In addition, the model correctly predicted 297 (96.74%) contracts out of 307 contracts that would not be recovered.

Mortgage Loan III - The model with the highest recall was obtained with the GBM algorithm. In a total of 884 delinquent contracts, there were 212 contracts recovered. The model was able to accurately predict 186 contracts, reaching a recall of 98.94%. In addition, the model correctly predicted 670 (99.70%) contracts out of 672 contracts that would not be recovered.

The predictive models obtained from the analysis of the first three segments, out of a total of 11, have already shown a potential great benefit to the bank, effectively assisting its customers with delayed operations and avoiding unnecessary efforts in attempts in attempts of negotiation in contracts with low probability of recovering.

5.1 Future Works

The results obtained so far strengthen initiatives for the development of predictive models using machine learning techniques in the Bank studied.

With the increase in the efficiency of credit recovery, the Bank will benefit from the reduction in Allowance for Loan Losses (PDA), directly promoting positive results, with the reversal of provisions already made.

Thus, the study will be expanded to the 8 segments that have not yet been modeled, increasing the use of models obtained through machine learning techniques in credit recovery. In addition, the models al-

ready obtained can be improved with the use of ensemble models.

3 DOF compensation

ABSTRACT

Height estimation of objects is a valuable information for locomotion of autonomous robots and vehicles. Even though several sensors such as stereo cameras have been applied in these systems, cost and processing time have been motivating solutions with monocular cameras. This research proposes two new methods: i) height estimation of objects using only a monocular camera based on flat surface constraints and ii) 3 degree-of-freedom compensation of errors caused by roll, pitch and yaw variations of the camera when applying the Flat Surface Model. Experiments outdoors with the KITTI benchmark data (4997 frames and 436 objects) resulted in improved accuracy of the estimated heights from a maximum error of 1.51 m to 1.12 m and reduced number of estimation failures by 4 times, proving the validity and effectiveness of the proposed method.

1 Introduction

This paper is an extension of work originally presented in the 2016 IEEE/SICE International Symposium on System Integration [1]. This previous work proposed a monocular height estimation method by chronological correction of road unevenness, which basic experiments in laboratory and asphalt correcting camera pitch variations proved the validity of the method. However, since only pitch variations were considered and experiments were conducted on asphalt in one environment, several items remained as future work. Therefore, we extended our work by the following:

- Analysis and 3 degree-of-freedom (3DOF) compensation of errors caused by roll, pitch and yaw variations.
- Extended experiments on asphalt with several conditions of road and objects, permitting further analysis of external disturbances.

Cameras have been applied in many fields such as robotics and autonomous driving for localization and object recognition [2]-[7]. Even though stereo cameras can provide the depth to obstacles, their higher cost and required processing have motivated several studies to estimate depth or height with monocular cameras. Height estimation permits the robot to detect and avoid potential obstacles on the road, becoming a valuable information of the surrounding environment. Studies [8] and [9] estimate height of objects with a steady camera. While the first relies on a previous calculation of the vanishing point, the latter relies on a known object height in the scene. On the other hand, other studies focus on height estimation using a moving camera. Study [10] estimates height by computing the focus of expansion in the scene and segmenting ground and plane by sinusoidal model fitting in reciprocal-polar space. The method proposed in [11] estimates height of objects on the road by obstacle segmentation and known camera displacement from odometric measurements, refining the measurements with several frames. Although there are many promising height estimation methods, they still strongly rely on extra extraction of information from the scene or external sensors. Moreover, the presented methods assume that the ground is flat and no discussions or analyses of eventual pose variations of the camera were mentioned. In this context, we propose in this work a height estimation method that requires no previous information of the scene, nor information from

external sensors. Furthermore, even though we assume flat surface, we analyze and compensate the effects of roll, pitch and yaw variations of the camera.

The rest of this paper is organized as follows. Section 2 introduces the existing issues of monocular cameras due to depth ambiguity and roll, pitch and yaw variations. Section 3 explains the proposed monocular height estimation method and compensations of roll, pitch and yaw variations. The conducted experiments are detailed in section 4. The obtained results are discussed in section 5. Lastly, the conclusions and future work are provided in section 6.

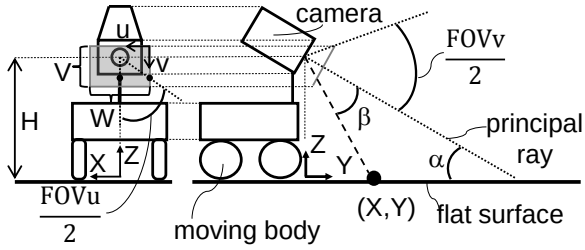

Figure 1: Conversion between pixels and meters using the Flat Surface Model.

2 Issues of Monocular Cameras

In this section, two main issues of monocular cameras are introduced: A) depth ambiguity and B) effects of roll, pitch and yaw variations.

2.1 Depth Ambiguity

In order to explain this limitation, we first briefly introduce the Flat Surface Model (FSM), a technique that permits easy relation of pixels (in camera coordinates) and meters (in real world coordinates), and is commonly applied with monocular cameras [12]-[14]. Figure 1 shows a moving body, a camera and flat surface. The camera is attached to the moving body at a known height H and angle α in relation to the flat surface. The line connecting the camera center and the flat surface with angle α is called principal ray. The coordinate system of the camera is defined by pixels (u,v), with a known and fixed vertical length V and a horizontal length W. The maximum angle seen by the camera (field of view) in both u and v directions are fixed and defined as angles $FOVu$ and $FOVv$. The coordinate system defined by (X,Y,Z) is fixed on the moving body. If we assume that the surface is flat, the relation between a pixel (u,v) and its real position (X,Y,Z) in meters is given by (1) to (3), where β is the angle in relation to the principal ray.

$$\beta = atan(\frac{(2v-V)}{V} tan(\frac{FOVv}{2})) \quad (1)$$

$$Y = \frac{H}{tan(\alpha+\beta)} \quad (2)$$

$$X = Y \frac{cos(\beta)}{\cos(\alpha+\beta)} \frac{(2u-W)}{W} tan(\frac{FOVu}{2}) \quad (3)$$

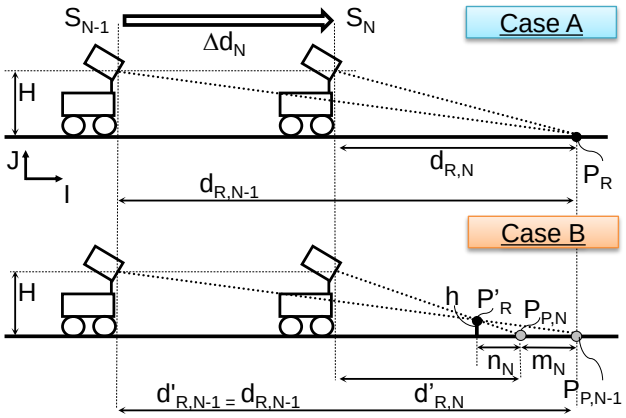

Figure 2: Example of application (A) and limitation (B) when applying the Flat Surface Model.

One common application of the FSM is to estimate the camera displacement by Visual Odometry (VO) [12]-[14], which is briefly explained in "Case A" of Figure 2. First, consider the moving body and camera described in Figure 1 running on a flat surface. In an initial position S_{N-1}, the camera takes a frame and shoots a point P_R on the ground, computing $Y_{N-1} = d_{R,N-1}$. Next, consider that the moving body moves Δd_N in direction I of a coordinate system (I,J) fixed on the ground, reaching position S_N. In this new position, it takes another frame, tracks point P_R and $Y_N = d_{R,N}$ is obtained by the FSM. Using the computed information Y_{N-1} and Y_N from the two positions S_{N-1} and S_N, the real camera displacement ΔCam_N can be correctly estimated by (4). By repeating the previous steps, the displacement of the moving body can be estimated on the following positions. Notice that we showed a simple case with only one point P_R and direction I, but many points and directions can be considered in VO.

$$\Delta Cam_N = d_{R,N-1} - d_{R,N} = \Delta d_N \quad (4)$$

The depth ambiguity can be visualized in "Case B" of Figure 2, which contains an object of height h on the ground. Let's assume that in position S_{N-1} the camera shoots a point P'_R on the top of the object, and the projection on the flat surface is point $P_{P,N-1}$, exactly on the same location as point P_R in "Case A". Although points P_R and P'_R belong to different (X,Y,Z) in the world, the FSM can't distinguish this ambiguity and computes $Y_{N-1} = d'_{R,N-1} = d_{R,N-1}$. However, when the camera moves Δd_N in direction I, it tracks point P'_R and consequently, computes $Y_N = d'_{R,N}$ at position S_N. Finally, the displacement $\Delta Cam'_N$ seen by the camera becomes as (5), what shows that the real displacement Δd_N is not correctly estimated due to the presence of the object.

$$\Delta Cam'_N = d'_{R,N-1} - d'_{R,N} \neq \Delta d_N \quad (5)$$

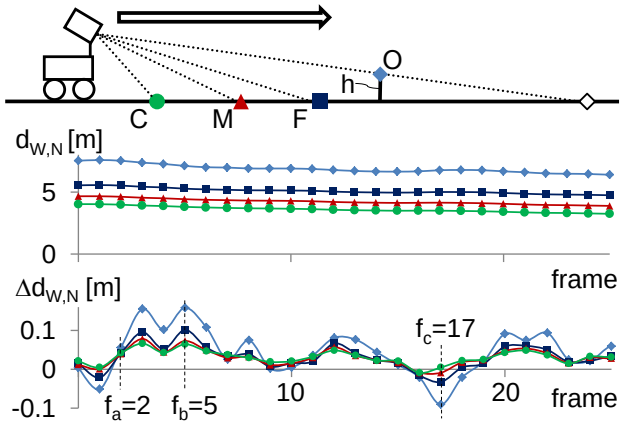

Figure 3: Influences of pose variation on the Flat Surface Model.

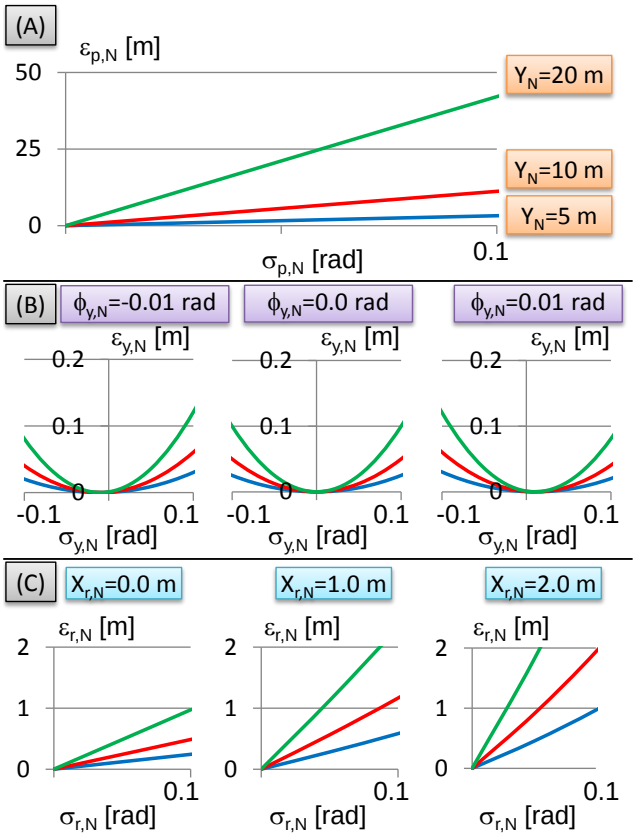

Figure 4: Expected errors of the calculated distances by the FSM in function of pitch (A), yaw (B) and roll (C).

2.2 Effects of Roll, Pitch and Yaw Variations

Even though the FSM assumes that the surface is perfectly flat, in fact small unevennesses exist. Such influences are detailed in Figure 3, with a simple analysis done on a real asphalt. A camera was fixed on a moving body and moved tracking four points: i) on a static object with height h (point O), ii) on the ground far from the camera (point F), iii) on the ground close to the camera (point C) and iv) on the ground with a distance between F and C (point M). In each frame, the distances $Y_N = d_{W,N}$ obtained by the FSM were computed. In order to better visualize the influences of unevennesses, the corresponding displacements $\Delta d_{W,N} = d_{W,N} - d_{W,N-1}$ are also displayed in the figure. If the surface of the asphalt was really flat, then the displacements $\Delta d_{W,N}$ of each point C, M and F were expected to be the same in each frame. However, while this happened in frame $f_a = 2$ for example (suggesting that the pose of the camera was exactly the one expected by the FSM), in frames $f_b = 5$ and $f_c = 17$ the displacements were different (suggesting that the pose of the camera was different from the one expected by the FSM). Moreover, Figure 3 shows another important pattern, which points closer to the camera have smaller magnitudes of $\Delta d_{W,N}$: the magnitude of $\Delta d_{W,N}$ calculated with C in a determined frame is smaller than the one calculated with M, which is smaller than the one calculated with F, which is smaller than the one calculated with O in the same frame. This example clearly shows the effect of unevennesses on the FSM. A further analysis according to roll, pitch and yaw variations is presented in Table 1 and Figure 4.

2.2.1 Pitch

Figure (a) of Table 1 shows the influence of pitch variations on the FSM. Consider that in a certain frame N a moving body that is shooting a point O_R on a static object on the surface has its pitch changed (represented by $\sigma_{p,N}$) by an unevenness. This variation shifts height H to $H_{p,N}$ and therefore the camera computes the distances by the FSM in relation to a new wrong flat surface, $FS_{p,N}$. In this wrong surface, the projection of point O_R becomes $P_{p,N}$ and consequently, $Y_N = d_{p,N}$ is calculated. However, the correct distance in such configuration is the one computed with G_R, the projection of O_R on the real surface on the ground, resulting in $Y_N = d_{R,N}$. The relation between the wrong ($d_{p,N}$) and correct ($d_{R,N}$) distances is shown by (6), (7) and (8), where l_p is the axis of rotation and $\gamma_{p,N}$ is the angle between the camera height H and l_p. It is important to notice that the presented equations don't explicitly contain the object height h. It happens because the computed $Y_N = d_{p,N}$ itself contains this information, since it is function of O_R, $P_{p,N}$ and h. We define the error caused by pitch variation $\sigma_{p,N}$ as $\varepsilon_{p,N}$, which is the difference between the wrong estimated distance ($d_{p,N}$) and correct one ($d_{R,N}$), according to (9). Figure 4 (A) quantifies this error $\varepsilon_{p,N}$ by adopting as example $H = 1.65$ m, $l_p = 1.03$ m, several camera pitch variations ($\sigma_{p,N}$) and apparent distances to a point by the FSM ($Y_N = d_{p,N}$). The adopted values of the constant parameters H and l_p are the same as the ones used in the experiments section for easier analysis of the obtained results. We can observe that $\varepsilon_{p,N}$ increases with the increase of $\sigma_{p,N}$ and Y_N. Even for a pitch variation of $\sigma_{p,N} = 0.1$ rad, the error $\varepsilon_{p,N}$ can reach nearly 50 m when $Y_N = 20$ m, what shows that $\varepsilon_{p,N}$ is very sensitive even to small $\sigma_{p,N}$.

Variation	Compensation
 (a) pitch	$\gamma_p = \arctan(\frac{H}{l_p})$ (6) $H_{p,N} = \sqrt{l_p^2 + H^2} sin(\sigma_{p,N} + \gamma_p)$ (7) $d_{R,N} = \frac{H_{p,N}[(d_{p,N} + l_p)cos(\sigma_{p,N}) - \sqrt{l_p^2 + H^2}cos(\sigma_{p,N} + \gamma_p)]}{H_{p,N} - (d_{p,N} + l_p)sin(\sigma_{p,N})}$ (8) $\varepsilon_{p,N} = \lvert d_{R,N} - d_{p,N} \rvert$ (9)
 (b) yaw	$\phi_{y,N} = atan(\frac{X_{y,N}}{d_{y,N}})$ (10) $d_{R,N} = \sqrt{X_{y,N}^2 + d_{y,N}^2} cos(\sigma_{y,N} - \phi_{y,N})$ (11) $\varepsilon_{y,N} = \lvert d_{R,N} - d_{y,N} \rvert$ (12)
 (c) roll	$\gamma_r = \arctan(\frac{H}{l_r})$ (13) $H_{r,N} = \sqrt{l_r^2 + H^2} sin(\sigma_{r,N} + \gamma_r)$ (14) $d_{R,N} = \frac{H_{r,N} d_{r,N}}{H_{r,N} - (l_r + X_r)sin(\sigma_{r,N})}$ (15) $\varepsilon_{r,N} = \lvert d_{R,N} - d_{r,N} \rvert$ (16)

Table 1: Error compensation of the calculated distances by the FSM caused by variations of roll, pitch and yaw.

2.2.2 Yaw

Figure (b) of Table 1 describes the influence of yaw variations on the FSM. Consider that in a certain frame N, a moving body that is shooting a point O_R on a static object on the surface has its yaw changed ($\sigma_{y,N}$). In the former pose ($pose'_N$), the camera computes the distance to point G_R as $Y_N = d_{y,N}$ and $X_N = X_{y,N}$. However, the correct distance in Y direction in the new pose ($pose_N$) is $d_{R,N}$. Equations (10) and (11) show the relation between the wrong and correct distances, where $\phi_{y,N}$ is the angle in which the camera sees the object in the former pose. The error $\varepsilon_{y,N}$ caused by $\sigma_{y,N}$ is defined as (12). Figure 4 (B) shows error $\varepsilon_{y,N}$ in function of yaw variation ($\sigma_{y,N}$), $\phi_{y,N}$ and apparent distance to the point ($Y_N = d_{y,N}$). First, when $\phi_{y,N} = 0$ rad, we can observe that $\varepsilon_{y,N}$ increases with the increase of Y_N and absolute value of $\sigma_{y,N}$. For similar conditions of Y_N and $\sigma_{y,N}$, when $\phi_{y,N} \neq 0$ the errors are shifted to the left or right according to the value of $\phi_{y,N}$. From this analysis we can observe that small yaw variations such as $\sigma_{y,N} = 0.1$ rad results in $\varepsilon_{y,N} > 0.1$ m for the adopted range of the parameters in the example, what shows that yaw variations cause smaller errors in the distances computed by the FSM comparing to the pitch variations.

2.2.3 Roll

Finally, Figure (c) of Table 1 shows the influence of roll variations on the FSM. Consider a camera tracking a point O_R on a static object of height h on the surface in a certain frame N. In the same frame, the moving body is affected by an unevenness on the flat surface, varying its roll ($\sigma_{r,N}$). This variation changes height H to $H_{r,N}$ and the camera computes the distances by the FSM in relation to a wrong flat surface, $FS_{r,N}$. In this wrong surface, the projection of point O_R becomes $P_{r,N}$ and $Y_N = d_{r,N}$ is calculated. However, the correct distance is the one computed with G_R, the projection of O_R on the real surface on the ground, resulting in $Y_N = d_{R,N}$. The relation between the wrong ($d_{r,N}$) and correct ($d_{R,N}$) distances is shown by (13), (14) and (15), where l_r is the axis of rotation

and $\gamma_{r,N}$ is the angle between the camera height H and l_r. We define the error caused by roll variation $\sigma_{p,N}$ as $\varepsilon_{p,N}$, which is the difference between wrongly estimated distance ($d_{r,N}$) and correct one ($d_{R,N}$), as shown in (16). Figure 4 (C) shows error $\varepsilon_{r,N}$ in function of camera roll variation ($\sigma_{r,N}$), X_r and apparent distance to the point ($Y_N = d_{r,N}$). We can observe that $\varepsilon_{r,N}$ increases with the increase of $\sigma_{r,N}$, X_r and Y_N. For roll variations of $\sigma_{r,N} = 0.1$ rad, $\varepsilon_{r,N} > 2.0$ m can occur for the adopted range of the parameters in the example, but those errors are still smaller than the ones caused by pitch variation.

3 Proposed Method

This section is divided into three parts: A) proposed height estimation method, B) compensation of roll, pitch and yaw variations and C) proposed algorithm.

3.1 Proposed Height Estimation

Although the FSM has the ambiguity limitation when computing VO, in fact, the difference of the obtained displacements caused by the object (ΔCam_N, $\Delta Cam'_N$) contains useful information. First, the presence of objects in the scene influence the apparent displacements in pixels seen from the camera. Such difference in apparent displacements is explored in [12] to find irregularities in the optic flow and detect precipices. On the other hand, no further information can be extracted by existing techniques. Here, our method is based on the principle that since the FSM assumes known H and α, then we can assume that the resulting projections are also function of these dimensions. If we further observe the geometrical relations caused by the FSM and triangulation in two positions (Case B in Figure 2), we can in fact obtain geometrical relations in function of H and α, as shown in (17), (18) and (19). From these equations and (4), we obtain (20) to (22). Several relations can be observed from the equations. First, the object causes an extra amount of apparent displacement, defined as m_N, and it is proportional to the object height h and camera height H. Second, the object height is function of the correct camera displacement ΔCam_N and wrong apparent displacement $\Delta Cam'_N$. As afore mentioned, ΔCam_N can be estimated by traditional VO and even though this technique will be applied, it is not the focus of this work.

$$\frac{H}{d_{R,N-1}} = \frac{h}{m_N + n_N} \tag{17}$$

$$\frac{H}{d'_{R,N}} = \frac{h}{n_N} \tag{18}$$

$$d'_{R,N} = d_{R,N} - m_N \tag{19}$$

$$\Delta Cam'_N = d_{R,N-1} - d_{R,N} + m_N = \Delta Cam_N + m_N \tag{20}$$

$$m_N = \frac{h(d_{R,N-1} - d'_{R,N})}{H} = \frac{h(d'_{R,N-1} - d'_{R,N})}{H} \tag{21}$$

$$h = H(1 - \frac{\Delta Cam_N}{\Delta Cam'_N}) \tag{22}$$

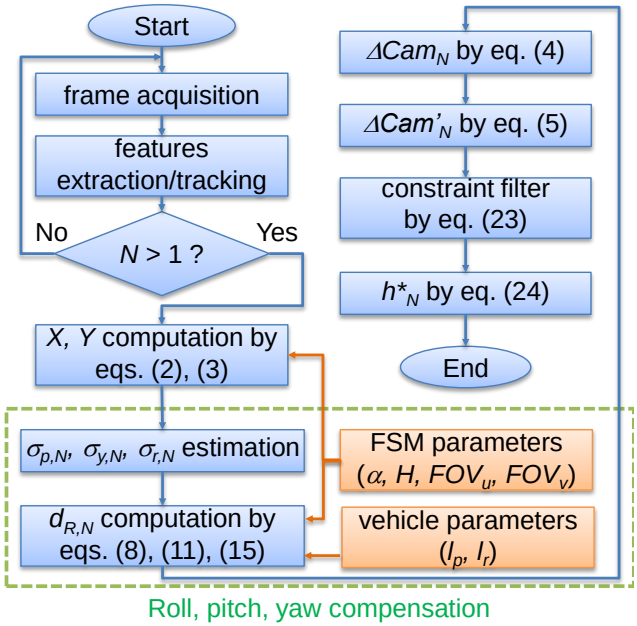

Figure 5: Flowchart of the proposed height estimation method and compensations.

3.2 Compensation of Roll, Pitch and Yaw Variations

The equations displayed in Table 1 show that the compensation of the influences caused by roll, pitch and yaw are straightforward and can be easily done if $\sigma_{p,N}$, $\sigma_{y,N}$ are $\sigma_{r,N}$ are known. Thus, for each acquired frame by the camera, we compute these variations and substitute them with the constant and known parameters of the vehicle (l_p, l_r) and the FSM (α, H, FOV_u, FOV_v) in (8), (11) and (15), obtaining the compensated value $d_{R,N}$. The main steps of the proposed compensations are illustrated in the bottom part of Figure 5.

3.3 Proposed Algorithm

Figure 5 summarizes the flow of the proposed algorithm. Frames are acquired, features are extracted and tracked in two frames. Next, the corresponding values of X and Y are computed by the FSM. Roll, pitch and yaw variations ($\sigma_{p,N}$, $\sigma_{y,N}$, $\sigma_{r,N}$) are estimated by VO and we compensate their influences using (8), (11) and (15), as explained in the previous section. The camera displacement (ΔCam_N) and compensated apparent displacement of the object ($\Delta Cam'_N$) are calculated by the FSM. Here, we propose to apply two filters. First, a filter based on displacement constraints to verify the applied compensations. Even though

the compensations strongly rely on the estimated roll, pitch and yaw, wrong estimations on the contrary lead to high errors. The filter works according to the observed in Figure 3. If a tracked point belongs to an object above the surface, then its apparent displacement must be bigger than the camera displacement ($\Delta Cam_N < \Delta Cam'_N$). Therefore, we check this condition by calculating the apparent displacement of the object with ($\Delta Cam'^{c}_N$) and without ($\Delta Cam'^{nc}_N$) compensations. If one of them satisfies the condition, then we adopt this displacement as $\Delta Cam'_N$. If both or none of them satisfies the condition, then we use the average of the two displacements to estimate the height, as show in (23). Finally, the median (h^*_N) of the previous estimations ($h_1, h_2, ..., h_{N-1}, h_N$) is also applied to filter eventual noises, as (24).

$$\Delta Cam'_N = \begin{cases} \Delta Cam'^{c}_N & if\ \Delta Cam'^{c}_N > \Delta Cam_N > \Delta Cam'^{nc}_N \\ \Delta Cam'^{nc}_N & if\ \Delta Cam'^{c}_N < \Delta Cam_N < \Delta Cam'^{nc}_N \\ \frac{\Delta Cam'^{nc}_N + \Delta Cam'^{c}_N}{2} & \text{otherwise} \end{cases} \quad (23)$$

$$h^*_N = median(h_1, h_2, ..., h_{N-1}, h_N) \quad (24)$$

4 Experiments

The proposed method was evaluated with data from the KITTI Vision Benchmark Suite (called hereon as "KITTI") [15] and processed with a computer Intel(R) Core(TM) i7-4600, 2.10 GHz, operating system Ubuntu (TM) 14.04, Eclipse (TM) development environment and OpenCV libraries [16]. Here, we want to verify the validity and effectiveness of the proposed height estimation and the proposed compensations of errors caused by roll, pitch and yaw variations. Thus, all estimated heights were done with two methods for later comparison: i) with roll, pitch and yaw compensation and ii) without compensation.

4.1 Applied VO

In order to estimate the camera displacement ΔCam_N in each frame, we adopted a simple VO with rotation estimation by Nister's 5-point algorithm [17] and translation by the FSM using features in a ground region close to the camera (details in the Appendix section), similarly to [12]. The parameters (FOV_u, FOV_v, W, V, H, etc) necessary for the experiments were adopted according to the provided by the KITTI. The camera inclination in relation to the ground was not directly provided, but we estimated that $\alpha = 1.1^o$ using the provided velodyne data. The feature extractor applied was FAST [18]. The features were automatically extracted when their number was bellow 1500 features. In order to evaluate the proposed monocular height estimation method, only the left images of the grayscale camera of the KITTI were used.

4.2 Evaluation Criteria

The evaluation was based on the error (ε_N) between the ground truth ($h_{GT,N}$) and the estimated height (h^*_N) in each frame N, according to (25). The ground truth adopted was mainly the height provided by the velodyne, available in the KITTI. Further details can be found in the Appendix section.

$$\varepsilon_N = |h_{GT,N} - h^*_N| \quad (25)$$

We also adopted a criterion to consider if the height estimation in a frame failed or not. For example, since we considered only objects above the ground surface, the estimated heights must be higher than 0 m (i.e., $h_{min} = 0$). Furthermore, since the FSM considers objects below the horizon line, all objects used in the experiment should have maximum height equal to the camera height ($h_{max} = H$). All estimated heights outside this maximum and minimum were considered as failure, as detailed in (26).

$$\text{height estimation} = \begin{cases} \text{success} & h_{min} \leq h^*_N \leq h_{max} \\ \text{failure} & \text{otherwise} \end{cases} \quad (26)$$

4.3 Results

Experiments were conducted with 10 video sequences of the KITTI, which contained many static objects (parked cars, poles, fences, houses, people, boxes, etc) in the scene. In total, height was estimated 4561 times with 436 objects. Objects with height $0 \leq h \leq H$ and distance from 4 to 31 m from the camera were used. The obtained results are summarized in Table 2, Table 3 and Figure 6.

Data	Video sequence (KITTI)	Valid frames	Valid objects
1	00	1103	85
2	05	384	35
3	07	229	18
4	08	373	29

5 Discussions

Table 2 shows the 10 data and corresponding video sequence belonging to the KITTI. The number of valid frames and objects used in each data are also displayed. The estimated heights of all objects chosen within this data are presented in relation to the pixel positions (u,v) in Figure 6. We can observe that the objects were well distributed along pixel u direction, covering many possible positions during the experiments. On the other hand, due to the geometrical limitations of the FSM only pixels below the horizon line (i. e., $v > 200$ pixels) were used, but we can also observe objects distributed along this interval. Next, the used data is displayed in relation to $\sigma_{p,N}$, $\sigma_{y,N}$ and $\sigma_{r,N}$. Variations of roll ($\sigma_{r,N}$) and pitch ($\sigma_{p,N}$) in the used data were smaller than those of yaw ($\sigma_{y,N}$): while the magnitude of roll and pitch variations were within 0.03 rad, the magnitude of the yaw variations were over 0.05 rad. The average error of all used data resulted in 0.20 m with the 3DOF compensations and in 0.23 m when no compensations were done. The maximum error resulted in 1.12 m for the compensated case an 1.51 m for the non-compensated one. Since both average and maximum errors were improved with the compensations, we can affirm that the proposed method is valid and effective. These cases of maximum errors are illustrated in Figure 7. In (a), the case of maximum error with compensations is displayed. The point was chosen too close to the horizon line, becoming very sensitive to noises and causing the high error. However, for the same case, the method without compensation failed to estimate the height. In (b), the case of maximum error without compensation occurred when the camera estimated the object height while climbing a slope. As presented in the previous sections, pitch variations cause higher errors comparing to yaw and roll, and a high error of 1.51 m was expected. Nevertheless, when the proposed compensations were applied in the same data, the estimation error dropped to 0.56 m. Furthermore, the distribution of $\sigma_{p,N}$, $\sigma_{y,N}$ and $\sigma_{r,N}$ in the experiments (Figure 8) shows that even though the data was taken on public roads, most of the pose variations were below 0.01 rad: 98.8% of the $\sigma_{p,N}$, 76.6% of the $\sigma_{y,N}$ and 99.7% of the $\sigma_{r,N}$. We can observe that the errors were higher for higher values of pitch variation $\sigma_{p,N}$ when no compensation was done, as expected by Figure 4. Even though in average the compensated and non-compensated methods had similar errors (0.20 and 0.23 m), the difference of both errors was higher for higher variations of $\sigma_{p,N}$, $\sigma_{y,N}$ and $\sigma_{r,N}$. During the experiments objects with distances further than 20 m were used, what was enough to cause more than 5 m error according to Figure 4. Since the obtained errors were below this expected ones, we can affirm that the obtained results were satisfactory. Examples of cases with higher yaw variations are shown in the Appendix section. We can observe a significant difference of the proposed method in terms of number of successful height estimations. During the experiments, the compensated method failed to estimate height 65 times, while the non-compensated one failed 283 times (4 times more). Such failures require further analysis in future work, but the effectiveness of the proposed compensations became clear.

Although this work relied on VO, it didn't focus on improving its accuracy. However, we estimated that the applied VO had around 13% error per frame and influenced directly the results, what means that the proposed method becomes more accurate with the improvement of VO itself. Such VO errors led to wrong

estimation of camera pose, generating higher height estimation errors and examples are shown in the Appendix section. Even though the proposed method improved the average and maximum error of the estimated heights, some limitations still exist. The small camera pose variation per frame suggests that further evaluation with higher variations is necessary, by for example, increasing the moving body's velocity and analyzing the relation between camera frame rate and obtained height estimation errors. Finally, the experiments made evident another necessary correction: we considered angular variations (rotation) during the proposed compensations, however translations in Y also occurred. According to the FSM, such translations change the camera height H and must be considered when computing the distance to objects. We believe that this consideration can further increase the accuracy of our height estimation method.

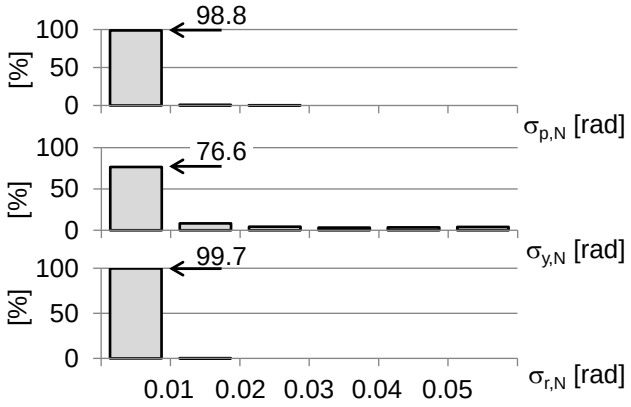

Figure 8: Distribution of the pose variation detected in the used data.

6 Conclusions and Future Work

A novel method of monocular height estimation with 3DOF compensation of roll, pitch and yaw variations was proposed. The method can estimate height of objects with only two frames of a monocular camera. Experiments outdoors with the KITTI benchmark data (4997 frames and 436 objects) resulted in improved accuracy of the estimated heights from a maximum error of 1.51 m to 1.12 m and reduced number of estimation failures by 4 times, proving the validity and effectiveness of the proposed method. This method can be enhanced by improving monocular visual odometry techniques and considering translational variations of the camera during height estimation. Further investigation about influences of frame rate, moving velocity and robustness are planned in the future.

Appendices

In this section, we provide further details of the experimental conditions and examples of compensations.

A Experimental Conditions

We further explain the experimental conditions adopted in the paper. The experiments were conducted according to Figure 9. The algorithm executed VO automatically for each frame (a), which were shifted manually by a human operator. Among all the extracted feature points, the operator chose with the mouse any point on a desired object (b). Here, since the FSM has geometrical restrictions, only points below the horizon (approximately in $v = \frac{V}{2}$) were chosen. The chosen point (in red) was tracked over the frames until the last frame possible (c), and its height and ground truth were computed and stored in each frame. The estimated position, stored data and extracted points of the current object were reseted after the heights were estimated (d) and the process repeated for all used data.

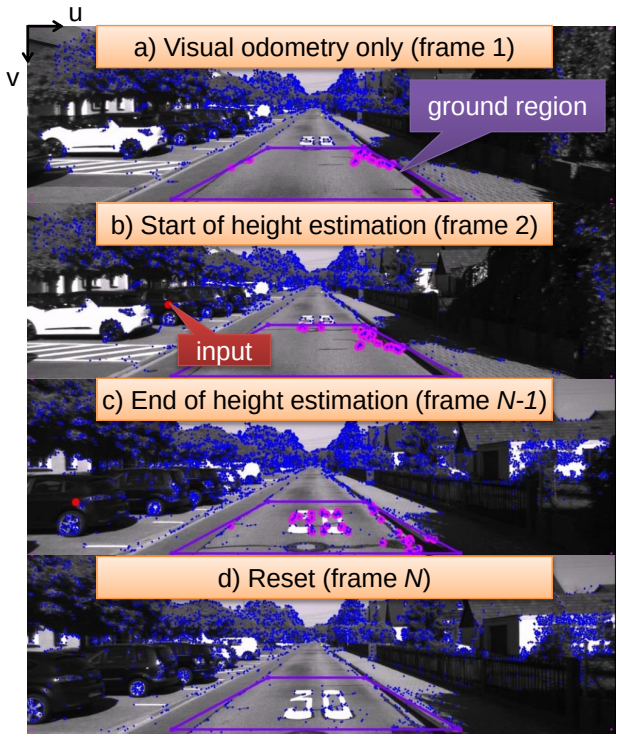

Figure 9: Adopted sequence to estimate the height of an object during the experiments.

First, all estimated heights and relevant data were saved and later verified for validity. Frames whose ground region contained few or no features (due to light conditions for example) or had a moving object were considered invalid (Figure 10). Tracking was also verified (Figure 11). Although we needed only two frames per estimation, we focused on features consistent in many frames (a minimum of 3 estimations per object). Thus, in case the tracking failed before the fourth frame, that object and estimations were considered invalid. If the tracking failed after the fourth frame, only the estimations before that were considered valid.

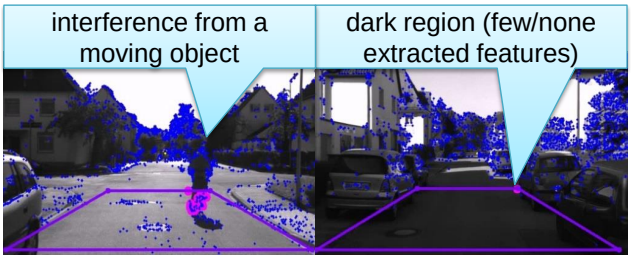

Figure 10: Examples of frames considered invalid: dark regions (right) and moving object (left).

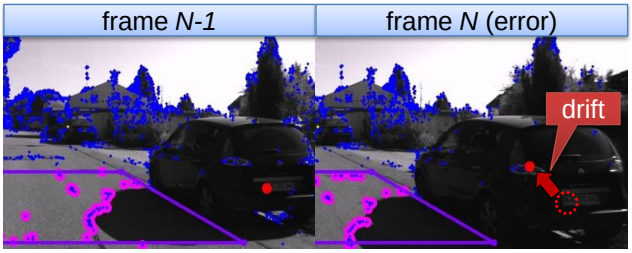

Figure 11: Example of tracked feature considered invalid.

We adopted as ground truth the height from the velodyne. The necessary information for converting the camera-velodyne coordinates were also provided by the KITTI. Due to limitations of the sensor resolution, we chose as ground truth the closest pixel with available velodyne data. This search was also automatically done by the algorithm in each frame. However, since the velodyne fails in some situations, we also computed the height by the disparity from the left and right images of the camera, using Semi Global Block Matching [19] in OpenCV. For each point chosen by the operator, its corresponding velodyne data was recorded. Since the camera was moving forward and approaching the object, we considered that the depth from the velodyne to the object on the next frame should become smaller than the one in the previous frame. In case it wasn't, we considered that the height estimated by the velodyne was also not consistent, and the one calculated by the stereo camera was used instead (Figure 12). In case both depths from the sensors were not smaller than the previous one, then the current estimation and frame were considered invalid. Since we considered the initial frame of each object as reference, variations in Y of the camera itself were also compensated when computing the ground

truth.

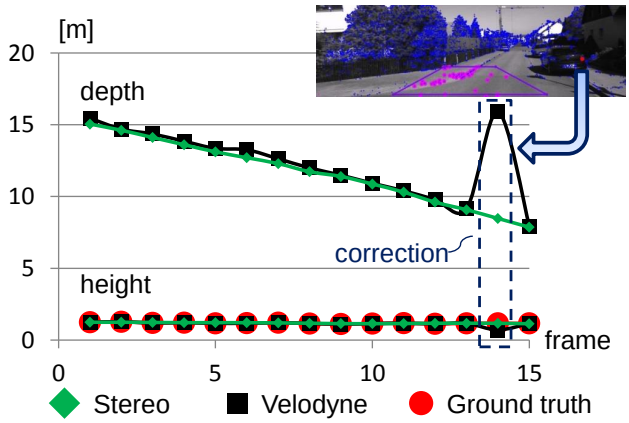

Figure 12: Example of adopted ground truth and correction. Data from the stereo camera was used when the velodyne data was considered inconsistent.

B Further Examples of Compensations

Even though there were few occurrences of yaw variations higher than 0.01 rad per frame during the experiments, we can further observe the benefits of the compensations in the example in Figure 13, which exemplifies the estimated heights during a curve. In the first frames, the camera was mostly moving forward so that ε_N was small for both compensated and not compensated cases. When the yaw variation started to increase the errors also increased. However, in frame 10 we can see ε_N decreasing to a minimum due to the decrease of $\phi_{y,N}$, increasing again when $\phi_{y,N}$ started increasing, as foreseen by Figure 4.

Figure 14 presents other examples of compensation. The cases in Figure 14 (iii) to (vi) had smaller average errors per frame after the compensations. On the other hand, even though the proposed method improved the average and maximum error of the estimated heights, some limitations as in Figure 14 (i) and (ii) still exist. We believe that such errors were caused by the errors of the adopted VO itself (13 % error) and improvements will be further investigated in future work.

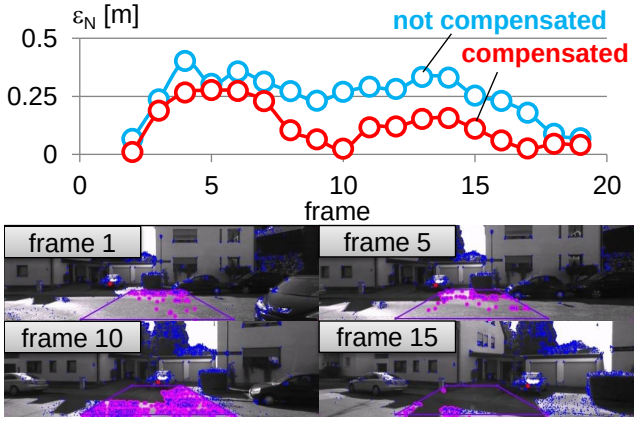

Figure 13: Example of yaw compensation.

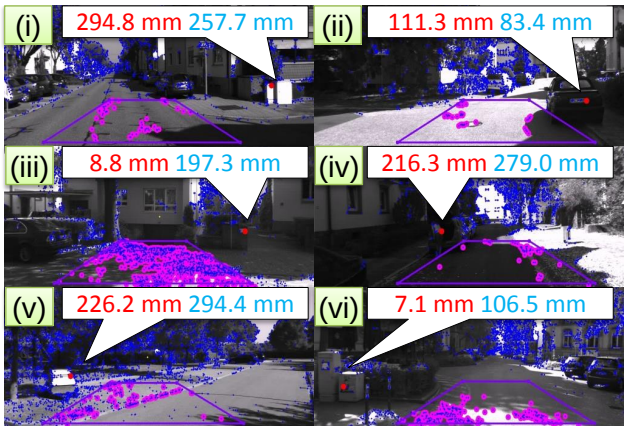

Figure 14: Examples of objects and average ε_N per frame. The numbers in blue (right) are the non-compensated cases and the numbers in red (left) are the compensated ones.

ABSTRACT

The For the last three decades, end-to-end computing paradigms, such as MPI (Message Passing Interface), RPC (Remote Procedure Call) and RMI (Remote Method Invocation), have been the de facto paradigms for distributed and parallel programming. Despite of the successes, applications built using these paradigms suffer due to the proportionality factor of crash in the application with its size. Checkpoint/restore and backup/recovery are the only means to save otherwise lost critical information. The scalability dilemma is such a practical challenge that the probability of the data losses increases as the application scales in size. The theoretical significance of this practical challenge is that it undermines the fundamental structure of the scientific discovery process and mission critical services in production today.

In 1997, the direct use of end-to-end reference model in distributed programming was recognized as a fallacy. The scalability dilemma was predicted. However, this voice was overrun by the passage of time. Today, the rapidly growing digitized data demands solving the increasingly critical scalability challenges. Computing architecture scalability, although loosely defined, is now the front and center of large-scale computing efforts.

Constrained only by the economic law of diminishing returns, this paper proposes a narrow definition of a Scalable Computing Service (SCS). Three scalability tests are also proposed in order to distinguish service architecture flaws from poor application programming. Scalable data intensive service requires additional treatments. Thus, the data storage is assumed reliable in this paper. A single-sided Statistic Multiplexed Computing (SMC) paradigm is proposed. A UVR (Unidirectional Virtual Ring) SMC architecture is examined under SCS tests. SMC was designed to circumvent the well-known impossibility of end-to-end paradigms. It relies on the proven statistic multiplexing principle to deliver reliable service using faulty components as the infrastructure expands or contracts.

To demonstrate the feasibility of such a theoretical SCS, an organized suite of experiments were conducted comparing two SMC prototypes against MPI (Message Passing Interface) using a naive dense matrix multiplication application. Consistently better SMC performance results are reported.

1. Introduction

For the last three decades, end-to-end computing has been the de facto paradigm for distributed and parallel programming. MPI (Message Passing Interface), RPC (Remote Procedure Call), OpenMP (share memory) and RMI (Remote Method Invocation) are all end-to-end programming paradigms. A myth persisted since the 1990's that while the data communication community is well served by the end-to-end paradigm, in 1997, direct use of the end-to-end protocol in distributed computing was cited as a fallacy [1]. The computing service scalability dilemma was predicted.

A reexamination of the 1993 proof of the impossibility of implementing reliable communication in the face of crashes [2] exposed the root cause of the alleged fallacy: the robust communication protocols are ineffective when either the sender or the receiver in the end-to-end communication could crash arbitrarily. No error detection and recovery methods can reverse this impossibility.

Direct use of end-to-end reference model in computing applications leaves massively many potential end-point crashes when the application runs (Figure 1). Although the probability of each end-point crash is very small, the growth in application size (thus the processing infrastructure) is guaranteed to increase the planned and unplanned service down times and data loss probabilities. The reproducibility of a large scale application

(service) becomes increasingly more difficult [3]. These risks are tolerable when the computing clusters are small. They have become increasingly unbearable as the computing services facing increasingly expanding loads.

Incidentally, reliable communication is possible using faulty components. This was also proved in early 1980's [4]. There are three assumptions in the proof: a) all data packets must decoupled from transmission devices, b) both the sender and the receiver must be reliable, and c) there are infinite supplies of resources. In literature, this is often called the "best effort" service. Theoretically, the best effort communication guarantees 100% reliability as long as the infrastructure affords the minimal survivable resource set at the time of needs. This was the theoretical basis of the OSI (Open System Interconnection) reference model [5].

It then follows that the "best effort" computing should also be possible by removing the reliable receiver assumption in the basic program-program communication protocols. In other words, while it is reasonable for a data communication application to assume reliable sender and receiver at the time of need, it is not reasonable to assume reliable receivers in any clustered computing services, since the growing service infrastructure will make it increasingly unlikely.

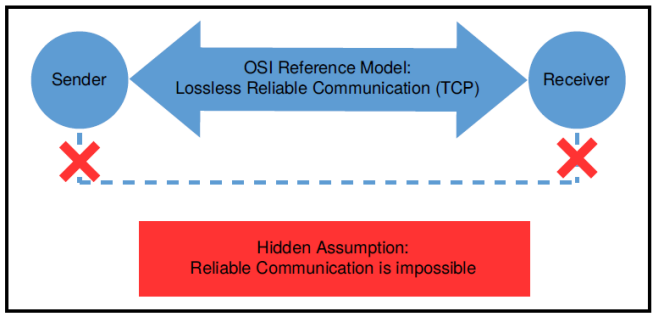

Figure 1. OSI Standards and Its Hidden Assumption

This has led to the design of a single-sided parallel computing paradigm. The new paradigm must multiplex all resources or the application fault tolerance is not attainable (Figure 2). This framework is called Statistic Multiplexed Computing (SMC) or Stateless Parallel Processing. Today, as the single processor speed approaches to a plateau, it seems that unconstrained clustered computing is the only likely future computing architecture. No single big-CPU machine, even if quantum class machines, would be able to meet the exponentially growing data processing needs.

This paper is organized as follows. Section 2 introduces the assumptions and a narrow definition of a Scalable Computing Service (SCS). It also includes three "Reproducible Architecture Tests" as the necessary and sufficient conditions for SCS. In this paper, the data storage is considered stable and lossless. Data intensive SCS will need additional requirements. A single-sided Statistic Multiplexed Computing (SMC) architecture is presented. Section 3 provides a high level examination of the single-sided SMC or Stateless Parallel Processing (SPP) paradigm using the proposed scalability tests. Section 4 illustrates the need for granularity tuning for optimal parallel processing. Section 5 evaluates MPI, Hadoop, Spark and two SMC prototypes: Synergy (SPP) and AnkaCom (SMC) using the scalability tests. Section 6 documents the experiment design and objectives. Section 7 reports the computational results. Section 8 contains the summary.

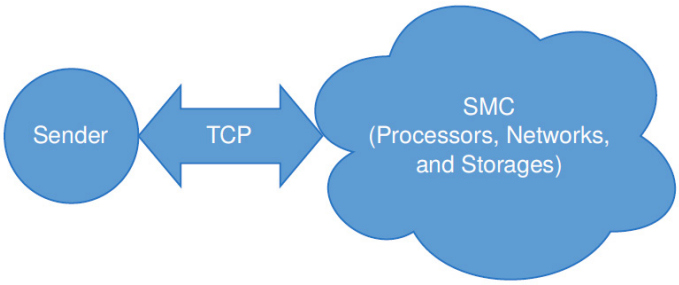

Figure 2. Single-Sided SMC Paradigm

2. Assumption, Definition and Tests

Scalability is the capability of a system to handle a growing amount of work. It is well understood in an economic context, where a company's scalability undermines the potentials economic growth of the company. Since the future societal economic growth depends on all available computing services, the importance of the computing service scalability is self-evident.

The economic law of diminishing returns states that in all productive processes, adding more of one factor of production, while holding all others constant, will at some point yield lower incremental per-unit returns. Parallel computing using multiple processors and networks obey the same law.

There are many possible dimensions in scalability measures. For compute intensive services, assuming infinite supplies of processors and networks, the scalable computing research challenge is to devise a computing service architecture that can scale indefinitely in order to meet the growing demands. The Internet and SMP (Symmetric Multiprocessing) systems are such service architectures. Delivering robust service for growing demands, however, has met the seemingly insurmountable challenge of the scalability dilemma. The infinite resource assumption was rooted in practice. This assumption also makes the theoretical discussions possible.

The dependency on reliable processors and networks for delivering reliable service is the root cause of the scalability dilemma. Since electronic components can suffer random failures, a robust computing architecture must be able to exploit all useable components at the time of need. Thus the *infinite resource assumption* can be translated into the *minimal survivable resource set* assumption in practice. That is, all discussions on scalable performance, reliability and service quality are based on the assumption that the processing architecture affords the ``minimal survivable resource set'' at the time of need. The architecture design challenge is to build a mechanical structure capable of leveraging all available resources at the time of need without reprogramming the application.

In this paper, we also assume that the storage is reliable. Data intensive SCS requires additional treatments following the same principles [6].

Definition: A Scalable Computing Service (SCS) is a computing service that allows unlimited infrastructure expansion without reliability and service quality degradation. Application performance should subject to the same definition until the law of diminishing returns applies.

Parallel applications are the integral parts of the scientific discovery processes. It is thus important to ensure that extreme

scale service architecture does not hinder the scientific discovery process. The service reproducibility requirement is implied. Further, it would be difficult to distinguish a computing architecture design flaw from a poorly composed non-scalable application (crossing the point of diminishing returns prematurely), the following reproducible SCS tests are proposed:

a. **Share-nothing Test**. No processors or networks can be assumed reliable while still delivering full range of services. Not passing this test breaks the scalable reliability definition.

b. **Sublinear Cost Test**. The runtime management overhead should be bound within a sublinear factor with regard to the infrastructure size. Failing this test means diminishing benefits when the application up-scales. It breaks the scalable performance definition.

c. **Reproducible Node Test.** Each node in the architecture must be able to reproduce identical semantically acceptable results given identical inputs. These include both deterministic and non-deterministic programs. Failing this test will break the service quality definition.

Test (a) requires a single-sided programming paradigm (such as Figure 2) and a multiplexing runtime architecture. Tests (a) and (b) are the necessary and sufficient conditions for SCS. Tests (a), (b) and (c) are the necessary and sufficient conditions for a reproducible SCS, since the infrastructure ensures reliable services in any scale using faulty components.

All modern computers running reasonable software can pass the *Reproducible Node Test*. The *Share-nothing* and *Sublinear Cost Tests* are more difficult.

Services built using the end-to-end reference model fail the *Share-nothing Test*. The end-to-end reference model requires explicit receiver addresses in an IP-addressable network. This seemingly innocent requirement causes the entire application to depend on the reliability of all processors and networks. This is the root cause of the scalability dilemma [1].

The following computing systems can pass the *Share-nothing Test*: a) Dataflow machines [7], b) Tuple Space machines [8], and c) services by Content Addressable Networks [9]. Similarly, the search engines and SMP (Symmetric Multiprocessing) systems also qualify. These systems have two common features: a) API (Application Programming Interface) has no fixed destination (single-sided), and b) every task can be processed by any processing elements.

Dataflow and Tuple Space machines are elegant automated parallel systems but suffer the poor performance stigma. Content Addressable Networks are designed for the next-generation Internet services. It is not typically used for parallel computing. Search engines and SMP systems are designed to service multiple clients effectively. They are ineffective for solving the single application's scalability dilemma.

However, putting these systems together brought a unique opportunity: Stateless Parallel Processing (SPP) or Statistic Multiplexed Computing (SMC) [10]-[15]. Specifically, it is possible to build a "Service Content Addressable Network" using the Tuple Space semantics and dataflow principle thus making the "best effort computing" practical.

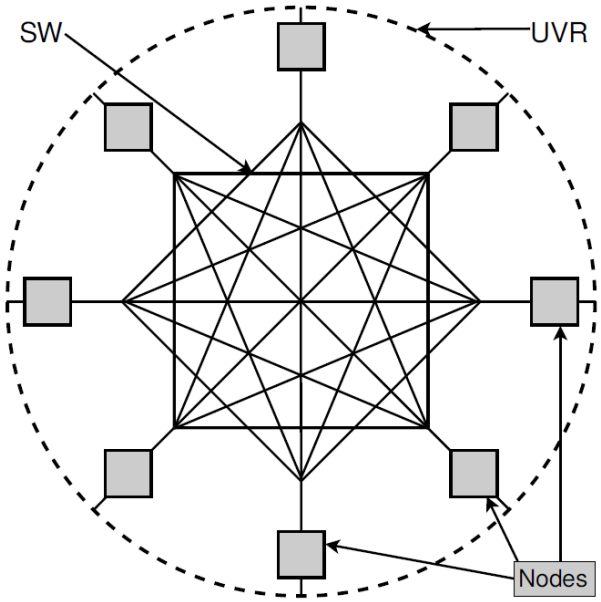

Figure 3. Statistic Multiplexed Computing Architecture

Figure 3 illustrates such a multiplexing computing service under a UVR (Unidirectional Virtual Ring) architecture.

3. Single-sided Statistic Multiplexing

Passing the *Share-nothing Test* for a computing architecture requires the absence of all component reliability assumptions (except for the storage for this paper). The service communication architecture must be capable of exploiting all possible network topologies. In Figure 3, SW is a collection of network switches in any topology. Each node is a standalone computer with any number of cores, local memory, storage and multiple network interfaces. UVR (Unidirectional Virtual Ring) implements a Service Content Addressable Network (or Tuple Switching Network (TSN) [16]) using all available processing and networking components. This allows zero single point failures regardless the number of networks and processors for a given application.

The UVR architecture ensures that except for the Master (the client of the parallel computing service), there is no need for explicit IP addresses for data exchanges.

Unlike traditional parallel Masters, the SMC Master is part of UVR architecture in that it is responsible for tuple retransmission discipline and redundancy handling. Actual data exchanges are implemented using all available network links directly. Services built using the TSN do not subject to the end-to-end impossibility. The high level UVR computing concept passes the *Share-nothing Test*. The "best effort computing" idea could become feasible, if the implementation also passes the same test.

Once the application runs, the dataflow semantics allow the computing infrastructure to automatically form SIMD (Single Instruction Multiple Data), MIMD (Multiple Instruction Multiple Data) and pipeline clusters at runtime. These effects are identical to early dataflow machines [7].

However, passing the *Sublinear Cost Test* needs more work. On the surface, it seems impossible to traverse $\boldsymbol{P}$ nodes paying less than linear traversal cost. However, $\boldsymbol{k}$-order multicast can cut the

UVR traversal complexity to $O(lg_kP)$ [17]. Further, once a tuple is matched against its processor, actual data exchange will be done directly. Imposing an order on the tuple values can further force the tuple matching overheads to $O(1)$ using the ideas from Consistent Hashing [18]. For practical applications, the one-time $O(lg_kP)$ traversal cost seems reasonable for deploying millions of nodes.

4. Single-sided Statistic Multiplexing

All compute intensive applications are typically partitioned into parallel tasks that can be processed using SIMD, MIMD and pipeline parallelisms. Since data exchange costs time, the partition size or *processing granularity* determines the ultimately deliverable performance by the service architecture. The best performance is delivered when all tasks terminate at the exactly the same time. A small granularity allows for higher concurrency but at the expense of higher data exchange costs. A bigger granularity risks lower concurrency and longer synchronization times due to differences in processing capabilities. The optimal granularity delivers the best possible parallel performance for the application running on a given processing environment.

The optimal *processing granularity* (G) of an application defines the Termination Time Equilibrium [19], [20] for that application. Finding the optimal G will allow the SMC applications to overcome the poor performance stigma of earlier dataflow and Tuple Space machines.

The principle of finding the optimal G is analogous to the use of Snell's Law for solving the Brachistochrone problem in physics and mathematics [21]. Figure 4 illustrates that the solution to the fastest descent under the influence of uniform gravitational field

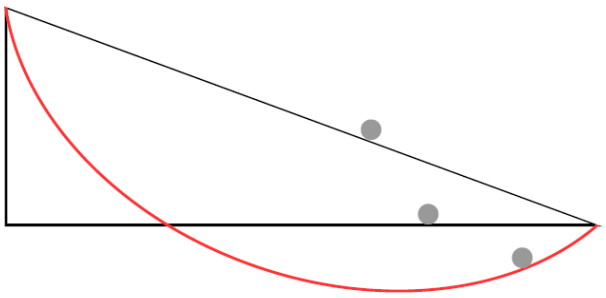

Figure 4. The Brachistochrone Problem.

and friction-less surfaces is not the straight line that connects the source and the destination, but the Brachistochrone curve that optimizes the gravitational and normal forces. It is a cycloid. Using fixed application partitioning is like the straight line (which happened to be the slowest descent). The astonishing feature of the Brachistochrone curve is that it is also called "Tautochrone" that regardless where you start on the curve, all will reach the destination at the same time. In parallel processing, the Brachistochrone curve represents the optimal G's where the overall computing time equals to the overall data exchange time. As will be shown, if we tune G carefully, there are indeed multiple optimal G's (modulated under a communication overhead curve) for every compute intensive kernel [19].

Further, the optimal G is only discoverable without reprogramming under the single-sided paradigms. For end-to-end computing programs, unless the task distribution is pooled [22] or using the single-sided "scatter_v" call in MPI, once compiled, changing processing granularity requires reprogramming.

Other single-sided systems include Hadoop [23] and Spark [24]. They have demonstrated substantially better reliability and performance than similar end-to-end distributed computing systems. But performance against bare metal HPC programs have not being rigorously investigated.

The remaining of this paper reports computation experiments comparing two SMC prototypes: Synergy and AnkaCom against MPI (Message Passing Interface). The Brachistochrone effects are also demonstrated.

5. Computing Service Architectures and Scalability Tests

The MPI parallel processing architecture is embedded in its application programs. The (node) operating systems are responsible for the basic data communication and task execution functions, the programmer has explicit controls of the parallel machines. The explicit end-point requirement makes it impossible to pass the *share-nothing test*. Even with a "task pool" implementation, unless the implementation is completely distributed, thus forming a "application content addressable network", passing the *share-nothing test* remains negative.

The Hadoop system uses the single-sided ***<key, value>*** API (Application Programming Interface) for reliable large scale distributed processing. It can pass the *share-nothing test* at the concept level. Unfortunately, it fails the same test at the implementation level due to the use of the RPC (Remote Procedure Call) protocol. This results in the "**single namenode architecture**". The "namenode" is the single-point failure of the entire system. However, even though Hadoop cannot pass the *Share-nothing Test*, its single-sided API allowed much better runtime fault tolerance than other systems. Many very large scale successful experiments are completed within the *100M* file design limitation.

The Spark system relies on the Hadoop File System (HDFS) but leverages high speed in-memory processing. It's scalability test is identical to Hadoop.

The Ethereum project [25] is a decentralized distributed computing platform that runs smart contracts: applications that run exactly as programmed without any possibility of downtime, censorship, fraud or third party interference. It can pass the *share-nothing test* easily. These applications run on a custom built blockchain, a shared global infrastructure that can move value around and represent the ownership of property. This enables developers to create markets, store registries of debts or promises, move funds in accordance with instructions given long in the past (like a will or a futures contract) and many other things that have not been invented yet, all without a middle man or counterparty risk. However, its Blockchain implementation cannot pass the *Sublinear Cost Test* due to linear overhead increases when the chain expands.

The Synergy system is also a distributed parallel computing system that uses named Tuple Space Servers to simulate the TSN. Although it can pass the *Share-noting Test* at the concept level, the actual implementation fails the test due to the use of the named Tuple Space Servers with fixed IP addresses [9].

The AnkaCom system [26] is a fully distributed peer-to-peer TSN implementation. It can pass the *share-nothing test* at the concept level and the implementation level. The fundamental

departure point of the AnkaCom implementation from others is the absence of the single-ACK/NAK assumption as compared to the RPC protocol. It can also pass the *Sublinear cost test* by implementing the one-time ***O(lg$_k$P)*** UVR traversal protocol.

6. Experiment Design

Matrix multiplication is frequently used in scientific simulations and engineering applications. Dense matrix multiplication has high computing and communication requirements that can saturate resources quickly. It is selected as the benchmark for this study. Matrix multiplication is a "regular" parallel applications that fixed application partition seems reasonable for using a dedicated cluster of bare metal processors. The MPI parallel matrix multiplication program is implemented in C. It is optimized for locality for the three nested *(i,j,k)* loops. The Synergy program is also implemented in C and similarly optimized. The AnkaCom program is implemented in Java. The loop order is also optimized.

The MPI and Synergy runtime systems are implemented in C. The AnkaCom runtime is implemented in Java.

The computing platforms include the NSF (National Science Foundation) Chameleon bare metal cluster [27] at TACC (Texas Advanced Computing Center) and the owlsnest.hpc.temple.edu traditional bare metal cluster [28] at Temple University. The benchmark application is a naive dense square matrix multiplication application. The SMC prototypes are Synergy 3.0+ and AnkaCom 1.0. OpenMPI versions 1.4.4 and 1.10.0 are used in the experiments.

- *Owlsnest cluster* has multiple IB (Infiniband) support. The Chameleon cluster only has single IB support at the time of experiments.}
- The *Chameleon* and *Owlenest* bare metal clusters have same number of cores (48) and sufficient memory for many-core experiments (256 GB for Chameleon) per node and (543GB for Owlsnest).

The Synergy implementation will only sustain to a small number of cores before saturating the single-threaded Tuple Space server. Thus, every test using large number of cores is also a sense of reliability test of the UVR concept.

The AnkaCom implementation will sustain to any number of nodes and cores due to the implementation of distributed TSN. The Java runtime overheads should be much higher than the C-MPI combination. For AnkaCom, the IB support comes from the built-in Java library. The C-MPI implementation has a custom IB driver.

There are three groups of experiments:

- *Single-Node Single-Core.* This group of tests examines the runtime's ability to leverage multiple hardware components in parallel by overlapping single-core computing, communication and disk activities.
- *Single-Node Multiple-Core.* This group of tests examines the parallel runtime system's ability to use up to 48 cores concurrently in addition to other communication and storage components.
- *Multiple-Node Multiple-Core.* This group of tests examines the parallel runtime system's ability to harness multiple multicore nodes effectively. In this study, we used twenty 12 core nodes on Owlsnest with dual IB support.

The single-sided API affords SMC applications a flexible parallel task pooling capability that is not supported by direct message passing systems such as MPI. The SMC workers can be programmed to compute for tasks of different sizes without re-programming. In contrast, the MPI applications rely on fixed ***N/P*** partitioning.

7. Computational Results

7.1. Single-Node Single-Core Results

. The Java compiler does not have an optimization option.

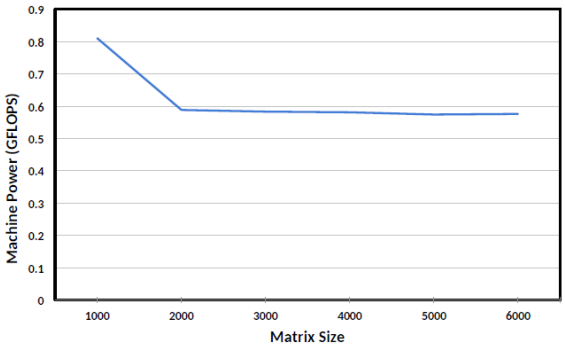

Figure 5. Single-Node Single-Core (Sequential)

The baseline experiment is provided by a sequential C-program running on a single core. Figure 6 shows the results in GLOPS on Owlenest running matrix of sizes 1000 - 6000.

The significance of the Figure 5 curve is that it depicts the typical "Cache, Memory, Swap and Die" (CMSD) single core performance behavior. Understanding this behavior enables further quantitative application scalability analysis [19].

A partitioned parallel program running on a single node with a single core will exhibit different behavior than a sequential program running in the same environment. The partitioned programs can exploit hidden concurrencies even in the single node single core environment. Figure 6 reports the single-core single worker tests for both MPI and Synergy against the sequential program (in yellow). Due to the restriction of end-to-end communication, the MPI (Open MPI 1.4.4) program was not able

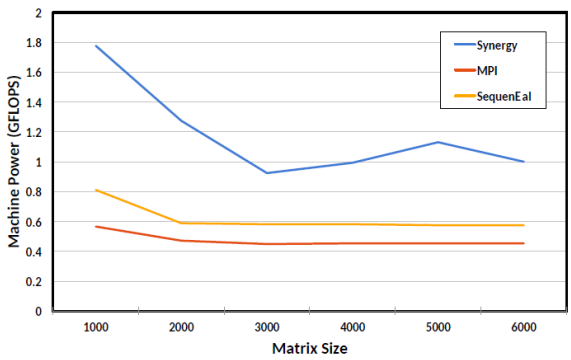

Figure 6. Single-Node Single-Core (Parallel)

to compete against the sequential code in different matrix sizes (1000-6000) consistently. The Chameleon results are similar.

7.2. Single-Node Multiple-Core Results

Single node multi-core is best suited for MPI and Synergy architectures since the inter-program data exchanges can be very fast. Figure 7 reports the granularity tuning results for MPI and Synergy on Chameleon for *N=9000*, *P=45* (factor of 9000). In Figure 7, the optimal granularity sizes are: 11, 22, and 33. The relationship between these sizes are given by the volatility power indices of the 45 cores at their peaks: 303, 409, and 818 [20]. At these optimal points, the synchronization overhead is near zero (note the Brachistochrone analogy). Further quantitative scalability analysis becomes possible using the optimized performance and simpler time complexity models [20]. The MPI (Open MPI 1.10.0) on Centos 7 delivered consistently worse performance than the worst tuned Synergy performance (5.1GFLOPS).

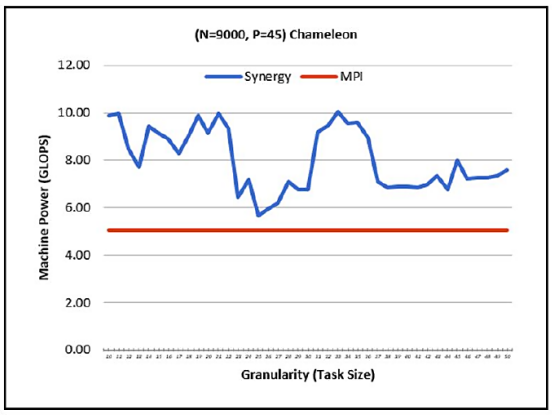

Figure 7. Single-Node Multiple-Core Granularity Tuned

Figure 8 reports a broader range of tests for different matrix sizes without granularity tuning (*G=20* fixed). Synergy still outperforms MPI when the matrix size exceeds 3,200. These results are consistent with Figure 6: the bigger the problem sizes, the better the Synergy performance.

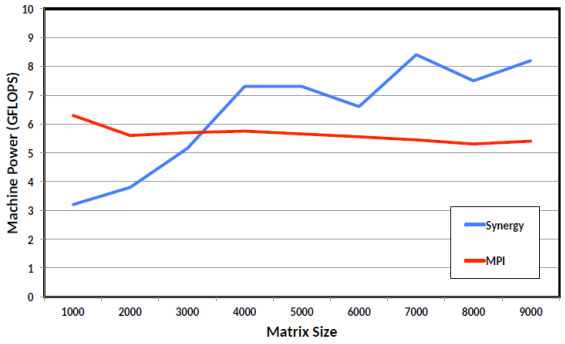

Figure 8. Single-Node Multiple-Core (Broader Range Tests)

7.3. Multiple-Node Multiple-Core Results

the granularity tuning effects in the multi-node multi-core environment. The Brachistochrone effects are shown again by the multiple optimal synchronization times at specific granularity points. These points are modulated by the increasing communication overheads (left to the optimal granularity (***70***) and increasing synchronization (waiting) time (right to the optimal point ***70***).

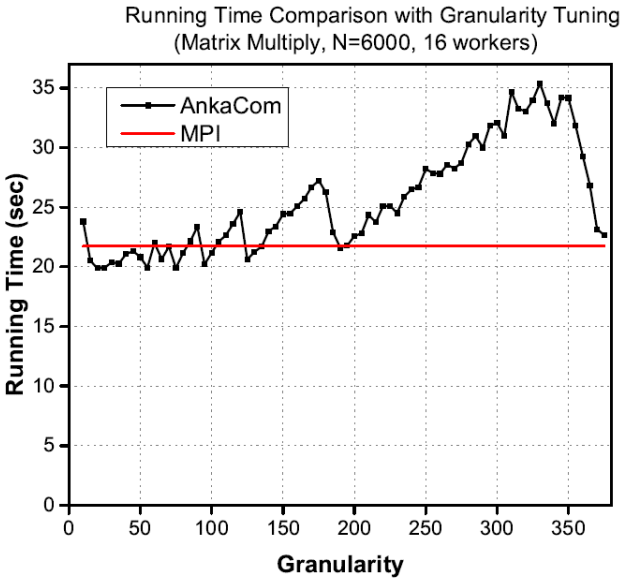

Figure 9. Multi-Node Multi-Core Granularity Tuned

Figure 10 reports AnakaCom performances against MPI using 120 cores.

AnkaCom implements multi-threaded distributed Tuple Space daemons following the UVR architecture. As discussed, this effectively decouples application programs and data completely from processors and networks. Each distributed Tuple Space server can replicate its contents elsewhere ($R > 0$). In this reported experiment, $R = 1$. This means that each tuple is replicated with 1 copy elsewhere. This experiment was designed to reveal the effects of "diminishing of return" as well as the power of granularity tuning.

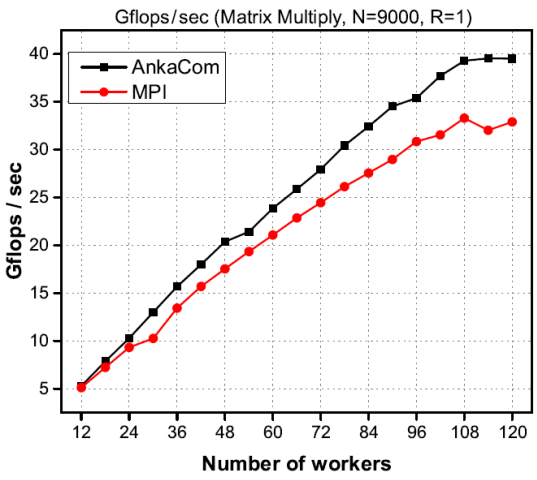

Figure 10. Multi-Node Multi-Core Tests

Each AnkaCom run is optimized by picking the best performing granularity through multiple runs. The recorded MPI run is the best of three runs with identical task size N/P.

Figure 10 shows consistently better AnkaCom performances over MPI. The performance differences grew bigger as the number of cores increased. The MPI performance started to trend down at P=108 while AnkaCom kept strong for yet another 12 more cores until the end where N/P became merely 75 (9000/120). Note that the Intel XEON clock cycle is 2.2GHZ. The 75 rows (9000 columns) of dot-products seems the break-even point for sustained performance of this particular application. After this point, both MPI and AnkaCom's communication overheads took over. This was a demonstration of the economic law of "diminishing return".

The C-MPI runs are via the "mpirun –np X -mca btl ib" option triggering the use of custom Infiniband driver. The AnkaCom Infiniband support is by the standard Java library.

8. Summary

Solving the scalability dilemma is of primary importance for developing robust computing services. End-to-end computing paradigms are suitable for small scale data processing needs. In the era of big data, with the Moore's Law approaching its end, extreme scale clustered computing is the only possible path for the future internet-scaled computing. The prior large scale HPC experiments uncovered the scalability dilemma, energy efficiency and reproducibility challenges in delivering robust computing services. It is time to eliminate the known fallacy in the making of distributed computing services.

According to the impossibility theory [2] and the possibility of delivering reliable service using faulty components [4], addressing the scalability challenges requires a paradigm shift: from IP-addressable programming to content addressable programming. This paper reports a single-sided Statistic Multiplexed Computing (SMC) paradigm in order to circumvent the impossibility and to fully leverage the possibility of statistic multiplexing. A narrow Scalable Computing Service definition and three reproducible scalable service tests are proposed. MPI, Hadoop, Spark, Synergy and AnkaCom are all examined using the same scalability tests.

In order to gain a sense of deliverable performance and reliability of the proposed service architecture in multi-node and multi-core environments, computational experiments are conducted in three groups: single node and single core, single node multiple core and multiple node and multiple core. The single-node single-core group provides the baseline for performance comparisons.

The computational results revealed the following:

- Low communication overhead is *not* a necessary condition for the optimized parallel performance. Figures 2-9 demonstrated overwhelmingly that parallel performance optimization by tuning the processing granularity can easily out-perform the low overhead MPI implementation.
- The choice of fixed *N/P* partition for MPI was deliberate. It is possible to build a task-pool layer in MPI or use single-sided "scatter_v" to allow dynamic granularity tuning without reprogramming. There will be significant implementation challenges considering passing the *Share-nothing* and *Sublinear Cost Tests*. However, when the problem size, the number of processors and the dynamic runtime load distribution happen to hit the "sweat-spot" (the fixed granularity is the optimal for the given runtime dynamics), MPI program will out-perform Synergy and AnkaCom.
- Both Synergy and AknaCom were running with built-in fault tolerance. Including checkpoints in the MPI program will push the performance to be much worse than reported.

The application reliability of the single-sided paradigm was also tested. Connection failures did occur during Synergy 48 core tests. The prototype SMC protocols worked flawlessly allowing all tests to complete without any check pointing.

The single-sided SMC application demonstrated consistently better performance in all experiments. Since SMC applications are natively protected by the TSN, the SMC application's performance and reliability have far exceeded the end-to-end computing MPI programs.

The SMC principle is also applicable for transactional and storage services [5]. Solving the data intensive SCS problem requires a solution to the CAP Theorem [29].

This paper tries to convince the reader that the robust service scalability dilemma of distributed and parallel computing is indeed solvable. The proposed single-sided SMC paradigm is a feasible solution for delivering efficient and robust computing services using faulty components. Correct implementation of the Statistic Multiplexed Computing principle ensures the reliability of large scale distributed services. Extracting the optimal processing performance is similar to finding the Brachistochrone curve in physics and mathematics. The SMC goal of building non-stoppable services is similar to the Etherem project [25]. The implementation of SMC paradigm, however, can promises high information security without linearly increasing overheads.

In addition to extreme scale parallel computing, the single-sided SMC service architecture is also suited for mission critical applications. It promises true non-stop computing service as long as the infrastructure affords the minimal survivable resource set, a task that can be automated completely in practice. This development will impact all existing mission critical distributed and parallel services. These include Enterprise Service Buses (ESB), mission critical transaction processes, mission critical storage systems, smart grid controllers and software defined network (SDN) control plane implementations. Finally, the use of service content addressable network for mission critical services makes all IP-based cyberattacks, such as DDOS (Distributed Denial of Service), ineffective. These developments will redefine the state of the Internet.

About Authors

The corresponding author is responsible for the scalability definition and tests, the UVR architecture design and the first prototype implementation Synergy. He is the original proposer of the Stateless Parallel Processing concept and the SMC framework. Author Yasin Celik is currently a PhD student completing a dissertation at Temple University. Yasin is responsible for the practical rendition of the SMC framework (AnkaCom) and validation tests. His dissertation includes both compute and data intensive SMC implementations and scalability studies.

ABSTRACT

Computer programming course that utilizes languages such as C/C++ is always packed with dreary syntax details that consume most of the students' learning time to obtain 'grammatically' correct source code. Consequently, it is difficult for most of the students to apply the theory they have learned in a real life context. Thus, this project proposed a hardware based learning approach for C programming curriculum and reports the effectiveness of using microcontroller board named FRDM-KL05Z to assist teaching and learning activities. The USB-powered microcontroller board is very easy to use and is programmable using C programming language. Students will have the opportunity to learn selection statement with real sensors, touse repetition statement to blink LEDs and utilizing function as well as structure to control actual input and output peripherals. In general we evaluated the students' response in five criteria namely the students attributes, lecturer's profile, implementation, facilities and students' understanding. From the survey, the results in exit survey are higher compared to entrance survey for all criteria. This shows that the students are satisfied with the implementation of the module which has increased their understanding in learning C Programming.

1. Introduction

Many educators realize the urgency of education reform to respond to the current needs and future trends of the society. The urge of re-engineering the curriculum is needed for new approaches in designing the curriculum and active learning methods for encouraging students to be more creative. Responding to these calls for education reform, this study was conducted as an extension of work originally presented in IEEE 8th International Conference on Engineering Education (ICEED2016) [1]. Project-based learning (PBL) and "learning by doing"approach have been recognized as one of the effective means for students to obtain the problem-solving capability [2-3].

Another method in learning approach for engineering students is embedded system education. Teaching embedded system design is a challenging undertaking because a teacher cannot assume that all students enrolled in a class have solid prerequisite knowledge across all these areas. To speed up the learning process and motivate students to learn actively, the project-based learning approach [4-7] is applied in this embedded system design laboratory.

Introduction to the C programming is one of the basic elements in Electrical engineering course. The subject currently is offered in semester 2 [8], and it contains 7 chapters. Each chapter introduces the student with basic command of C programming to execute specific task such as compiling, linking, control flow statement, function and array [9]. The students will be evaluated based on the laboratory task which is only a computer-based laboratory, test that covers theoretical part of the syllabus and mini project. The main objective of the mini project is to gauge the understanding of students in the overall C programming course.

C programming is one of the most important subjects in Electrical Engineering course. However, the process of teaching and learning a programming subject is not an easy task as stated by many studies [10]. Students were reportedly having problem in grasping this subject due to the complex nature of this subject. The development of a program involves similar step like any problem-

[*]Zulzilawati Jusoh, Electrical Engineering Faculty, Universiti Teknologi MARA, Dungun, Terengganu, Malaysia | Email: zulzilawati@tganu.uitm.edu.my

solving task. The processes include definition of the problem, planning of the solution, coding the program, testing the program and documenting the program. Thus, the ability to execute the whole flow of the process is very critical for a student in mastering the subject well.

Various methods in teaching and learning programming courses have been reported. As an example, several researchers have come with game-based digital learning for teaching C programming course [11-12]. Other method includes active learning by students, which may include in-class activities like peer learning, games and mnemonics [13-14]. A more advance approach as discussed in [15] described how LEGO Mindstorms robot was used as hands-on educational technology in teaching introductory programming courses. This proves that C programming is a complex subject and it requires creative way of delivering it to students.

More recently, Conceive - Design - Implement – Operate (CDIO) initiative are gaining significant popularity among educators around the world [16]. Authors in [17-20] reformed their teaching approach in delivering C/C++ curriculum based on CDIO approach.CDIO concept emphasis on the knowledge development by integrating engineering skills such as team cooperation, problem solving, communication andknowledge-application ability of students in real-life context. Results indicated that such initiative can effectively improve the students' ability to comprehend basic knowledge in programming and their applicationin engineering system analysis.

Throughout this course, the main drawback that has been observed by the lecturer is that students having difficulty to implement the theoretical part of the subject into practical. This may be caused by lack of experimental design task exposure. Majority of the students do not have the skill to expand their learning of C programming after finishing this course. This situation can be seen in their final year project course (FYP) where most of the students will use microcontroller in their project and majority of them do not have the ability to apply the C programming knowledge to program the microcontroller to execute the desired task. Therefore, a module has been proposed to help the lecturer to resolve this situation. The module will be included in the students' learning process throughout the semester and it does not change the main objective of the syllabus. This module will only be used as a tool to help the student to gain more knowledge and skill in C programming language.

In fact, the microcontrollers are commonly utilized in numerous industrial applications such as remote control devices, office machines, electrical gadgets, automobiles, motor control systems, robots and other industrial fields. For that reason, it is taught as an applied course at universities, especially in the departments such as engineering of electrical and electronics engineering. Freescale has designed the FRDM-KL05Z in collaboration with MBED for prototyping all sorts of devices, especially those requiring the size and price point offered by Cortex-M0+. It is packaged as a development board with connectors to break out to strip board and breadboard, and includes a built-in USB FLASH programmer.

The aim of this study is to measure the effectiveness of the proposed module which is C programming based on embedded system approach, and the students' perception of this course is also evaluated so that there will be more effective changes that can be made to this course to enhance the student's ability in the real application after their graduate.

2. Methodology

In order to enhance the students' understanding and interest in Introduction to C Programming (ECE126) subject, a one-day training module was conducted to expose them with the implementation of C-programming as shown in Figure 1.0. During the training, participants were given a set of training materials listed in Table 1.0 so as to boost students' engagement throughout the session, harness their interest and motivate them to use the knowledge learnt in ECE126 curriculum in real-life context. A laptop was used to write a program code in C language. Next, the code was transferred to FRDM board and after that user will run the program from the board. The execution of the code was monitored using a smart phone application in real time via a Bluetooth connection.

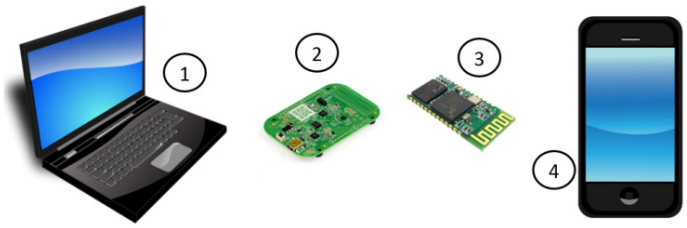

Figure 1: Examples of a real-life implementation of C-programming

Table I. List of training materials

No	Item
1	Personal Computer/laptop
2	FRDM-KL05Z micro controller board
3	HC-05 Bluetooth Module
4	Smart phone

Figure 2 depicts the overall programming process carried out during the training session. Participants were taught to write a program code using a web-based MBED compiler. The software can be used to write and edit a program code using high-level languages such as C and C++. Next, a linking process was carried out in which the written code was linked to FRDM-KL05Z controller board or any hardware platform supported by the compiler. After that, the code was compiled and a binary machine code was generated should there be no syntax error. Next, the compiled code was transferred to the board via mass storage device (MSD) flash programming interface. Subsequently, a communication link between the FRDM board and a smart phone was established via HC05 Bluetooth module so that students can observe their program simply through their own smart phones.

This approach is slightly different from the current practice where students were normally taught to create a console application that produced an executable file, which can only be used within the Windows environment [21].

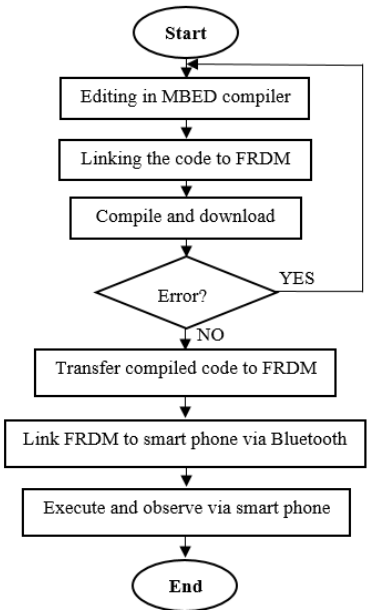

Figure 2: The programming process

2.1 *FRDM KL05Z controller board*

The FRDM-KL05Z microcontroller board depicted in Figure 3 was used in this project. It is one of the ARM Mbed supported platform based on 32-bit ARM Cortex-M processor [21]. It is a powerful tool to build an embedded system from prototyping stage to mass production. One can also write their own software on top of the board's operating system, Mbed OS, which offers an easy way of hardware control, interaction and integration with other tools. It offers convenient on-board sensors such as a touch sensor, an accelerometer and a Red-Yellow-Green (RGB) Light Emitting Diode (LED) that allow new users to practice and test their code without any need of additional hardware interface.

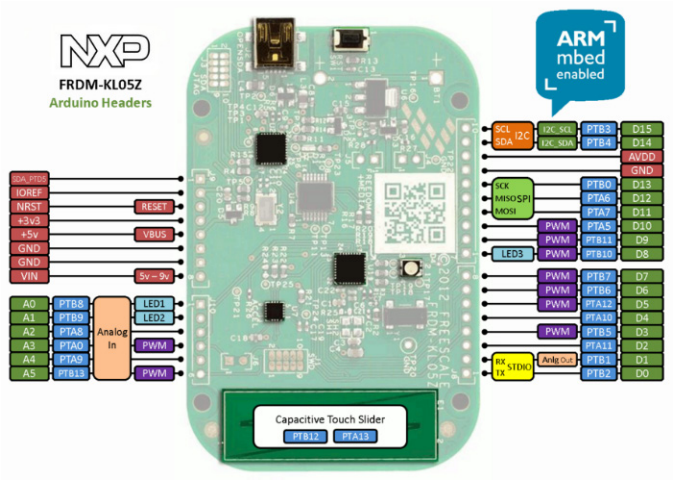

Figure 3: The FRDM-KL05Z development board [22]

2.2 Training Modules

There were seven topics related to ECE126 subject that have been covered during the training session. They include selection statement, repetition, functions, arrays, pointer and structure. These topics were delivered in seven different modules utilizing the on-board peripherals such as the LED, accelerometer and touch sensor. The modules used during the training were listed in Table II.

Table II. Training modules

No	Topic	Module
1	Basic input/output	Hello world!
2	Selection	LED control
3	Repetition	LED blinking
4	Functions	LED pattern
5	Arrays	Sensor Reading
6	Pointer	User login
7	Structure	LED dimmer

In the first module, the participants were taught to observe the execution of their program via smartphones using a Bluetooth serial application known as "BT Term" developed by Futaba Inc. A printf() statement was used to output a "hello world!" sentence via the Bluetooth application as depicted in Figure 4.

Figure 4: Output from the BT Term application

Besides, the second, third and fourth module manipulate the behavior of the on-board RGB LED using several sets of program codes. Students were taught to apply their knowledge on the selection statement to decide on the activation of the LED. Other than that, repetition statements such as while, do-while and for were also employed to create replications of the LED action. Participants were also assigned to blink the LED, in which they need to determine the suitable increment, decrement or assignment operators. Besides, they also learnt how to use break and continue statement to stop the repetition or to skip some iteration within the loop structure. In addition, functions were also been used in module 4 so that the participants can create several set of LED actions according to their preferences. Figure 5 illustrates the use of function to activate the red LED upon receiving value from the user. The program indicates that if a user specifies an input value is equal to 1, the red LED will be activated while red LED will be deactivated if other input value is given. The response of the LED is shown in Figure 6.

```
#include <mbed.h>
#include <frdm.h>
int main(){
scanf("%d",&value);
    if (value == 1)
        RED_LED_ON();
    else
        RED_LED_OFF();
}
```

Figure 5: A function to control the red LED

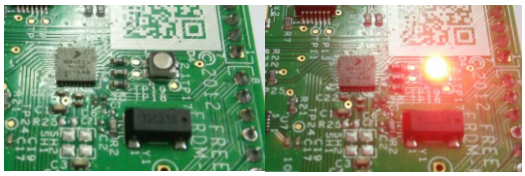

Figure 6: LED OFF (left) and LED ON (right)

Besides, one of the most important topic in C programming such as arrays were also been given much attention during the training session. It has always been useful to store information about certain things under a single variable name. For example, in module 5, students were taught to use such concept to store measured data obtained from the accelerometer sensor every one second into an array variable. Next, they can manipulate the content of each array to do additional action such as activating the LED if certain condition is met. This allows students to think, try and explore more about the concept as well as drawing connections between what have been taught and real-world contexts.

Meanwhile, module 6 focuses on the workings of pointer variable, how to use them as well as the common mistakes faced by a programmer when dealing with it. In this exercise, pointer was used to access a memory location that contains user information. Participants were required to create a login interface that prompt user to input their login ID and password. The program will evaluate the input entered via the serial Bluetooth application before triggering the green LED if correct input is given and red LED if otherwise.

The final module attempted to enlighten the participants about the basic concept of structure in C programming language and how it can be used to hold several information within the same category that share common attributes. Figure 7 demonstrates the use of structure concept to control the brightness of the LED. A structure with a tag named LED was declared in this context and three members named "bright", "medium", and "dim" were defined. The member attributes can be accessed by using "." operator such as "RED.bright" which will provide the variable "LAMP" with 1.0 value.

```
#include "mbed.h"
#include "jenggott.h"
struct LED{
    float dim;
    float medium;
    float bright;
    }
int  main( )
{
    LED RED = {0.2,0.5,1.0};
    LAMP = RED.bright;
}
```

Figure 7: Brightness control using structure

In order to evaluate the approach's acceptability and its effect on learning C programming within the training period, a statistical studies were carried before and after the training program. The results of the survey will be discussed in the following section.

3. Results

Figure 8 shows the bar graph descriptions for Criteria 1 to measure the students attribute towards C Programming subject. As shown in the figure, the mean scores for all questions in exit survey are higher compared to the entrance survey. The students responded that they have better programming skills and sufficient knowledge and understanding in C Programming after the module was implemented.

From the survey, we also measured lecturer's ability in teaching the subject from the students' point of view and the statistic is depicted as in Figure 9 below. The mean scores in exit survey are higher than the entrance survey. Majority of the mean scores for all questions in this criteria are higher than 4.00. This indicates that the students felt that the lecturer is capable of teaching this subject.

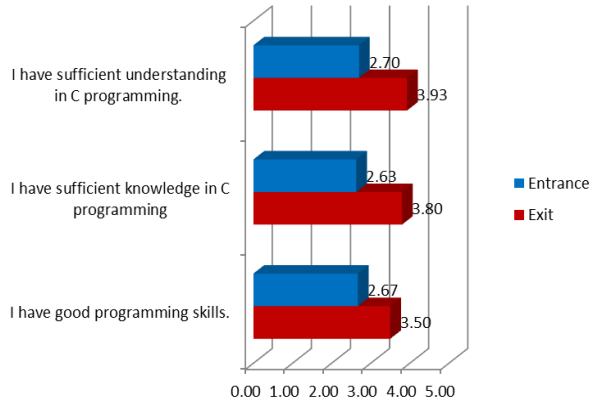

Figure 8: Criteria 1 Students Attributes

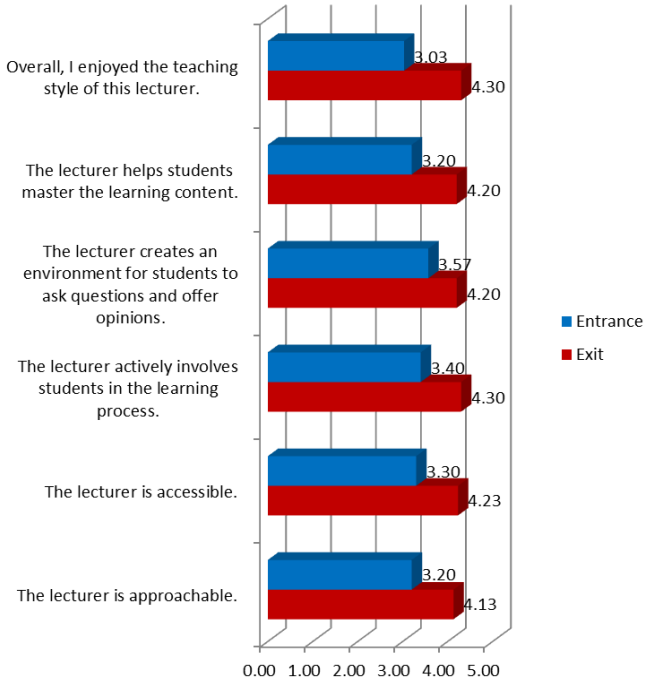

Figure 9: Criteria 2 Lecturer's Profile

We also evaluated the effectiveness on how the lecturer implemented the module as shown in Figure 10 below. The mean scores for all questions are higher in exit survey than entrance survey, which are above 4.00. This shows that the students are satisfied with the implementation of the module.

Other than that, the students gave positive response towards the facilities provided during the module session. Figure 11 below shows the statistic of the criteria. The mean scores for equipment space (mean = 4.13) and functionality (mean = 4.10) are higher in the exit survey compared to entrance survey.

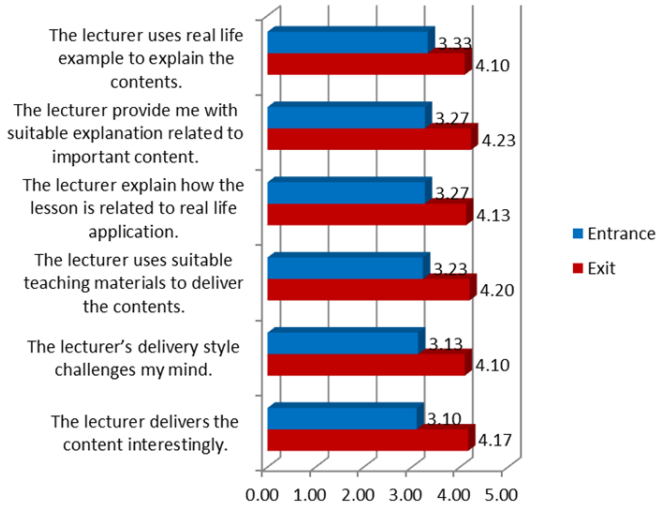

Figure 10: Criteria 3 Implementation

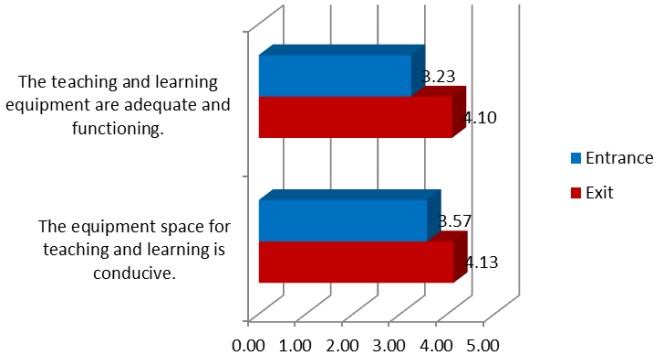

Figure 11: Criteria 4 Facilities

The survey also tested the students understanding of the module as can be seen in Figure 12 below. From the figure, mostly students gave positive response that the module enhances their understanding of C Programming.

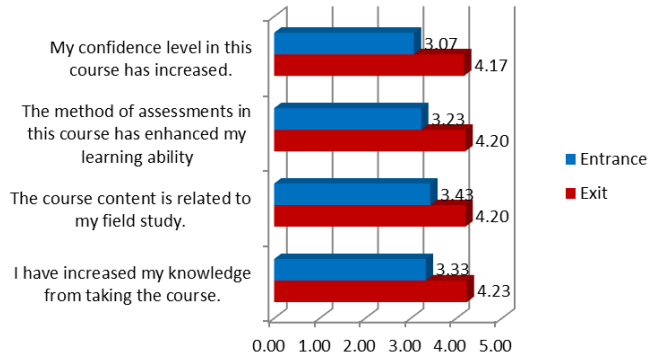

Figure 12: Criteria 5 Students' Understanding

This research study was further extended to evaluate the students' response reflecting the module execution and implementation. Figure 13 to 16 below depict the students' responses regarding the overall module assessment.

Figure 13 shows the bar graph for Criteria Motivation and Students' interest toward the C Programming. The highest score from this criterion was 'Agree' for all three questions and this shows that they are motivated and interested in learning C Programming.

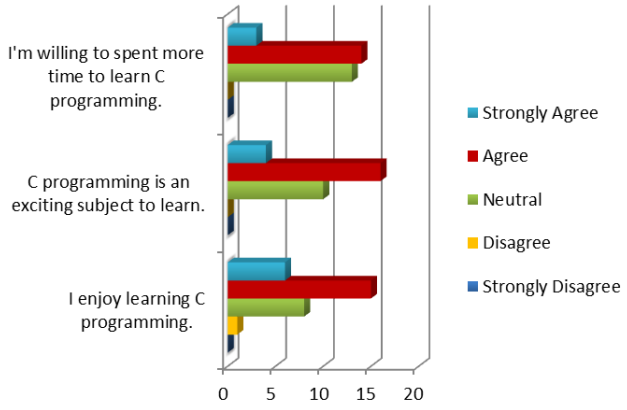

Figure 13: Criteria Motivation and interest

Figure 14 describes the difficulty of the course from the students response. Majority of the students found that the course was quite challenging which they were struggling to understand and complete the task given.

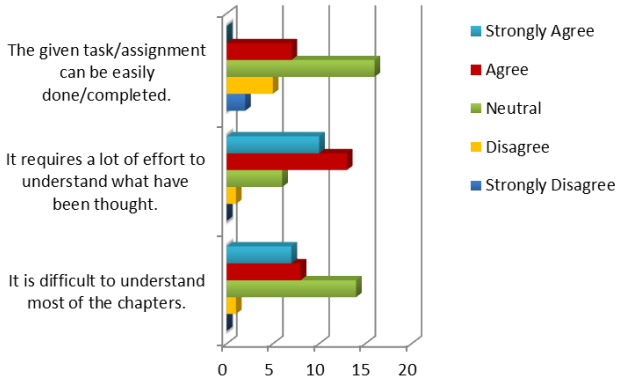

Figure 14: Criteria Difficulties

Figure 15 displays the third criterion which measured the Expectancy for Success among the students. The results shows positive feedback from the students which they believe this course will improve their academic performance.

Figure 16 depicts the students response on the implementation of the course. They found that this course was enjoyable and they highly recommend that the course should be more fun and interesting which interactive games can be integrated and real life application can be interfaced.

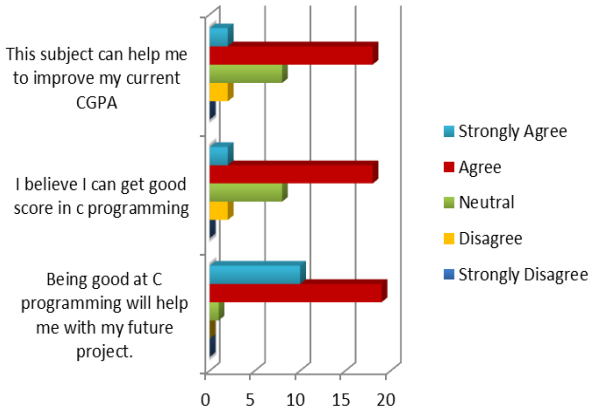

Figure 15: Criteria Expectancy for success

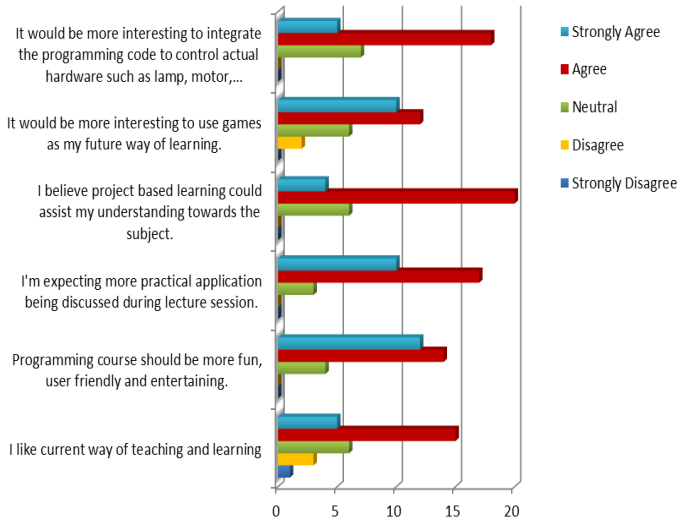

Figure 16: Criteria Deliveries

4. Conclusions

This paper reports the effectiveness of the implementation of the C Programming module. In general we evaluated the students' response in five criteria namely the students attributes, lecturer's profile, implementation, facilities and students' understanding. From the survey, the results in exit survey are higher compared to entrance survey for all criteria. This shows that the students are satisfied with the implementation of the module, which has increased their understanding in learning C Programming.

Open loop resonator slot
Bandwidth enhancement

ABSTRACT

A novel, modified square patch antenna with square open loop resonator slot, operating at 5.5 GHz, for improved bandwidth performance is proposed in this article. A complementary square open loop resonator is introduced on the patch to enhance the bandwidth more than twice that of the conventional square patch antenna operating at the same frequency. A prototype of the antenna operating at 5.5 GHz is designed and fabricated. Results show that 2:1 VSWR bandwidth of the antenna is 7% whereas the conventional square patch antenna offers only 3% bandwidth. The proposed antenna has a compact size of 1.9 cm x 2 cm. It offers a uniform gain of 4.25 dB and a directivity of 6.1 dB at the frequency of operation.

1. Introduction

Owing to their small size, low cost/weight, conformability, and ease of manufacturing, microstrip patch antennas are chosen in many designs applied to standard mobile services and satellite systems [1-2]. However, the main barrier of considering these antenna types for a large range of applications is related to their limited bandwidth [3-5]. The 'Long Term Evolution' (LTE) and 'Long Term Evolution-Advanced' (LTE-A) new standards for 4G, require large bandwidths (up to 200MHz) and it is expected, that newer standards will require even higher bandwidths [6-9]. In that respect, several techniques were discussed in the literature, for bandwidth improvement, including changing the feed type, stacking the patch, modifying the geometry of the patch, and changing the feed location [10-14]. Each method has its own trade-offs, particularly involving the size of the antenna. The use of resonant slots for increasing the bandwidth was proposed in [1]. The resonant frequency of the slot could be chosen in such a way that its operating frequency is different than the resonant frequency of the conventional antenna. This leads to the staggering of two frequencies which, in turn, will increase the bandwidth significantly.

This paper is an extension of work originally presented in the International Conference on Electronic Devices, Systems and Applications [15]. In this extended version, the design of novel square patch antenna with a complementary square open loop resonator (C-SOLR) is explained with the support of measurement results. A square patch antenna with and without C-SOLR is explained. In the proposed design, C-SOLR utilizes proximity coupling. At first, a patch antenna without C-SOLR operating at 5.5 GHz is designed. C-SOLR can reject the corresponding frequency enabling bandwidth enhancement. C-SOLR has been introduced on the patch without affecting the radiation characteristics of the antenna. The proposed antenna offers 400 MHz, 2:1 VSWR bandwidth which is significantly higher than that of the bandwidth obtained by other techniques like changing the feed of the patch proposed in [2], [14]. The proposed antenna offers simulated directivity and gain of 6.1 dB and 4.25 dB respectively.

The remaining sections of this article is organized as follows: Section II explains the design of C-SOLR antenna; Section III, presents simulation results followed by the measurement validation. Finally, the paper is concluded in Section IV.

2. Antenna Design

The geometry of the proposed antenna is shown in Figure 1 (a). The substrate used is FR-4 with relative permittivity of 4.4, loss tangent of 0.02 and thickness of 1.6 mm. The proposed antenna is a square patch with a complementary square open loop resonator (Figure 1 (c)). The square patch used in this design is the conventional square patch antenna. In order to achieve the broadband operation of the antenna, a resonating slot is introduced. Square open loop resonator (S-OLR) has been chosen here because of their compact size and ease of design [15]. S-OLR can resonate at half the frequency as that of the closed loop resonator with the same dimension. S-OLR are also considered as a microstrip line, loaded with folded open stubs at both ends. Figure 1(b) shows the structure of classical square open loop resonator (S-OLR). The fundamental resonance frequency f_0 of S-OLR can be given by:

$$f_0 = \frac{c}{2(P_{av}-s)\sqrt{\varepsilon_{eff}}} \quad (1)$$

In (1), $\boldsymbol{P_{av}}$ is the average perimeter, s is the gap between the open ends and $\boldsymbol{\varepsilon_{eff}}$ is the effective permittivity of the substrate [16]. Inspired by its compactness, we are introducing the 'negative square open loop resonator' which can also be called 'complementary square open loop resonator (C-SOLR) in analogy to the concept of complementary split ring resonator (CSRR) (see Figure 1(c)). From simulation study, we have observed that C-SOLR behavior is governed by eq. (1). When C-SOLR is coupled to a transmission line, the wave propagation is rejected in the vicinity of the resonant frequency. This property of the C-SOLR is exploited here which enables a larger bandwidth compared to the antenna without C-SOLR. The antenna has a compact dimension of 19 mm x 20 mm. The width of the square patch ($\boldsymbol{W_P}$) is 12.3 mm and can resonate at 5.5 GHz. Ansoft High Frequency Structure Simulator (HFSS) is used to perform simulations. The optimum gap $\boldsymbol{g}$ between the C-SOLR and feed line uses proximity coupling A parametric study has been done and the optimum gap is found to be 0.6 mm. This, ensures better coupling and impedance matching as shown in Figure 2. The square patch is matched to a transmission line of characteristic impedance Z_0 (50 Ω line) by using a quarter wavelength transmission line transformer of characteristics impedance Z_1 as shown in Figure 1 (a). The optimum width of the quarter wavelength transmission line is $\boldsymbol{W_T}$=0.9 mm. The 50 Ω line is mitered to alleviate the small mismatch between the high and low impedance line by chopping off the small amount of capacitance introduced due to the sudden transition from the high impedance to low impedance line. Thus, it can also reduce the unwanted reflections due to the abrupt change. The width of the C-SOLR is determined from a parametric study and the optimum value is found to be 0.3 mm for better impedance matching and gain as shown in Figure 3 (a) & (b). Table I summarizes the optimized parameters of the C-SOLR antenna.

Figure 3: Influence of C-SOLR width on gain and bandwidth. a) C-SOLR width versus gain b) C-SOLR width versus bandwidth.

3. Results and Discussion

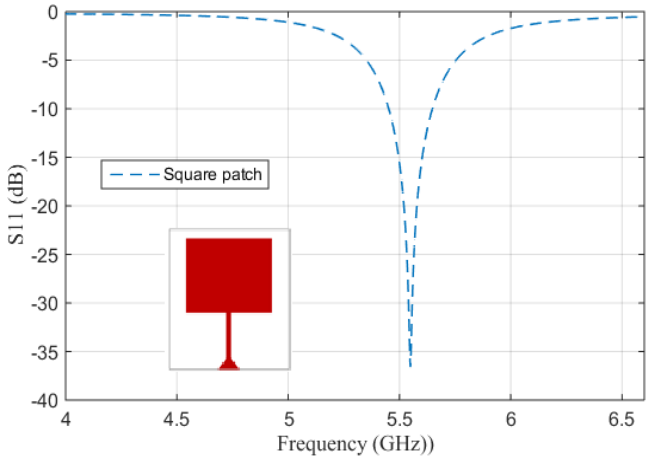
Simulation and measurement of proposed antenna is discussed in this section. Antenna measurements were conducted using Agilent Network Analyzer (PNA-X N5242A).

Firstly, a square patch antenna without resonating slot has been simulated. Figure 4 (a) shows the simulated S-parameters of the square patch antenna without any slot. As shown, it produces a narrow bandwidth of 170 MHz. Figure 4 (b) shows the corresponding E-plane and H-plane pattern. As can be seen, the patterns are unidirectional. The square patch antenna offers a gain and directivity of 4.3 dB and 6.1 dB respectively.

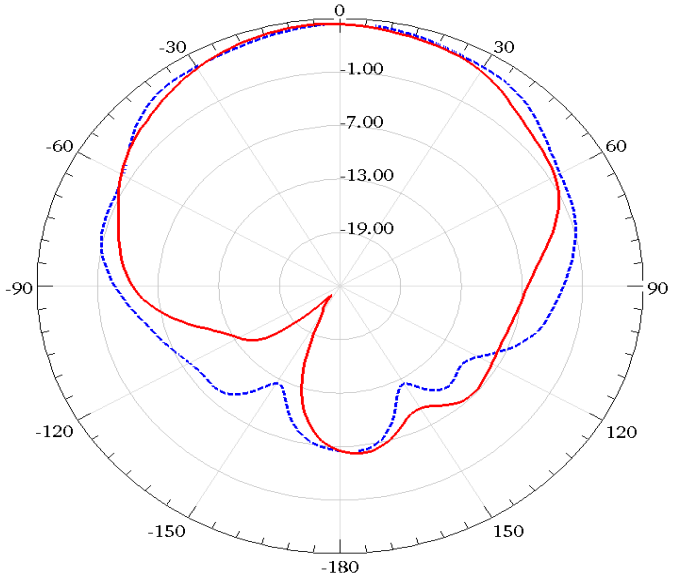
Table I Optimal parameter values of the proposed antenna

Parameters	***g***	***Pav***	W_T	***Wp***
Value (mm)	0.6	15.2	0.9	12.3

By properly placing the C-SOLR on the patch, the prototype has been transformed to the C-SOLR patch antenna as depicted in Figure 1(a). From simulations it was found that the parameter ***g*** places an important role in the impedance matching and coupling to the feed line as well. Figure 5 shows the influence of *g* on VSWR bandwidth. Thus, the optimum value of ***g*** has been found as 0.6 mm (see Table I). The resonance frequency of the C-SOLR has been chosen as a frequency near to the resonance frequency of the square patch without any slot.



(a)



(b)

Figure 4: Simulated reflection and 2-D radiation characteristics of a conventional patch antenna. a) simulated S-parameters, b) E-plane (solid line) and H-plane (dashed line) pattern.

The designed antennas were fabricated on standard FR4 substrate with relative permittivity of 4.6 and a dielectric height of 1.6 mm. Figure 6 (a) shows the fabricated antenna. The simulated and measured reflection characteristics are depicted in Figure 6 (b). As shown in the figure, they are in good agreement. From simulations, we have observed that C-SOLR operates in accordance with eq. (1). Moreover, more than twice bandwidth of the conventional antenna can be obtained using the C-SOLR antenna. The proposed antenna offers 7%, 2:1 VSWR bandwidth whereas, the conventional antenna offers only 3%, 2:1 VSWR bandwidth.

Figure 7 shows the 2-Dimensional radiation characteristics of the proposed antenna. The antenna provides a directive radiation pattern towards the patch surface. Notably, the C-SOLR has been introduced without disturbing the radiation characteristics of the antenna. This is the main advantage of our proposed methodology.

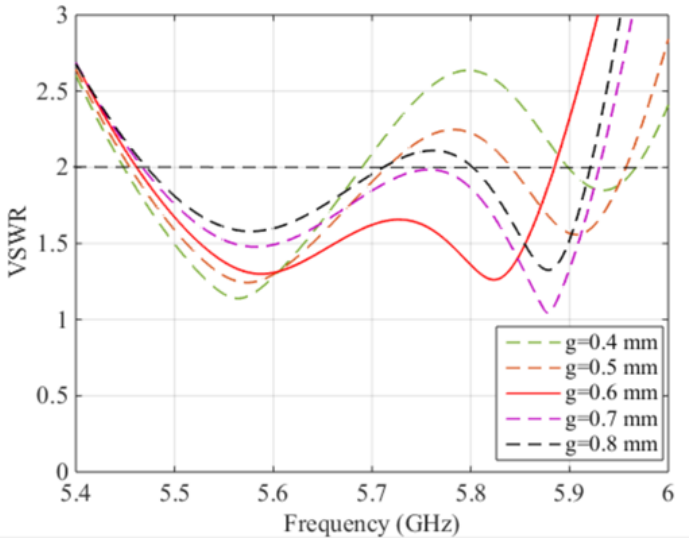


Figure 5: Influence of gap g on VSWR bandwidth.

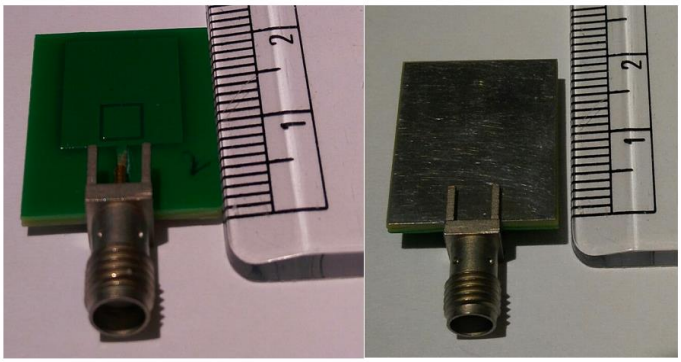
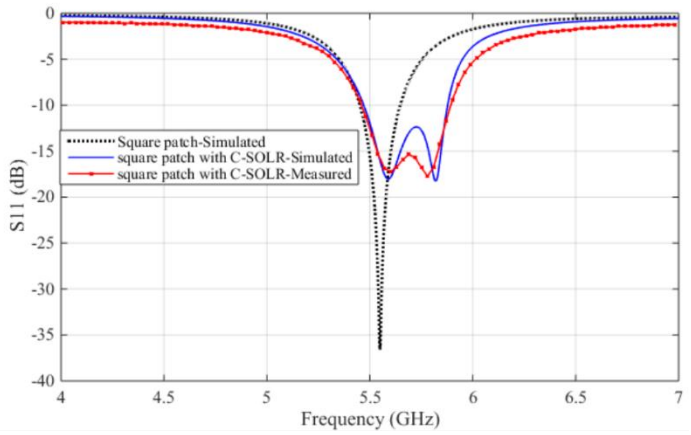


(a) (b)



(c)

Figure 6: Fabricated antenna and corresponding simulated and measured reflection coefficient, a) antenna front view, b)antenna rear view, c) reflection coefficient.

Thus, the slotted SOLR antenna offers almost the same gain and directivity as a conventional square patch antenna with 4.25 dB gain and 6.1 dB directivity as shown in Figure 8. From simulations, the proposed antenna offers a uniform gain and directivity. In Figure 8, the gain tend to decrease above 5.87 GHz and indicates the appearance of cross polarized component as a consequence of using the C-SOLR structure.

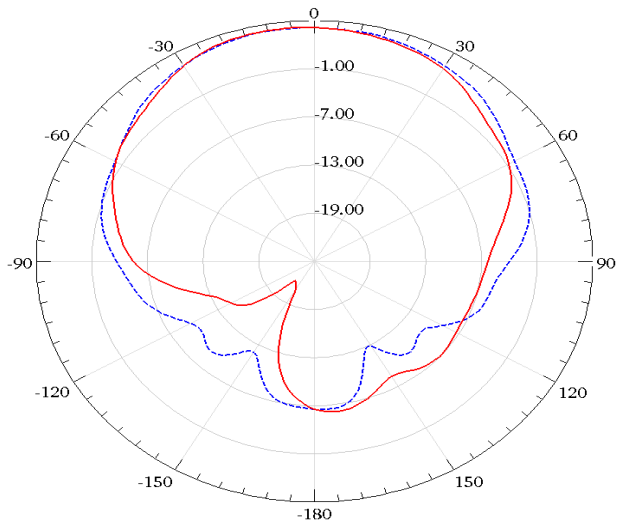


Figure. 7: Simulated 2-D radiation characteristics of C-SOLR patch antenna. E-plane (solid line) and H-plane (dashed line) pattern.

Thus, if we didn't chose the optimum frequency for the C-SOLR, this cross-polarizing component will appear inside the band of interest, causing a non-uniform gain. The uniform gain is an advantage of SOLR in comparison to a rectangular loop resonator in which, the longitudinal arm of the resonator produces the cross polarized component within the band of interest. The rectangular loop resonator causes a non-uniform gain but has comparable bandwidth with that of the SOLR.

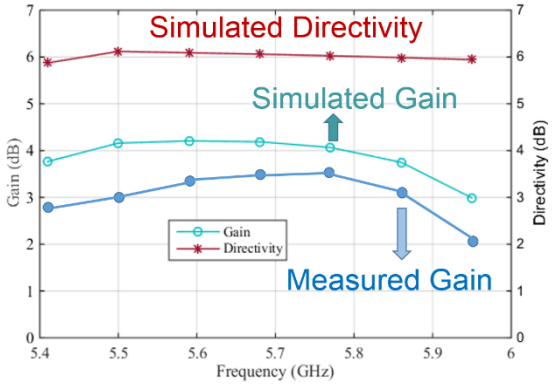

Figure.8: Simulated/measured gain and directivity of C-SOLR patch antenna.

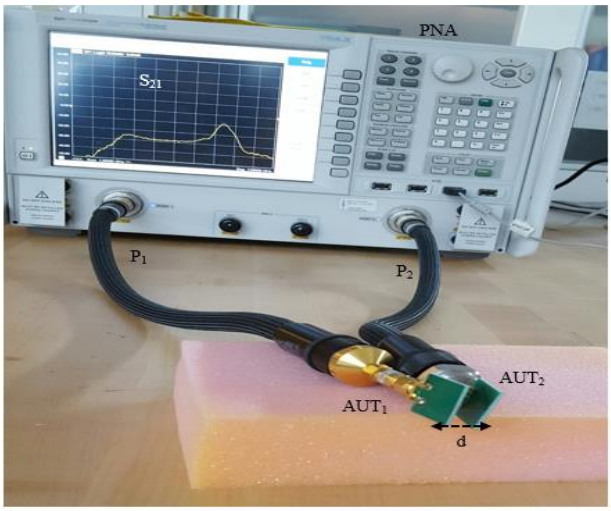
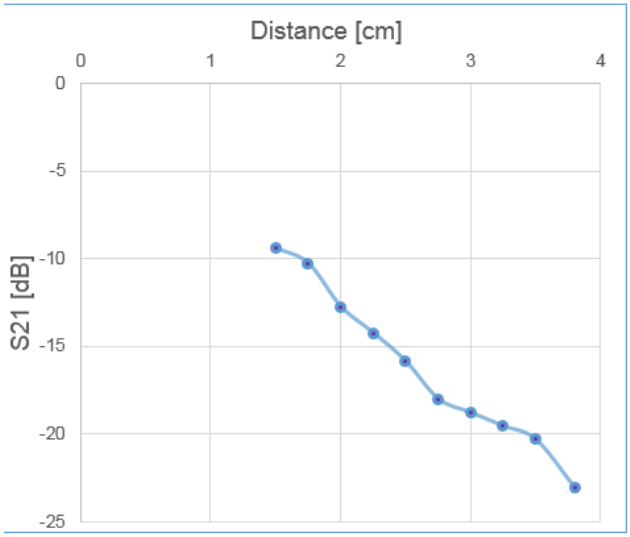
The power transfer measurement of the proposed antenna has also been conducted as depicted in Figure 9 (a). Two identical antennas separated with a distance *d* were connected to the two ports of the Network Analyzer and corresponding S21 was measured. The power receiving capability of the antenna was tested for different distances. As shown in Figure 9 (b), the magnitude of power level is decreasing with increasing the distance. The measurement was conducted for a range of *d* from 1.5 cm to 3.8 cm.

4. Conclusion

The presented article proposes a novel C-SOLR patch antenna with enhanced bandwidth with the support of measurement. A proximity coupled complementary square open loop resonator is placed on the patch. C-SOLR rejects this frequency and, as a result, the bandwidth is enhanced. Results proves that C-SOLR antenna



(a)



(b)

Figure 9: Power transfer measurement of the proposed antenna. a) Measurement setup, b) received power versus distance between the two antennas.

offers more than twice the bandwidth of a conventional square patch antenna, without disturbing the radiation characteristics. The proposed antenna offers the same uniform gain and directivity as that of the square patch antenna, as well. It can operate from 5.47 GHz- 5.87 GHz and could be used for WiFi applications. The antenna can be easily redesigned for another frequencies, e.g. to meet the extensive bandwidth requirement of 200 MHz for LTE standards applied to 4G systems.

Image compression

ABSTRACT

This paper is an extension of work originally presented at conference Applied Machine Intelligence and Informatics (SAMI), 2017 IEEE 13th International Symposium. The article performs a comparative study between the image compression technique Local Binary Compressed format (LBC) proposed by the authors and the standard image compression techniques used today (BMP, JPEG, PNG and GIF). The study is carried out for large medical images that need to be stored for longer periods of time. In the study, the most common types of medical images used are: X-rays and ultrasounds images. This study aimed to determine the distribution laws parameters used to reconstruct the image as well as to determine the influence of the most used medical image formats on the compression process. The effective representation of image format LBC is proven using an image quality index type, the Structural Similarity Index (SSIM).

1. Introduction

The progresses made in the computer technology field in the last decade, had as result the almost exponential increase of generated data. Thus, the amount of generated data has increased from five Exabyte's (EB) in 2003 to 2.8 zettabytes (ZB) in 2012. Compared to 2010, the amount of data [1, 2] increased more than 50 times. In 2020, the world will produce an amount of about 40 ZB data. According to the same study, only 1% of the amount of data produced in 2012 was analyzed. It is worth noting that in late 2012 there were 550 billion archived images comprising over 60% of medical type. For an average size of 20MB of images, amount of archived information [3] with an index of 0.15 compression is 550 billion * 20MB / .15 = 73 Exabyte's. Therefore, compressing images, especially those of medical nature, has become a topical issue, which will require finding new techniques and formats to be represented by reduced size. This article makes a comparative analysis of LBC compression technique proposed by the authors [1, 2] compared to standard techniques of representation images.

2. Related work

The image compression term refers to the process of reducing the amount of data required to represent the image quality subjective acceptable. This can be achieved by removing the redundancy present in an image [4]. The compression advantage is that it reduces the important resources consumption, such as hard disk space. Implementing an image compression involves storing the image in a bit stream as compact as possible and image decoding as accurately as possible. The needed items are an encoder and a decoder. The encoder receives and converts the image into a series of binary data, which then is transmitted to the decoder input. The decoder decodes picture as accurately as possible [5].

The most important properties of a compression algorithm are the compression rate and the reconstruction quality. The compression ratio is the ratio between the number of bits necessary for representing the data before and after compression.

The best-known image compression techniques are lossless and lossy compression. The first technique does not cause any loss on image quality and is used in cases where image accuracy is very important, like technical drawings. When using the lossy compression, the original image differs from the reconstructed one but to determine the algorithm's efficiency an estimation between the two versions is needed.

The following methods are some known image compression techniques [6, 7].

*Corresponding Author: Ildikó-Angelica Szöke, Automation and Computers, Politehnica Timisoara, 300223, Romania | Email: ildiko.szoke@yahoo.com

The Run Length Encoding (RLE) technique relies on image colors repetition. If the image is read from the top left, reading one row of pixels at a time, often rows of pixels of the same color will be obtained. If more than 3 pixels from the row have the same color, then the color and the color number are stored. Using this technique, no information is lost. RLE has been used in PCX format that no longer exists.

Standard Joint Photographic Experts Group (JPEG) specifies the algorithm used for compression and decompression (codec). This format involves loss of visual information. JPG format is good for photos but not equally suited for high-contrast images, such as screenshots or computer art. It is based on the fact that the eye is not sensitive to small color changes. Compression ratio may vary when the image is saved. This format is re-compressed every time a backup is performed; repeated compressions to an image can lead to loss of quality.

Graphics Interchange Format (GIF) is based on limiting the colors depth used in the image. Usually up to 256 colors are used to achieve the color palette - a table that assigns colors to 256 numbers from 0 to 255. The image pixels are then stored using an 8-bit number that represents the color position table. This format is suitable for cartoons and for produced computer art - supports transparency.

Portable Network Graphics (PNG) is using a lossless data compression. PNG is an open-source format, which was created to improve GIF's algorithm.

Current compression methods are not final. Interesting issues, such as obtaining accurate models of images, optimal representations of these models and rapid processing of those representations are the greatest challenges we face.

3. Proposed Method

The Local Binary Pattern (LBP) method is used to summarize the local structure of images. It labels the image pixels and creates a binary number used for classification in computer vision. This method "looks" at each pixel and tests it with its neighborhood. LBP is tolerant to monotonic illumination changes. The important property is the computational simplicity, which makes it possible to analyze images in challenging real-time settings.

Timo Ojala [5,8] introduced the Local Binary Pattern (LBP) as a fine scale-texture descriptor. LBP is the particular case of the Texture Spectrum model proposed in 1990 [9].

The LPD method divides the image into small 3x3-pixel matrix; each pixel is then compared to its eight neighbors. Then the LBP operator creates label's forms for the image pixels by looking at the surrounding points (of a central point) and tests whether the surrounding points are greater than the central point resulting in a binary result. It is applied to a 3x3 matrix neighborhood, which means that there are 8 points of comparison thus it produces an 8-bit binary number ($2^8 = 256$ different labels), which will be converted to decimal and used as a texture descriptor. This operator is effective in the computing plan because it works only with integer arithmetic (allows to reach real-time productivity in some problems), and also invariant to brightness changes on the image, it may be caused by shooting in various conditions of illumination.

As shown in [1, 2], Local Binary Pattern technique (LBP) allows to describe the image texture using a vector with various sizes, depending on the LBP version used. In the classic version, LBP describes a 3x3-texture image area through a single pixel. This pixel defines the border zone relative to the center pixel from the 3x3 area. The values obtained from the entire image texture analysis, lead to a vector with a 256 values size that uniquely defines the original image, which came from. Using this concept, the authors proposed a new image compression technique, which is called Local Binary Compressed format (LBC). The compression technique described in [1, 2] consists in defining the image through two complementary images (by the average and by the dispersion values) of much smaller size obtained by applying the Local Binary Pattern technique method. These two images obtained from analyzing the original image are used for image compression or image decompression [10].

3.1. Image compression

Based on the LBP value constructing mode in the base form [4] previously described, the description for a grayscale image is proposed using two smaller size images [1, 2]:

The first image represents the central values from the 3x3 size areas, which are used in building the LBP value. This image is seen as representing an average pixel defining image texture.

The second image represents the LBP values obtained using the basic version of this technique. This set of values is the ratio (the pixel has a higher or lower value) between the pixels from the 3x3 border area and the central pixel. For this reason, this image is seen as a pixels "dispersion" from the border relative to the center pixel area.

The two images sets represents the compressed image seen in Figure 1.

3.2. Image decompression

Based on the two images – the average and "dispersion" values – the original image can be reconstructed by generating pixels around the average value. The generation process uses existing information in the "dispersion" image. The reconstruction around the average pixels value can use two techniques. Both techniques assume that the distribution pixel values law around the mean value can be a uniform distribution law or a Gaussian distribution law. In both cases, it is necessary to define a dispersion factor [11].

The dispersion factor is used for building the time interval that pixels can take values. Dispersion factor is a numerical percentage applied to the average value type used for constructing the range of pixel dispersion around the mean value. After defining this range, based on the distribution law, pixels values can be generated, then can be added or removed from the central pixel value, depending on the operation direction specified by the attached "dispersion" image (Figure 1).

The factor's dispersion size and the distribution law are experimentally determined. The criterion in scope is to obtain a similarity index as big as possible between the original image and the resulted image after the compression / decompression. The study was conducted using the ultrasound medical image database containing 6264 JPEG images [12, 13]. All the images from this database were compressed and reconstructed using the [0.1 - 2] % interval dispersion around the LBP range, which was followed by a step of 0.1 in the Gaussian and uniform distribution case. In figures 2a and 2b, the similarity index variation can be seen when using Gaussian or uniform distribution that is used for calculating the dispersion interval of LBP values. It can be noted, for a value of one, for the dispersion range - percentage constant - around the LBP value was obtained a maximum value for the similarity index.

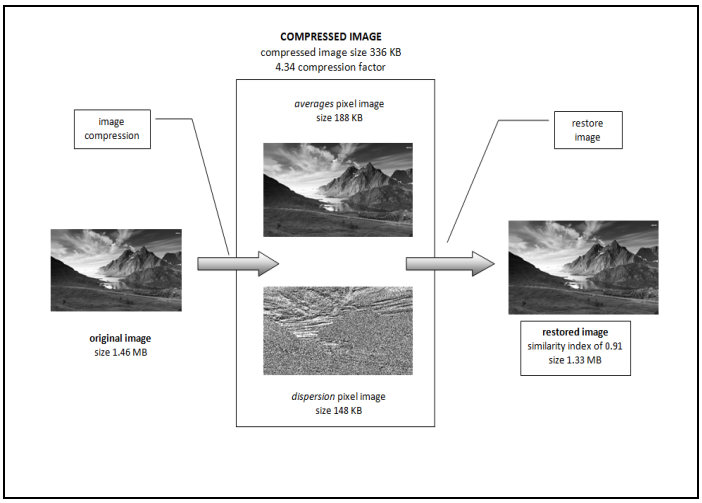

Figure 1. The principle of representing the LBC image format

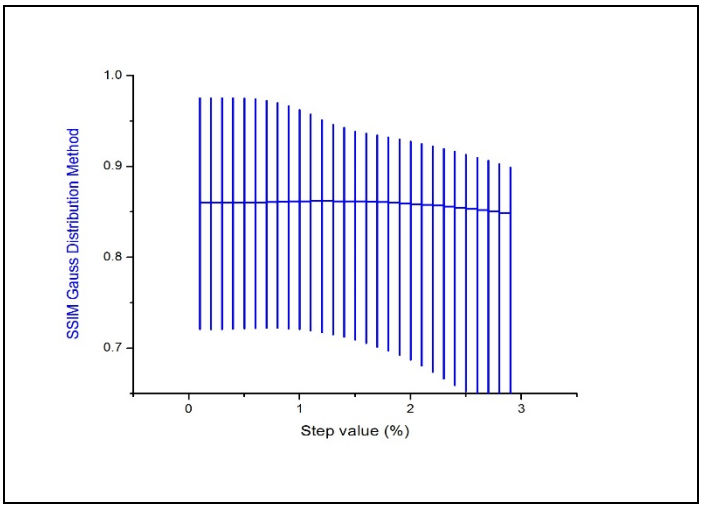

Figure 2a

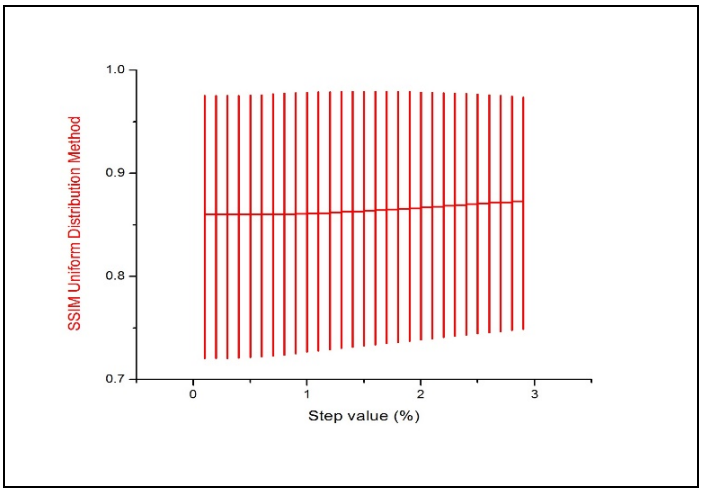

Figure 2b

Figure 2a, 2b Similarity index variation for Gaussian or uniform distribution, which is used for calculating the dispersion range of LBP values.

It has been shown that compression index value and the distribution law depend on the image nature and their formats (JPEG, PNG, BMP, JPEG.).

4. Experimental results

Medical images, regardless their source (radiographs, ultrasound, various types of CT scans) have a characteristics set which distinguish them from the photographic images taken with a modern photo equipment. The main feature refers to the fact that they are large images and for the same medical condition, there is a relatively large number of images taken from different angles, trying to capture that medical condition. In general, these are greyscale images. Color images origin from special histological analysis cases or from special ultrasound cases.

The study was carried out on two types of medical images, radiography and ultrasound images. The Structural Similarity Index Metric (SSIM) is used for measuring the similarity between two images and was used [12 - 17] to assess the similarity between the original image and the reconstructed one. For each image types like BMP, JPEG, GIF and PNG formats were considered. The analysis was carried with a dispersion factor of one for the uniform distribution as well as for the Gaussian distribution; a tool developed by the authors was used. A number of six medical images were taken to be analyzed - ultrasound and radiography images.

4.1. X-rays medical image compression

For the experiments, two types of images were taken into consideration: X-ray medical image in JPEG format, for the lossy image compression technique and X-ray medical image in BMP format, for the lossless image compression technique. The obtained results are shown in the following tables: 1a and b. The images taken into account for this study are presented in Figure 3.

Figure 3 X-ray medical image

Table 1a. X-ray image compression on BMP format

Image	OrigSize (KB)	Compression index (LBP method)	SSIM index Uniform distribution	SSIM index Gaussian distribution
a	550.223	4.038	0.902	0.862

Table 1b. X-ray image compression on JPEG format

Imagine	OrigSize (KB)	Compression index (LBP method)	SSIM index Uniform distribution	SSIM index Gaussian distribution
a	514.960	3.895	0.896	0.858
b	380.746	3.966	0.953	0.913
c	387.021	3.578	0.951	0.914
d	720.333	4.310	0.856	0.813
e	642.341	3.970	0.865	0.823
f	383.333	3.838	0.884	0.849

Table 1c. X-ray image compression on GIF format

Imagine	OrigSize (KB)	Compression index (LBP method)	SSIM index Uniform distribution	SSIM index Gaussian distribution
a	482.378	2.085	0.883	0.835
b	417.590	2.174	0.918	0.872
c	434.548	2.176	0.845	0.806
d	544.431	2.185	0.862	0.831
e	672.021	2.209	0.892	0.864
f	548.002	2.137	0.855	0.844

Table 1d. X-ray image compression on PNG format

Imagine	OrigSize (KB)	Compression index (LBP method)	SSIM index Uniform distribution	SSIM index Gaussian distribution
a	550.223	4.038	0.902	0.862
b	357.528	4.091	0.958	0.911
c	414.877	4.167	0.950	0.910
d	544.431	2.185	0.862	0.831
e	536.009	4.020	0.873	0.832
f	420.034	3.986	0.884	0.855

For the experiments were also used GIF and PNG images format.

Analyzing the results, the compression ratio is in the range [2.1, 4.3] for the radiography images types; the similarity index context for uniform distribution is in the range [0.8, 0.96] and the Gaussian distribution it belongs to the range [0.8, 0.92].

4.2. Ultrasound medical image compression

Images, taken into account in this study, are those from Figure 4. Analyzing the results, only JPEG images format were used.

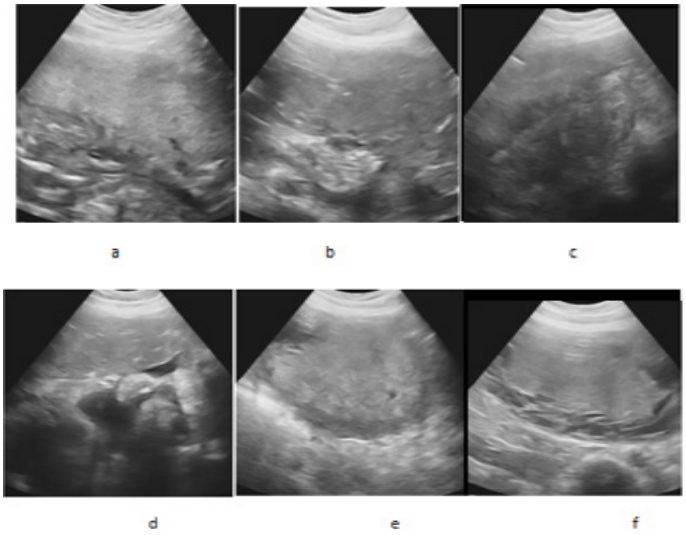

Figure 4. Ultrasound medical images

The results are shown in table 2:

Table 2. JPEG ultrasound medical images

Image	OrigSize (KB)	Compression index (LBP method)	SSIM index Uniform distribution	SSIM index Gaussian distribuion
a	642.341	3.970	0.865	0.823
b	720.333	4.310	0.856	0.813
c	471.541	3.885	0.948	0.907
d	387.021	3.578	0.951	0.914
e	514.960	3.895	0.896	0.858
f	320.896	3.851	0.960	0.913

The calculations made to determine the static medical image format influence on the compression process led to the results presented in Table 3. It can be observed that the index compression has the lowest value for the JPG image format (around 3.6), a little higher for BMP image format (around 3.99) and for PNG image format (around 4.01). Behavior is the opposite when we talk about the similarity index, so JPG images show the highest similarity index, and BMP, PNG images have a slightly lower similarity. We can assume that the image format slightly influences the compression index and related similarity regardless of the distribution law type used to reconstruct the compressed image (uniform or normal) [18].

Image format	Compression index	SSIM Uniform Distribution Method	SSIM Gauss Distribution Method
BMP	4.013	0.899	0.914
JPG	3.593	0.912	0.933
PNG	3.999	0.899	0.915

Table 3 Relationship between image format, compression factor and similarity index.

5. Conclusions and future work

Images have become necessary and useful nowadays. The image quality and clarity was developed and improved over time. The image formats performance has increasingly improved over time because our society has become digital. The most used image formats are still widely used because of Microsoft Company - JPEG, BMP, GIF and PNG.

Digital data almost exponential growth is due to the computer technology progress from the last decade and because of the continuous improvement or creation of new algorithms for processing digital data, particularly digital images.

Local Binary Pattern operator is one of the tools that led to improvement in the quality and performance o image compression / decompression, and it is a statistical method and structural analysis for improving the image texture.

One of the many LBP operator benefits is that the topologies can be changed and was changed, according to our app, to get the best results. The method presented so far, use the LBP operator to analysis the static images; there is a controller for dynamic images analysis named space-time. It is used to analyze moving textures, patterns along the proposed method (volume) on the three orthogonal planes.

Compression with the LBC image technique, which is defined by two components (an average value and a dispersion value calculated with the LBP technique type), had better result when for restoring the original image a dispersion factor of 1 was used, in the uniform distribution context used for generating the pixel values.

1. The proposed method allows obtain a compression factor in the range [2, 4.5] for medical images. The compression index depends on the image format (PNG, JPEG and BMP). The similarity index obtained belongs to an interval [0.81, 0.94]. From this point of view, the method is part of the lossy compression methods [18]. The study led to the following conclusions:

- The maximum indices performance (compression factor, SSIM similarity index) was obtained when the value 1 is used as the constant that determines the LBP dispersion range size.
- It was determined that the best law that can be used to reconstruct the pixel values is the uniform one. Between the use of the uniform distribution law and the Gaussian distribution law for the reconstruction of pixels, studies have shown that there are small differences between the two laws with a higher quality (compression factor, SSIM similarity index) for the uniform distribution law cases.
- Studies have shown that the original image type that is compressed (the most commonly used medical image formats - BMP, JPG and PNG) do not significantly affect the compression process. However, a conclusion is that BMP and PNG images lead to a higher compression factor with a decrease on the similarity index insignificant.

2. The LBC compression method lends itself to further developments; the similarity index can be increased by using new versions of the existing extraction technique – Local Binary Pattern feature

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Navigation is often performed using the Global Positioning Satellite system. However, the system is not always reliable for use at all times in all contexts. Reliance solely on such systems could endanger a vessel or get people lost. Another approach to provide navigation is to use known landmarks and triangulate one's position. A navigation solution can be automatically generated using image data. In this paper, a target-tracking based approach for navigation using imagery is developed. The technique is based on an extended Kalman filter that uses angle measurements only. The technique is developed to use landmarks known a priori and landmarks that are first tracked by the vessel navigating and then used as known landmarks. The issues of observability to the development are considered. Image tracking from video frame to video frame is a further element. The frame-to-frame image correlation technique, the phase-only filter, is used to provide a low uncertainty estimate of the position of elements based upon the image frame. This provides an estimate of bearing angle that can be combined with a bearing from other known landmarks to fix and track the platform to provide a navigation solution.

1. Introduction

Visual cues used in navigation have a very long tradition, as is evident from Homer's *The Odyssey* [1],

At night he (Odysseus) never closed his eyes in sleep, but watched the Pleiades, late-setting Bootes, and the Great Bear that men call the Wain, that circles in place opposite Orion, and that never bathes in the sea. Calypso, the lovely goddess, had told him to keep that constellation to larboard as he crossed the waters.

Besides the stars, landmarks such as Poseidon's Temple at Cape Sunion, the Lighthouse of Alexandria, and the Roman lighthouse of Dover Castle provide testament to ancient use of upon a relative point. Using visual cues for navigation has long fixed reference points from which to understand location based been a standard procedure to ensure that ships could know where they were and get to desired locations.

Today, the primary navigational resource is GPS for systems from cell phones to vehicle navigation systems. In some cases, GPS signals are used to direct autopilot systems. But, at times, total reliance on GPS can be a detriment to navigation. There are places where the loss GPS can play havoc with a commuter. GPS signals are not available in urban canyons [2], such as in the heart of New York City or in Boston's Ted Williams Tunnel near Logan airport.

GPS also can be jammed or spoofed. In [3], the weakness and danger of sole reliance on GPS was presented. In 2011, a United states spy drone was reported captured by Iran through jamming and spoofing of the GPS signal [4]. Even if untrue, the fact that it could be considered a plausible scenario, it shows the need for other navigation system in places when vessel or individual needs to navigate in precarious places.

For their submarine fleet, the uses "eyes-on" navigation and piloting for the ingress to or egress from a port. This kind of navigation of a submarine through the channel is both time and human-power intensive. This procedure uses a labor-intensive visual-based approach with a company of sailors stationed on the sail and hull of the vessel to point out channel markers, landmarks, and hazards. Information on what they see is relayed to the captain who can then act upon the information. Besides the potential dangers with relying on GPS, other navigation capabilities available to the submarine are not capable enough for navigation. Standard inertial navigation systems (INS are not currently accurate enough for such tight piloting [5]. Other types of sensors such as electromagnetic log and velocity sonar are unreliable in littoral conditions [5]-[7].

A number of techniques have been developed to overcome the issues that can arise relying solely on GPS navigation. Many incorporate inexpensive INS [2],[8]. It is well known, though, that these inertial systems have drifts and biases that without corrections will grow [8], [9]. For short periods of time and for operations where an human can control the motion of the navigating object easily, these systems are useful. To compensate for the drifts and biases, some of these non-GPS reliant navigators uses other sensors. In [10], the uses of imagery of the helmet that contains INS is used to compensate for the INS's biases and drifts. Some systems, such as unmanned autonomous vehicles or drones, may be equipped with vision-based systems (video capabilities) rather than INS elements. In [11], [12] are typical techniques that use imagery for navigation. They use the image to provide a map over time. Complex image processing is then used to determine the relative position of the navigating object. In [13], [14], the concept of navigation using a target tracking approach based on the imagery was developed.

Unlike imaging techniques, such as [15], [16], the proposed method does not rely on an artifically-generated range estimate but instead on the angle-only information. Angle-only navigation is a common littoral navigation technique [17]. It is can also be considered the dual angle-only tracking [18]. In the tracking problem, the sensor platform has a known location and velocity while the targets' kinematics are unknown. For angle-only navigation, landmarks with known fixed locatios are known. The sensor platform which wants to navigate uses its measured relationship to the landmarks to provide a crossfix of its positio. By repeating the crossfix estimate over time, a navigation track of the vessel can be computed. This method of navigation based upon tracking can handle obfuscation of individual landmarks, and can be used to locate new landmarks.

In [14], the concept of new landmarks being added to the existing set was discussed. That work is extended with the development of the approach and analysis of the performance.

In Section 2, the concept and effects of observability for angle-only navigation are presented. The use of the Phase-only Filter (POF) for the frame-to-frame image tracking and bearing generation is discussed in Section 3. Section 4 provides the improved navigation technique, including its functional flow. In Section 5, the bearings-only Kalman filter used within the technique is summarized along with the procedure to switch from tracking to navigation. Then this is then applied to frame-to-frame tracking in Section 6. An analysis of a simulation a maritime channel with multiple located landmarks some known and some unknown is provided.

2. Observability and Analysis Summary

2.1. Maintaining the Integrity of the Specifications (Heading 2)

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

Observability provides the ability to determine the state of system from the measurements. In [19], the standard observability Gramian for time-invariant linear system defined as

$$\mathbf{x}_{k+1} = \mathbf{F}\mathbf{x}_k + \mathbf{G}\mathbf{u}_k \tag{1}$$

$$\mathbf{y}_k = \mathbf{H}\mathbf{x}_k \tag{2}$$

was shown to be

$$\mathbf{G}_O = \begin{bmatrix} \mathbf{H} \\ \mathbf{HF} \\ \mathbf{HF}^2 \\ \vdots \\ \mathbf{HF}^{n-1} \end{bmatrix}, \tag{3}$$

if $\mathbf{G_o}$ is of maximal rank then the system is considered fully observable.

The image navigation problem defined for this problem is more complex. The measurement is defined as

$$\mathbf{z}_k = \beta_{i,k} = \text{atan}\left(\frac{y_{LMi} - y_{platform}}{x_{LMi} - x_{platform}}\right) \tag{4}$$

where the subscript *LMi* denotes the i[th] landmark that can be used by the sensor platform. As seen in Figure 1, the platform and two landmarks are present. The measurement to a single landmark is an angle, which is a nonlinear relationship from the landmark position and the platform position to the measurement space. As shown in [20], one way to obtain observability is to use multiple landmarks. This provides the well-known concept of a cross-fix as seen in Figure 1.

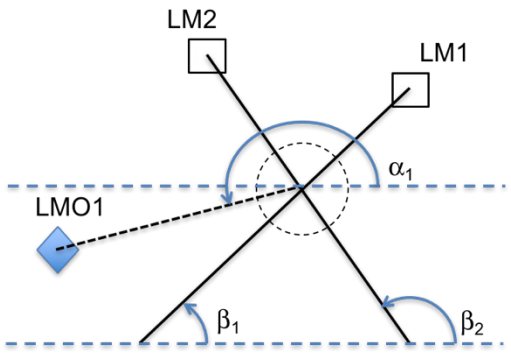

Figure 1. Example of creating a position of a nonsurveyed landmark to be used for crossfixing when one of the surveyed landmarks is no longer visible.

The navigation-solution initialization is created using bearing angles and knowledge of landmark locations:

$$x_{platform} = \left(\left(y_{LM} - y_{LM2}\right) - \left(\text{atan}\left(\beta_2\right)x_{LM2} - \text{atan}\left(\beta_1\right)x_{LM1}\right)\right) \cdot \left(\frac{1}{\text{atan}\left(\beta_2\right) - \text{atan}\left(\beta_1\right)}\right)$$

$$y_{platform} = y_{LM2} - \text{atan}\left(\beta_2\right)\left(x_{LM2} - x_{platform}\right)$$

Since the horizontal location of the platform contains the information of both landmarks, only a single landmark's information is necessary for the vertical component.

Figure 2 shows the old harbor entrance at La Rochelle, France. The two towers would be used as fixed landmarks on egress. The two channel markers in the front of the picture would make landmarks of opportunity as they are not as permanent structures as the towers would be.

For a landmark of opportunity, the structure being used must be fixed in position. The location of a fixed target can be determined by a moving platform. If the platform's location is known at two time points, then the landmark of opportunity can have its position generated with a crossfix:

$$x_{LMO1} = \left(\left(y_{platform}\left(t_2\right) - y_{platform}\left(t_1\right)\right) - \left(\text{atan}\left(\alpha_2\right)x_{platform}\left(t_2\right) - \text{atan}\left(\alpha_1\right)x_{platform}\left(t_1\right)\right)\right) \cdot \left(\frac{1}{\text{atan}\left(\alpha_2\right) - \text{atan}\left(\alpha_1\right)}\right)$$

$$y_{LMO1} = y_{platform}\left(t_2\right) - \text{atan}\left(\alpha_2\right)\left(x_{LMO1} - x_{platform}\right)$$

Crossfixing works very well for the case of small measurement uncertainties. However, since the platform is moving, a tracking algorithm, such as an extended Kalman filter (EKF) should be used to capture not only the position but the velocity dynamics. To capture the landmark of opportunity a tracking solution should also be used because of the uncertainty in the image sensor and the platform location. An EKF will smooth the error estimation noise than the single cross-fixes described in (5) - (8). To measure the observability of both the navigation solution and the landmark of opportunity position, the observability Gramian

$$\mathbf{G}_O = \sum_{k=k_0}^{k_f} \mathbf{F}^T\mathbf{H}^T\mathbf{H}\mathbf{F} \tag{9}$$

is used. Since the measurement is the bearing angle between the navigating platform and the i^{th} landmark, β_i from (13) and (14), the measurement-coupling matrix **H** becomes the linearized Jacobian of bearing angle with respect to each position's coordinate direction of the platform position for navigation

$$\mathbf{H} = \begin{bmatrix} \frac{\partial \beta_i}{\partial x_{platform}} & 0 & \frac{\partial \beta_i}{\partial y_{platform}} & 0 \end{bmatrix}$$

where the partial derivatives of each angle to the fixed, known i^{th} landmark with respect to the platform coordinates is

$$\frac{\partial \beta_i}{\partial x_{platform}} = \frac{\left(y_{LMi} - y_{platform}\right)}{\left(1+\Delta^2\right)\left(x_{LMi} - x_{platform}\right)^2}$$

$$\frac{\partial \beta_i}{\partial y_{platform}} = \frac{-1}{\left(1+\Delta^2\right)\left(x_{LMi} - x_{platform}\right)^2}$$

$$\Delta = \frac{y_{LMi} - y_{platform}}{x_{LMi} - x_{platform}}$$

A similar Jacobian is generated with respect the landmark of opportunity's position for the tracking problem.

$$\frac{\partial \beta_i}{\partial x_{LMOi}} = \frac{-\left(y_{LMi} - y_{platform}\right)}{\left(1+\Delta^2\right)\left(x_{LMi} - x_{platform}\right)^2} \tag{13}$$

$$\frac{\partial \beta_i}{\partial y_{LMOi}} = \frac{1}{\left(1+\Delta^2\right)\left(x_{LMi} - x_{platform}\right)^2} \tag{14}$$

where Δ is defined as above.

The state-coupling matrix **F** is

$$\mathbf{F}_{Nav} = \begin{bmatrix} 1 & dt & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & dt \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{15}$$

for the navigation solution, while it is defined as

$$\mathbf{F}_{LMOtrack} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{16}$$

for the landmark tracking problem. The uncertainty of the sensor and platform location is incorporated by modifying (9) to be

$$\mathbf{G}_O{}^T \left(\mathbf{R}+\mathbf{I}\right)^{-1} \mathbf{G}_O, \tag{17}$$

where

$$\mathbf{R}_k = E\left[\left(\mathbf{z}_k - a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)\right)\cdot \left(\mathbf{z}_k - a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)\right)^T\right]$$

$$= E\left[\mathbf{z}_k\mathbf{z}_k^T - \left(2\mathbf{z}_k a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)\right) + a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)^2\right]$$

$$= E\left[\mathbf{z}_k\mathbf{z}_k^T\right] - E\left[\left(2\mathbf{z}_k a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)\right)\right] + E\left[a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)^2\right]$$

$$= E\left[\mathbf{z}_k\mathbf{z}_k^T\right] + E\left[a\tan\left(\frac{y_{LMi}-y_{platform}}{x_{LMi}-x_{platform}}\right)^2\right]$$

$$\approx \mathbf{R} + f\left(\frac{\sigma(y_{LMi})}{r}, \frac{\sigma(x_{LMi})}{r}, \beta\right) \tag{18}$$

$$\approx \mathbf{R} + f\left(\frac{\sigma(y_{LMi})}{\hat{r}}, \frac{\sigma(x_{LMi})}{\hat{r}}, \hat{\beta}\right)$$

where **R** is the uncertainty covariance of the image measurement which models the sensor uncertainty. The added function f incorporates the uncertainty of the tion of the sensor platform (navigating vessel) for the Landmark of Opportunity tracking problem and, for the navigation problem, the Landmark of Opportunity's own position uncertainty. This function is based on the estimated range from the navigating platform to the landmark and relative bearing from the navigating platform to the landmark. Since these two values are not known, they must be estimated from the filter solutions.

Figures 2 - 5 show the bearing uncertainty for four different relative platform-to-landmark angles. These angles are 0º, 30º, 60º, and 90º. The x-coordinate depicts the estimated position error of the platform (for tracking) or the landmark (for navigation) in relation to the actual range. The x-position error is in percent of the range. Figures 2-5 each depict 41 different plots corresponding to the range error in the y-direction. The range of error starts at -50% of the range and, in 2.5% steps, goes to 50% error in range.

These graphs were created by generation of 10000 Monte Carlo runs to compute the bearing error for each x-y position error. The plots indicate the expected symmetry in the position errors from -50% position error to +50% position error in each direction. As the position error in one direction gets smaller and nearer to direction of dominance (0º for the x-direction and 90º for the y-direction), the bearing error diminishes.

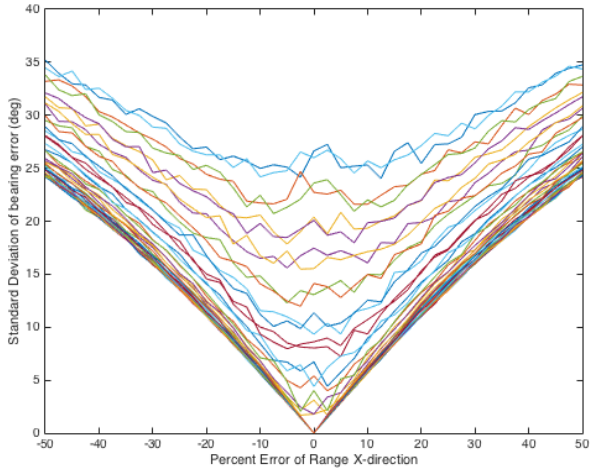

Figure 2. Bearing uncertainty (target is at 0º from the platform) based on the x-direction error in position.

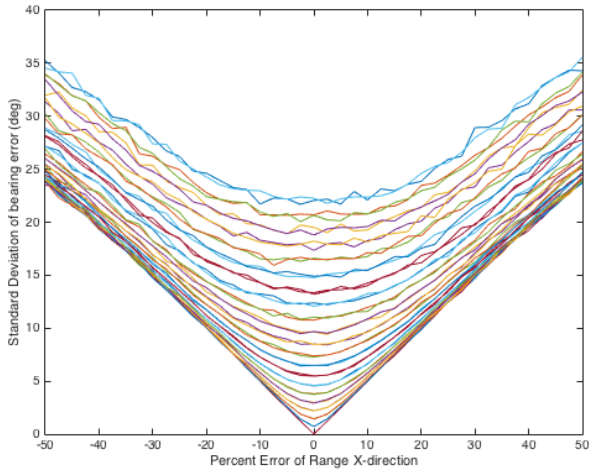

Figure 3. Bearing uncertainty (target is at 30º from the platform) based on the x-direction error in position.

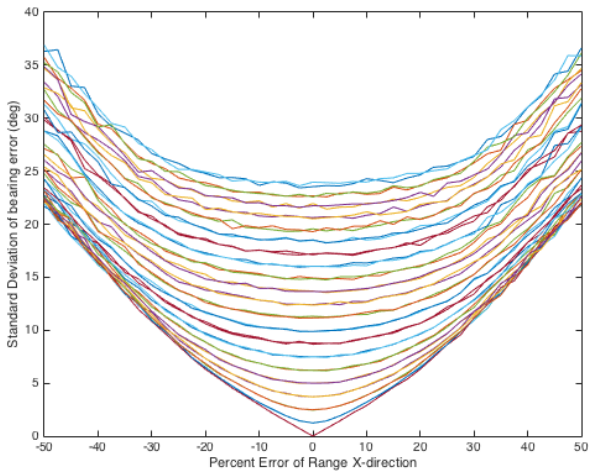

Figure 4. Bearing uncertainty (target is at 60º from the platform) based on the x-direction error in position.

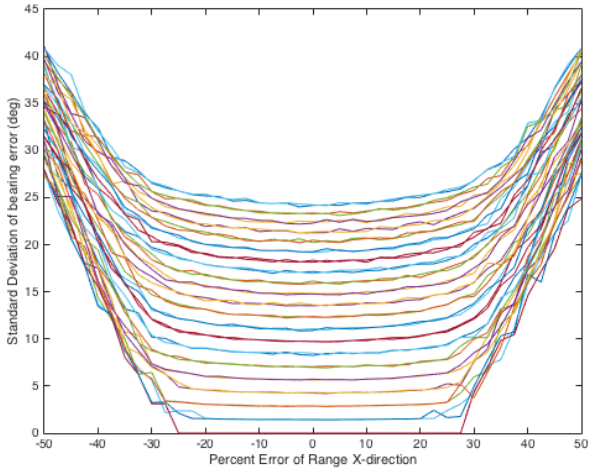

Figure 5. Bearing uncertainty (target is at 90º from the platform) based on the x-direction error in position.

3. The Phase-Only Filter

To generate the bearing measurements, the processor must know the orientation of the image sensor from the front of the navigating vessel. For a submarine this would be the rotation angle of the periscope from the bow of the submarine. This provides the center of the image frame. The landmarks in the image frame are then measured from the centroid to provide the angle adjustment from the pointing angle of the sensor.

The approach that has been chosen to generate the image angle uses a two-dimensional image correlation process referred to as the phase-only filter (POF). The POF is a variant the Fourier correlation method. Using a two-dimensional Fast Fourier Theorem (FFT) algorithm, two images can be correlated element-by-element with speed and efficiency. Despite the large number of operations necessary to do such correlation, the process is still applicable to real-time situations. The frequency-domain version of the correlation function [21] is defined as (19):

$$\begin{aligned}&\sum\sum g^{*}(x,y)*f(x+X,y+Y)\\&=\sum\sum G^{*}\left(k_x,k_y\right)F\left(k_x,k_y\right)e^{-j\left(k_xX+k_yY\right)}\\&=\mathrm{Re}\left\{\mathbf{F}^{-1}\left\{G^{*}\left(k_x,k_y\right)F\left(k_x,k_y\right)\right\}\right\}\end{aligned}$$

While the FFT approach may seem useful, the actual physics of an image correlation problem using an optical correlator show that primarily the comparable information of images lies in the phase of the frequency information [21]. Mathematically this causes the amplitude information of the input image to be normalized. Thus, the correlation function becomes the phase-only filtered image correlation:

$$\sum\sum G^{*}\left(k_x,k_y\right)\frac{F\left(k_x,k_y\right)}{\left|F\left(k_x,k_y\right)\right|}e^{-j\left(k_xX+k_yY\right)}$$

$$=\mathrm{Re}\left\{\mathbf{F}^{-1}\left\{G^{*}\left(k_x,k_y\right)\frac{F\left(k_x,k_y\right)}{\left|F\left(k_x,k_y\right)\right|}\right\}\right\}$$

The image correlation requires the template and the comparison image to be the same size, so padding the template image with zeroes to match the size of the scene image allows 2-D image correlation to indicate a match and also provides the location of the match within the scene.

For this application, the template would be the current image from the image sensor. While this seems backwards, the image being tracked is trying to be located in the image. As seen in Figure 6, Arabic letter pairs are being located on a license plate. The POF result of Figure 7 shows two peaks that align with the centroid of the letter pairs. The image angle will be computed as

$$\alpha=\left(num_horz_pixel-\frac{1}{2}\cdot total_num_pixels_{horiz}\right)\cdot angle_ppixel \tag{21}$$

where the term *angle_ppixel*, the view angle per pixel, is computed from the optical view angle of the sensor and the number of pixels horizontally the sensor has:

$$angle_ppixel=\frac{field_of_view_angle}{total_num_of_pixels_{horiz}} \tag{22}$$

The input image is from a database or from the previous frame. The POF image correlation has been demonstrated to be a reliable technique to match and localize an object within a scene in many efforts [22]. In [14], the improved localization of the image correlation centroid, because of a sharper correlation peak, was shown than that for the straight FFT correlation method. This reduction in centroid area reduces the uncertainty of the total image uncertainty.

Figure 6. Example of POF correlation. Two Arabic characters are looked for in a license plate. Two sets of the character pairs exist.

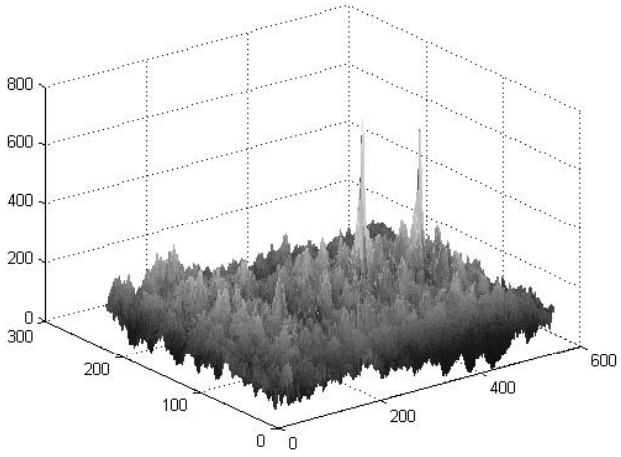

Figure 7. POF correlation result in two correlation peaks located at the center of each character pair.

4. Image-Based Navigation

Figure 8 outlines the functional flow of the overall image-based navigation.

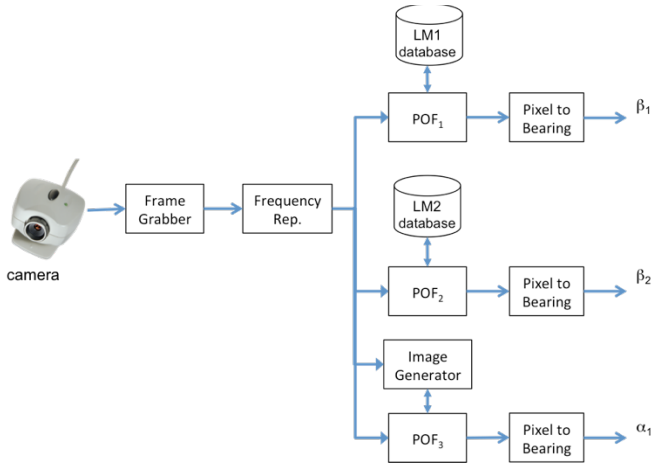

Figure 8. The functional flow of the image navigation system when unsurveyed landmarks are visible and can be used when surveyed landmarks are not available.

This section outlines the 10-step process, delving into the details of the components that this effort focuses on: image landmark tracking and image-based tracking. The steps are as follows:

Step 1: Initialize the navigation state of the platform. To determine which landmarks are surveyed in your database, a general knowledge of your location is required. This initialization need not be exact.

Step 2: Initialize the landmark database files. Once the known landmarks are defined, then the existing image databases for the local surveyed landmark positions are incorporated into the navigation algorithm.

Step 3: Grab the next video frame.

Step 4: Compute the angle of the electro-optical (EO) sensor with respect to the front of the vessel. This angle provides the relative angle of the center of the image with respect to the vessel.

Step 5: Correlate the known landmarks with the frame image. With the image data bases from Step 2 as the input to the POF algorithm and the video frame from Step 3 as the template, generate correlation peaks. If the peaks pass a predetermined threshold, the correlation peaks are considered a detection.

Step 5a: Calculate the angle of the landmark within the image. Using the computations from (21) and (22) for each correlation peak, the angle of the landmark with respect to the center of the image is computed.

Step 5b: Compute the landmark angle relative to the vessel. Add the angle from Stepb 5a to that of Step 4. This new angle is the measurement angle to the landmark.

Step 5c: Update or track image. As discussed in [13], the image is updated based on the previous frame to get a better aspect angle of the landmark for the next comparison. An image tracking algorithm can also be incorporated to estimate where the landmark should lie within the frame based on the estimated location of the vessel and the angle orientation of the sensor.

Step 6: Reinitialize the navigation solution with a crossfix. When two or more known landmarks are first available and their angles are computed, a crossfix initialization can be computed.

Step 7: Repeat Steps 5a – 5c. Start generating the angles for the navigation tracking algorithm.

Step 8a: Predict the estimation location of the vessel. Using the prediction equations of the EKF,

$$\mathbf{x}_{k+1|k} = \mathbf{F}_k \mathbf{x}_{k|k} \tag{24}$$

$$\mathbf{P}_{k+1|k} = \mathbf{F}_k \mathbf{P}_{k|k} \mathbf{F}_k^T + \mathbf{Q}_k \tag{25}$$

where **x** is the navigation state. The matrix **P** is the estimated error covariance of the state vector which indicates its quality. The state transition matrix **F** is defined in (15) while **Q,** the process noise is given as the integrated white noise process from [23],

$$\mathbf{Q}_k = q^2 \begin{bmatrix} \frac{dt^3}{3} & \frac{dt^2}{2} & 0 & 0 \\ \frac{dt^2}{2} & dt & 0 & 0 \\ 0 & 0 & \frac{dt^3}{3} & \frac{dt^2}{2} \\ 0 & 0 & \frac{dt^2}{2} & dt \end{bmatrix} \tag{26}$$

The location of where the vessel should be based on past measurements is the calculated result. This prediction takes the navigation estimate to the current time when a new measurement is available.

Step 8b: Update the estimation of the vessel's location. Using the bearing measurements generated in Step 5b and the estimated location from Step 8a for computing the Jacobian, the location of the vessel is updated. The equations for the EKF are defined as

$$\mathbf{K}_k = \mathbf{P}_{k|k-1}\mathbf{H}_k\Big|_{\hat{x}_{k|k-1}}^{T}\left(\mathbf{H}_k\Big|_{x_{k|k-1}}\mathbf{P}_{k|k-1}\mathbf{H}_k\Big|_{\hat{x}_{k|k-1}}^{T}+\mathbf{R}_k\right)^{-1} \quad (27)$$

$$\mathbf{x}_{k|k} = \mathbf{x}_{k|k-1} + \mathbf{K}_k\left(\mathbf{z}_k - \mathbf{h}\left(\mathbf{x}_{k|k-1}, \mathbf{x}^{LM}\right)\right) \quad (28)$$

$$\mathbf{P}_{k|k} = \left(\mathbf{I} - \mathbf{K}_k\mathbf{H}_k\Big|_{x_{k|k-1}}\right)\mathbf{P}_{k|k-1} \quad (29)$$

The matrix-vector **K** is referred to as the Kalman gain. The measurement uncertainty **R** is the composite measurement error defined in (18). The Landmark location is a fixed value. The superscript is used only in these equations to avoid confusion with the timing subscript.

Step 8c: If bearings of multiple landmarks are available, the update process of Step 8b is repeated. Since the landmarks are updated at the same time a zero-time-step prediction is used. This means that Step 8a is not repeated. Equations (28)-(29) are repeated but with the previously updated state values from the process of Step 8b.

Step 9: Define new landmarks of opportunity. As discussed with Figure 1, landmarks of opportunity are defined. Once identified, the image is placed in it own database.

Step 10a: Track each landmark of opportunity. An bearing-only stationary tracking is implemented. The EKF for this application is defined as

$$\mathbf{K}_k = \mathbf{P}_{k|k-1}\mathbf{H}_k\Big|_{\hat{x}_{k|k-1}}^{T}\left(\mathbf{H}_k\Big|_{x_{k|k-1}}\mathbf{P}_{k|k-1}\mathbf{H}_k\Big|_{\hat{x}_{k|k-1}}^{T}+\mathbf{R}_k\right)^{-1} \quad (29)$$

$$\mathbf{x}_{k|k} = \mathbf{x}_{k|k-1} + \mathbf{K}_k\left(\mathbf{z}_k - \mathbf{h}\left(\mathbf{x}_{k|k-1}, \mathbf{x}_k^{platform}\right)\right) \quad (30)$$

$$\mathbf{P}_{k|k} = \left(\mathbf{I} - \mathbf{K}_k\mathbf{H}_k\Big|_{x_{k|k-1}}\right)\mathbf{P}_{k|k-1} \quad (31)$$

$$\mathbf{x}_{k+1|k} = \mathbf{F}_k\mathbf{x}_{k|k} \quad (32)$$

$$\mathbf{P}_{k+1|k} = \mathbf{F}_k\mathbf{P}_{k|k}\mathbf{F}_k^T + \mathbf{Q}_k \quad (33)$$

The Jacobian **H** is defined by (10) while the target kinematic dynamics $\mathbf{F}_{LMOtrack}$ are defined by (16). The measurement uncertainty is defined not only by the sensor noise by also the location error of the navigation solution. The new measurement uncertainty **R** is calculated from (18).

Step 10b: Incorporate the new landmark into the available set. After the landmark has reach an acceptable level of accuracy, the tracking algorithm is stopped. The measurement noise is updated using (18). This measurement noise is used throughout the use of the new landmark. The new landmark and associated measurement noise is then used in Step 3 - 9. Note that a landmark of opportunity cannot be used in the initialization step as that would contain too many unknowns to solve the location calculations.

5. Analysis Scenario

In [14], a scenario using road data along United States Interstate 15 in the state of California was demonstrated to provide excellent performance when surveyed landmarks were available. In this effort, the analysis extends to a simulation of what occurs when landmarks of opportunity are incorporated into the scenario.

The example is a variant of the scenario developed in [20]. The scenario simulates a simple port entry and is illustrated in Figure 9. A platform wishing to use angle-only navigation heads north for 1000 s at 4.0 kts. The platform then heads east for 500 s at 4.0 kts. The platform starts at location 0, 0. There are four landmarks, Landmarks 1 – 4 in order are located at positions (1.5 nmi, 0.6 nmi), (0.375 nmi, -1.25 nmi), (0.5 nmi, 1.5nmi), and (2.2 nmi, -1.125 nmi), respectively. Landmarks 1 and 2 are defined as known landmarks with pre-surveyed locations. Landmarks 3 and 4 are defined as landmarks of opportunity. A 5.0° Gaussian random error was placed on each bearing measurement as the sensor component of the error.

After 60 seconds, the vessel starts tracking Landmarks 3 and 4 as landmarks of opportunity. This tracking continues to 850 seconds. After that point, the landmarks of opportunity are used with Landmarks 1 and 2. After 1000 seconds into the scenario, Landmarks 1 and 2 are no longer used. Only Landmarks of 3 and 4 are used through the rest of the scenario.

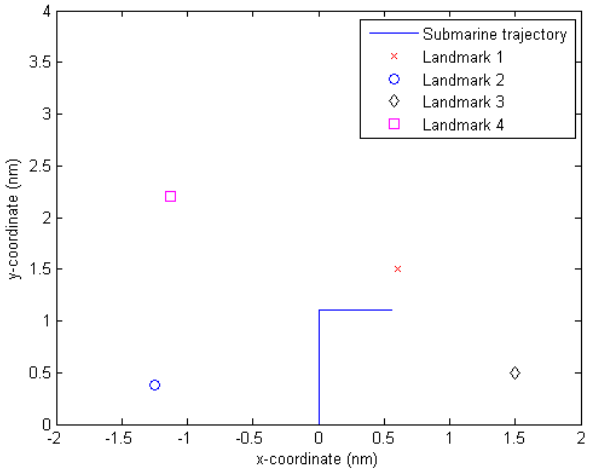

Figure 9. A Simple Scenario of a Submarine Navigating with Potentially Four Landmarks.

6. Analysis Results

The tracking error estimate provides approximately a 3.0% of error in the x-direction and 3.5% error in the y-direction for Landmark 3. For Landmark 4, a 2.0% error and 2.2% error in the

x and y directions, respectively are generated. Using the results in Figures 2 and 3, the added bearing error is approximately a 2.1° error. This makes the matrix **R** increase from 0.0076 radians-squared to 0.0090 radians-squared using (18). The tracking solution for Landmark 3 is tracked to be at position (0.492, 1.488). The tracking solution for Landmark 4 is tracked to be at position (2.296, -1.232).

The uncertainty for Landmark 3 navigation is defined as 23% for each direction. This results in a 12° added error to the measurement uncertainty. For Landmark 4 uncertainty in position is 4% and 4.5% in relation to the range in the x and y directions, relatively.

The results of the navigation accuracy are shown in Figure 10. As clearly seen, the navigation error is quite small when the surveyed landmarks are used. When only the landmarks of opportunity are used, error spikes appear. Deeper analysis indicates there are two reasons for this. The first is that Landmark 3 has too great of an uncertainty in its tracked location for it too be very effective. The second is that, at times near the end of the scenario, Landmarks 3 and 4 align reducing the observability.

The analysis indicates that the landmarks of opportunity require that the a figure of merit be used to determine if such a landmark is viable for navigation purposes. Also, the angular disparity between two landmarks is a necessary decision in selection.

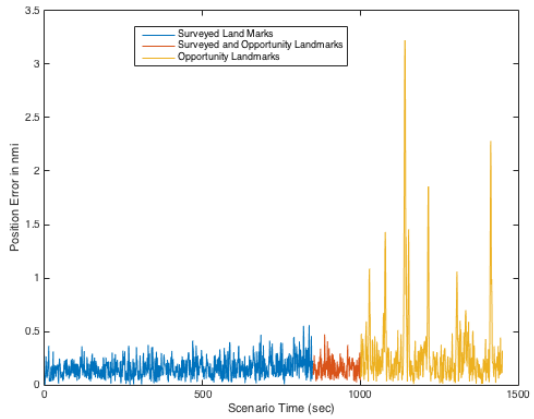

Figure 10. Position error of the navigation solution for three segments of the scenario: two surveyed landmarks, two surveyed landmarks and two landmarks of opportunity, and two landmarks of opportunity.

7. Conclusions

An image-based navigation system was developed using a bearings-only tracking system. The technique uses image correlation to measure the bearings by fixing on visible surveyed landmarks. The initial simulations and the test case have shown that this technique has merit as a navigation approach for ingress and egress operations where more standard forms of navigation are not available but surveyed locations in the region are. Tracking potential landmarks of opportunity can help if the tracking solutions are a quality level of accuracy.

In the next phase of this system's development, maritime data will be collected and utilized in testing. The results of this paper also indicate the need to develop figure of merit tool to determine if landmarks of opportunity can be incorporated into the approach.

Energy efficiency

ABSTRACT

A Linear Wireless Sensor Network (LWSN) is a kind of wireless sensor network where the nodes are deployed in a line. Since the sensor nodes are energy restricted, energy efficiency becomes one of the most significant design issues for LWSNs as well as wireless sensor networks. With the proper deployment, the power consumption could be minimized by adjusting the distance between the sensor nodes which is known as hop length. In this paper, analytical and algorithmic approaches are presented to determine the number of hops and sensor nodes for minimum power consumption in a linear wireless sensor network including equidistantly placed sensor nodes.

1. Introduction

This paper is an extension of work originally presented in conference 2016 National Conference on Electrical, Electronics and Biomedical Engineering (ELECO 2016) "Eşit Mesafeli Çok-Sekmeli Kablosuz Algılayıcı Ağlarda Minimum Güç Tüketimi için Optimum Düğüm Sayısının Belirlenmesi"[1].

A Wireless Sensor Network (WSN) consists of a large number of low power, low cost, wirelessly communicating sensor nodes which can be deployed either inside the phenomenon or very close to it. The features of ease of installation, self-organization, scalability and low maintenance requirements make WSNs have a great potential in many different application areas from disaster relief to health applications, from military to environmental applications [2].

Sensing unit, processing unit, transceiver and power unit are the basic components of a wireless sensor node. According to the application requirements, location finding system, mobilizer and power generator could be added [2]. The main tasks of a sensor node are sensing the events, processing the data and transmitting it. Communication is the most energy consuming process among them [3]. Sensor nodes usually supply power from batteries in wireless sensor networks. Since changing or recharging these batteries is very hard or impossible in most of the applications, efficient use of these restricted energy sources is vital importance from the aspect of lifetime. There are several various definitions of sensor network lifetime found in the literature. WSN lifetime is defined as "the time span from the deployment to the instant when the network is considered as nonfunctional." in [4]. The most common lifetime definition is that the time from the instant the network starts operating to the first sensor node failure [5]. The sensor nodes with depleted energy source are assumed as "dead", they could not transmit data. Therefore the lifetime of the network depends on how the limited amount of energy is utilized. Many researches about energy efficiency in WSNs have been found in the literature. This paper presents both analytical and algorithmic approaches to determine the number of hops and sensor nodes for minimum power consumption in linear wireless sensor networks.

The remainder of the paper is organized as follows. In section 2, linear wireless sensor network (LWSN) definition, classes and applications of LWSNs are given. The details of the power consumption model used are in section 3. Algorithmic and analytical approaches are explained in section 4 and section 5, respectively. The conclusions of the study are presented in section 6.

2. Linear Wireless Sensor Networks (LWSNs)

Linear Wireless Sensor Networks have a large number of applications. Monitoring of railways, borders, AC power lines, oil,

*Corresponding Author: Nukhet Sazak, Sakarya University, Department of Electrical and Electronics Engineering, 54187, Turkey, nsazak@sakarya.edu.tr

gas and water pipelines are some application examples of LWSNs [6]. A subclass of wireless sensor networks satisfying some conditions is called as Linear Wireless Sensor Networks (LWSNs). If all nodes are aligned on a straight line or all of the nodes exist between two parallel lines that extend for a relatively long distance as compared to their transmitting range and the distance separating them constitute a semi-linear sensor network, this wireless sensor network is called as linear wireless sensor network [6].

LWSNs can be classified into some categories from topological and hierarchical perspectives. There are three types of sensor nodes according to their functions. Basic sensor nodes sense and transmit data to the relay nodes. Data relay nodes collect the data from their one-hop neighborhood. Data dissemination nodes deliver the collected data to the network control center. One-level, two-level and three-level are the categories of hiearchical classification. At one-level sub-category, there are only basic sensor nodes which sense, aggregate, compress and route information to the sink. All nodes consisting of basic sensor nodes and data relay nodes are lined up linearly at two-level structure. Basic sensor nodes sense and transmit data to the data relay nodes which have routing, aggregation and compression tasks. Basic sensor nodes sense and transmit data to the data relay nodes in three-level hierarchical structure. Routing, aggregation, compression are the duties of data relay nodes. Data dissemination nodes disseminate the collected data to the network control center.

There are three levels as thin, thick and very thick for topological classification. The LWSN where sensor nodes are lined up in a 1-dimensional linear form is called as thin LWSN. This kind of structure provides linearity of the nodes and the predictability of the structure to minimize energy consumption and increase the network reliability [6]. In the kind of thick structure, basic sensor nodes can have a 2- or 3-dimensional geographic distribution. Linearity only exists at the levels of data relay and data dissemination nodes. At all levels, nodes are placed randomly between two parallel lines that extend linearly for a long distance and this is called as very thick LWSN.

Multi-hop communication is the common method used to gather data for linear wireless sensor networks. In a multi-hop fashion, all nodes (sensor and relay) send their data to the sink. A multi-hop 1-dimension linear WSN model [7] consisting of equidistantly deployed sensor nodes is given in Figure 1. The aim of this network is to deliver the data generated at the source node (S) to the destination node (D). The relay nodes operate as routers and they are numbered as N_i, i=1,2,.n-1. According to the deployment type and sensor functions, this network structure can be called as thin-one level LWSN since each node acts as both a sensor and relay node.

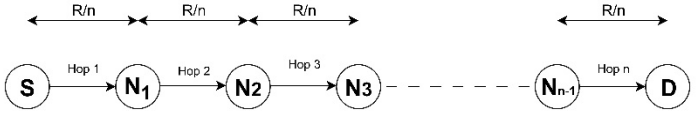

Figure 1. Multi-hop 1-D linear WSN model [7]

3. The Power Consumption Model Used

Wang et.al. [7] compared single-hop and multi-hop communication by using their own power consumption model and concluded that multi-hop communication is the optimal solution when sensor nodes are placed equidistantly between the source and destination nodes.

In this study, Mica2dot sensor nodes data and power consumption model proposed in [7] are used. The main difference of this model from the others in the literature is its dependence of the power amplifier performance which is drain efficiency (η).

There are some assumptions for this model. Communication bandwidth is so much low that interference and collisions could be avoided by using simple protocols without significant power consumption. Physical communication rate is assumed as constant.

The multi-hop power consumption over a given distance with equal hop distance between nodes is given in (1):

$$P(n) = (n-1)P_{R0}+nP_{T0}+[(nx\varepsilon x(R/n)^{\alpha})/\eta] \quad (1)$$

n: number of hops

P_{R0}: power consumption of a sensor node for receiving data

P_{T0}: power consumption of a sensor node for transmitting data

ε: constant

R: distance between source and destination nodes

R/n: hop length

α: path loss exponent

η: drain efficiency (the ratio of RF output power to DC input power)

Table 1 Typical values of path loss exponent [8]

Environment	α
Free-Space	2
Urban area LOS	2,7 to 3,5
Urban area no LOS	3 to 5
Indoor LOS	1,6 to 1,8
Factories no LOS	2 to 3
Buildings no LOS	4 to 6

The path loss exponent has different values depending on the propagation environment as given in Table 1 [8]. In this study, the value for free space (α=2) is used.

4. Algorithmic Approach

The aim of the algorithm is to determine the optimum hop number at which minimum power consumption is obtained. The distance between the source and destination nodes is the input, the optimum hop number is the output of the algorithm. Optimum number of nodes, power consumption value at the optimum hop number, the required minimum number of hops and nodes are also given as the output at the end of the algorithm.

The flow diagram of the algorithm is given in Figure 2. The algorithm gets the distance between source and destination nodes as input. Minimum number of hop is obtained by dividing this distance to the Mica2dot sensor node maximum transmission

distance. If the result is a non-integer number, it is rounded to the upper integer number and assigned to a variable. According to the power consumption model, the number of hop (n) is increased one by one starting from the minimum required hop number. The power consumption is calculated for each n. The number of hop and power consumption at this n are displayed on the screen every computation. The power consumption value for each n is compared to the one at the previous hop within the algorithm. If the previous power consumption is greater than current one, the computation is continued by increasing the n. When the computed power consumption value is firstly greater than the previous one, that critical point is determined as optimum hop number and the iteration is ended.

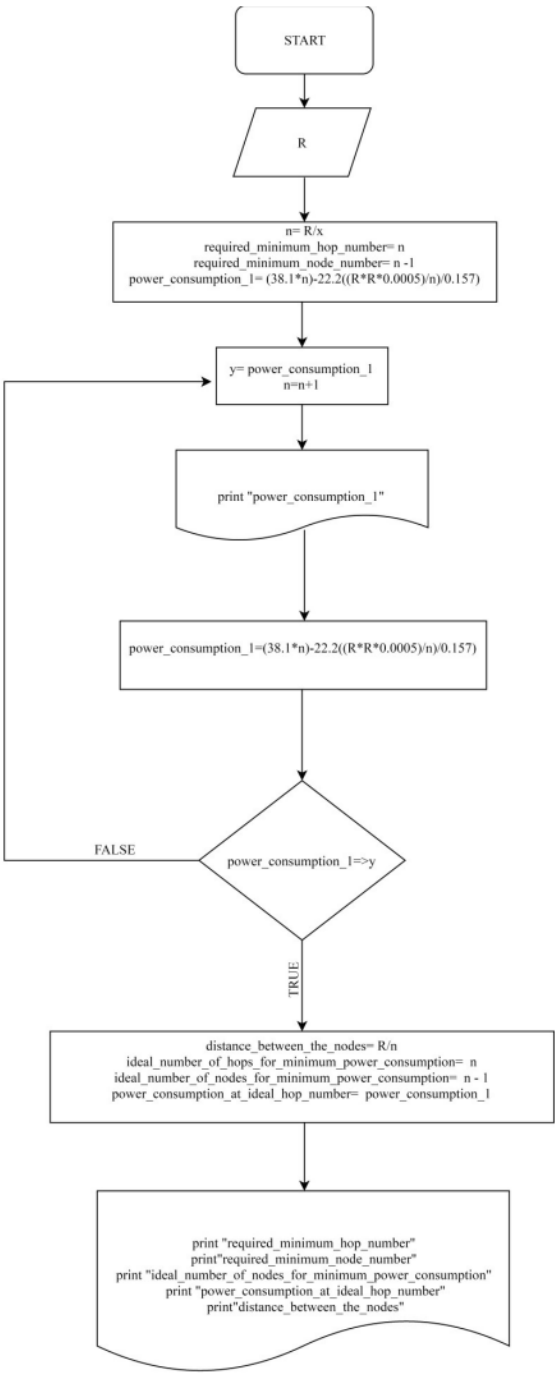

Figure 2. Flow diagram of the algorithm

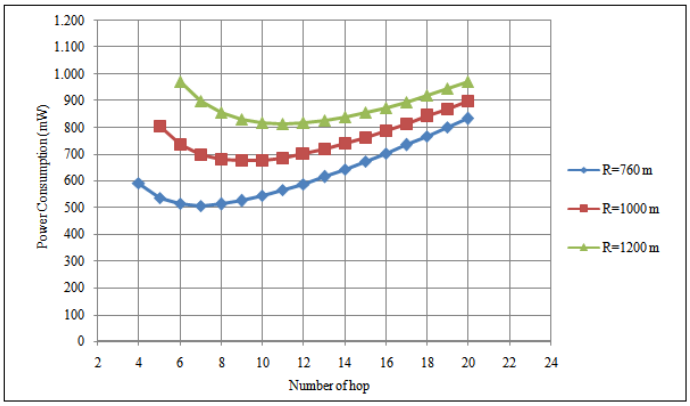

Figure 3. Power consumption versus number of hop

The distance between the source and destination nodes is asked by the algorithm. Then the beginning node number is computed by dividing this distance value to the node distance with maximum transmission power which is 230m for Mica2dot sensor node. The number of nodes is increased one by one from the starting value and iteration goes on until the minimum power consumption value is obtained. The power consumption decreases at first and it starts to increase after reaching its minimum value as expected from the results given in [8]. Since the minimum power consumption value is determined, no more calculation is required and the algorithm ends up.

During the development of this algorithm, Mica2dot sensor nodes are used [9] and Mica2dot sensor data is given in Table 2. However, this algorithm can be employed for any type of sensor node by using its hardware parameters or asking the required paramater values at the beginning as the input.

Table 2 Mica2 sensor node data

P_{R0}	22.2 mW
P_{T0}	15.9 mW
η	15.7 %
α	2
ε	0.0005

For the distance between source and destination nodes as 760m, 1000m and 1200m, power consumption versus number of hop graph is obtained and given in Figure 3. When the number of hops is increased, the power consumption decreases at the beginning and then increases after reaching the minimum value.

This algorithm provides not only the optimum hop length and as a result optimum hop number but also the number of sensor nodes required for minimum power consumption directly without computing power consumption for each hop number.

5. Analytical Approach

As it is seen from Figure 3, the power consumption decreases at the beginning and then increases after reaching the its minimum value. Therefore, this is considered as mathematical issue finding minimum point and analytical approach is developed [1].

The hop number at which the minimum power is consumed is called as optimum hop number. Taking the derivative of (1) with respect to hop number, optimum hop number (n_{opt}) is obtained as:

$$n_{opt} = R\{[\eta(P_{R0}+P_{T0})]/[\varepsilon(-1+\alpha)]\}^{-1/\alpha} \quad (2)$$

For the α=2 value, (2) can be rearranged as:

$$n_{opt} = R\{[\eta(P_{R0}+P_{T0})]/\varepsilon\}^{-0.5} \quad (3)$$

As it can be seen from (3), optimum hop number depends on sensor node receiving power (P_{R0}), transmitting power (P_{T0}), α, ε, η parameters and also the distance between source and destination nodes.

The optimum number of sensor nodes is defined as the sensor nodes required for minimum power consumption in a linear wireless sensor network with equidistantly placed sensor nodes. After optimum hop number is obtained, the optimum sensor nodes (d_{opt}) can also be calculated by subtracting 1 from (3):

$$d_{opt} = n_{opt} - 1 \quad (4)$$

The more generic expression for optimum number of sensor nodes is given in (5).

$$d_{opt} = R\{[\eta(P_{R0}+P_{T0})]/[\varepsilon(-1+\alpha)]\}^{-1/\alpha} - 1 \quad (5)$$

Thanks to these mathematical expressions, the number of sensor nodes which are placed with equal hop length can be calculated directly from P_{R0}, P_{T0}, ε, η, α for a linear wireless sensor network.

6. Conclusion

WSNs can be deployed over the locations where are difficult to install traditional systems and this makes them attractive. On the other hand, sensor nodes are left unattended for a long period of time, lifetime of the network depends on how the limited energy supply of the nodes is used. Therefore energy efficiency issue is required to be considered during the application design. From the engineering design perspective, the aim of this study to determine the number of hops and sensor nodes for minimum power consumption in LWSNs including equidistantly deployed sensor nodes. For this purpose, both algorithm and analytical approaches are presented in this paper. Thanks to these approaches, the number of hops and thus the number of sensor nodes required for a LWSN application are determined according to the hardware parameters of the sensor nodes during design phase.

ABSTRACT

In this work, a compact system for the automatic estimation of the tilt angle at any location of the world is presented. The system components are one computer, one GPS receiver and one Python program. The tilt angle is calculated through the maximization of the flux of direct radiation incident upon a flat solar collector. An estimation of the adjustments of this angle at different time periods are obtained. This angle is calculated in steps of six minutes during a whole year. Daily, monthly, biannually and yearly averages of this value are obtained. A comparison of the energetic gain when the tilt angle changes at the different time periods is made as well. Because, the algorithm doesn't receive as an input the solar radiation incident upon a surface at the location of the calculation, a comparison was made between the results obtained and the results reported for the monthly tilt angle of 22 different places. The root mean square error obtained with this comparison was between 1.5 and 9.5 degrees. The monthly tilt angle estimated deviated in average for less than 6.3° with respect to the values reported for the different locations. Finally, the application of a correction factor in the monthly estimated angles is proposed, which might increase the collected energy.

1. Introduction

Recently, we reported a system having as a purpose the calculation of the sun trajectory during one day in a specific location [1]. In this paper, another system presenting enhanced capabilities with respect to the system presented in the above work is reported.

The energy that can be extracted from a flat solar collector depends to a large extent on the direction of solar radiation in relation to the surface of the panel. This will be maximum, when the sun rays and the surface are perpendicular to each other. Through, a solar tracking system the above condition can be fulfilled the whole time. However, it is cheaper and simpler to keep a fix solar collector for a period of time than to make two rotations along two different axes to achieve tracking. In systems with dual axis tracking the panel is rotated along the line pointing to the vertical of the place (surface azimuth angle) and it is rotated along the line east-west (tilt angle or slope).

In general, for the fixed panels the optimal surface azimuth angle is zero degrees. Therefore, the tilt angle is the only one that is adjusted to maximize the collected energy. In this respect, several studies to obtain the optimum tilt angle β_{opt} at different locations of the world have been conducted. As for example: Athens [2], Izmir [3], four places in India [4], 5 regions in China [5], Sanliurfa [6], Tabass [7], two locations in India [8], eight provinces of Turkey [9], New Delhi [10], Helwan [11], Brunei [12], Syria [13], Surabaya [14], 35 sites of the Mediterranean region [15], Taiwan [16], Madinah [17] and the examples could continue.

In the literature, it is suggested that in the northern hemisphere the panels must be facing south. The optimum tilt angle depends of the geographical latitude of the place ϕ. Not all of the studies are focusing in the calculation of an annual β_{opt}. In some cases, this angle is reported in monthly or biannual (twice a year) time periods. Because, the selection of different time periods impacts the efficiency of the solar collector. For example, it was reported that in Madinah, a monthly adjustment of the tilt angle can enhance in 8% the captured energy than the one that can be obtained when this angle is kept fix during the whole year [17]. Numerous suggestions for β_{opt} are found in the literature. For example, in the

*Corresponding Author: Jorge Fonseca-Campos, Col. Barrio La Laguna Ticomán, GAM, Ciudad de México, C.P. 07340. México, Email: fonsecj@live.com

References [3, 11, 18] is proposed $\beta_{opt} = \phi \pm 15^o$, in the Reference [19] is suggested $\beta_{opt} = \phi \pm 10^o$, where the minus sign refers to the summer season and the plus sign is for the winter. In the Reference [10] is proposed $\beta_{opt} = \phi + 90^o$ for the winter and $\beta_{opt} = \phi - 60^o$ for the summer. In the Reference [20] is recommended $\beta_{opt} = 0.917\phi + 0.321^o$, in the Reference [21] is suggested $\beta_{opt} = \phi + (10^o \rightarrow 30^o)$, in the Reference [22] is proposed $\beta_{opt} = \phi - \delta$, where δ is the declination and the examples could continue. Unfortunately, the only way to obtain the optimum tilt angle is through radiation measurements at the place of interest for an extended period of time. This is due to the fact that solar radiation has different components, which are the direct, the diffuse and the albedo radiation. The optimum tilt angle, which is the ones that maximize the energy extraction is influenced in the way that these radiation components are distributed.

In this work, a system for estimation of the tilt angle considering exclusively the direct radiation is presented. This can be used in the locations that does not have a record of radiation measurements, or when the users or designers of the solar installations do not have a direct access to available radiation data. With this system in a very few minutes and with a minimum of interaction of the end user, several data used in the solar designs are obtained. Also, the tilt angle is calculated in time periods of six minutes, daily, monthly, biannual and yearly. A comparison of the energetic gain when the tilt angle changes at the different time periods is made as well. Finally, a comparison was made between the results provided with the proposed system and the ones reported for the monthly tilt angle of 22 different places. The root mean square error (*RMSE*) obtained through this comparison was between 1.5 and 9.5 degrees. The estimation of the monthly tilt angle deviated in average for less than 6.3°. Also, an adjustment for each of the estimated monthly slope angles is proposed, which might reduce the energy loss.

2. Direct Radiation Incident on a Tilted Solar Flat Panel

2.1. Sun Position

In a fixed point on the Earth, due to the Earth's rotation and its movement around the sun, the direction of the beam radiation is changing in time. It is customary to describe the trajectory that follows the sun by using two angles, when the representation of the Celestial sphere is used. These are: the hour angle ω and the declination angle for an equatorial coordinate system and the solar altitude angle α_s and the solar azimuth angle γ_s for a horizontal coordinate system. The angle between the two planes; the one containing the Earth's axis and the meridian plane of the point of observation, and the other containing the Earth's axis and the meridian plane of the sun is ω. At solar noon, i.e., when the sun is on the observer meridian $\omega = 0^o$. The angle between the equator and the sun position at solar noon is the declination. This angle in degrees is given by [23]

$$\delta = 23.45 \sin\left(360 \frac{284 + n}{365}\right), \tag{1}$$

where n is the integer day number, being January 1st $n = 1$. The declination is changing in time, but during one day is almost constant.

In the Figure 1 are shown the angles α_s, γ_s and θ_{sz}, where the latter angle is the solar zenith angle. α_s is the angle between the direct sun rays and the horizontal plane of the specific location, $\alpha_s = 0^o$ when the sun is on the horizontal plane, $\alpha_s = 90^o$ when the sun is at the zenith. During the sun hours this is an angle between 0^o and 90^o. Its value is negative before sunrise and after sunset. The relationship between the solar altitude angle and solar zenith angle is $\theta_{sz} = 90^o - \alpha_s$. γ_s is the angle between the south and the projection of the direct sun rays on the horizontal plane. This is an angle between -180^o and 180^o. Displacements east of the south are negative and west of the south are positive.

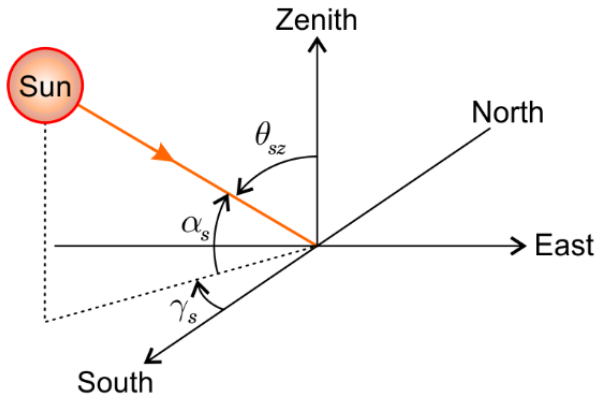

Figure 1. Sun position relative to one fixed point on Earth.

In the References [24-28] have been reported algorithms to calculate the sun position. The complexity and accuracy differ from each other. In this work, the fifth algorithm of the Reference [28] is employed, because it is easier to program and it is accurate from 2010 to 2110. The output of this algorithm are the angles ω, δ, α_s and γ_s. The inputs are the date (month, day, year), the time in decimal format, the latitude, the local longitude L_l, the atmospheric pressure P and the room temperature T. In this algorithm, the following conventions are applied: the latitude is an angle between -90^o and 90^o, in locations up north of the equator it is positive, otherwise is negative. The longitude is an angle between 0^o and 360^o, being 0^o at the prime meridian. At the east of this meridian has a value between 0^o and 180^o. It is measured in a counter clockwise fashion to the east.

The angles of the equatorial and horizontal coordinate systems are related to each other by [18]

$$\cos\theta_{sz} = \sin\alpha_s = \cos\phi\cos\delta\cos\omega + \sin\phi\sin\delta \tag{2}$$

and

$$\gamma_s = \text{sign}(\omega)\left|\cos^{-1}\left(\frac{\cos\theta_{sz}\sin\phi - \sin\delta}{\sin\theta_{sz}\cos\phi}\right)\right|, \tag{3}$$

where the sign function is equal to $+1$, if ω is positive; otherwise is -1.

2.2. Angle of Incidence on a Tilted Flat Solar Collector

In a fixed location, the sun moves across the sky along the day. By this reason, the beam radiation vector will make an angle θ_i with respect to the normal of the collector surface. Most solar energy can be captured when $\theta_i = 0^o$. If a unit vector $\hat{\mathbf{n}}$ is pointing from a fixed point in the Earth to the direction of the beam radiation and another unit vector $\hat{\mathbf{m}}$ is normal to the collector surface, the angle between both vectors can be computed with the dot product, i.e., $\theta_i = \cos^{-1}\left(\hat{\mathbf{m}} \cdot \hat{\mathbf{n}}\right)$.

To minimize the angle θ_i during a specific time period, the fixed flat solar panels are subjected to two rotations. On one hand, the panel is rotated in a counterclockwise fashion an angle β along the line east-west (tilt angle or slope). On the other hand, the panel is rotated in a clockwise fashion an angle γ along the line pointing to the zenith of the place (surface azimuth angle). Both rotations are shown in the Figure 2.

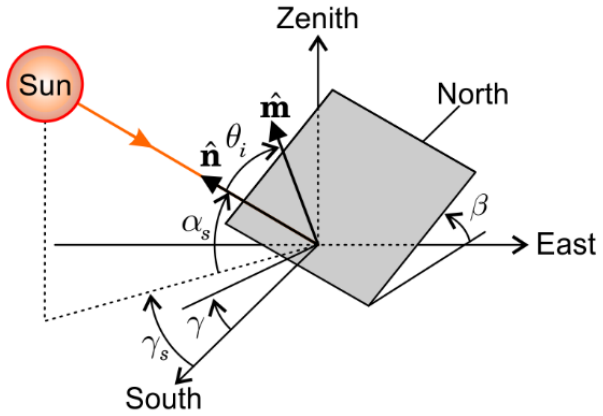

Figure 2. Flat surface rotated along the lines east-west and south-north.

According to the geometry shown in the Figure 2. The unit vectors $\hat{\mathbf{m}}$ and $\hat{\mathbf{n}}$ are given by

$$\hat{\mathbf{m}} = \sin\beta\cos\gamma\hat{\mathbf{e}}_x - \sin\beta\sin\gamma\hat{\mathbf{e}}_y + \cos\beta\hat{\mathbf{e}}_z \tag{4}$$

and

$$\hat{\mathbf{n}} = \cos\alpha_s\cos\gamma_s\hat{\mathbf{e}}_x - \cos\alpha_s\sin\gamma_s\hat{\mathbf{e}}_y + \sin\alpha_s\hat{\mathbf{e}}_z\,. \tag{5}$$

Thus, the angle of incidence between both vectors after a few simplifications is

$$\cos\theta_i = \cos\alpha_s\cos(\gamma - \gamma_s)\sin\beta + \sin\alpha_s\cos\beta\,. \tag{6}$$

The tilt angle is an angle between -90^o and 90^o, when $\beta > 0^o$ the collector is facing the south, which is the most used slope in the northern hemisphere. If the panel is horizontal $\beta = 0^o$ and $\theta_i = \theta_{sz}$. Finally, if $\beta < 0^o$ the surface of the panel is facing the north. In most situations, the collectors are adjusted to have an azimuth angle $\gamma = 0^o$. This angle is varied, when there are objects that produce shadows over the collector surface, or in some cases when a set of two fixed panels are used for extracting energy. In this configuration, one of them is used in the morning and the other is employed after the solar noon [14].

2.3. Maximization of the Flux of Energy in Terms of the Tilt Angle

Recently, Handoyo and co-workers have exposed a mathematical procedure to calculate the optimum tilt angle of a solar flat collector [14]. In that work, $\cos\theta_i$ is expressed in the equatorial coordinate system in terms of the following angles: δ, ω, β, γ and ϕ. This equation is reported elsewhere as in Reference [18]. They do the first derivative and the second derivative test for a single variable to maximize $\cos\theta_i$ in terms of β. At first, $\left(d\cos\theta_i/d\beta\right) = 0$ is calculated and later the condition $\left(d^2\cos\theta/d\beta^2\right) < 0$ is tested. These tests will be applied to (6), which is expressed in terms of a horizontal coordinate system. The value of β, which corresponds to the critical point of (6) is

$$\beta_{max} = \tan^{-1}\left(\frac{A}{B}\right), \tag{7}$$

where $A = \cos\alpha_s\cos\left(\gamma - \gamma_s\right)$ and $B = \sin\alpha_s$. The second derivative is

$$\frac{d^2\cos\theta_i}{d\beta^2} = -\left(A\sin\beta_{max} + B\cos\beta_{max}\right). \tag{8}$$

Computing β_{max} of (7) requires as inputs the date (month, day and year), the hour in decimal format, the geographical coordinates and the panel azimuth angle. If the magnitude of any of these variables changes, the value of β_{max} is modified as well.

2.4. Sunrise, Sunset, Day Length and Local Standard Time

In the equator, the day length is 12.0 h during the whole year. But at latitudes different to this geographical point, this quantity is changing in daily basis. Up north of this latitude, during the summer the sun light is shining for a longer time, on the contrary during the winter. Therefore, the net energy that can be captured by a collector will depend to some extent on the day length. Of course, if there is no sun light, no solar energy can be obtained. By this reason, it is interesting to calculate the evolution of this variable, which is related to the sunrise and the sunset time. From (2), the sunrise hour angle in degrees can be obtained by making $\alpha_s = 0^o$, i.e.,

$$\omega_{sr} = -\cos^{-1}\left(-\tan\phi\tan\delta\right). \tag{9}$$

The sunset hour angle is $\omega_{ss} = -\omega_{sr}$. The day length DL in decimal hour is

$$DL = 2\,\mathrm{abs}\left(\omega_{sr}/15^o\right). \tag{10}$$

The solar time ST in decimal hour is related to the hour angle by

$$ST = \left(\omega/15^o\right) + 12\,. \tag{11}$$

In terms of the local standard time LST and a time correction factor TC is

$$ST = LST + TC\,. \tag{12}$$

The time correction factor in minutes is given by

$$TC = 4\left(L_{st} - L_l\right) + EoT - C_{DST}\,, \tag{13}$$

where L_{st} is the standard longitude, L_l is the observer's longitude, C_{DST} is a time correction due to the daylight-saving time (DST) and EoT is the equation of time. In (13) the following conventions must be employed: L_l is an angle between -180° and 180°. It is considered negative at the west of the Greenwich meridian, and positive at the east of it. In this work, the DST changes are not considered, thus $C_{DST} = 0$. Also, $L_{st} = 15^{\circ} TZ$, where TZ is the time zone in decimal hour. TZ is positive at the west of the prime meridian and negative at the east of it.

The equation of time in minutes is

$$EoT = 9.87\sin\left(2B\right) - 7.53\cos B - 1.5\sin B\,, \tag{14}$$

where B in degrees is

$$B = \left(\frac{360}{365}\right)\left(n - 81\right). \tag{15}$$

By combining (11) and (12), it can be obtained the local standard time in decimal hour as

$$LST = \frac{\omega}{15^{\circ}} + 12 - \frac{TC}{60}. \tag{16}$$

With (9) and (16) the sunrise time LST_{sr} is obtained. Similarly, by substituting ω_{ss} in (16) the sunset time LST_{ss} is obtained.

The coordinated universal time UTC is employed to calculate the sun position. It is related to the LST by

$$UTC = LST + TZ\,. \tag{17}$$

This time doesn't observe the DST, and TZ follows the same convention applied to (13).

3. System Description

3.1. GPS Receiver

The global positioning system (GPS) receiver used in this work was the model ND-105C GPS Dongle from GlobalSat WorldCom Corporation. But, any GPS receiver that meets the National Marine Electronics Association (NMEA) requirements and that has the possibility of sending sentences through the serial port can be employed.

The above GPS receiver for the output data follows the protocol NMEA 0183. It returns four the sentences: GGA, GSA, GSV and RMC. The GGA sentence contains all the useful data introduced as an input in the program as the validity of satellite fix, the geographical latitude with the corresponding hemisphere and the local longitude with its relative position with respect to the prime meridian.

3.2. Python Program

The program used to perform the calculations was written in Python 3.6. It can be requested by email to the corresponding author. The flowchart of the program is shown in the Figure 3.

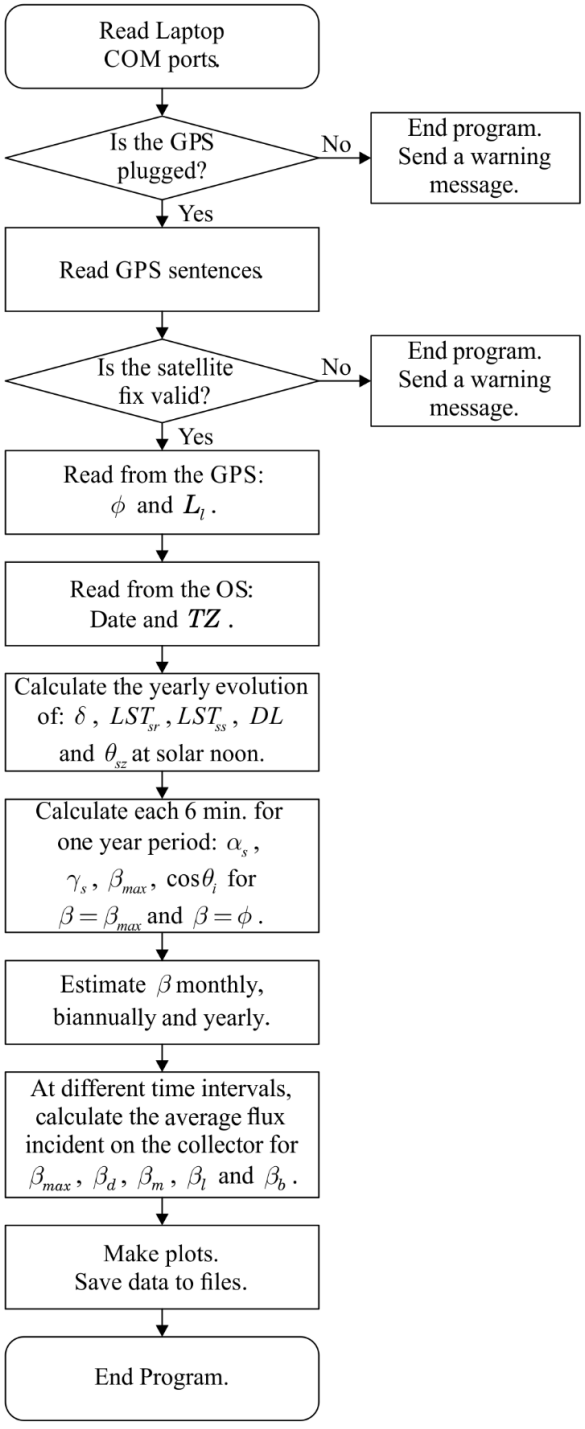

Figure 3. Flowchart of the Python program.

The time frame set in the calculations corresponds to one year. They will begin in the first day of the month at which the program

was run, and they will end in the same day and in the same month of the next year.

The Spyder integrated development environment (IDE) included in the Anaconda distribution was chosen to debug and to run the program. The communication between the GPS and the computer is realized through the serial port. Therefore, pyserial module must be installed, it is freely available at: (https://pypi.python.org/pypi/pyserial). In order to the program to work properly the end user must provide the communication (COM) port at which the GPS is connected to the computer and it must configure the time zone of the Windows operating system (OS). This must correspond to the region at which the calculation of the tilt angle is going to be done. The DST changes are not considered in the program, and they must be ignored in the above configuration.

As it shown in the Figure 3, if the GPS is plugged, the GPS sentences are read through the serial port. From the GGA sentence all the required inputs are extracted (valid fix, ϕ and L_l). When the fix is invalid the program will stop displaying a warning message. Otherwise, the program will continue doing computations. From the OS the date and the TZ are read by the program.

To obtain DL the program computes (9) and (10). The first equation requires the declination, which is calculated with (1). The latitude is provided by the GPS. LST_{sr} is obtained with (16), when ω is substituted by ω_{sr}, which is obtained with (9). LST_{ss} is get when ω is substituted by ω_{ss} in (16). The zenith angle at solar noon is calculated with the declination and the latitude. For places with greater latitudes than the tropics, this angle never will reach zero. For both tropics will be zero once a year. In places between the above latitudes will be reach zero twice a year.

Once the daily behavior of LST_{sr} and LST_{ss} are obtained a daily time interval is set for the calculation of the variables α_s, γ_s, β_{max} and $\cos\theta_i$. Initially, (6) is evaluated with two different tilt angles ($\beta=\beta_{max}$ and $\beta=\phi$). A few averages are realized once β_{max} is obtained. These are done for the following time periods: daily β_d, monthly β_m, from April to September and from October to March (biannual) β_b and yearly β_y.

However, the magnitude of the above angles depend of the daily time interval selected in the simulation. For example, their magnitude will have one value for the daily time interval $t\in\left[LST_{sr},LST_{ss}\right]$ h, which differs to the obtained if $t\in\left[10.0,14.0\right]$ h is considered. Therefore, a daily time interval for the simulation must be chosen. In this work, the user can select one of two possible options for the daily time interval. The first comprehends the daily time interval $t_{long}\in\left(t_i,t_f\right)$ in steps of 0.1 h (six minutes). The initial time of this interval is $t_i=\left(\max\left(LST_{sr}\right)-\min\left(LST_{sr}\right)\right)/2$, and the final time of this interval is $t_f=\left(\max\left(LST_{ss}\right)-\min\left(LST_{ss}\right)\right)/2$. This daily time interval will be called long time. The functions max and min are referring at the maximum and minimum values that reaches the variable over a one year period. The second time interval will be called short time. This is the default time considered in the program. It is given by $t_{short}\in\left(\max\left(LST_{sr}\right),\min\left(LST_{ss}\right)\right)$ in steps of 0.1 h. It is worth mentioning, that the user can input the magnitude of γ, which appears in the coefficient A of (7), but its default value is set to $\gamma=0^{o}$. If t_{long} is chosen in the simulations, for some days and in some specific times could result that $\alpha_s<0^{o}$ .This means that the sun is not in the local horizon. In these particular situations, the program assign NaN values to all variables.

To estimate the average flux of solar radiation incident in the solar collector, the different values of β (β_{max}, β_d, β_m, β_b and $\beta=\phi$) are evaluated in (6). Finally, the average of $\cos\theta_i$ for the each of the above angles in different time periods is calculated.

All the calculated variables are saved in files, which have a comma separated value (csv) format. The plots of the yearly evolution of LST_{sr}, LST_{ss}, DL, θ_{sz} at the solar noon, β_d, β_m and β_b are generated by the program. In addition, the plot of the annual variation of $\cos\theta_i$ is generated, when is evaluated with the following angles: β_{max}, β_d, β_m, β_b and $\beta=\phi$. After this step, the program ends.

3.3. System Applications

The applications that can have the system can be briefly summarized as follows:

- To have an insight of the working hours of the solar installations during a whole year, because these can operate just during the sun hours. The above variable is related to the day length, the sunrise and sunset times, which are provided graphically and in csv format files.
- To control a dual axis tracking system by the knowledge of the solar azimuth and the solar altitude angles. Both angles are provided by the system.
- To estimate the tilt angle that should follow one single axis tracking system in different periods of time. This can be done every six minutes, daily, monthly or biannual. To have an insight of the energetic gain that can have any of the above systems.
- To modify the program to extend its capabilities.

4. Results and Discussion

As stated above, the system can work at different locations. Just two conditions must be meet. On one hand, the correct COM port at which the GPS is detected by the computer must be set. On the other hand, the time zone of the location and the configured in the OS must match.

Several tests were realized to verify the proper operation of the system. However, they were realized in different places of same city, which was Mexico City.

As an example of the output data provided by the program, the results obtained during one test made in Mexico City will be presented.

4.1. Annual Evolution of LST_{sr}, LST_{ss}, DL and θ_{sz} at Solar Noon

In the Figure 4 the plot of LST_{sr} for 366 days is shown. The minimum value of the sunrise time is 6:09 h and it will be reached in June 6th, 2017. The maximum value is 7:17 h and it will be reached in January 19th, 2018. Due to the geographical location of Mexico City, there is no a significant daily variation associated to this variable.

In the Figure 5 is shown the plot of the yearly variation of LST_{ss}. The minimum value of the sunset time is 17:52 h and it will occur in November 23rd, 2017. The maximum value is 19:14 h and it will occur in July 6th, 2017.

In the figure 6 the yearly evolution of DL is presented. The shortest day length will be in December 21st, 2017 and it has a value of 10 h and 49 min. It is not surprising that this date corresponds to the winter solstice. The day length reaches a maximum value of 13 h and 10 min. This will happen in June 21th, 2017, which corresponds to the summer solstice.

In the Figure 7 the yearly evolution of the θ_{sz} at solar noon is presented. Due to the fact that Mexico City is located between the equator and the Tropic of Cancer, twice a year θ_{sz} is zero at solar noon. One of these dates corresponded to May 18th, 2017 and the other will occur in July 25th, 2017. The global maximum of θ_{sz} is $42.96°$ and it will be reached in the winter solstice. The local maximum, with a value of 3.94°, will happen in June 21st, 2017, which corresponds to the summer solstice.

Once LST_{sr} and LST_{ss} are known the daily time interval (t_{long} or t_{short}) is obtained.

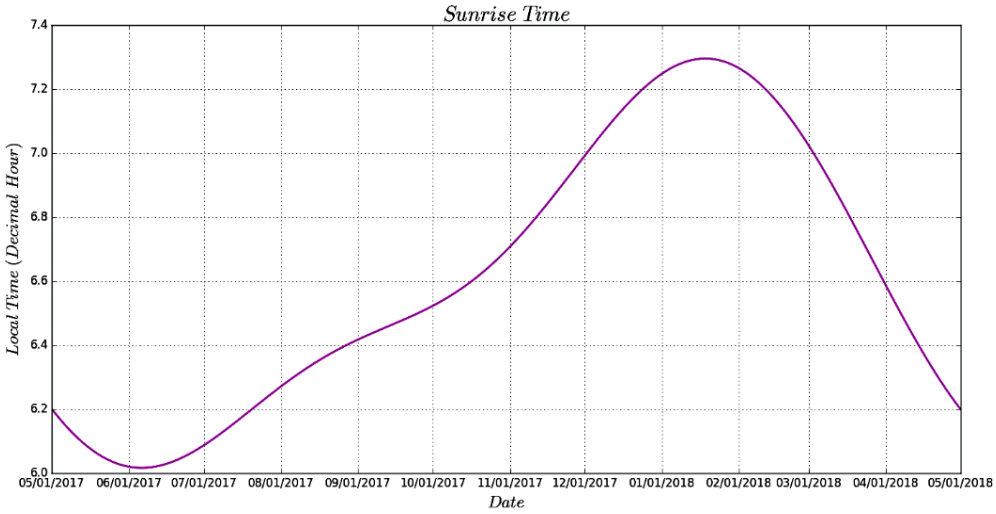

Figure 4. Yearly evolution of the sunrise time

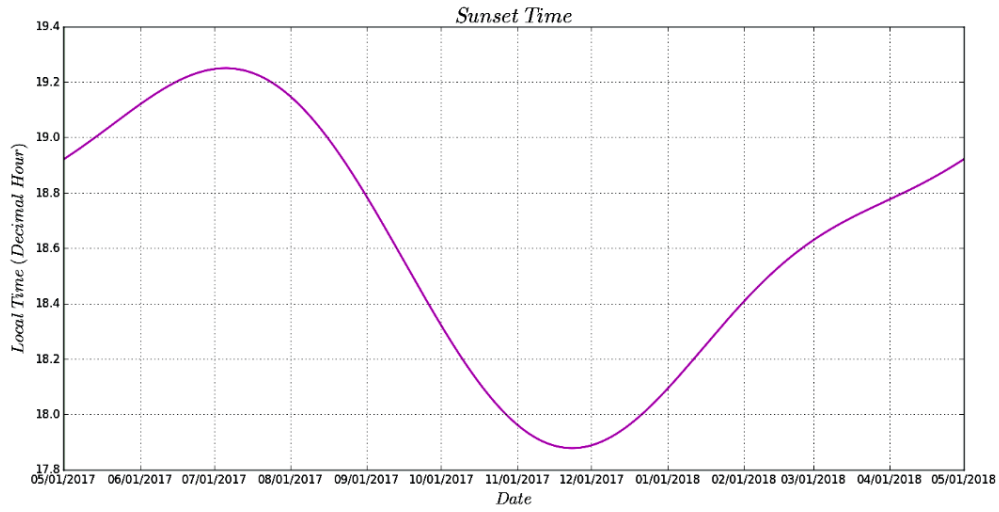

Figure 5. Yearly evolution of the sunset time.

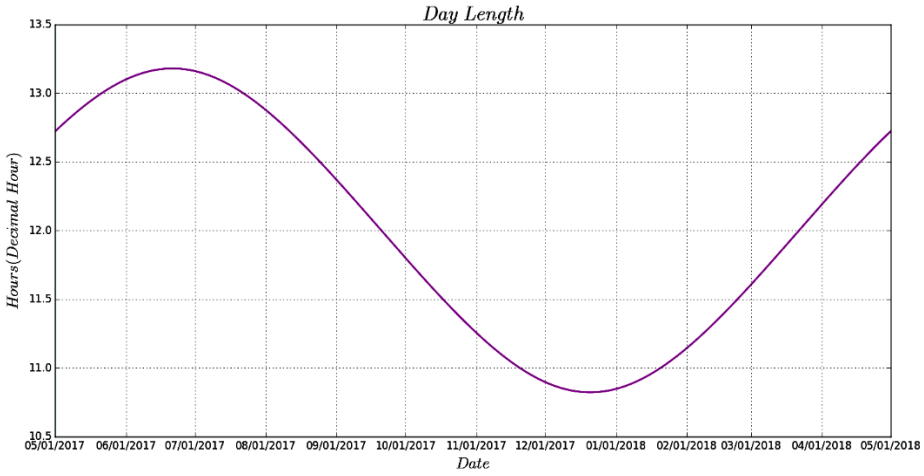

Figure 6. Yearly evolution of the day length.

Figure 7. Yearly evolution of the solar zenith angle at solar noon.

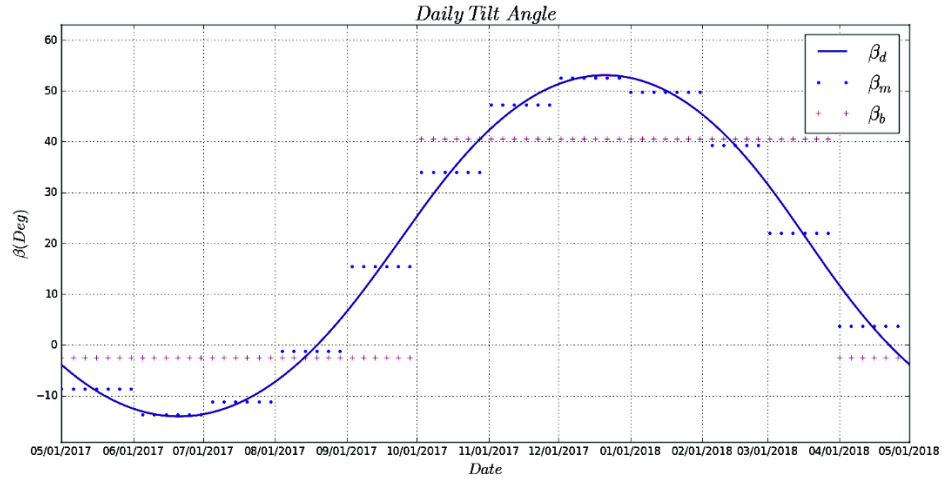

Figure 8. Yearly evolution of the daily, the monthly and the biannual tilt angles.

In the Figure 8 are shown the values of β_d, β_m and β_b, which were obtained averaging β_{max}. This angle was calculated in steps of 0.1 h. The simulation was made by choosing the daily time interval as t_{short}. As it can be seen in the figure 8 from April 23th to August 18th the daily tilt angle must be negative. It means that during this period the solar collector must face to the north. When a monthly adjustment of the tilt angle is realized, the panel should face the north from May to August. As well as $\beta_b < 0^{\circ}$ from April to September. In the Figure 9 it is shown how $\cos\theta_i$ is varying during an entire year in terms of the angles β_{max}, β_d, β_m, β_b and β_l, where $\beta_l = \phi$.

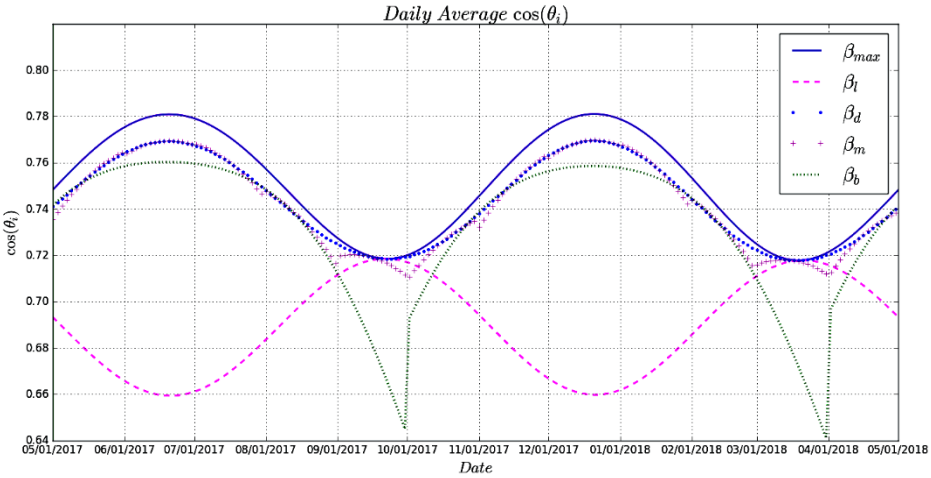

Figure 9. Yearly evolution of average radiation flux incident on the collector surface. When different tilt angles are evaluated in (6).

Time Period	β_m (Deg)	$\cos\theta_i(\beta_{max})$	$\cos\theta_i(\beta_d)$	$\cos\theta_i(\beta_m)$	$\cos\theta_i(\beta_b)$	$\cos\theta_i(\beta_l)$	DL (h)	LST_{sr} (h)	LST_{ss} (h)
May, 2017	−8.73	0.763	0.753	0.752	0.752	0.679	12.93	6.09	19.01
June, 2017	−13.7	0.779	0.768	0.768	0.76	0.661	13.16	6.04	19.19

November, 2017	47.23	0.761	0.751	0.75	0.749	0.68	11.06	6.84	17.9
December, 2017	52.61	0.779	0.768	0.768	0.758	0.662	10.84	7.13	17.97
January, 2018	49.76	0.768	0.758	0.757	0.753	0.672	10.97	7.28	18.25
February, 2018	39.29	0.739	0.733	0.731	0.73	0.699	11.36	7.17	18.52
March, 2018	22.06	0.72	0.719	0.717	0.678	0.716	11.89	6.82	18.7
April, 2018	3.68	0.733	0.729	0.727	0.72	0.707	12.45	6.39	18.84
Yearly	19	0.751	0.743	0.742	0.732	0.689	12	6.61	18.61
April-September	−2.48	0.755	0.748	0.747	0.738	0.693	12.72	6.25	18.97
October-March	40.6	0.753	0.747	0.745	0.735	0.694	11.27	6.97	18.24

As expected, the greater flux incident on the collector surface is obtained when the panel is moved every six minutes. Surprisingly, $\cos\theta_i$ doesn't vary much when is evaluated with β_{max}, β_d or β_m. In September and in March a biannual movement of the panel can provide less energy than the energy extracted with the tilt angle equal to the latitude of the location. Most of the year, $\cos\theta_i(\beta=\beta_l)$ will have the smallest magnitude.

One file with the csv format summarizing the above results is generated, when the program is executed. This report is presented in the Table 1

The Table 1 must be read in the following way. The first twelve rows are referred to the monthly values. Taking as an example the month of May, β_m should be -8.73^{o}, the radiation flux incident on the collector surface in average will be 0.763, 0.753, 0.752, 0.752, 0.679, when β is evaluated in (6) with angles β_{max}, β_d, β_m, β_b and β_l, respectively. The day length will be 12.93 h in the decimal hour, and the sunrise and the sunset times will be 6.09 h and 19.01 h, respectively. Both values are as well given in decimal hour.

It is not very surprising to find that the yearly tilt angle is almost equal to the latitude as it is shown in the first column of the table 1, that is $\beta_y \approx \phi$. In the last two rows of the first column the results for β_b are shown. As expected yearly DL is 12.0 h. Finally, in the row related with the yearly values, and average of $\cos\theta_i$ for the different tilt angles is shown. These magnitudes are 0.751, 0.743, 0.742, 0.732 and 0.689, for β_{max}, β_d, β_m, β_b and β_l, respectively. It is interesting to note that an energetic gain of ~1% is obtained by adjusting the tilt angle every six minutes than doing it every month.

4.3. Evaluation of the Algorithm

The optimum tilt angle at a given location requires of the measurements of the solar radiation. Therefore, to evaluate the algorithm one comparison was made between the results obtained and the results reported for the monthly tilt angle of 22 different places. To do this comparison the geographical coordinates were

input manually to the algorithm. The monthly optimum tilt angle of this places is reported in the References [3-13]. As a measure of the deviation the $RMSE$ was calculated. This is given by

$$RMSE = \sqrt{\frac{\sum_{t=1}^{n}\left(x_{1,t} - x_{2,t}\right)^2}{n}}, \quad (18)$$

where $x_{1,t}$ and $x_{2,t}$ are two time series, and n in (18) is the number of data. The results of this comparison are shown in the Table 2. During these simulations the daily time interval was always t_{short}. In each of the rows corresponding to the twelve months of the year the difference between the reported tilt angle and the calculated with the algorithm is shown. A negative sign means that β_m was underestimated, on the contrary the angle was overestimated. In these simulations, the average β_m always was overestimated as it can be seen in the last row. Near the winter and summer solstices the variation was larger than in other months. The better estimations of β_m were obtained in March and in October. The greatest $RMSE$ was found for the city of Mohe (9.21°). The smallest discrepancy for this variable was found for the city of Aligarh (1.59°).

Table 2. Comparison between the results of this work and the results of 22 locations reported in the literature.

In each of the rows corresponding to the twelve months of the year the difference between the reported tilt angle and the calculated with the algorithm is shown. A negative sign means that β_m was underestimated, on the contrary the angle was overestimated. In these simulations, the average β_m always was overestimated as it can be seen in the last row. Near the winter and summer solstices the variation was larger than in other months. The better estimations of β_m were obtained in March and in October. The greatest *RMSE* was found for the city of Mohe (9.21°). The smallest discrepancy for this variable was found for the city of Aligarh (1.59°).

4.4. Correction Factor

The results of the section 4.3 suggests that by considering exclusively the direct sun radiation, β_m is overestimated. Therefore, we propose an empirical expression, in which the monthly tilt angle might be estimated better by

$$\hat{\beta}_m = \beta_m - \Delta\beta \,, \tag{19}$$

where $\hat{\beta}_m$ is a new estimation of the monthly tilt angle and $\Delta\beta$ is the correction factor, which can be obtained from the last row of the table 2. This correction might help to improve the value of the monthly tilt angle calculated with the program presented in this work.

5. Conclusions

A system for the estimation of the tilt angle in different world locations has been implemented. The computation of this angle is realized for different time periods.

Data provided by a GPS receiver are automatically passed to an algorithm without the intervention of the user. This approach might be more effective and it may avoid errors.

The code is written in a high-level programming language, which makes the process of increasing its capabilities simpler.

The estimation of the yearly evolution of average radiation flux incident on the collector surface for different angles shows that the monthly variation of the tilt angle produces almost the same energetic gain than moving this angle every six minutes.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors want to thank to the Instituto Politécnico Nacional (IPN) and the Comisión de Operación y Fomento de Actividades Académicas COFAA-IPN for the financial support provided to do this work.

ABSTRACT

An empirical study that examines the usage of known vulnerable statements in software systems developed in C/C++ and used for IoT is presented. The study is conducted on 18 open source systems comprised of millions of lines of code and containing thousands of files. Static analysis methods are applied to each system to determine the number of unsafe commands (e.g., strcpy, strcmp, and strlen) that are well-known among research communities to cause potential risks and security concerns, thereby decreasing a system's robustness and quality. These unsafe statements are banned by many companies (e.g., Microsoft). The use of these commands should be avoided from the start when writing code and should be removed from legacy code over time as recommended by new C/C++ language standards. Each system is analyzed and the distribution of the known unsafe commands is presented. Historical trends in the usage of the unsafe commands of 7 of the systems are presented to show how the studied systems evolved over time with respect to the vulnerable code. The results show that the most prevalent unsafe command used for most systems is memcpy, followed by strlen. These results can be used to help train software developers on secure coding practices so that they can write higher quality software systems.

1. Introduction

This paper was originally presented in 2016 IEEE 3rd World Forum on Internet of Things (WF-IoT) [1]. Additional research has been done to extend the research to examine the security of a much larger group of IoT software systems. While the IoT continues to grow to billions of devices running a huge variety of software systems, both open source and proprietary, security becomes a major concern for individuals and organizations who use the IoT in both academia and industry. The security of every software system becomes vital as each software system and device could be a target or an access point to hackers, or lawbreakers [2-4]. Most of the software and embedded systems used for IoT applications are currently available as open source systems and are therefore developed by programmers from varying disciplines and with different backgrounds. Many of those programmers have little to no background on security challenges imposed by the usage of vulnerable source code in some programming languages (e.g., C/C++) caused by commands that are well known to the research community as being unsafe and are banned by companies such as Microsoft.

According to [5, 6], most of the detected security threats are due to vulnerabilities in the code. Thus, minimizing usage of insecure commands can play an important role in protecting the software systems from any potential attacks. In order to minimize the use of unsafe commands at the source code level, developers need to be made aware of those unsafe commands and the security issues their usage can cause. Educating developers and ensuring that they follow good programming practices can minimize the time and effort spent on finding and fixing them in later stages, as well as lessen the expense of fixing a security issue if it's exploited

[*]Corresponding Author: Saleh Mohamed Alnaeli, 1478 Midway Rd, Menasha Wisconsin 54952, (920) 832-2615, USA | Email: saleh.alnaeli@uwc.edu

by an attacker. For example, C/C++ programming languages are preferred by developers because of the level of performance, flexibility, and efficiency that they offer. However, security vulnerabilities (e.g., integer vulnerability, buffer overflow, and string vulnerability) need to be addressed and avoided from the beginning when writing the source code to save the time and expense that comes with having to refactor the system at a later date to remove those security vulnerabilities. Additionally, programmers also need to make sure that they do not use commands that are known to cause security concerns (e.g., memcpy, strlen, and strcmp).

As an example, the standard C library includes a function called gets() that is used primarily for reading strings input by the user. This function accepts a pointer from data type char as a parameter and reads a string of characters from the standard input, placing the first character in the location specified by that pointer and subsequent data consecutively in memory. The gets() function will continue reading until a newline is detected, at which point the buffer is terminated with a null character. The issue is that the developer cannot determine the size or length of the buffer passed to gets() prior to runtime. Because of this, when the buffer is size bytes, an attacker trying to write size + extra bytes into the buffer will always succeed if the data excludes newlines [5]. Consequently, memory locations that are adjacent to the buffer in the memory may be overwritten, which could lead to sensitive data being modified if it is stored in those adjacent memory locations. Additionally, an attacker could even overflow the stack and lead the program to run into an arbitrary or unexpected status. A safe alternative to gets() is fgets(), which, unlike gets(), also accepts an integer number as a parameter that acts as the limit of characters copied into the string, including the null-character at the end.

The process of protecting software systems from vulnerability issues at the source code level is done by either completely removing known unsafe commands and functions, or by replacing them with safer replacements (e.g., strncpy, strncmp, strncat etc.). Here, we have extended a previous empirical examination of some of the open source software systems used for IoT to better understand how well IoT developers do when it comes to the usage of vulnerable code by studying a larger group of IoT systems and the history of some of those systems to analyze the change in the usage of unsafe commands over time. We are particularly interested in determining the most prevalent unsafe statements that occur in a wide variety of IoT software applications and if there are general trends, and are interested in seeing if the trends stay the same or change among a larger group of systems, as well as if there are historical trends for the group of systems whose history was also examined. While this work does not directly address the problem of removing unsafe source code from the systems, it does serve as a foundation for understanding the problem requirements in the context of a broad set of applications. Moreover, the focus of this research is on unsafe statement detection and identifying their distribution over time.

In this study, several software systems used for IoT and developed in C/C++ are analyzed and evaluated with respect to the usage of vulnerable commands that can affect the quality of IoT systems. Each of the studied systems are written in C/C++. For each system, the source code is analyzed a count is created for each of the unsafe functions as well as the safer replacement functions. These counts are compared against the counts of each other system to uncover trends and make observations about the usage of unsafe functions. Furthermore, the history of some of the systems, if it was available and of a sufficient length, is examined and the number of detected unsafe functions is calculated for each release.

This work focuses on addressing the following questions: how many unsafe functions are used in these systems, which of those are the most frequent, and what are their respective distributions? Are the numbers or distributions of unsafe functions changing over the history/versions of a software system? When a larger group of systems is studied, do the trends uncovered in the original study remain the same, or do new trends emerge?

This work contributes by extending one of the only studies on the usage of vulnerable functions in IoT software applications. We found that the functions memcpy and strlen represent most of the unsafe functions occurring in these systems, in both the original systems and the additional systems studied in this extension. Moreover, the findings show that, for the most part, the systems reviewed have become more vulnerable to attacks over time due to the increase in the number of the unsafe functions used over time. This knowledge will assist researchers in formulating and directing their work to efficiently address this problem when refactoring and designing new systems.

The remainder of this paper is organized as follows. Section 2 gives background information and related work on the topic of source code vulnerabilities and security of IoT and its challenges. Section 3 describes the methodology used in the study along with how we performed the analysis to create counts for each unsafe function. Section 4 presents the findings of our study of 18 open source software systems used for IoT. There is a discussion of results in the same section as well. The historical trends of 7 of the systems found are explained in section 5, followed by threats to validity and future enhancement in 6 and 7. Finally, conclusions are found in section 8.

2. Background and Related Work

Most of the previous research conducted on IoT security has focused on identifying security concerns related to the communication processes and authentication methods used with IoT. Some other studies have examined data privacy within various levels. To the best of our knowledge, no study has examined the usage or distribution of vulnerable code in IoT systems that are developed in C/C++.

A study has been conducted by VERACODE [7] to investigate a selection of always-on consumer IoT devices to understand the security posture of each product. They found that product manufacturers prioritized design instead of security and privacy, putting consumers at risk for an attack or physical intrusion. Their team performed a set of uniform tests across all devices and organized the findings into four different domains: user-facing cloud services, back-end cloud services, mobile application interface, and device debugging interfaces. The results showed that most of the tested devices exhibited vulnerabilities across most categories. The findings prove that there is a need to perform security reviews on device architecture and accompanying applications to minimize the risk to users.

Hui Suo, Jiafu Wan, Caifeng Zou, and Liu in [2] reviewed security in the IoT and analyzed security characteristics and requirements from four layers: perceptual layer, network layer, support layer, and application layer. They discussed the research status in this field from encryption mechanism, communication security, protecting sensor data, and encryption algorithm. While they confirmed the need to develop technologies and methodologies that meet the IoT needs for meeting the higher requirements of security and privacy, they did not discuss security concerns that can be caused by programming standards or by using vulnerable code.

A research group from George Mason University and National Institute of Standards and Technology in [3] presented a set of use cases that leverage commercial off-the-shelf services and products to raise awareness of security challenges in current practices and prove that there is a need for IoT security standards to be developed, as well as their possible implications. They recommended that experts begin formulating suitable guidance and identifying the right security and privacy primitives for more secure and reliable IoT products. However, the study has not discussed any security issues related to vulnerabilities at the source code level and possible security risks that might be caused by the usage of unsafe statements.

Although literature is rich with studies that focus on the methods and tools used for detecting vulnerable source code [5], no studies have been conducted specifically in the domain of IoT that evaluate the usage and the distribution of vulnerable source code in IoT software systems and applications prior to the study of which this is an extension.

This work extends a previous work on IoT security in which we conducted an empirical study of unsafe functions on the source code level. We empirically examined 18 systems to determine how many unsafe functions are used and their distributions to help software engineers develop better software systems for IoT and to show how these systems evolve over time in terms of secure programming standards based on the usage of unsafe versus safe replacement functions. We extended the work by examining a larger group of IoT systems, adding 15 more to the original group of software systems studied.

3. Methodology for detecting unsafe functions

A function is considered unsafe if it is one of the functions well-known to both the research community and industry to cause security concerns. Some of those unsafe functions and commands are already banned by compiler producers (e.g., Microsoft). Literature is abundant with lists of unsafe C/C++ commands. We used a tool, UnsafeFunsDetector, developed by one of the main authors, to analyze source code files and, if they contain any unsafe function calls, create a count for each unsafe function. First, we collected all files with C/C++ source-code extensions (i.e., c, cc, cpp, cxx, h, and hpp). For the systems whose history was analyzed, the last version of the system for each year was used. Then, we used the srcML (www.srcML.org) toolkit [1,11] to parse and analyze each file. The srcML format wraps the statements and structures of the source code syntax with XML elements, allowing tools, such as UnsafeFunsDetector, to use XML APIs to locate pieces of code, such as unsafe functions, and to analyze expressions in a quick and efficient manner. Once the system is converted into XML, UnsafeFunsDetector iteratively parses every source code unit to find each call of the unsafe functions and safe replacement functions and adjusts the counters. That is, a count of each unsafe function was recorded. Finally, all calls of unsafe functions were counted and their distributions determined.

Table 1. The 18 studied systems along with the total unsafe functions used in them and the most prevalent unsafe function.

System	Total Unsafe Functions	Most Prevalent Unsafe Function
ApacheMyNewtOS	1,524	memcpy
AtomThreads	62	strlen
Contiki	1,859	memcpy
DistortOS	3	memcpy
Embox	10,286	memcpy
FemtoOS	0	N/A
FreeOSEK	48	memcpy
Lepton	3,928	memcpy
nOS	4	memcpy
OpenTag	58	memcpy
openWSN	220	memcpy
PicoOS	12	free
POK	49	memcpy
TinyOS	772	memcpy
Tneo	1	memcpy
Trampoline	637	free
uOS-Embedded	15,556	puts
Zephyr	3,340	memcpy

The systems chosen in this study were carefully selected to represent a variety of open source systems developed in C/C++ and used for IoT and well-known to both academia and research IoT communities. Our findings are presented and discussed later in this paper, along with the limitations of our approach.

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar.

4. Findings, results and discussion

We now study the usage of unsafe functions in the studied systems and with their distributions, along with the historical trends of their distributions of for 7 of the studied systems.

OpenWSN is an open source project that provides open-source implementations of a complete protocol stack based on Internet of Things standards, for a variety of software and hardware platforms. This implementation can help both academia and industry verify the applicability of these standards to the Internet of Things for those networks to become truly ubiquitous [8].

The TinyOS is an open source, operating system designed for low-power wireless devices, such as those used in sensor networks, ubiquitous computing, smart buildings, and smart meters [9]. Contiki is a lightweight and flexible operating system for tiny networked sensors [10]. These were the original 3 IoT systems studied in the original paper, but this paper has extended the work

to analyze 18 total systems, along with the most recent 5-year history of 7 of those systems.

4.1. Design of the Empirical Study

This study focuses on three aspects regarding the security of software systems used for IoT in terms of unsafe function and vulnerable code usage. First, we examine the number of calls to known unsafe functions. This gives an idea of how much of the system needs to be refactored to remove or replace the vulnerable code and, therefore, increase its security and quality. Next, we examine which unsafe functions are the most prevalent. This can give the developers of IoT software an idea about the most prevalent unsafe function to they should make a priority, if they plan on refactoring for the purpose of improving their system's security and quality, so that they can increase their system's security in the most efficient way possible. Finally, we examine how the presence of unsafe commands (as opposed to some safer replacements functions) changes over the lifetime of a software system.

The following is our study defined by a set of formal research:

RQ1: What is the total number of unsafe functions called in each system?

RQ2: Of those called, which unsafe functions are the most prevalent?

RQ3: Over the history of a system, is the presence of unsafe functions, and the use of safe replacement functions, increasing or decreasing?

We now examine our findings within the context of these research questions.

4.2. Number of Detected Unsafe Function and their distribution

In the original study, Contiki had the largest number of unsafe functions. In this extension, uOS-Embedded has the largest number of unsafe functions at 15556 total unsafe functions, as opposed to Contiki's 1859 unsafe functions. The smallest number of unsafe functions was 0 for FemtoOS. To address RQ1, Table 1 shows the total number of unsafe functions for each of the 18 systems studied. For the systems whose history was also studied, Table 1 shows the number of unsafe functions of the most recent version. Some of the systems had very few unsafe functions called, while others had thousands of calls to unsafe functions.

In this study, snprintf is considered an unsafe function. Some compliers consider it as a safe replacement function, but it was considered unsafe in this study as it is banned by Microsoft.

For most of the systems, memcpy was the most called unsafe function. In some of the systems, memcpy was the only unsafe function called (e.g., DistortOS, nOS, and Tneo). This trend matches the trend for the original study on only Contiki, TinyOS, and openWSN. Even when a much larger group of IoT systems is studied, mempy remained the most prevalent unsafe function for the majority of the systems, which could allow us to start making better generalizations about the IoT domain when it comes to security than we could when a smaller group was studied.

To address RQ2, Table 2 shows the top 3 most prevalent unsafe functions called across the 18 IoT systems studied. When the top 3 most prevalent for each system was analyzed, memcpy appeared in the top 3 most prevalent functions of 15 systems, strlen appeared in the top 3 most prevalent functions of 10 systems, and strcmp appeared in the top 3 most prevalent functions of 6 systems. The rest of the functions were in the top 3 most prevalent functions of 2 or 3 systems, or they were not present in the top 3 most prevalent functions of any system. The difficulty in generalizing the top 3 most prevalent unsafe functions was that many of the systems varied in the unsafe functions that they called the most, and for some systems, the only unsafe function called was memcpy. While memcpy was the most prevalent unsafe function for the majority of the systems, it was not the most prevalent for all of the systems. The most prevalent for uOS-Embedded was puts, which was not in the top 3 most prevalent unsafe functions for any of the other systems studied.

Table 2. The top three most prevalent unsafe functions across most of the systems

System	memcpy	strcmp	strlen
ApacheMyNewtOS	771	221	220
AtomThreads	12	0	24
Contiki	712	90	343
DistortOS	3	0	0
Embox	2,363	1,726	1,720
FemtoOS	0	0	0
FreeOSEK	17	10	9
Lepton	766	398	662
nOS	4	0	0
OpenTag	42	0	0
openWSN	211	0	2
PicoOS	0	0	0
POK	28	4	6
TinyOS	236	133	94
Tneo	1	0	0
Trampoline	78	40	135
uOS-Embedded	1,500	2,016	1,790
Zephyr	1,778	404	616

Clearly, there is still a noticeably presence of well-known unsafe functions in most of the studied systems, which complicates security concerns when it comes to systems used for IoT. But no matter how we present the data, it is apparent that unsafe functions present one of the most serious security issues that need to be addressed through refactoring systems to remove the unsafe functions. While literature is rich with studies focusing on addressing the problems of how to remove those unsafe functions from software systems, it appears that software developers are underestimating, or lack understanding of, the real threats imposed by the use of unsafe functions.

5. Historical Change of unsafe function frequency

In order to address RQ3, we looked at the most recent 5-year history for 4 additional systems to the original 3 studied. We examined the most recent version of each year and recorded the number of unsafe functions used, along with the number of safe replacement functions used. We are interested in knowing whether

the number of unsafe functions is increasing over time and the security risks are becoming more prevalent, or if the number is

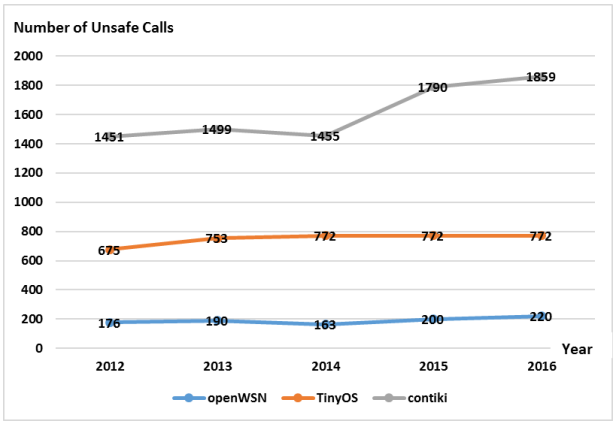

Figure. 1. The change in use of unsafe functions over time for the original three systems studied previously.

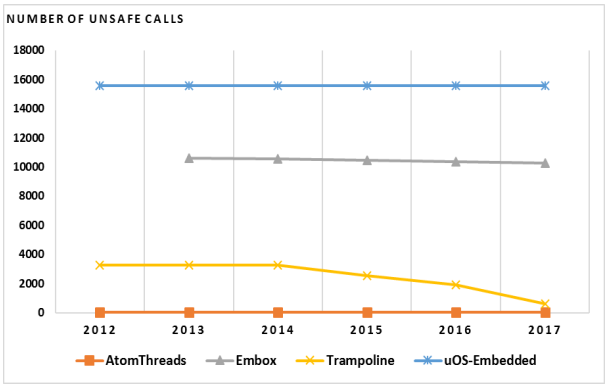

Figure. 2. The change in use of unsafe functions for the additional four systems studied.

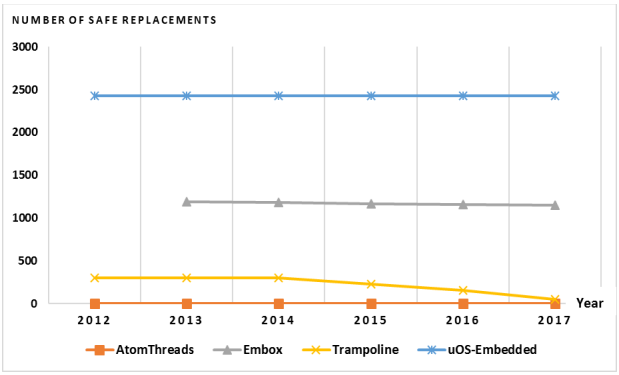

Figure. 3. The change in use of safe alternatives for the four additional systems studied.

lowering, possibly that the developers worked on removing the unsafe functions to increase the security and quality of their system. Figure. 1. shows the change in number of unsafe functions used for the original study [1]. Figure. 2. shows the change in number of unsafe functions for the 4 additional systems studied.

It can be seen that in the original 3 systems, the trends for two systems were relatively flat, while the trend for one system showed an increase in the use of unsafe functions over the 5-year period. We can also see in Figure. 2. that in the 4 additional systems, 3 of them showed very flat trends with 2 of those not having any change in the number of unsafe functions or safe replacements, shown in Figure. 3., beyond the first few years, over the 5-year period. The system, Trampoline, that did not show a flat trend instead showed a decreasing trend in the use of both unsafe functions and safe replacement functions. In 2012, Trampoline had 3265 unsafe functions. In 2017, that number had decreased to 637, although there had been a flat trend for the years 2012-2014.

While most of the systems don't show an increasing trend, as in they are not becoming more vulnerable to security risks, they are also not showing a decreasing trend, which can be seen as equally bad. The presence of unsafe functions remains the same, and the developers are not removing those functions in order to increase the security and quality of their systems. This could be that the developers of those systems are unaware of the risks imposed by the use of well-known unsafe functions, which leads to the need for better education on the topic of software security at the source code level to help those developers create higher quality systems.

6. Threats to Validity

The tools we developed and used for this study only work with languages supported by srcML (C/C++). Because of this limitation, we were unable to include systems written in languages such as Python and Java for this study.

Another limitation is that the tool we used is unable to differentiate between unsafe functions used in dead code, which means that some of the unsafe functions counted may never be called during the system's runtime. This might affect the accuracy of the results we present in terms of the systems' security and vulnerability. Additionally, the calls to unsafe functions that are included in wrappers are not excluded.

7. Future Enhancement

In the future, we are planning to improve the tool so that it only includes active code and exclude the calls to the unsafe functions that are protected with wrappers. We would also like to be able to include more systems written in different programming languages.

In this study, all calls to unsafe functions were counted including regardless the potential wrappers. We are planning to improve the tool so that it excludes the calls that are protected by proper wrappers.

8. Conclusion

This study empirically examined the usage of known unsafe functions and commands in eighteen open source software systems. The systems are all IoT applications written in C/C++ specifically for IoT architectures. There are no other studies of this type currently in the literature. The results show that usage of vulnerable functions is still common for most of the systems, although some systems had very few or even no calls to unsafe functions. Of the eighteen systems studied, memcpy was the most prevalent for the majority of the systems followed by strlen, free and strcmp. The historical trend, for selected systems, shows that developers are not working to improve a problem that still exists.

The vast majority of literature, concerning IoT security, focused on the security issues in the communication layer rather than vulnerabilities at the source code level. As such, more attention needs to be placed on dealing with source vulnerability,

reduce the usage of unsafe statements, especially the most prevalent statements to improve IoT platforms in terms of security, and educate developers on ways to both refactor their systems and to avoid the use of unsafe functions from the beginning when writing code, thus enhancing performance.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In this paper, Constant False Alarm Rate (CFAR) detection of spatially distributed targets embedded in compound Gaussian clutter with Inverse Gamma texture is addressed. By taking into account the fact that clutter parameters are unknown in practical situations, we propose mean level based on Lookup Tables detectors, that operate as a two-step approach, which consists of computing threshold factors that maintain a Constant Probability of False Alarm (Pfa) using intensive Monte Carlo simulations, and storing these factors in Lookup Tables, this first step is done independently from the detection algorithm. Then, at the detection stage, the detectors structure is associated to the Maximum Likelihood (ML) estimation technique to estimate the shape and the scale parameters, and compare them to the closest integer and half integer values in the Lookup Tables, to select the suitable threshold factor. Under the High Resolution Radar (HRR) assumption, the target is spread over a number of cells according to the Multiple Dominant scattering centers (MDS) representation. The binary total binary hypothesis tests are derived using the expression of the overall target energy, which is computed as the sum of the energies reflected from each cell.

Performance analysis of the proposed detectors is carried out using Monte Carlo simulation for various couples of clutter parameters and MDS models, and are compared to those of the Cell Averaging Based on Lookup Tables detector (CA-LT). In order to assess the performances of the proposed detectors in terms of the radar resolution, their performances are compared to the case of point-like targets.

1. Introduction

It is well established in Radar detection systems that High Resolution Radar systems (HRR) can resolve a target into a number of scatterers, leading to a spatial distribution of the target energy on a number of cells, which is commonly referred to as "distributed targets". This paper is an extension of the work presented in [1] , in which the detection of spatially distributed targets in compound Gaussian clutter with Inverse Gamma texture has been addressed. In fact, Two detectors are proposed: the Greatest Of based on Lookup Tables (GO-LT) , and the Smallest Of based on Lookup Tables detector(SO-LT) . As for the CA-LT [2], and Both detectors are designed to operate without à priori information about the clutter parameters by first storing threshold factors that maintain a Constant Probability of False Alarm (Pfa) in Lookup Tables, and then estimating the actual clutter parameters using the Maximum Likelihood (ML) method to select the suitable threshold factor to be used in the hypothesis test.

The target energy is considered spread over a number of cells, according to the MDS concept, three MDS models are taken into account, and both the target energy profile and the scatterers locations are specified for each considered model. Moreover, expressions of binary hypothesis tests for both detectors are derived using the expression of the total target energy, formerly proposed in [2]. Detection Performances of (GO-LT) and (SO-LT) are analyzed in terms of the Probability of Detection (Pd) using intensive Monte Carlo simulations, and is compared to those of the Cell-Averaging based on Lookup Tables detector (CA-LT) [2] assuming different MDS models, number of primary cells and couples of clutter parameters.

Detection of range spread targets under the Gaussian assumption has been widely explored with reference to the MDS target model [4]. Initially, it has been analyzed under the Gaussian

*Correponding author: Nabila Nouar, Département d'électronique , Université des Frères Mentouri Constantine, Algeria | E-mail : nabila_nouar@yahoo.com

assumption (see [5,6 and references therein]) . However, with the support of experimental data, it has been demonstrated that the clutter samples from sea clutter returns are better described as a *compound Gaussian process.* The latter *is* the product of a temporally slowly varying texture component and a locally rapidly varying speckle component [4, 7, 8, and 9]. Consequently, various adaptive detection schemes of range spread targets embedded in compound Gaussian clutter have been proposed and investigated. For instance, the GLRT-based detector [8], the detectors with Rao and Wald tests [4], the GLRT linear quadratic (GLRT-LQ) [9]. Also, the Non-Scatterer density dependent GLRT (NSDD-GLRT) [10], the normalized adaptive matched filter (NAMF) [11] have been investigated under compound Gaussian assumptions.

In [2], the authors introduced the Cell averaging based on Lookup Tables detector (CA-LT), which detects spatially distributed targets embedded in K-distributed clutter with unknown parameters. An expression of the binary hypothesis test for range spread targets has also been derived using the expression of the total target energy, and the performances of the CA-LT have been compared to those of the Logarithmic Cell Averaging detector CAL [12]. Another based on Lookup Tables approach, with non-coherent integration of multiple pulses have been proposed. The latter is designed to detect range spread targets without *a priori* information about the clutter parameters. By taking into account the non-coherent integration technique, and the target energy profile, the authors derived a new expression of the range spread target energy, and an expression of the binary hypothesis test. The performances of the proposed detectors have been compared to those of OS-GLRT [13], and results indicated that even though both detectors present better detection performance when the target is uniformly distributed on the primary cells, the (M-pulse CA-LT) still outperforms the OS-GLRT [13].

2. Assumptions and problem formulation

2.1. Clutter model

Under the HRR assumption, sea clutter returns are better described using the compound Gaussian model. In fact, the clutter e_i is sampled from the i^{th} range cell, and is expressed as the product of two components, namely, the texture τ_i and the speckle S_i, as follows:

$$e_i = \sqrt{\tau_i} S_i \tag{1}$$

Where $S_i = S_{iI} + jS_{iQ}$ is a stationary complex Gaussian process, and S_{iI} and S_{iQ} represent the in-phase (I) and quadrature (Q) components of S_i respectively [16]. In this work, we consider that the texture component follows the Inverse Gamma distribution [14], with the Probability Density Function (PDF) of τ_i [14, 15]:

$$f_{\tau_i}(\tau;\alpha,\beta) = \frac{1}{\beta^{\alpha}\Gamma(\alpha)} \tau^{-(\alpha+1)} e^{-1/\beta\tau} \tag{2}$$

Where α is the shape parameter, β represents the scale parameter and Γ (.) is the Gamma function.

Consequently, the magnitude of the clutter, denoted by X_i can be written as [14,15]

$$X_i = |e_i| = \sqrt{\tau_i}|S_i| \tag{3}$$

The PDF of X_i , namely $f_{X_i}(x)$, is expressed as [16]:

$$f_{X_i}(x) = \frac{2x\beta\Gamma(\alpha+1)}{(\beta x^2+1)^{\alpha+1}\Gamma(\alpha)} \tag{4}$$

2.2. Target model

According to the MDS representation, the target is considered spread over a finite number of cells , also referred to as "primary data, and its total energy , namely Δ, is expressed as the sum of the partial energies reflected by each range location as follows [2]:

$$\Delta = \sum_{k=1}^{Np} a_k {X_0}^k \tag{5}$$

Where a_k are multiplicative factors representing the energy proportion of the k^{th} range cell, and ${X_0}^k, k = 1,2, \ldots Np$ refer to the group under test. Motivated by the work presented in [1,2].We consider in this paper three MDS models , with three and (Np=3) four primary cells (Np=4) . The total useful energy backscattered from each cell and corresponding range locations are given in Table 1.

Table 1: Discrete Scatterers Locations and the amount of the total reflected energy.

Model Number	Cell number			
	1	2	…	Np

3. Greatest Of and Smallest Of based on Lookup Tables detectors

3.1. Working principle of GO-LT and SO-LT

The proposed detectors are based on the Greatest Of (GO) detector and the Smallest Of (SO) detector to detect spatially distributed targets embedded in compound Gaussian clutter with inverse Gamma texture. The (GO-LT) and (SO-LT) are designed to detect distributed targets using Lookup Tables (LT) and online clutter parameters estimation. As illustrated in Figure 1, the threshold factors $T(\alpha,\beta)$ that maintain a constant Pfa are computed for different couples of clutter parameters (α,β) using intensive Monte Carlo simulations and are stored in Lookup Tables (LT). At the detection stage, the clutter parameters the (α,β) are not *a priori*, and must be estimated. Therefore, the detectors structures are associated to the Maximum Likelihood estimation (ML) method, which estimates the shape and the scale parameters $(\hat{\alpha},\hat{\beta})$. These estimates are compared to the couples of clutter parameters in the Lookup Tables and are approximated to the closest integer or half integer pre-computed value of (α,β), once the closest couple of clutter parameters is selected, the suitable threshold factor $T(\alpha,\beta)$ is indexed accordingly .

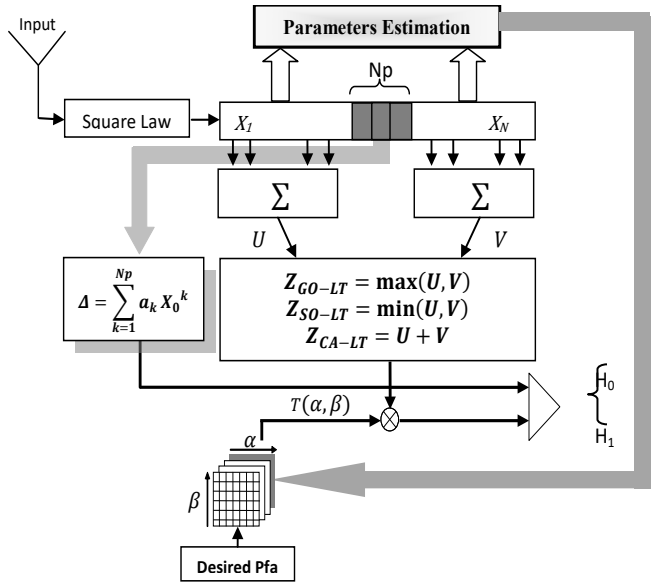

Figure 1: Working principle of GO-LT, SO-LT and CA-LT

The decision about the presence or the absence of a distributed target among the group under test ${X_0}^k, k = 1,2, \dots Np$ if taken by comparing the total reflected energy Δ to the adaptive threshold $T(\alpha,\beta)$ multiplied by the clutter level estimate Z. With respect to the proposed detectors, (GO-LT) and (SO-LT), we refer to the clutter level estimates as $Z_{GO\text{-}LT}$ and $Z_{SO\text{-}LT}$ respectively. The latter are estimated using the N reference cells by selecting the greatest and the smallest of the outputs *U* and *V*, as follows:

$$Z_{GO-LT} = \max(U,V) \tag{6}$$

$$Z_{SO-LT} = \min(U,V) \tag{7}$$

Here, the outputs U and *V* are computed as the average of the leading and the lagging reference windows respectively:

$$U = \frac{2}{N}\sum_{i=1}^{\frac{N}{2}} X_i \tag{8}$$

$$V = \frac{2}{N}\sum_{i=\frac{N}{2}}^{N} X_i \tag{9}$$

Where N/2 refers to the length of the lagging and the leading window.

Moreover, it is well known that in the CA-LT detector [2], the clutter level, namely, $Z_{CA\text{-}LT}$ is estimated by computing the mean of the reference cells surrounding the primary cells as follows:

$$Z_{CA-LT} = U + V \tag{10}$$

Consequently, the binary hypothesis tests of the GO-LT, SO-LT and CA-LT detectors can be respectively written as:

$$\sum_{k=1}^{Np} a_k {X_0}^k \underset{H_0}{\overset{H_1}{\gtrless}} T(\alpha,\beta) \begin{cases} \max(U,V) & GO-LT \\ \min(U,V) & SO-LT \\ \mathrm{U+V} & \mathrm{CA-LT} \end{cases} \tag{11}$$

It is important to note that the previous binary hypothesis test can be used to detect point like-targets by setting *Np* to 1, and Δ to X_0 in (11). Otherwise stated, when the number of primary cells reduces 1, we obtain a single cell under test X_0 which leads to:

$$X_0 \underset{H_0}{\overset{H_1}{\gtrless}} T(\alpha,\beta) \begin{cases} \max(U,V) & GO-LT \\ \min(U,V) & SO-LT \\ U+V & \mathrm{CA-LT} \end{cases} \tag{12}$$

3.2. Clutter parameters estimation using the Maximum Likelihood (ML) approach

Since the clutter parameters are not known in real radar application, many estimation methods, such as the (ML) estimation method [16] have been explored. In this study, we consider two mean level based on Lookup Tables detectors that are each associated to the (ML) method. The latter is associated to the detectors structure to estimate the shape and the scale parameters in order to automatically switch to the suitable threshold factor $T(\alpha,\beta)$ among the pre-computed values in the Lookup Tables. This method is used to estimate the clutter parameters (α,β) of the compound Gaussian clutter with inverse Gamma texture. As presented in [16], the ML estimate of the shape parameter, namely $\hat{\alpha}$, is expressed as a function of the clutter samples as follows:

$$\widehat{\alpha_{ML}} = \frac{N}{\beta \sum_{i=1}^{N} \frac{X(i)^2}{\beta X(i)^2 + 1}} - 1 \tag{13}$$

The scale parameter is estimated using the following concentrated Log Likelihood function of *β*, $\mathcal{L}_c(\beta)$ [16]:

$$\mathcal{L}_c(\beta) = \frac{N\beta \sum_{i=1}^{N} \frac{X(i)^2}{\beta X(i)^2 + 1}}{N - \beta \sum_{i=1}^{N} \frac{X(i)^2}{\beta X(i)^2 + 1}} - \sum_{i=1}^{N} log\,(\beta X(i)^2 + 1) \tag{14}$$

The ML estimate of *β*, namely, $\hat{\beta}$, is a zero point of this function [16]. Therefore, we use the following approach:

First, we compute the function $\mathcal{L}_c(\beta)$ for different values of the scale parameter β. Then, the estimate of β corresponds to the value of β that leads to a zero point of the function.

4. Results and discussion

Performance analysis of the proposed detectors is carried out using Monte Carlo simulations based on 100/Pfa independent trials and considering a nominal Pfa=10^{-3} and Pfa=10^{-2}.

We analyze the effect of different clutter parameters *(α,β)*= (1.5,1), (2,1),(2.5,1), and (3,1) on the detection performances of the proposed detectors. For the target, it is considered distributed over Np=3 and Np=4 primary cells respectively, and three MDS models that describe the target energy profile are investigated. Moreover, by taking into account the clutter parameters estimation approach, we set N=64 reference cells

We also consider the following Signal to Clutter Ratio (SCR):

$$SCR = 10log_{10}\left(\frac{2\sigma^2}{\frac{1}{\beta}\frac{\Gamma(\alpha-1)}{\Gamma(\alpha)}}\right) \quad (15)$$

Here , The parameter σ is used to generate the primary cells ${X_0}^k, k = 1,2, \dots Np$ for different SCR. The term $2\sigma^2$ refers to the target power. As for the CA-LT detector [2], the cells under test ${X_0}^k$ are scaled by a_k and are summed according to (5). The target's envelope echoes are described as independent random variables distributed according to the Chi-square law with mean square value ${\sigma^2}/{Np}$ [1].

4.1. Threshold factors T(α,β)

The threshold factors $T(\alpha, \beta)$ maintaining a Constant Pfa of 10^{-3} of the detectors GO-LT, SO-LT and CA-LT , assuming Np=4 primary cells are given in Table 2, Table 3 and Table 4 respectively. From Table 2 , that refers to the (GO-LT) detector, we observe that for the couple (α,β)=(2,1) , the threshold factor T=0.1514, where as for the couple (α,β)=(1.5,1) the threshold factor T=0.1920 . In fact, the threshold factor values continue decreasing as the shape parameter α increases, which is the case of α=3, where the highest values of T (T=0.1262) is required to maintain a Constant Pfa. Moreover, for couples of parameters with the same values of the scale parameter β, we have the same value of T. For instance, if we consider different couples (α,β) with α=1.5 : (α,β)=(1.5,1) , (1.5,1.5) and (1.5,2) , the required value of T is 0.1920.

From Table 3 and Table 4, we observe that the (SO-LT) and the (CA-LT) detectors exhibit the same behavior with regards to the threshold factors. Lower values of the threshold factor *T(α, β)* are required to maintain a Constant Pfa for higher values of the shape parameter α, and the same values of T are required to maintain a Constant Pfa when different values of β are considered.Hence, the scale parameter β does not affect the Pfa of all detectors. Hence, it can be scaled to 1 *(β=1)*. We conclude that the proposed detectors guarantee the CFAR property with regards to the scale parameter. Also, by comparing the threshold factors of all detectors, we observe that the SO-LT exhibits the lowest threshold factors for any couple of parameters *(α, β)*.

Table 2: Threshold factors of the detector GO-LT Np=4 , Pfa=10^{-3}

α / β	1.5	2	2.5	3
1	0.1920	0.1514	0.1352	0.1262
1.5	0.1920	0.1514	0.1352	0.1262
2	0.1920	0.1514	0.1352	0.1262

Table 3: Threshold factors of the detector SO-LT Np=4 , Pfa=10^{-3}

1	0.2573	0.1950	0.1715	0.1605
1.5	0.2573	0.1950	0.1715	0.1605
2	0.2575	0.1950	0.1715	0.1605

Table 4: Threshold factors of the detector CA-LT Np=4 , Pfa=10-3

α / β	1.5	2	2.5	3
1	0.1090	0.0842	0.0745	0.0681
1.5	0.1090	0.0842	0.0745	0.0681
2	0.1090	0.0842	0.0745	0.0681

Table 5: Threshold factors of the detector GO-LT Np=4, Pfa=10-2

α / β	1.5	2	2.5	3
1	0.1080	0.0915	0.0900	0.0848
1.5	0.1080	0.0915	0.0900	0.0848
2	0.1080	0.0915	0.0900	0.0848

Table 6: Threshold factors of the detector SO-LT Np=4, Pfa=10-2

α / β	1.5	2	2.5	3
1	0.1320	0.1202	0.1109	0.1100
1.5	0.1320	0.1202	0.1109	0.1100
2	0.1320	0.1202	0.1109	0.1100

For comparison purposes, we also present threshold factors $T(\alpha, \beta)$ maintaining a Constant Pfa of 10^{-2} of the detectors GO-LT, SO-LT and CA-LT , assuming Np=4 in Table 5, Table 6 and Table 7 respectively. We observe that the threshold factors exhibit the same behavior with regards to the clutter parameters, and that the scale parameter β still does not affect the threshold factors values. We also observe that among the three detectors, the SO-LT still requires the lowest value of the threshold factor. On the other hand, by comparing the obtained values of the threshold factors with Pfa=10^{-2} (Table 5, Table 6, Table 7) to those obtained with Pfa=10^{-3},(Table 2, Table 3, Table 4), it is clear that the threshold factor is affected by the value of the prescribed Pfa. In other terms, if we consider the same couple of parameters (α,β), the value of the threshold factor that required in the case of Pfa (10^{-2}) is lower than the the threshold factor required in the case of (10^{-3}).

Table 7: Threshold factors of the detector CA-LT Np=4, Pfa=10^{-2}

α / β	1.5	2	2.5	3
1	0.0581	0.0520	0.0488	0.0475
1.5	0.0581	0.0520	0.0488	0.0475
2	0.0581	0.0520	0.0488	0.0475

At this point , it is also important to stress that the previous results have been obtained considering four primary cells (Np=4). Thus , for comparison purposes , and in order to analyze the proposed detectors for different scenarios, we also considered the case of three primary cells (Np=3). The threshold factors *T(α, β)* that are required to maintain a Constant Pfa of 10^{-3} in case of three primary cells (Np=3) for the GO-LT, SO-LT and CA-LT are given in Table 8, Table 9 and Table 10 respectively. An interesting result is that higher values of threshold factor T are required to maintain a Constant Pfa for a lower number of primary cells. Otherwise stated , by comparison to the case of (Np=4) , if we decrease the number of primary cells (Np=3), the threshold factor that is required to maintain a Constant Pfa increases .

Table 8: Threshold factors of the detector GO-LT Np=3, Pfa=10^{-3}

2	0.1244	0.0954	0.1520	0.0778

4.2. Detection performance

In this section, we examine the detection performances of the GO-LT, SO-LT and CA-LT detectors considering different couples of clutter parameters , MDS models and numbers of primary cells Np , including the conventional case of single range cell , i.e, point like target.Performances are plotted using the Pd versus SCR plots. Detection performances of GO-LT, SO-LT and CA-LT for Np=4 (MDS-1) and Np=3 (MDS-1) considering different couples of clutter parameters (*α,β)* are presented in Figure 2 and Figure 3, respectively

We first observe that all detectors exhibit better detection performance for higher values of the shape parameter α, which is the case of the couple (α,β)=(3,1). However , all detectors behave the same for any couple of parameters, i,e, all detectors present the same behavior with the couples (α,β)=(1.5,1), and (α,β)=(3,1). This result remains true for any number of primary cells (Np=3 or Np=4).

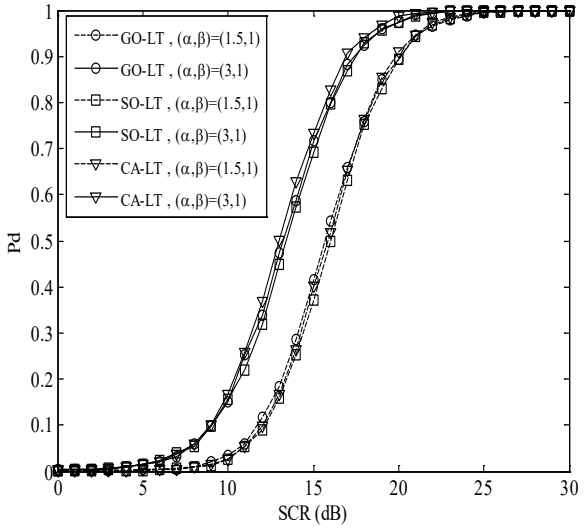

Figure 2: Pd of GO-LT, SO-LT and CA-LT for different clutter parameters (α, β) for Np=4 , MDS-1 ,Pfa=10^{-3}

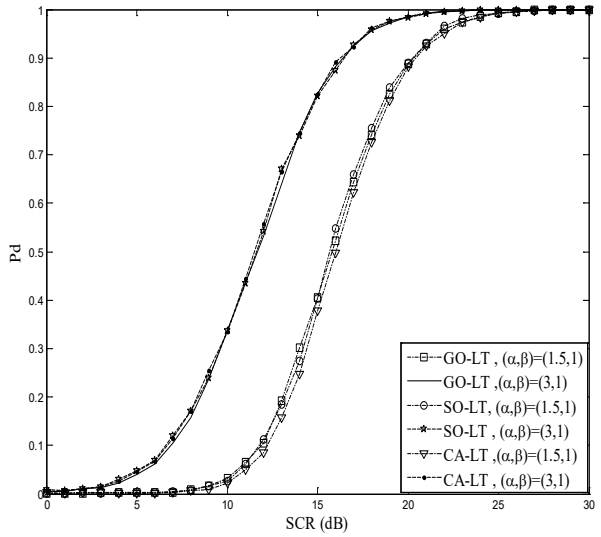

Figure 3: Pd of GO-LT, SO-LT and CA-LT for different clutter parameters (α, β) for Np=3 , MDS-1 ,Pfa=10^{-3}

Moreover, it is important to analyze the effect of the target energy profile, i,e, the MDS model on the detection performances of the proposed detectors. Hence, the Pds of GO-LT, SO-LT and CA-LT against SCR are illustrated in Figure 4, Figure 5 and Figure 6 respectively. We consider that the target is spread over four primary cells (Np=4) according to three different MDS models (MDS-1, MDS-2 and MDS(3). It is shown that all detectors present the best performance with MDS-1 model, and it is degraded with MDS-2 and MDS-3. This result can be interpreted by the fact that all detectors perform best when the target energy is uniformly distributed on the primary cells $X_0{}^k, k = 1,2, \dots Np$, and it is degraded as the energy becomes more concentrated in a specific cell as it is the case of MDS-2, and MDS-3 models. Therefore, the MDS-1 model is adopted for the next simulations.

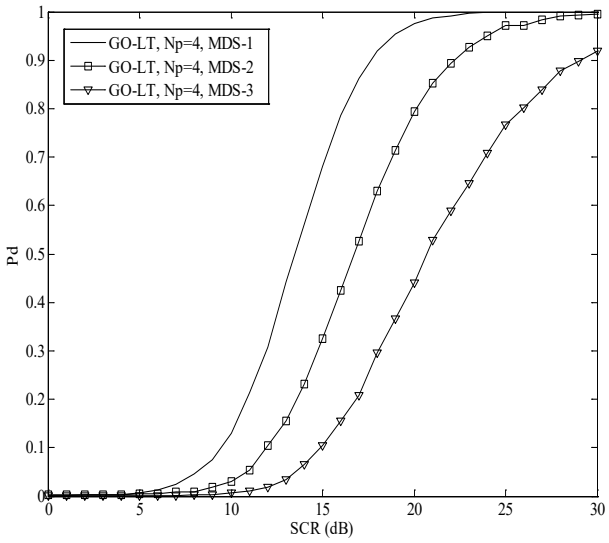

Figure 4: Pd of GO-LT for different MDS models for Np=4

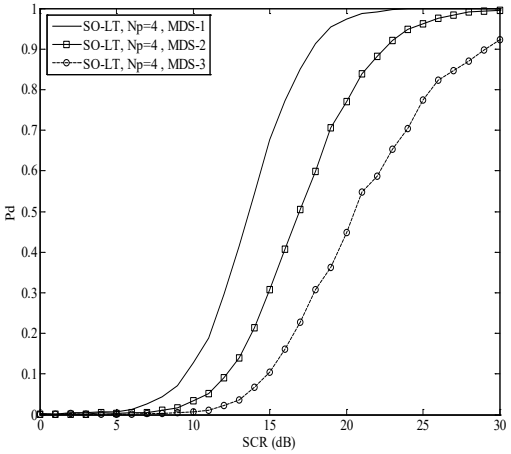

Figure 5: Pd of SO-LT for different MDS models for Np=4

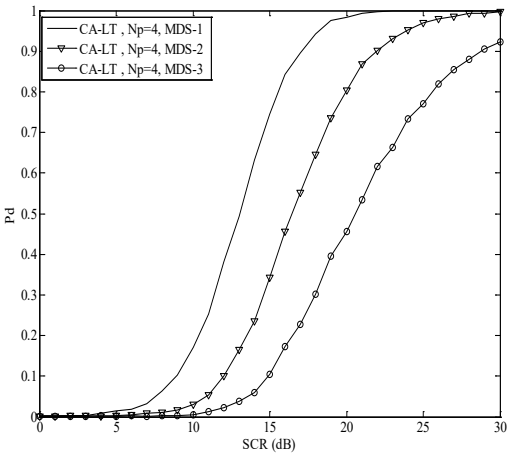

Figure 6: ,Pfa= Pd of C-LT for different MDS models for Np=4

On the other hand, it is important to compare the performances of the proposed detectors considering different numbers of primary cells Np. In Figure 7, we analyze the performances of the GO-LT, SO-LT and CA-LT detectors considering spatially distributed targets with Np=4 and Np=3 , and compare them to the case of point-like targets (Np=1). The plots indicate that the best detection performance is achieved with Np=4 , and it is degraded as the number of primary cells Np decreases (Np=3). We also observe that the proposed detectors exhibit the worst performance with point like targets (Np=1), which is expected since the detection performance is enhanced by increasing the radar resolution, i,e, the number of primary cells.

Another interesting aspect of the proposed detection approach is the online clutter parameters estimation. Therefore, it is important to check the dependency of the Pfa of the proposed detectors on the clutter parameters. In fact, we present the Pfa of the GO-LT , SO-LT and CA-LT , considering a nominal Pfa of 10^{-3} and 10^{-2} in Figure 8 and Figure 9 respectively. It is clear that the Pfa of the three detectors does not depend on the clutter parameter α, and it is maintained almost constant for all the values of α. As stated above, the Pfa of the proposed detectors does not depend on the values of the scale parameter β, which indicates that the proposed detection approach ensures the CFAR property with respect to both the shape and the scale parameters.

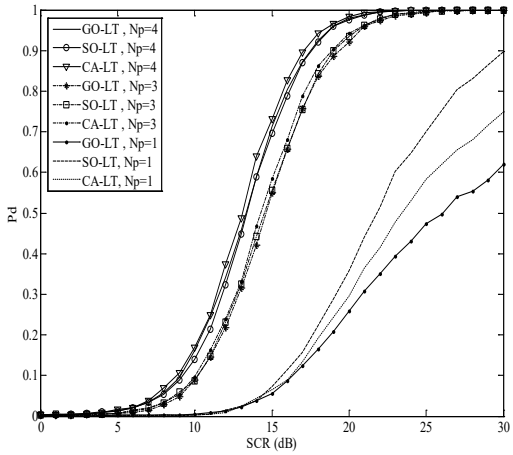

Figure 7: Pd of GO-LT , SO-LT and CA-LT for distributed targets (Np=4) and point-like targets (Np=1)

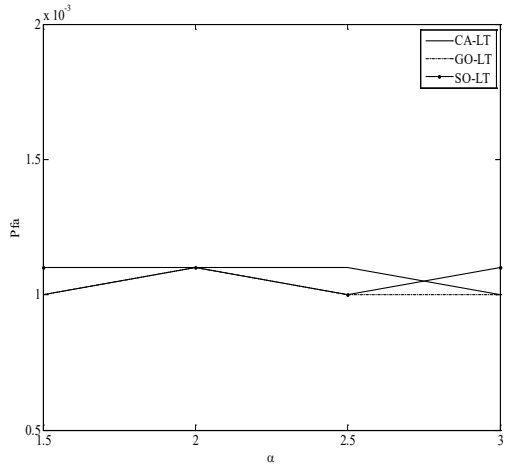

Figure 8: Pfa of CA-LT, GO-LT and SO-LT as a function of the shape parameter α for a nominal Pfa=10^{-3}

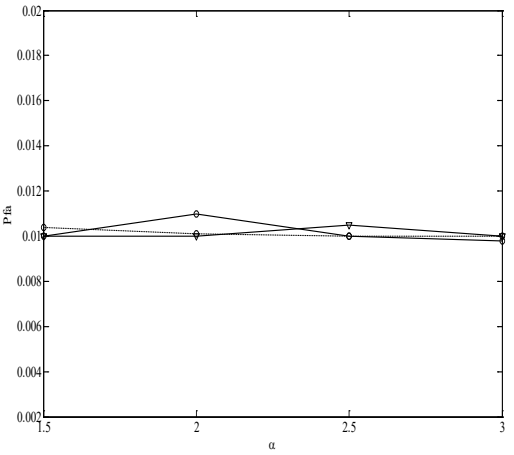

Figure 9: Pfa of CA-LT, GO-LT and SO-LT as a function of the shape parameter α for a nominal Pfa=10^{-2}

Finally, the effect of the scale parameter β on the performances of the CA-LT detector is presented in Figure 10. We observe that the same performance is achieved for different values of β.

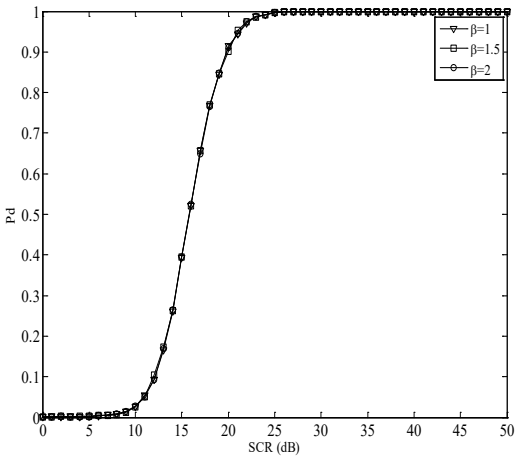

Figure 10: Effect of the scale parameter β on the detection performances of the CA-LT

5. Conclusion

In this paper, the detection of distributed targets in compound Gaussian clutter, with Inverse Gamma texture have been examined by designing a new Look-up Tables based detection approach . In fact, the proposed detectors are based on Lookup Tables that contain threshold factors, maintaining a constant Pfa, for different clutter parameters. Then, the ML technique is associated to the detectors structure in order to automatically switch to the most suitable threshold factor. To decide the presence of the target among the group of cells under test, the selected threshold factor is multiplied by the clutter level estimate and is compared to the total target energy. The performances of the proposed detectors have been investigated assuming three MDS models and compared to the point like targets. Simulation results indicated that all detectors present the best performance, when the target energy is uniformly distributed over the primary cells. However, they still present similar performance when the same MDS model is considered.

Another interesting result with regards to the proposed target energy profile is that all detectors perform better when the number of primary cells increases. Indeed, increasing the number of primary cells in the proposed detection scheme is equivalent to increasing the radar resolution, which can enhance the detection performances.

Finally, we conclude that the proposed detectors are applicable in practical situations since they can operate in more realistic situations such as: target energy profile when HRR systems are considered, and non-availability of priori information about the clutter parameters.

ABSTRACT

All multimedia devices now incorporate video CODECs that comply with international video coding standards such as H.264 / MPEG4-AVC and the new High Efficiency Video Coding Standard (HEVC), otherwise known as H.265. Although the standard CODECs have been designed to include algorithms with optimal efficiency, a large number of coding parameters can be used to fine-tune their operation, within known constraints of for example, available computational power, bandwidth, energy consumption, etc. With the large number of such parameters involved, determining which parameters will play a significant role in providing optimal quality of service within given constraints is a further challenge that needs to be met. We propose a framework that uses machine learning algorithms to model the performance of a video CODEC based on the significant coding parameters. We define objective functions that can be used to model the video quality as Peak Signal-to-Noise Ratio (PSNR), CPU time utilization and Bit-Rate. We show that these objective functions can be practically utilised in video Encoder designs, in particular in their performance optimisation within given constraints. A Multi-objective Optimisation framework based on Genetic Algorithms is thus proposed to optimise the performance of a video codec. The framework is designed to jointly minimize the complexity, Bit-rate and to maximize the quality of the compressed video stream.

1. Introduction

This paper is an extension of work originally published in Future Technologies Conference FTC 2016 San Francisco, United States[1].

Applications that benefit from accurate video capture, efficient representation and coding, error-free transmission and subjectively optimised display, have been growing over the years due to the availability of higher network bandwidth, faster processor speed and advanced capture and display technologies. Recent studies have shown that coded video data is contributing a the major part of consumer internet traffic with a predicted share of 90% by 2019.

Some of the most extensively used applications include real-time video conferencing, video streaming over broadband networks and digital TV broadcasting. Most current mobile hand-held devices come equipped with a video camera that is able to capture and encode a video stream in a standard format. These devices also include video players, which can decode and play back video. All the above developments continuously demand more efficient video coding algorithms that are able to reduce the bitrate without sacrificing video quality or to enable the increase of video resolution, without increasing the bitrate. High Efficiency Video Coding (HEVC) also known as H.265 is the most recent answer to this consumer demand, demand which supersedes the more widely used video coding standards such as MPEG-2 and H.264.

All advanced video CODECs have many parameters that can be used to control their operational characteristics, both at the encoder and decoder ends, enabling the possibility of fine tuning their operation for maximum efficiency within environments and application scenarios that are bound by various constraints. For example the available bandwidth will have an upper limit, the network will be subjected to delays and the decoder/display unit may have limitations in processing and display capabilities. Yet the encoder, transmission and decoder have many parameters that can be adjusted for them to be efficiently operational under the above mentioned constraints. Identifying the values of these parameters that results in the CODECs optimal performance under given constraints remains an open research problem of vital importance.

*Correponding author: Maryam Al-Barwani, Department of Computer Science, Loughborough University, UK | Email: m.al-barwani@lboro.ac.uk

The first step of parameter based optimisation of a video CODEC is the identification of the coding parameters that have a significant impact on its key properties, such as, bandwidth, image/video quality, and CPU cycles. Although an experienced user of a video CODEC can guess these parameters with some accuracy when the content of the video is known, a formal scientific approach is needed to accurately decide the parameter set, with minimum subjective error. Having obtained these parameters, it is then possible to model the key properties of the video CODEC described above based on the significant parameters. These models can then be used to optimise the performance of the video codec when operated under practical constraints, thus making the parameter based characterisation and modelling practically useful.

In this paper we propose a framework that is based on the fundamentals of machine learning that can be used to scientifically determine the significant coding parameters of a video CODEC. These parameters are then used to model the operational behaviour of the video CODEC for which machine learning algorithms are further utilised. We also show that this model can be used to establish the foundations of a multi-objective optimisation framework. Optimisations algorithms are widely used to solve many difficult optimisation problems in other research areas. Although the experiments conducted are limited to H,.264 and H.265 standards, the proposed framework can be used in relation to any video coding standard.

For clarity of presentation, the remainder of this paper is structured as follows: Related work and the background of H.264 & H.265 video coding is introduced in section 2. Section 3 presents the proposed framework for performance modelling and the experiments conducted for establishing the framework. Section 4 presents a comprehensive analysis of the results of the performance modelling of H.264 along with analysis of Optimisation. Section 5 presents the results and analysis of H.265 video codec and Optimisation stages carried out using a Matlab based implementation. Finally, section 6 concludes the paper.

2. Related Work

A significant amount of research has been conducted in the past and presented in literature on the optimization of video coding/compression algorithms. Parameter-based optimization focuses on the selection of the optimal set of coding parameters that will influence the optimal overall performance of the video CODEC, given operational constraints such as bandwidth, distortion, and CPU.

In [2] , a joint power-rate-distortion (P-R-D) framework, for the analysis, control and the optimization of the behaviour of rate-distortion (R-D) algorithms of a wireless video communication system, under constraints of energy consumption, was proposed.

In [3] it was shown that the approach presented in [4] cannot be easily extended to other video encoders. It presented a novel power-rate-distortion (P-R-D) optimization algorithm that can be used to minimize energy consumption of delay tolerant applications in portable video communication.

2.1. H.264 video codec.

A joint power-distortion model was presented in [5] and was analysed under two constraints, namely, power consumption and video quality. The approach jointly considered the power consumption and video quality and analysed the two problems within a uniform optimization framework. The work presented in [6], proposed a power-rate-distortion (P-R-D) model of a video encoding system to maximize its operational lifetime. In [7] a novel equation for the prediction of distortion was proposed that was used for the optimization of quantization parameter (QP) selection. An improvement of image quality as compared to the standard rate control algorithm of the H.264 reference software JM15.01 was recorded.

A large number of coding parameters poses a practical operational problem of how to best select the set of parameters that will ensure the CODECs optimal performance, especially under multiple operational constraints. In [8], the challenge to determine H.264 parameter settings that have low complexity but still offer high video quality was investigated.

An improvement to the work presented in [8] was proposed by the same authors in [4], in which two further algorithms for finding additional parameter settings for the GBFOS-basic algorithm were presented. However, a significant constraint of the work of [7,3] is its limited use only within two constraints namely, complexity and video quality.

The author in [9] presented a detailed study of the importance of a multi-objective optimisation framework and the approach presented in [10] as a solution. The presented framework focused on the development of a joint complexity-rate distortion (C-M-R-D) optimization framework for a H.264 video CODEC, which could be extended to cover any number of constraints and to be used within any type of video CODEC.

2.2. H.265 video codec.

High Efficiency Video Coding (HEVC) is the next generation video coding standard being developed, the newest video coding standard of the ITU-T Video Coding Experts Group and the ISO/IEC Moving Picture Experts Group [11].

In [12] it was shown that HEVC provides significantly improved compression performance, i.e. an approximately 50% reduced bit rate as compared to the best existing video coding standards, under the same visual quality. The paper proposed a hardware-friendly method for RDO of HEVC intra coding. The results of the study showed that the proposed RD cost function provides 85.8% area reduction and 1260% throughput improvement in hardware design, with slight loss of bitrate and PSNR, which is suitable for real-time encoder applications.

A performance comparison of H.265, VP9 and H.264 encoders was presented in [13]. According to the experimental results, obtained for a whole test set of video sequences, by using similar encoding configurations for all three examined representative encoders, H.265/MPEG-HEVC was shown to provide significant average bit-rate savings of 43.3% and 39.3% relative to VP9 and H.264/MPEG-AVC, respectively.

In [14] it was shown that for resolutions of up to HD (1920x1080), code optimizations including heavy use of single instruction multiple-data (SIMD) instructions are sufficient to achieve HEVC real-time software decoding. It was further shown that when it came to decoding UHD video (3840x2160), single threaded execution with code optimization was not enough.

To improve the compression performance of current video coding standards by 50%, especially when it comes to transmitting high resolution video like 4K over the internet or in broadcast, the

50% bitrate reduction is essential. [15] shows that real-time decoding of 4K video with a frame- level parallel decoding approach using four desktop CPU cores is feasible.

Emerging video compression standard H.265/HEVC provides up to 2 times better compression efficiency compared to H.264/AVC standard. Iterative intra prediction search in [16] was proposed for the H.265/HEVC encoder to reduce the number of prediction modes for estimation: about 40% encoding time reduction for HM 10.1 intra-only coding with negligible bitrate increase and PSNR quality degradation. Additional speed-up techniques, including fast prediction error estimation, were offered.

3. Proposed Framework for Performance Modelling

The proposed framework for a MOO Multi-Objective Optimisation [2] is developed to determine the optimum coding parameters for a H.265 video CODEC, when working under multiple constraints as shown in Figure 1. The MOO framework is intended to minimize the complexity (CPU utilisation), bit-rate and to maximize the quality of the compressed video stream. The MOO framework proposed is accomplished by following the steps below.

1) Profiling experiments on the encoder and decoder were carried out to determine the coding parameters that have a significant impact on each of the objectives/constraints related to rate, distortion and CPU utilization. This was achieved by measuring the impact of each parameter (while being varied) on each of the above aspects.

2) Developing the objective function for each objective/ constraint, based on the above significant parameters, by using a suitable regression procedure.

3) These objective functions can then be used within a genetic algorithm (GA) based multi-objective optimization framework to determine optimal parameter values.

In a practical multimedia application scenario a device captures a video, encodes it and transmits it via a network to another device that decodes and displays the content to a viewer. Assuming that the network has bandwidth constraints and the device in which the encoder is placed has compute power constraints and the potential viewers of content may demand at least meeting minimal quality levels, a situation occurs in which the proposed MOO framework can be used may arise.

The significant number of encoder parameters that control the encoder's bit rate, quality and computational power requirements can be selected, to ensure the encoder performance is optimal, under the given multiple constraints. However this requires the modelling of the encoder's bit-rate, quality and CPU utilisation, based on the large number of selectable encoder parameters. If mathematical objective functions can be derived for each of the above, a standard approach to optimisation can be used. Deriving objective functions, for example using mathematical regression, will need the determination of the significant coding parameters, the key focus of the research presented below. The same explanation can be applied to the selection of decoder parameters that results in optimal decoder performance. Within the research context of this paper, we assume that the data transmission network is assumed to be perfect, i.e. no delays, no bit losses, no errors etc. Therefore the bit stream generated by the encoder is transmitted without any loss or alteration to the decoder, in real-time. The following section proposes the experimental process adopted to determine the significant coding parameters for both the encoder and decoder.

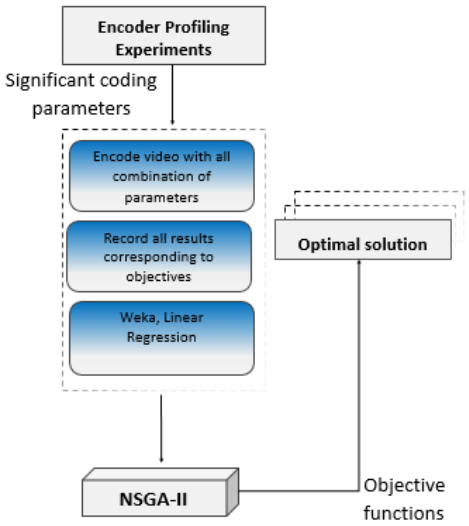

Figure 1: Proposed Multi-objective Optimisation framework.

4. Machine Learning based Framework for the analysis of significant coding parameters of H.264.

4.1. Profiling Experiments/ Determining the Significant Coding Parameters of H.264.

This experiment was carried out using a configuration file of the encoder software named JM (Joint Model) Reference software version 18.6 [17]. Six video sequences were encoded and decoded in the H.264 encoder by using a configuration file to set parameters of the mentioned video sequences. In this analysis, six QCIF video sequences were chosen for the experiment with a QCIF Quarter Common Intermediate Format, a videoconferencing format that specifies data rates of 30 frames per second (fps), with each frame containing 144 lines and 176 pixels per line. This is one fourth the resolution of Full CIF.

The first 30 frames were encoded for each video. Starting with Claire, a video sequences have a simple motion foreground and a non-moving area in the background, with a news presenter is talking by moving her head and eyes and mouth slowly. Coastguard video sequences have fast movement; on both regions foreground and background simultaneously, a boat is moving fast, waving water and a second boat will come into the scene within the final frames. A football video sequence has complicated fast motion with many players moving very quickly at the same time. Foreman video has a slight movement in the background; the Foreman is talking and his head is moving quite rapidly.

Mobile video sequences has a fast background and foreground movement; simultaneously, with a calendar moving upward, a ball and train are moving towards the left side with background. Tennis video sequences have a slow motion foreground and gentle movement in the background: the player's hand is moving and bouncing the ball and slightly zooming out of motion in the last few frames. The above six videos have different properties and motions as shown in Table 1.

Table 2 also tabulates the sample values used in our experiments for each parameter from within their corresponding value ranges. The control variable Intra-Period, can take values: 0 (meaning that the first frame is coded as an I-frame and subsequent frames are coded as P-frames), 5 and 8. The search window size is assumed to take either of the two values 16 or 32. The control variable Quantization Parameter (QP) is assumed to take two possible values 17 or 49. The number of reference frames (NRF) can take values 2, 5 and 8.

Table 1: H.264 Selected Video Sequences.

Claire 494 frames	**Coastguard 300 frames**
Football 260 frames	**Foreman 300 frames**
Mobile 300 frames	**Tennis 150 frames**

Table 2: Significant parameters and value used

Variables	Parameters	Values Range	Variable Type
IP= x(1)	Intra-Period	(0,5,8)	Numeric
SR= x(2)	Search-Range	(16, 32)	Numeric
QP= x(3)	Quantization Parameter	(17,49)	Numeric
NRF= x(4)	Number-Reference- Frames	(2,5,8)	Numeric

The computer chosen for the experiment has the following specification: HP Intel, Microsoft Windows 8.1 (64-bit), Intel® Core™ i5 CPU 4200Y @ 1.40 GHz, 4.00GB RAM.

The total encoding CPU time for each video sequence was recorded using Intel VTune Amplifier XE [18]. The following are the parameters used, with each video containing 3*2*2*3 = 36 Total Number of Instances. Table 3 presents 12 Instances out of the 36 Instances.

In each experiment one parameter will be changed while the rest of the parameters are fixed. This will help to observe the effect all parameters have on each Objective as shown in Table 3. The selected values of each coding parameter, the distortion (as PSNR is measured in decibels (dB)), bit-rate in kbps and the encoding time in seconds were recorded. Subsequently, the results were fed into the Linear Regression Analysis tool of WEKA [19] to generate the linear regression function for each objective.

Table 3: selected set of parameters for foreman sequence.

x_1	x_2	x_3	x_4	Bitrate	PSNR	Encoding Total Time
0	16	17	2	44.606	547.62	61.627
0	16	17	5	44.635	473.74	75.058
0	16	17	8	44.636	471.7	84.624
0	32	49	2	22.871	9.98	41.24
0	32	49	5	23.449	9.21	57.3
0	32	49	8	23.405	9.38	71.303
5	16	17	2	45.751	819.97	55.727
5	16	17	5	45.819	712.66	69.253
5	16	17	8	45.822	714.2	75.729
8	16	17	2	44.818	618.74	57.825
8	16	17	5	44.906	544.33	69.269
8	16	17	8	44.899	540.87	77.812

Based on the output of the linear regression, only the functions of three objectives of the Foreman video sequences are given in equation (1), (2) and (3). Following are the obtained models for each video sequence, with *f(1)* representing PSNR, *f(2)* rate and *f(3)* encoding-time. x_5, representing PSNR as parameter and x_6, representing Bit-rate.

Foreman Linear Regression Model

$$f(1)_{PSNR} = -0.5926 * x(3) + 0.0798 * x(4) + 0.0046\ x(6) + 52.0225 \quad (1)$$

$$f(2)_{Bitrate} = 6.8133 * x(1) - 18.5023 * x(3) + 890.0319 \quad (2)$$

$$f(3)_{Enc_Time} = -0.5347 * x(1) + 0.1297 * x(2) - 0.5646 * x(3) + 4.0201 * x(4) + 60.362 \quad (3)$$

4.2. H.264 Encoder Analysis

Experimental analysis was conducted separately for the encoder and decoder. Table 4 tabulates the correlation coefficients of the objective functions. They range between 0-1. In analysing the objective functions above, higher positive coefficients of coding parameters indicate higher positive dependency and higher negative coefficients represent higher negative dependency. If a certain parameter is not present in the objective function that means that the objective is independent of that parameter.

Table 4: Encoder Correlation Coefficient.

Video	PSNR	Bit-rate	CPU
Claire	1	0.9424	0.9460
Coastguard	0.9865	0.9865	0.8917
Football	0.9997	0.9967	0.9849
Foreman	0.9998	0.9678	0.9746
Mobile	0.9999	0.9809	0.9588
Tennis	0.9998	0.9757	0.9883

A careful analysis of the coding parameters that have non-zero weighting factors in the objective functions obtained and a comparison of relative magnitudes of the coefficients can lead to a direct correspondence with the properties of the video. For example, the analysis of the linear regression equations obtained for the Foreman video sequence identifies all four parameters to have significant impact on CPU utilisation (Encoding time) as in equation (3), namely:

- IntraPeriod
- Searchrange
- Quantization parameter
- NumberReferenceFrames

The most significant impact on CPU utilisation is the number of reference frames. This is expected due to the need to repeat the motion estimation process when NRF increases. The next significant impact is from the Quantization parameter. The impact from Search Range (SR) and Intra Period (IP) is relatively insignificant. For most videos with fast movement of objects (i.e. Football and Mobile) there is no impact from the Search Range. This is true given the fact that for videos with fast moving objects, best matches will not be found quickly, i.e. without having to scan the entire video.

For the same video, the following parameters were identified to have a significant impact on Bit-rate as in equation (2).

- IntraPeriod
- Quantization

In equation (1) the parameters that are identified to have a significant impact on PSNR are:

- Quantization parameter
- NumberReferenceFrames
- Bit-rate

The parameter that has the most significant impact on PSNR is bit-rate. It is noted that these two parameters are highly dependent

4.3. H.264 Decoder Analysis

An H.264 decoder takes a .264 file as input and outputs a raw YUV video stream. **Error! Reference source not found.** shows the output video artifact of frame 30 with quantization parameter (QP) of 49 that gives very low quality with PSNR of 24.189 db and 5.83 Bitrate compared to QP 17 that has 43.418 db and 979.02 Bitrate.

(a) (b)

Figure 2: Sample image of frame at (a) QP= 17; (b) at QP= 49

The more QP is increased during the encoding of the video, the more the video lost information and the bitrate reduced.

Note that the Decoder parameters have no impact on Bit-rate and PSNR as these are determined by the encoder. In the proposed framework, the quality and the bit-rate received by the decoder are the same as the encoder output.

The computational complexity of the decoder is analysed using the same method used at the encoder end. For the six given video sequences, experiments were performed in order to find out those coding parameters that can significantly influence CPU utilisation. The objective functions thus obtained are listed within the equations below.

Claire Linear Regression Model

$$f(1)_{Dec_Time} = 0.004 * x(1) + 0.0008 * x(2) - 0.0039 * x(3) + 0.373$$

Coastguard Linear Regression Model

$$f(1)_{Dec_Time} = -0.0042 * x(2) - 0.0118 * x(3) + 0.8945$$

Football Linear Regression Model

$$f(1)_{Dec_Time} = 0.0016 * x(1) - 0.022 * x(3) - 0.0033 * x(4) + 1.3455$$

Foreman Linear Regression Model

$$f(1)_{Dec_Time} = -0.0146 * x(3) + 0.9353$$

Mobile Linear Regression Model

$$f(1)_{Dec_Time} = 0.0071 * x(1) - 0.022 * x(3) - 0.0059 * x(4) + 1.3396$$

Tennis Linear Regression Model

$$f(1)_{Dec_Time} = -0.0158 * x(3) - 0.0072 * x(4) + 1.0304 \quad (4)$$

Table 5 tabulates the correlation coefficients of the decoder objective functions. The Football video sequence has the highest correlation coefficient closely followed by mobile. From the analysis of the linear regression equations obtained to identify parameters that have significant impact on CPU utilisation, Equation 4 reveals that the quantization parameter has the most significant impact. QP has an impact in all the video sequences as evidenced by its presence in all objective functions and being the parameter having the highest magnitude coefficient.

Table 5: Decoder correlation coefficient

Video Sequences	Decoder Time
Claire	0.9593
Coastguard	0.9217
Football	0.9984
Foreman	0.9786
Mobile	0.9958
Tennis	0.9873

The Encoder and Decoder analysis indicates that the objective functions obtained as a result of using the proposed framework is able to accurately define the significant coding parameters and further detail the level of significance of each parameter. They can also be related to the motion and content information of the videos.

4.4. Multiobjective Optimisation of H.264.

This section presents a framework for multi-objective optimisation of video CODECs. Specifically, an optimization scheme is proposed to determine the optimum coding parameters for a H.264 AVC video codec in a bandwidth constrained environment, which minimises codec complexity and video distortion. Solutions to the optimization problem are reached through a Non-dominated Sorting Genetic Algorithm (NSGA-II). NSGA-II is implemented in the genetic algorithm gamultobj, available in the MATLAB optimisation tool-box and the settings are fixed as shown in Figure 3.

4.4.1. Optimising the Encoder of h.264

The objective functions given in section 4.1 were used to optimise the encoder. These functions are then provided to the NSGA-II optimization tool along with the fitness function and number of variables. The fitness function corresponding to the objective function of the encoded videos is computed. Then populations are generated by applying the crossover and mutation operators described with the settings shown in Figure 3.

The NSGA-II provides all sets of optimal results that jointly minimize complexity, bit-rate and maximize quality. Since a single 3D graph is complex to visualize the optimality of the results, pairs of graphs were plotted.

Since optimization implemented in MATLAB minimizes the objective or fitness function, it solves problems of the form

$$\min_{x} f(x).$$

If you want to maximize *f(x)*, *–f(x) should be minimised,* because the point at which the minimum of *–f(x)* occurs is the same as the point at which the maximum of *f(x)* occurs.

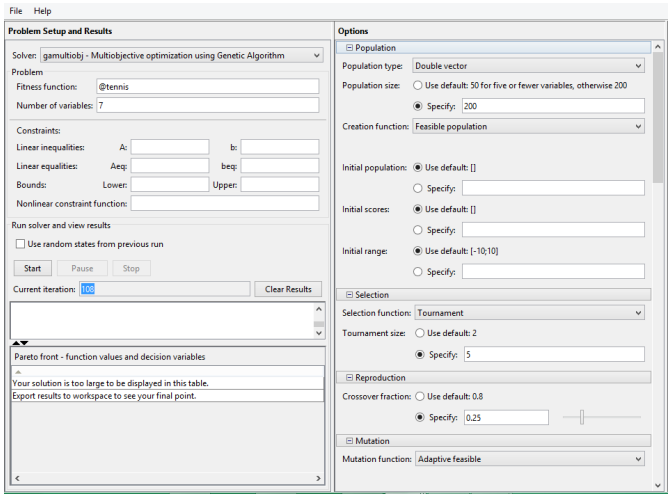

Figure 3: Set options for the problem

To obtain a Pareto front for two objective functions, the optimization is implemented using the above equations in section 4.1. A Pareto plots will appear as shown in Figure 4 – 6.

Figure 4 shows the Pareto front or set of non-dominated solutions for Bit-Rate and PSNR at the final stage of generations being used in the optimization process. One example optimised point is defined as:

IntraPeriod is -14.1153, SearchRange is 4.953125, QP is -9.39187, NRFrames is 21.66449, PSNR is 8.107256 and Bit-rate is 8.700779. Whereas the optimal values for PSNR is -59.357, Bit-Rate is 967.6315 as shown in Figure 4. Similarly, the results showing the Pareto front of non-dominated solutions for PSNR vs. CPU in Figure 5 and Bit-rate Vs. CPU time are presented in Figure 6.

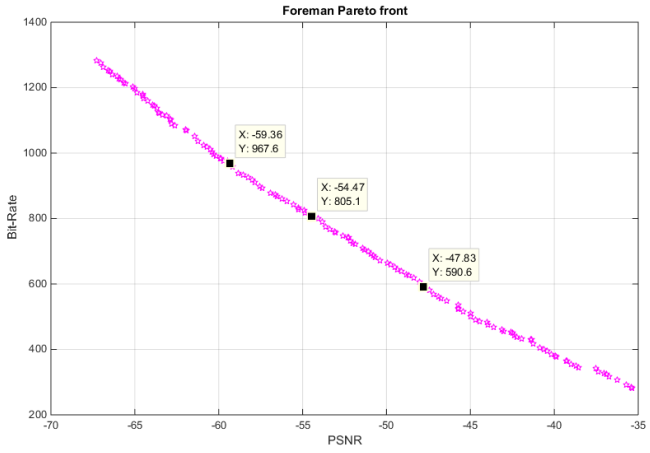

Figure 4: Pareto points for foreman PSNR vs. Bit-Rate.

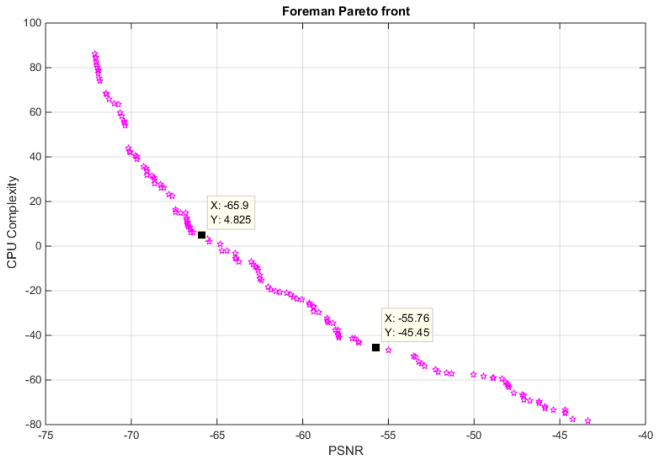

Figure 5: Pareto points for foreman PSNR vs. CPU.

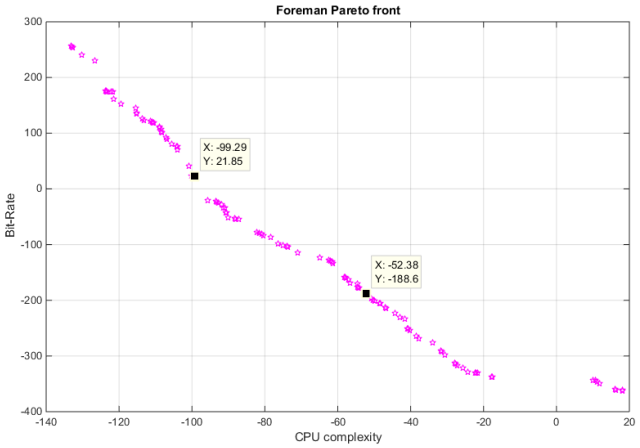

Figure 6: Pareto points for foreman CPU vs. Bit-Rate.

It is noted that the optimisation procedure described above results in a number of optimal solutions.

Table 6 Output data describing the results of MOO with GA for Figure 4 Figure 6.

Problem	Number of generations	Population Size	Pareto fraction	Size of non-dominated set	Function count	Average distance	Spread
PSNR vs. Bit-rate	107	200	.7	140	21601	0.0043	0.3793
PSNR vs. CPU	127	200	.7	140	25601	0.0196	0.3164
CPU vs. Bit-rate	246	200	.7	137	49401	0.0442	0.5231

According to Table 6, population size and Pareto fraction for the GA are set at 200 and 0.7, respectively, which are considered sufficient to generate a search for optimal solutions. The solver will try to limit the number of individuals in the current population that are on the Pareto front to 70 percent of the population size since the Pareto fraction is set to 0.7.

As the MOO algorithm is implemented in MATLAB, and stops at 107 generations and 21601 function counts, the GA selected 140 of the best individuals that are considered as non-dominated solutions out of 200 individuals in the population. Average distance between individuals is 0.0043, which indicates good convergence of the MOO solution, since it has a distance of less than 0.05 from the nearest point in the Pareto set.

4.4.2. Optimising the Decoder.

The analysis of the decoder is limited to decoder parameters that have a significant effect on only the decoder's computational complexity. In the proposed framework, the quality and the bit-rate received by the decoder are the same as the encoder output. This means the decoder receives all data transmitted by the encoder at the same rate. In such cases, the decoder totally depends on encoder coding parameters.

Figure 7 illustrate graphs between Bit-Rate vs. CPU complexity and PSNR vs. CPU complexity on the way to final generation.

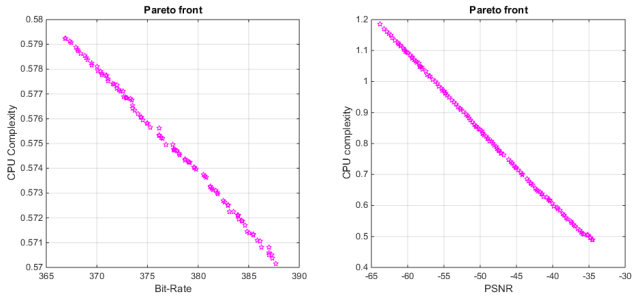

Figure 7: CPU a) Bit-Rate vs. CPU complexity and b) PSNR vs. CPU complexity

5. A Machine Learning based Framework for Parameter based Multi-Objective Optimisation of a H.265 Video CODEC.

5.1. H.265 Profiling Experiments.

This experiment was carried out using the Random Access (RA) configuration file of the Reference software for ITU-T H.265 high efficiency video coding named the HEVC test model (HM) version 16.8. Different resolutions can be used in each profiling experiment: 1080p which is representative for (Full HD) high definition systems with resolution of 1920x1080 pixels in a 16:9 aspect ratio, 2K Video a display resolution of 2560x1600 pixels with a 16:10 aspect ratio and 2160p (Ultra HD) which is representative for the next generation of high quality video. Each video sequence was encoded using a selected combination of possible parameter values of the initial set of encoder parameters.

In other words, each encoding instance corresponds to a combination of coding parameter values, selected from the possible exhaustive set that can be determined by varying each parameter within its entire range. For example, instead of using quantization parameter variations between 1-51 (that is the exhaustive set), only three sample values, 27, 37 and 45, were used (for further examples see Table 7). The table also tabulates the sample values used in our experiments for each parameter from within their corresponding value ranges.

Table 7: Settings for the Encoder in HM.

Parameter	Meaning	Values Range
SourceWidth SourceHeight	Specifies the width and height of the input video.	1920x1080 2560x1600
FrameRate	Specifies the frame rate of the input video.	Depends on video
Internal Bit Depth	Specifies the bit depth used for coding. When 0, the setting defaults to the value of the MSBExtendedBitDepth.	8
Coding Unit Size/Depth	Maximum coding unit width in pixel Maximum coding unit height in pixel	64/4 64/4
IntraPeriod	Period of I-frames. Specifies the intra frame period. A value of -1 implies an infinite period.	(16,32,48)
GOPSize	Specifies the size of the cyclic GOP structure.	8
FastSearch	The use of a fast motion search.	1:TZ search
SearchRange	Sets allowable search range for motion estimation.	(64,128)
Fast Encoding	Fast encoder decision	(0 or 1)
Quantization Parameter	Specifies the base value of the quantization parameter. If it is non-integer, the QP is switched once during encoding.	(27,37,45)
Asymmetric Motion Partitioning (AMP)	Enables or disables the use of asymmetric motion partitions.	1
Sample adaptive offset (SAO)	Enables or disables the sample adaptive offset (SAO) filter.	1
Rate Control	Rate control: enables rate control or not.	0

Table 8 shows selected sample frames of a set of six video sequences with different resolutions. Note that typical resolutions used in conjunction with H.265 video coding standard, i.e., 1080p and 2K resolution videos are used in all experiments, to carry out the analysis and make the relevant conclusions of this research. However, without any restrictions the proposed framework can be used in relation to a video sequence of any resolution, in particular

HD and full-HD 2K, 4k and beyond. The six selected video sequences have different properties of object motion, both in the foreground and background. Further differences exist in the scene content.

The experiments were initially conducted on a HP computer, running Microsoft Windows 8.1 (64-bit), having an Intel Core i5 CPU 4200Y @ 1.40 GHz and 4.00GB RAM. However it was found that coding HD resolution video is an intensive task that required for example, if encoded in the computer with the above specification, 10 hours to encode 50 frames of a 1920x1080 video at QP 37, intra period 48 and search range 64. Consequently, a decision was made to make use of a High Performance Computing (HPC) facility. Thus for all the experiments a HPC system using Redhat Enterprise Linux v6, with 20 cores of Intel Ivy Bridge Xeon E5-2670 containing 64GB RAM was used, significantly reducing the execution time per experiment.

Table 8: HEVC Tested Video Sequences.

YachtRide_1920x1080	**Traffic_2560x1600**
BasketballDrive_1920x1080	**Jockey_3840x2160**
Cactus_1920x1080	**YachtRide_3840x2160**

A sample of 36 data instances of the Cactus video sequence is presented in Table 9. These were used in the final stage of modelling the PSNR, Bit-rate and CPU utilisation. These are the inputs to the [19] linear regression based modelling process that result in the three objective functions that include the significant parameters, Intra Period as x_1, Search Range x_2, Quantization Parameter x_3 and Fast Encoding x_4.

The resulting objective functions for Bit-rate, PSNR and CPU time are the final outcomes of the performance modelling of the CODEC. Separate experiments are performed for each of the sample test videos.

Based on the output of the linear regression algorithms applied as explained above, the objective functions for the three objectives (for the Cactus video) are found as presented in equation (5). These functions provide the means to discuss in detail the significance of each parameter and how they affect the PSNR, Bit-rate and CPU encoding time. The following section provides an analysis of the experimental results. In particular the analysis considers the test videos separately and discusses the impact of each coding parameter given the known properties of the contents of each video. [Note that for each video, a different model is generated based on the video's inherent properties.]

$$f(1)_{Bitrate} = -22.4664 * x(1) - 386.2482 * x(3) + 18066.616$$

$$f(2)_{PSNR} = -0.0039 * x(1) - 0.4404 * x(3) + 48.873$$

$$f(3)_{Enc_Time} = 3.9537 * x(1) + 2.5501 * x(2) - 36.2174 * x(3) + 545.1239 * x(4) + 2768.025 \quad (5)$$

Table 9: Selected Set of Parameters for Cactus video Sequence.

x_1	x_2	x_3	x_4	Bitrate	PSNR	Encoding Total Time

5.2. H.265 Encoder Analysis.

The Encoder objective functions obtained as a result of the experimental procedure presented in section 5.1 enables one to discuss the significance of each of the coding parameters. Following are the obtained models for each video sequence, with $f(1)$ representing PSNR, $f(2)$ rate and $f(3)$ CPU encoding time.

Otabulates the correlation coefficients of the objective functions. They range between 0-1. A value closer to 1 represents the fact that the dependant variable (in this case Bit-Rate, PSNR or CPU utilisation) can be predicted very accurately from the coding parameters that play a role and have been included within the objective functions.

Table 10: Encoder Correlation Coefficient.

Video	PSNR	Bit-rate	Enc_Time
Cactus	0.9989	0.9551	0.988
YachtRide	0.9981	0.9532	0.9837

In analysing the objective functions (5), higher positive coefficients of coding parameters indicate higher positive dependency and higher negative coefficients represent higher negative dependency. If a certain parameter is not present in the objective function, that means that the objective is independent of that parameter. A careful analysis of the coding parameters that have non-zero weighting factors in the objective functions obtained and a comparison of relative magnitudes of the coefficients can lead to a direct correspondence with the properties of the video; for example, the presence of motion in the foreground and background, the speed of movement of objects, sudden scene changes, camera pan/tilt/zoom effects and the general characteristics of the content of the video as well.

For example, the analysis of the linear regression equations obtained for the cactus video sequence identifies all four parameters to have significant impact on CPU utilisation, namely:

- IntraPeriod
- Searchrange
- Quantization parameter
- Fast Encoding

For the same video, the following parameters were identified to have a significant impact on Bit-rate.

- IntraPeriod
- Quantization parameter

The parameters that are identified to have a significant impact on PSNR are:

- IntraPeriod
- Quantization parameter

A more detailed and video sequence specific analysis can be presented as follows.

- ***Analysis of the CPU Utilisation Experiment:***

The objective functions obtained for all tested video sequences for CPU encoding time indicates that the parameter that has the most significant impact on CPU is Fast encoder decision. Further, in the selection of the Intra-Period, more I frames (smaller intra period) results in a higher processing time. The next significant impact is from the Quantization parameter. The impact from search range (SR) and Intra Period (IP) is relatively insignificant.

When search range increases, encoding time will slightly increase. These tests have no major impact on the quality of the video. Disabling FEN will also slightly increase encoding time. However it has no major impact on quality.

- ***Analysis of the PSNR Experiment:***

The parameter that has the most significant impact on PSNR is QP. The PSNR results tabulated in 0 indicate that the two videos with the least amount of movement/changes, namely Cactus and YachtRide have the best correlation coefficients. This is expected due to the stability of the CODEC during the encoding of the individual frames of the coded sequence.

- ***Analysis of the Bit-Rate Experiment:***

The parameter with the most significant impact is the QP. Lower quantisers result in higher bitrate and correspondingly higher visual quality as illustrated in Figure 8. (QP) has a very important impact on the compression rate of H.265.

In cactus, both PSNR and Bit-Rate have no impact from the Search Range. This is true given the fact that for videos with fast moving objects, best matches will not be found quickly, i.e. without having to scan the entire video. All objective functions include a similar constant term indicating that a fixed computational cost for encoding is present, which is independent of the selection of coding parameters. This is expected given the processes that exist, which are independent of the coding parameters.

5.3. H.265 Decoder Analysis

The computational complexity of the decoder is analysed using the same method used at the encoder end. Experiments were performed in order to find out those coding parameters that can significantly influence CPU utilisation. The objective functions thus obtained are listed within equation (6).

$$f_{Dec_Time} = 0.0023 * x(2) - 0.0819 * x(3) + 0.1178 * x(4) + 8.2928 \quad (6)$$

Table 11 Decoder Correlation Coefficient

Video	Dec_Time
Cactus	0.9509
YachtRide	0.9263

Table 11 presents the correlation coefficients of the objective functions. The cactus video sequence has the highest correlation coefficient. The analysis of the linear regression equations is carried out to identify parameters that have significant impact on CPU utilisation. Equation (6) reveals that the Fast Encoding has the most significant impact, being the highest magnitude coefficient.

The Encoder and Decoder analyses indicate that the objective functions obtained as a result of using the proposed framework are able to accurately define the significant coding parameters and further detail the level of significance of each parameter. They can also be related to the motion and content information of the videos. More importantly, these objective functions model the behaviour/properties of the encoder and decoder thus allowing them to be used in multi-objective optimisation as described in the next section.

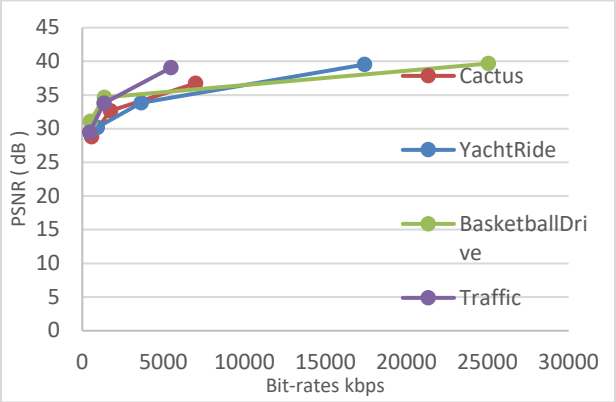

Figure 8: PSNR versus Bit-rate at QP 27, 37,45.

The HM encoder/ decoder configuration file takes a .265 file as input and outputs a raw YUV video stream as ReconFile. The output shown in Figure 9 indicates that the output video artifact of yacht video at frame 30 with quantization parameter (QP) of 45 gives very low quality with PSNR of 28.7877 dB compared to QP 27, which has 36.7323.

The more the QP is increased during the encoding of the video, the more the video loses information and bitrate reduces.

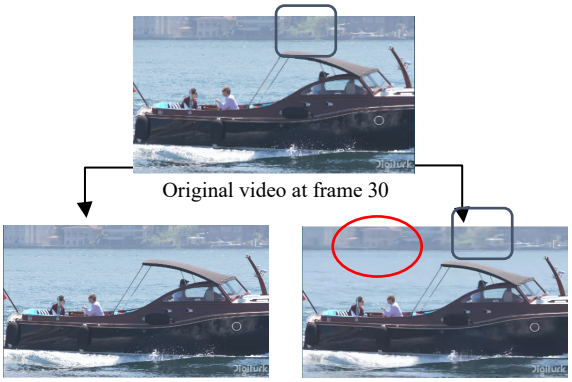

Figure 9: Shows the visual artifact with different QP

5.4. Optimising the Encoder of H.265

In this section, the objective functions given in equation (5) were used to optimise the encoder performance under multiple constraints. The experiment was conducted, and the following setting of parameters for the GA were chosen (see Table 12)

Table 12: Settings for Multiobjective Genetic Algorithm Solver.

gamultobj settings	
Fitness function:	@function
Number of variables:	4
Bounds Constraints:	lb = [16,64,27,0] ub = [48,128,45,1]
Creation Function:	Constraint dependent
Population Size:	60
Initial Population:	Default
Crossover Fraction:	0.8
Mutation Function:	Constraint dependent
Crossover Function:	Intermediate
Crossover Ratio:	0.8
Pareto Front Population Fraction:	0.35
Maximum Generations:	300
Plot functions:	Pareto front

The results of Multi-Objective Optimisation (MOO) Pareto set analysis are presented in Figure 10 and Figure 11. Figure 10 shows the Pareto front or set of non-dominated solutions for Bit-Rate and PSNR. The Pareto front illustrated is within a limited range and hence shows that the points lie on a straight line. In practice, when the range of testing is increased the shape of the curve would represent a typical shape of a Pareto curve. The Pareto curve allows one to select optimum performance points and hence select the corresponding coding parameters that resulted in the objective function optimal values for coding the videos.

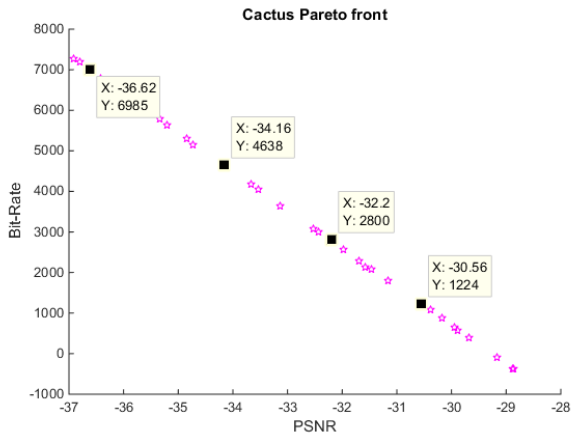

Figure 10: Pareto front for cactus video sequences PSNR vs. Bit-Rate.

For one optinal point of operations, the IntraPeriod is 27.49851, SearchRange is 83.34469, QP is 33.16743, Fast Encoding is 0.264558, PSNR. Whereas the optimal value for PSNR (X) is -34.1591, Bit-Rate (Y) is 4637.964 as shown in Figure 10. Similarly, the results showing the Pareto front of non-dominated solutions for Bit-rate Vs. CPU complexity are presented in Figure 11.

Table 13: Output data describing the results of MOO with GA for cactus.

Problem	Number of Generations	Size of population	Pareto fraction	Size of non-dominated set	Function count	Average distance	Spread
PSNRvs.Bit-rate	259	60	0.35	35	13001	0.0149	0.1487
CPU vs. Bit-rate	220	60	0.35	21	13261	0.0308	0.1050

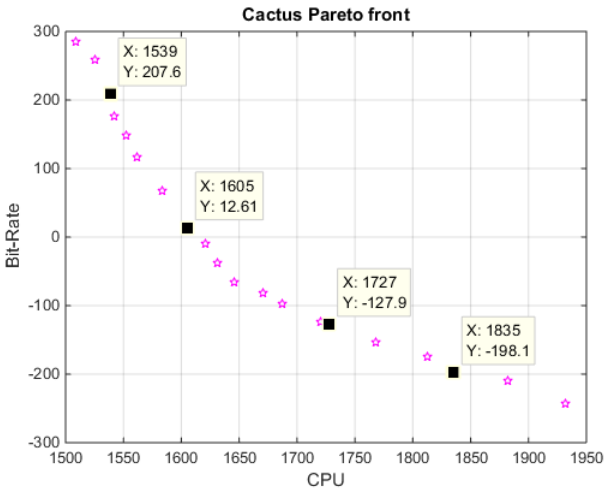

Figure 11: Pareto front for cactus video sequences CPU vs. Bit-Rate final Generation.

In Table 13, population size and Pareto fraction for the GA are set at 60 and 0.35, respectively, which are considered sufficient to generate search for optimal solutions.

At 259 generations and 13001 function counts, the GA selected 35 best individuals considered as non-dominated solutions out of 60 individuals in the population. Average distance between individuals is 0.0149, which indicates good convergence of the MOO solution.

Conclusion

In this paper we have proposed a machine learning based approach for the determination of significant coding parameters of a H265 video CODEC. In particular, we have used multivariate regression analysis in defining objective functions for CPU utilisation, PSNR and the bit-rate of a video CODEC when a given video is being Encoded/Decoded. We have been able to use known information about the content and the motion present in the test videos to justify the formation of the objective functions. We have shown that these regression equations provide the means for modelling the performance of a typical H.265 video CODEC. Finally, we have used these models to optimise the performance of a video CODEC under multiple constraints. For this purpose we demonstrated the effective use of a Genetic Algorithm based approach.

The proposed framework for the performance analysis, modelling and multi-objective optimisation of a H.265 video CODEC can be applied to any video CODEC and provides a useful contribution to the video coding community who are often faced with the dilemma of selecting values for a large number of coding parameters with the intention of obtaining optimal performance of the CODEC under multiple performance constraints.

6. Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of this paper.

3-D primitive
Many-to-many relationship

ABSTRACT

With the unprecedented wave of Big Data, the importance of information visualization is catching greater momentum. Understanding the underlying relationships between constituent objects is becoming a common task in every branch of science, and visualization of such relationships is a critical part of data analysis. While the techniques for the visualization of binary relationships are widespread, visualization techniques for ternary or higher relationships are lacking. In this paper, we propose a 3-D visualization primitive which is suitable for such relationships. The design goals of the primitive are discussed, and the effectiveness of the proposed visual primitive with respect to information communication is demonstrated in a 3-D visualization environment.

1 Introduction

Understanding the relationships between the entities is an important matter in any type of data analysis project whether scientific or non-scientific. Visualization is generally viewed as complementary to traditional text-based analysis. Visualization also plays an indispensable role in data analysis. At times, visualization comes with an unexpected surprise such that it reveals auspicious patterns that may not be intuitive otherwise. In this paper, we address the design issues of 2-D and 3-D visualization techniques for many-to-many relationships. This paper is an extension of work originally presented in the proceedings of the 19th IEEE International Symposium of Multimedia (ISM 2016).

Augustus De Morgan insightfully stated, "When two objects, qualities, classes, or attributes, viewed together by the mind, are seen under some connexion, that connexion is called a relation" [1]. It is critical to understand the relationships between the objects in order to analyze the full drama played by the objects. For example, given the information that each of the two pairs of persons A and B, and A and C holds a friendly relationship in a social network, it may be important to know if the friendly relationship "clique" comprising A, B, and C together exists at a statistically significant level in psychology or cyber security. The authors of [2] identified two types of friendship from their study on Facebook. One type is the sympathy group which consist of approximately 15 close friends. The other type is the support clique of "friends on whom you would depend for emotional/social support in times of crisis." The size of the second group is approximately 5.

Relationships may be characterized by attributes such as type (e.g., "co-authorship" [3] and "trust" in social networks [4], "presidential election", etc.), weight (boolean or continuous), direction (directional or undirectional) and etc. The set of attributes for relationships is determined by the nature of the application domain. In our work, relationships are attributed only by the degree of participation of an object in its relationships to other objects, defined below, and the weight of the relationship.

Definition 1.1 (Degree of participation in relationship) *Given a set of objects $O = \{o_1, o_2, \ldots, o_n\}$, the relationship of an arbitrary type t between the members of O is many-to-many when each o_i $(1 \leq i \leq n)$ holds a relationship of the same type t with zero or more other objects in O simultaneously. Furthermore, we use the term k-relationship to denote a relationship whose degree of participation is k.*

Among the various degrees of relationships in terms of participation, binary relationship is the most common in and the primary target of many data analysis projects. Examples of binary relationship include the gravitation between two masses in physics, symbiotic organisms in biology, term co-occurrence in information retrieval, co-citation [5] in bibliographic coupling studies, spatial co-location [6] in spatial data

*SeungJin Lim, North Andover, MA, U.S.A., 978-837-3404, lims@merrimack.edu

https://dx.doi.org/10.25046/aj0203191

mining, frequent 2-itemsets in association mining, and friend relationship between two persons in social networks.

At the same time, we recognize the rise of the relationships of a higher degree where three or more objects participate in the relationship simultaneously. Co-authorship [3] is such an example, because a paper can be published by more than two authors. The "support clique" of size 5 mentioned above is an example of relationships of a higher degree. As another example, the 34.7% of the papers are coauthored by three or more authors out of the 5.5 million journal articles, conference papers, and other publications on computer science listed at the DBLP Computer Science Bibliography website as of February in 2017. And the 0.5% of them are published by 10 or more co-authors as shown in Figure 1.

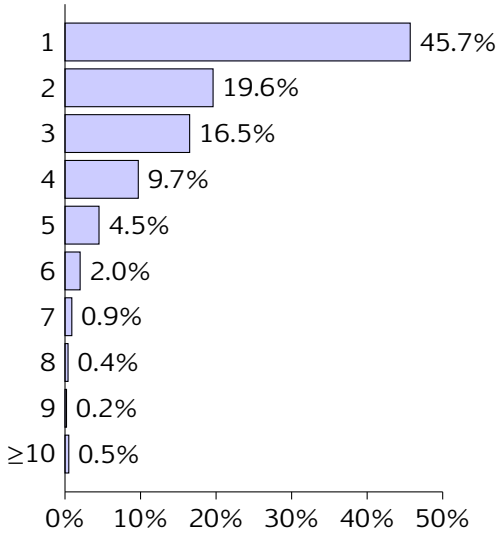

Figure 1: The fraction of publications listed in the DBLP Bibliography by number of coauthors.

Object relationships are commonly represented using a textual format in accordance with a data structure specifically designed for the data. A classic example is a tuple notation which is widely used in the relational database model. Relationships are also represented graphically. A graph $G = (V, E)$ where V is a set of vertices denoting objects and E is a set of edges representing relationships between the objects is a common example of this kind of representation, which has a dominant appearance in data/information visualization such as in social network analysis, web graph, and so forth.

When object relationships are analyzed over a large volume of data, overall descriptive patterns manifested in the underlying data is often the primary objective of the analysis. Individual or local patterns may or may not be of interest. Visualization helps us understand both overall and local patterns and offers a unique added value to data analysis of a large scale such as big data.

The visualization of binary relationships is conveniently and effectively done by drawing a line between the two related objects. In Figure 2, for example, the binary coauthorship relationship between Barkerma and Moursseau is apparent. We can also easily observe other binary relationships involving Barkerma, such as (Barkerma, Leeuw) and (Leeuw, Moursseau). A drawback of this visualization is that the readers are prone to mistakingly derive the ternary relationship (Barkerma, Leeuw, Moursseau) from (Barkerma, Leeuw), (Barkerma, Moursseau) and (Leeuw, Moursseau), unless noted otherwise.

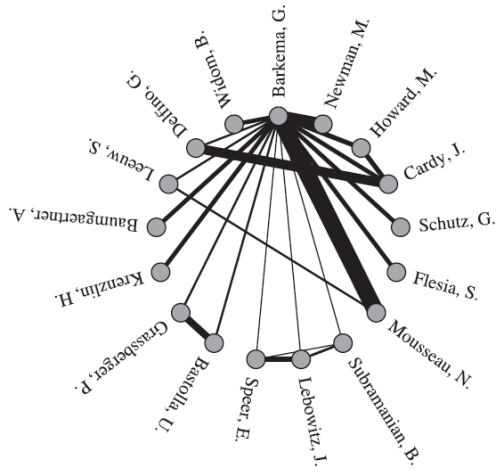

Figure 2: A visualization of G. Barkerma and collaborators in scientific publication [3].

The purpose of this paper is two-fold.

- We compare the merits of the selected 2-D visualization techniques and present the merits and challenges they impose for the purpose of data analysis when the degree of participation or the number of relationships grows large.
- We propose a geometric primitive which is suitable for visualizing ternary or higher-degree many-to-many relationships in 3-D. A set of design goals are also discussed. The effectiveness of the proposed primitive is demonstrated with various real-world datasets as well as artificial datasets.

The remainder of this paper is organized as follows: In Section 2, some selected related works are presented. We first discuss on the selected popular 2-D visualization layouts in Section 3. We then present the proposed visualization primitive along with design goals and technical details in Section 4. A demonstration of the primitive is presented in Section 5. We conclude our presentation with what we plan to do in the future in Section 6.

2 Related Works

The topic of our work is generally related to scientific visualization in which a global summary of data is often the primary interest. On the other hand, local

details are also important in visual data exploration and mining to which our work is closely related. A review on visual data exploration and mining can be found in [7]. Undirected relationships between entities are largely visualized as 2-D or 3-D matrices [8, 9] or undirected graphs [10, 3, 11, 12]. A number of different approaches exist. Determination of which approach is better than others is largely domain-specific as observed in [13]. We conveniently categorize most common approaches in the literature with respect to the layout of objects and visual cues representing relationships.

Difference in layout. The decision for the layout of objects is commonly influenced by the number of domains underlying the data objects or the number of attributes describing the data object. When the objects are from different domains, their membership to a different domain should be visually encoded so that the user may discern their membership easily. Intuitively, n orthogonal axes are used to make n domains distinguishable.

In case of bipartite relationships, for example, one approach is to arrange the objects in accordance to two axes that are visually perpendicular or parallel to each other. Bipartite graphs are examples of this kind. An alternative approach found in the literature is to arrange them anywhere in the visual space with two different object shapes to make them distinguishable. This approach can be thought of "zero" axis.

Though the objects belong to a single domain, we may still need multiple axes when these objects are associated with multiple attributes. A technique called parallel coordinates [15] is an example of this kind where objects are arranged vertically and each object is attributed by a number of parallel axes which are spaced out horizontally, each of which represents an attribute.

In our work, objects belong to a single domain. Two types of object layouts are commonly found in the literature and in practice.

1. Single set of objects: Only one set of objects is rendered in the visualization. The objects are arranged along the circumference of a circle (Figure 3a), on a single linear axis (Figure 3b), or anywhere in the given visual space (Figure 3c). Notice that the three visualizations in Figure 3 are *isomorphic*. In other words, they carry the exact same set of relationships between the same set of objects though they may produce different visual impression. Graph is the basis of these visualization techniques.

2. Two sets of objects: This layout can be thought of as an Euclidean space where one axis carries the full set of objects, and the second axis perpendicular to the first axis carries the same set of objects in the same ordering.

   In Figure 4a, a set of 19 performance statistics of baseball players is arranged along both the horizontal and the vertical axes to show the correlation (a particular type of relationship) between them for the 1986 season. The statistics include season and career batting averages and so forth, calculated from "Hits" and "At bats".

   This layout is extended often to capture the correlation between two variables, as illustrated in the H-R diagram of stars showing star categories with respect to temperature and luminosity (Figure 4b). The layout is also extended to a 3-D space to amplify the visual effect of the significance of relationships as illustrated in Figure 5b.

Difference in the representation of relationships.

1. Presence or absence of relationship: When the presence or absence of a relationship between two entities is what matters, connecting the two entities by an edge or a marker on a 2-D plot is sufficient. The three visualizations in Figure 3 and the one in Figure 4b are examples of this category. Unweighted graphs and scatter plot-like visualizations belong to this category.

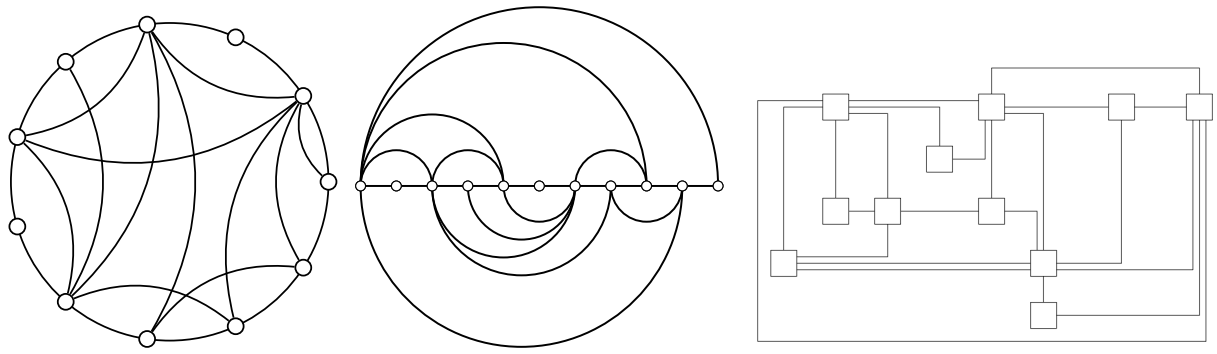
2. Significance of relationship: In contrast, Figures 2, 4a, and 5a show the significance of a relationship using another visual cue such as thickness of edges as in Figures 2 and 5a, color or density of color (Figure 4), or height of object in a 3-D space (Figure 5b).

As for the visualization techniques designed specifically for data mining, the authors of [9] chose to show cluster analysis results in a 3-D matrix such that the square grid of horizontal axes represent data objects and the vertical axis represents the similarity between the two corresponding objects. Visualization of geospatial point sets presented in [18] is inherently a similar 3-D matrix visualization since longitude and latitude values constitute X- and Y-axes. [10] uses multiple visual cues in a 2-D square matrix to enhance the visual feedback from a large dataset.

There also exist tools which employs a circle rather than a rectangle or square as the layout of the data objects. In [3], coauthorship is represented in a circular image such that the authors are arranged on a non-interactive 2-D canvas whose visual feedback may lose effectiveness as the data size grows large. As an extension of a circular grid, a concentric 2-D ring view of a coauthorship network is presented in [12] in which each ring represents the authors' contribution in a particular year, which is useful to show temporal trends in the underlying information.

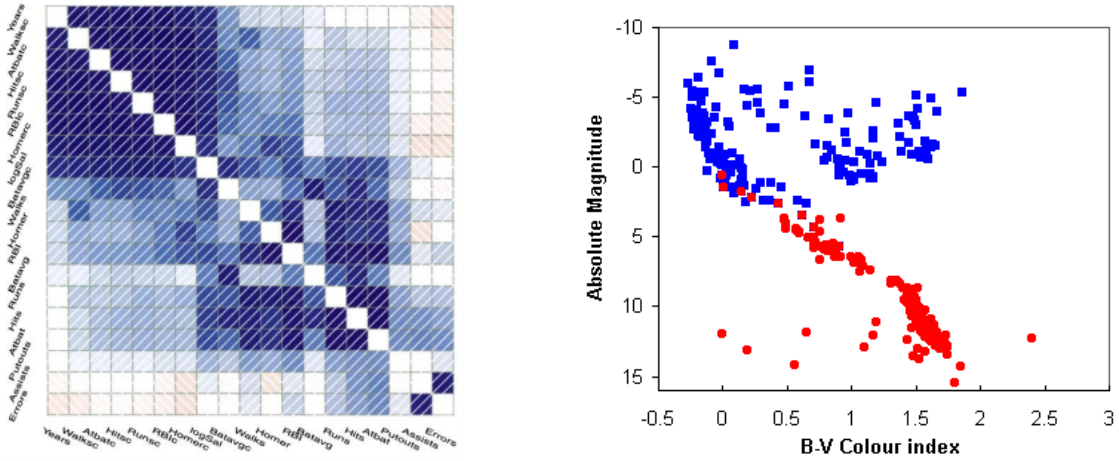
We notice that these visualization techniques discussed above are designed for binary relationships and we are not aware of a technique suitable for relationships whose degree of participation is higher than binary at the time of this writing.

Evaluation of the effectiveness of visualization techniques. Authors of [13] propose evaluation strategies for the effectiveness of visualization techniques. One approach is to solicit feedback from users in the form



(a) Circular layout (b) Kandinski layout (c) Podevsef layout

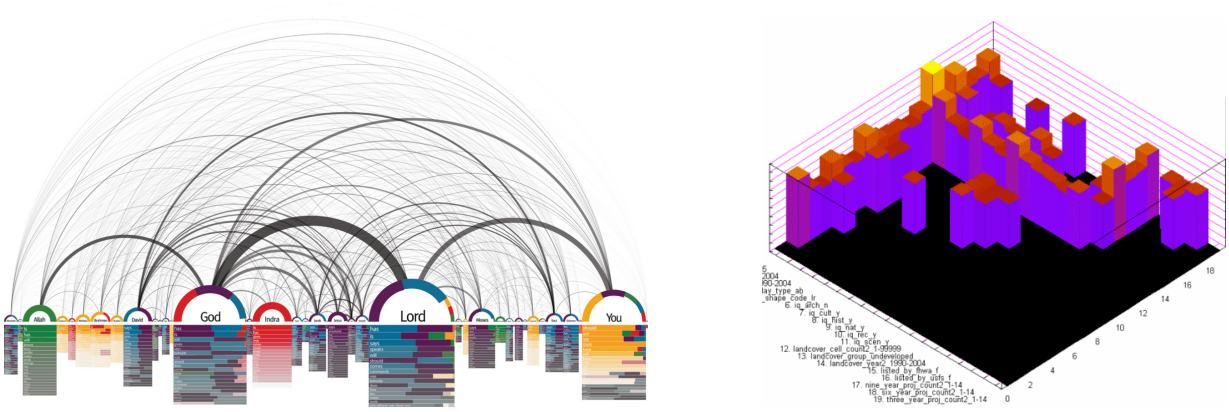
Figure 3: Various approaches to visualization of relationships using a single set of objects [14]. Objects are arranged along the circumference of the base circle (a) or along a single linear axis (b), or they can appear anywhere in the given visual area (c).



(a) 2-D visualization of the performance correlation between baseball players. The strength of a correlation is expressed by the intensity of color shade. [16]

(b) Hertzsprung–Russell diagram is a scatter plot of stars showing their relationships in terms of temperature and luminosity. (http://www.jb.man.ac.uk/distance/life/sample/stars/)

Figure 4: Matrix-like plots for visualization of relationships using two sets of entities.



(a) "A visualization of the similarities and differences between the holy books of five world religions: Christianity, Islam, Hinduism, Buddhism, and Judaism." [17]

(b) The significance of a relationship is represented by the height of the relationship as well as the color of the top surface as a 3-D bar graph.

Figure 5: Line thickness, color and object height are commonly used visual cues for the magnitude of interval and ratio values.

of qualitative interviews and quantitative usage statistics collected from the access log of the tool. Another approach is a more formal user study in which they found that visualization-based instructions help the

workers complete the assembly task 35% faster with fewer errors than traditional instructions.

3 2-D Visualization of Many-to-Many Relationships

In this section, we first compare the three 2-D strategies presented in [14]. The three approaches use a single set of objects. Our motivation is to see their suitability for the visualization of many-to-many relationships.

Data set. For an experiment of the visualization of relationships, we use a social network analysis data set that we generated from the book of Genesis in the Bible. The analysis was aimed at analyzing the interpersonal interactions in the book. There are 402 persons appearing in 1,064 interaction events in the book. The result of the analysis comprises 1,230 binary relationships and 225 maximal interactions. A maximal interaction in this study is defined as an interaction which is not contained in another interaction.

In this study, all the relationships belong to the same domain, namely *interpersonal interactions*. They have two attributes: degree of participation, ranging from 2 to 11, and significance of appearance, ranging between 0.0 and 1.0. The relationship in this data set is undirectional.

3.1 2-D Kandinski Layout

The objects are arranged on the single linear axis in the Kandinski layout illustrated in Figure 3b. The ordering of the objects is domain-specific. They can be arranged in the lexicographical order of the object labels. When the objects are associated with an ordinal quantity, such as rank or weight, they can be ordered according to the quantity. We can easily see that there are n-th factorial number of different arrangements of n objects and that a different ordering of objects will yield a different visual impression from the same set of relationships.

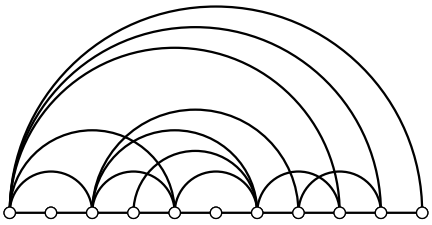


Figure 6: A variation of Kandinski shown in Fig. 3b where all the arcs are rendered only on the northern hemisphere of the axis.

The arrangement of arc between objects in the Kandinski figure is arguably arbitrary. Some arcs are arranged on the northern hemisphere while some others are on the southern hemisphere primarily for the purpose of the most comfortable visual effect. This approach may be prone to misinterpretation of the arcs. Viewers may mistakingly interpret the northern arcs may be superior to the ones on the south or vice versa.

Arcs can be rendered on a particular side of the axis for a specific purpose if relationships are associated with a bipolar attribute such as male or female and friendly or antagonistic.

As noted in Section 2, the three common layouts for a single set of objects shown in Figure 3 are *isomorphic*. In fact, the variation of Kandinski shown in Figure 6 is also isomorphic to the layout shown in Figure 3b. The benefit of this variation is to avoid the probability of misinterpretation of the arcs by the fact that the objects appear on a particular side of the axis.

Based on this observation, we generated Figure 7 using the Kandinski layout for the 1,230 binary relationships from the 1,064 interaction events in the book of Genesis. The objects (persons) are arranged in the order of name. The statistical significance of an interaction is encoded using the red-orange-yellow-green-blue-gray color scheme with red being the most significant level. With this configuration, it is relatively clear that Abraham has higher interaction with God, Isaac, Sarah and Lot than other associates. God has distinctively higher interaction with Abraham than with anyone else, followed by Joseph. Most other relationships rendered in gray are equally insignificant in terms of occurrence frequency.

One drawback of Kandinski is that viewers may interpret incorrectly that a relationship of a larger arc may be more significant than the arcs of smaller radius. However, the significance of a relationship cannot be expressed by means of the radius or height of the arc. Hence, if the relationship is not boolean, a visual cue, such as thickness or color, must be carefully designed to represent different significance. Note that Figure 5a uses thickness for the significance of an arc. We opt out this option for color because thick arcs tend to mask thin arcs especially as the number of arcs grows large.

The figure is generated using the TikZ library from a script produced by a tool developed in-house.

3.2 2-D Podevsef Layout

We experiment the same interaction relationships using the Podevsef layout. In this layout, objects are laid out freely anywhere in the visual space. However, the common objective is to spread the objects in a "desirable" order to minimize the link distance and node collision. One practical implementation of this layout is found in the Sankey plugin (`https://bost.ocks.org/mike/sankey/`) of the d3.js library.

Figure 8 shows the interaction relationships as a Sankey diagram. The algorithm built in the library has chosen to place 5 objects as middle layer nodes between the node on the left and the nodes on the right. We can see the interactions between a pair of persons by the link between them and the significance of the interaction by the width of the 'cable ribbon'-shaped

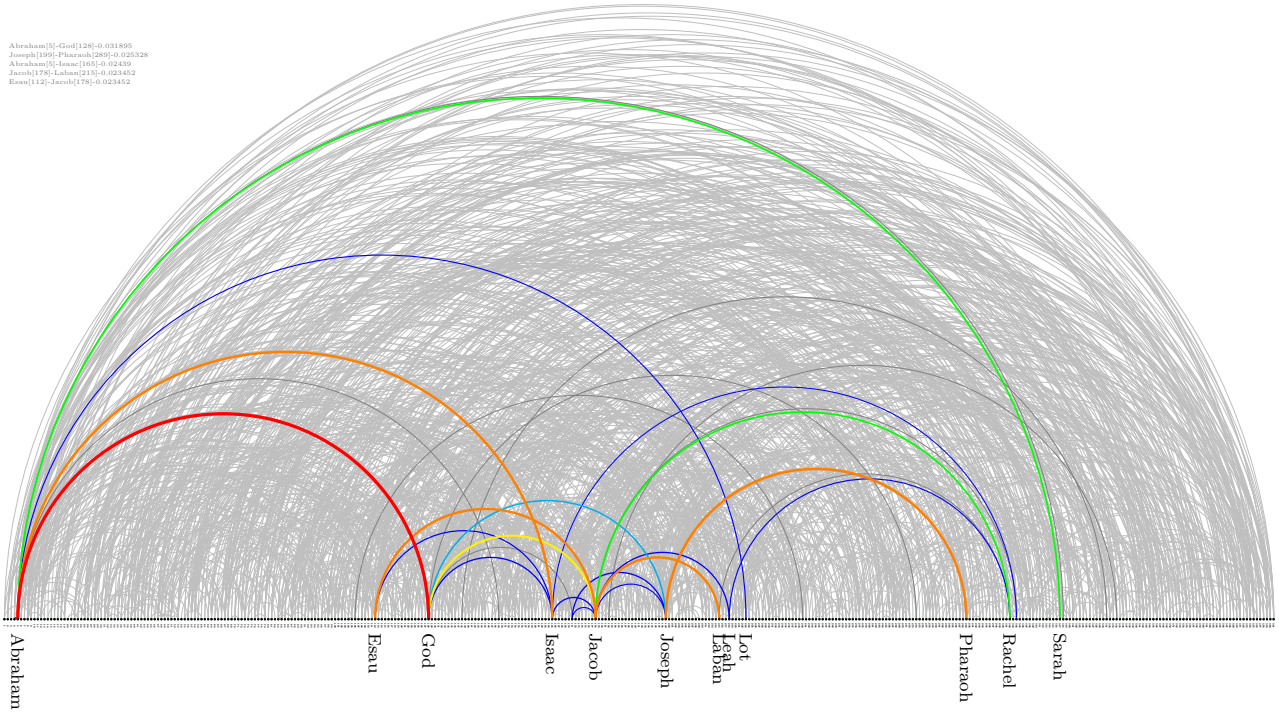

Figure 7: Interpersonal interactions among the 402 persons found in the book of Genesis, shown in Kandinski layout

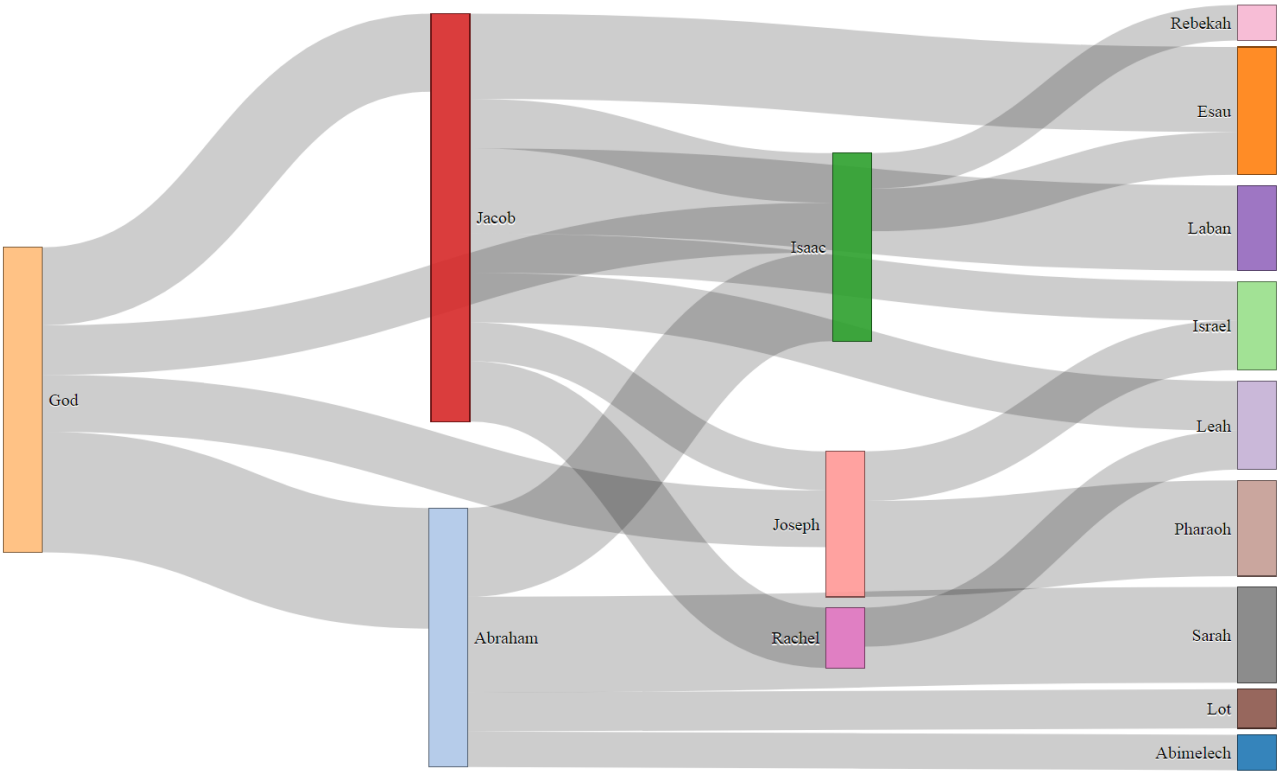

Figure 8: Interpersonal interactions among the 402 persons found in the book of Genesis, shown as a Sankey graph

link.

Note that Sankey graphs are generally used to visualize the flow of communication between the nodes, usually from left to right. Its application as a Podevsef layout should be used with care. Undirectional interactions are rendered on both sides of an internal node. Therefore, the cumulative total interactions of a person in the figure should be obtained by adding the width of every ribbon on both sides of a node. With this constraint, the Sankey visualization shows the dominating person-to-person interactions and the dominating persons in the interaction events.

We have observed that the Sankey cannot handle over 1,230 binary relationships of 406 objects effectively. The result was nearly unreadable, defeating the primary motivation of visualization, "a picture is worth a thousand words." Because of this scalability issue, it is mainly used with a small number of selected objects.

3.3 2-D Circular Layout

One way to avoid the potential visual bias caused by the orientation of the edges observed in Kandinski and Podevsef layouts is to place all the objects on the equal ground without the orientation of left and right and all the edges on the same side of the visual space. This idea is implemented using the circular layout (Fig. 3a).

In circular layout, the nodes are nominal, but not ordinal. There is no notion of left-end or right-end. There is no beginning nor end. Nodes may be placed in a random order or in the lexicographical order for the merit of object search visually. Edges are rendered within the disc.

In our approach, objects are arranged by alphabetical order of the object label. The significance of a relationship is represented by the color of the corresponding edge. The length of an edge is irrelevant. Using this configuration, we generated Figure 9 from the same interaction events found in the book of Genesis.

Circular layout exhibits the similar advantages and disadvantages of the Kandinski layout. However, a distinctive advantage of the circular layout over Kandinski is that it uses a twice larger area than Kandinski to present the same number of edges when both layouts use the diameter of the same length. Another advantage is that the circumference of a disc is 3.14 times longer than the diameter. Hence, the objects on a circular layout are 3.14 times more spaced out than the objects on the Kandinski axis. These differences generally make the circular layout more preferred.

We have presented thus far the visualization of binary relationships only using the three 2-D layouts that are commonly used. For the visualization of k-relationships where k is 3 or larger, we first propose a geometric shape which is suitable for such a purpose since we are not aware of any one in the literature. Recall that the ternary relationship (A, B, C) is not a valid logical consequence of three binary relationships $(A, B), (B, C)$, and (A, C). Suppose, for example, that $\{(A, B), (B, C), (A, C)\}$ is a set of co-authorship relationships. It does not necessarily mean A, B, and C publish an article together. For this reason, we opt out the traditional approach which connects a pair of related objects by a line.

4 A Geometric Shape for Many-to-Many Relationships

We now present a discussion on our strategy for the visualization of ternary or higher-degree relationships. The heart of the visualization of higher-degree relationships is to design a visualization primitive suitable for the purpose. The primitive should not only be capable of rendering k-relationships ($k \geq 3$) accurately, but it must also guarantee to prevent the visualized relationship from being interpreted incorrectly for any degrees less than k. In our presentation of the geometric shape, we assume that objects are arranged along the circumference of a circle using the circular layout for its advantages discussed in the previous section.

4.1 k-Relationships as Hyperedges

In developing an effective visual metaphor for k-relationships where k can be a reasonably large integer value, we investigated several geometric shapes as options. In particular, we have considered three approaches to the design of hyperedges.

The first approach is to connect the constituent objects to the center point of the objects with k lines for k-relationships. An example of this approach is shown in Figure 10a. This approach is computationally efficient. Also, each hyperedge is thin and occupies less pixels on the screen than the other two approaches in the same figure. Hence, it offers more visual information on the screen than the others. However, it presents a challenge to identify the correct connecting center point of a relationship. When the number of relationships is large and the degrees of the relationships are diverse, the problem will become unbearable.

The next approach is to add a geometric surface to the hyperdge at the expense of incurring more computation and leaving less visual information space. In Figure 10b, we add to the edges a polygon which has k sides for k-relationships. The advantages of this approach is that higher-degree relationships can be visually recognized quicker and easier with the aid of the polygon surface and that it is relatively easy to implement. However, it has a considerable drawback: each hyperedge occupies a much larger area than the previous edge-only approach, leaving less amount of unoccupied pixels on the screen. Hypothetically, when the degree of a relationship is close to the maximum degree of participation, it is possible that the single hyperedge would block nearly the entire visualiza-

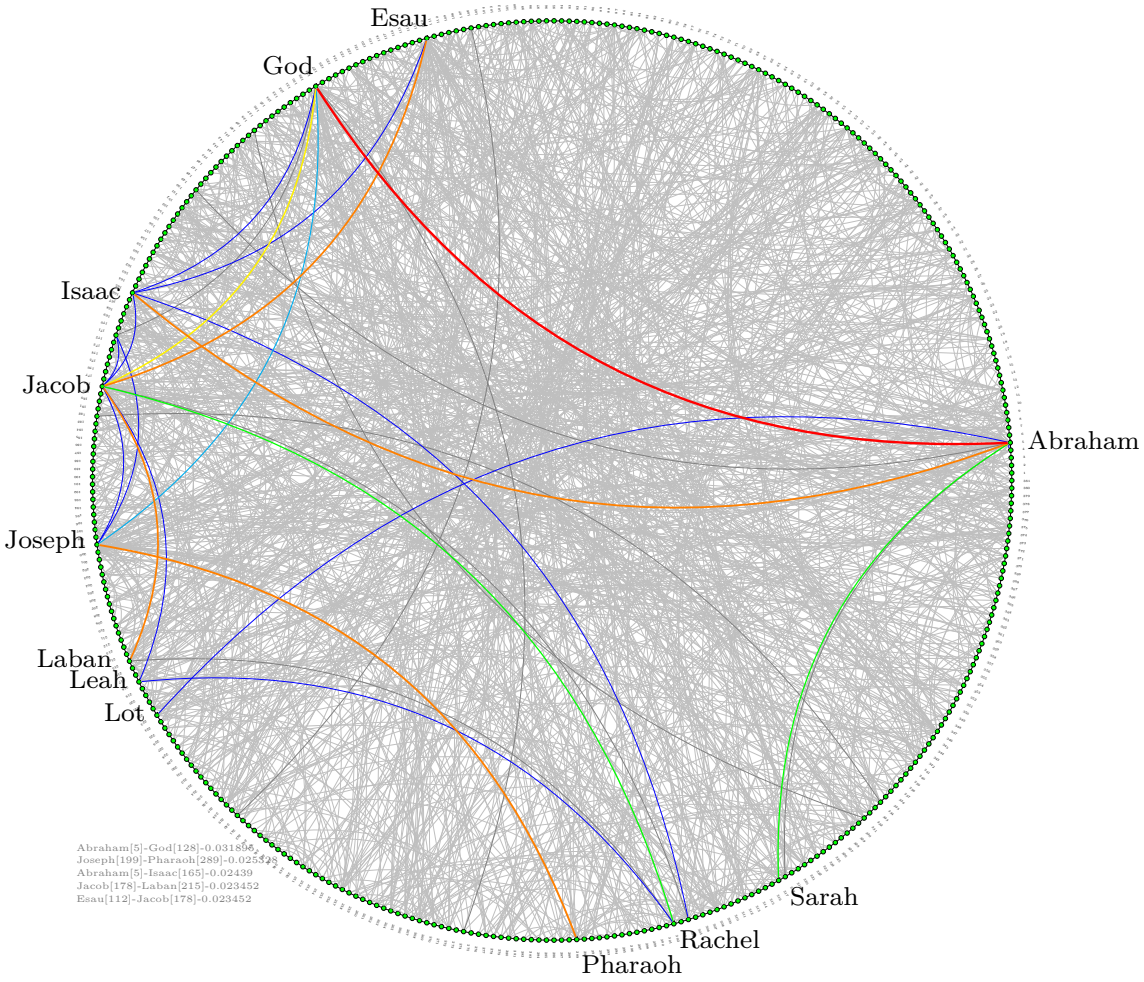

Figure 9: Interpersonal interactions among the 402 persons found in the book of Genesis, shown in circular layout.

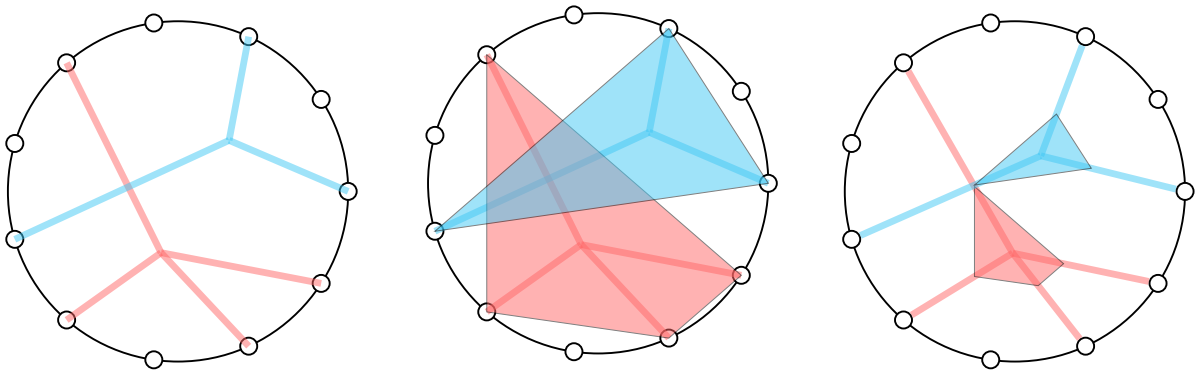

(a) A geometric shape with k legs only. (b) A geometric shape with k legs and a covering surface. (c) A geometric shape with k legs and a smaller covering surface.

Figure 10: A conceptual design of the hyperedge for the visualization of k-relationships where $k = 3$ and $k = 4$.

tion space (although such high-degree relationships are rare in real-world datasets).

Between these two approaches, we take the second approach, with a modification, mainly because of its strength in distinguishing relationships and their degrees.

The improvement that we made to the second hyperedge approach is three-fold: we use smaller hyperedge covers as illustrated in Figure 10c, use concave sides for the polygon surface to further reduce the amount of pixels to use, and spherical edges are used so that the proposed hyperedges may be used in a 3-D visualization as well.

For an example of a hyperedge connecting 3 objects, we can employ a *hyperbolic triangle* that can be found in hyperbolic geometry. The characteris-

tics of a hyperbolic triangles are well studied in a 2-D space. However, extending the theory of hyperbolic triangles to a higher-dimensional geometric shape for the purpose of implementation requires substantially more effort. The novelty of our work in implementing spherical edges and accompanying concave-sided polygon surfaces is to use Bezier curves as discussed below.

4.2 Geometry of hyperedges

As discussed earlier, the proposed hyperedge primitive has edges (we call them "legs") and a cover that is well suited in a 3-D metaphor. A k-ary hyperedge has k legs plus a 3-D surface covering the midpoint of the legs to make it easier to identify the degree of the underlying relationship and to augment the 3-D look of the hyperedge. In designing and implementing such hyperedges, we ought to maximize the separation of hyperedges from each other for effective data analysis. We begin with the construction of legs.

Each k-relationship is first mapped to a k-ary hyperedge of k legs, each of which is a *second-order (quadratic) Bezier curve* standing vertically. A quadratic Bezier curve requires three control points to define, i.e., two line segments between the first and second points and between the second and the third points. Given the three control points p_0, p_1 and p_2, the quadratic Bezier curve is defined as a function of the parameter $t \in [0,1]$:

Definition 4.1 (Second-order Bezier Curve)

$$B(t) = (1-t)^2 \cdot p_0 + 2t(1-t) \cdot p_1 + t^2 \cdot p_2$$

where t denotes a curve segment.

The polynomial expressed in second-order Bezier curves can be approximated by the following repeated steps:

1. Start with a line segment L_1 connecting p_0 and p_1 and another line segment L_2 between p_1 and p_2.
2. Place a marker M_1 along L_1 at distance t from p_0 and another marker M_2 along L_2 at the same distance from p_1.
3. Draw a line L between M_1 and M_2, and place a marker at distance t from M_1. Emit the marker as a point on the Bezier curve.
4. Repeat the steps with respect to the next value of t.

Notice that the finer the line segments (controlled by the division of t), the smoother the resulting curve will be as illustrated in Figure 11. Since the calculation of the emitting point take a constant amount of time, the time complexity of drawing a second-order Bezier curve is proportional to the number of the curve segments s, i.e., $O(s)$.

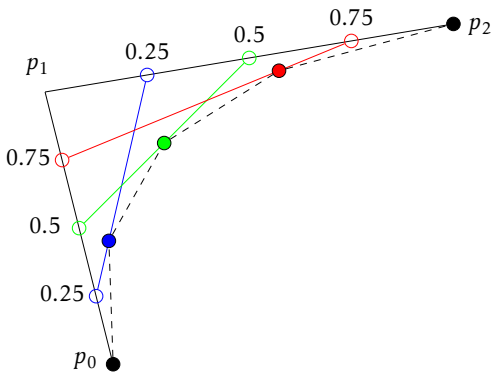

Figure 11: The effect of the number of curve segments on the Bezier curve generated from p_0 and p_2 with a control point p_1 in between. With 4 line segments at the interval of 0.25, the Bezier curve is approximated by the three interpolated points (in blue, green and red) plus p_0 and p_2, resulting in the coarse dashed curve.

Construction of hyperedge. Adapting the quadratic Bezier curve, we construct hyperedges as follows: Let I be a k-relationship comprising k objects, i_1, ..., i_k, which are located on the circumference of a circle in the circular layout, and let p_m be the center point of the k objects on the x-z plane. Then, we can construct the hyperedge for the k-relationship as follows: First, take i_1 as p_0 of the corresponding quadratic Bezier curve. We can compute the location of p_2 such that p_2 is the opposite point of p_0 on the circle about p_m. Furthermore, set the y-axis value (i.e., the height) of p_m to the statistical significance value of I. Now we can create a quadratic Bezier curve using the three control points p_0, p_m and p_2. Take the half of the curve on the p_0 side as the component curve for i_1. Repeat the steps to construct the other $k-1$ component curves from the other $k-1$ objects of I. The resulting hyperedge is generated by joining the k component curves at their peak point (located at the same x–y coordinate with p_m). Figure 12 shows how six half-length Bezier curves join at the crest in a 3-D space. The resulting hyperedge is parabolic-shaped, and its height is scaled by the statistical significance of the corresponding k-relationship automatically. The hyperedge is further decorated with a concave-sided polygon cover over the peak point for visual clarity.

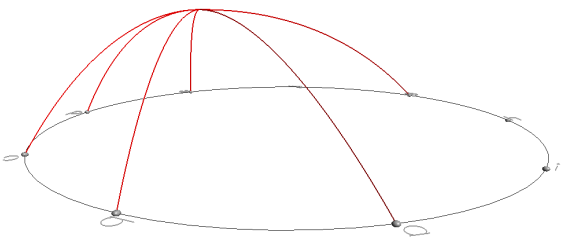

Figure 12: An hyperedge of 6 legs, each of which is a half-length second-order Bezier curve.

Figure 13a shows examples of hyperedge imple-

mentations for 3-, 4-, 5-, 6- and 7-relationships. Hyperedges for 3-relationships are constructed from three Bezier curve components with a cover at the joining point of the component curves as shown in the figure. The figure also illustrates that relationships of higher degree can also be constructed seamlessly using the same algorithm. Notice also in Figure 13c that each side of the polygon cover of a hyperedge is also a Bezier curve, the exact shape of which is determined by the locations of the control points.

The length of the portion of a leg which is not covered by the corresponding cover is about 50% of the leg length (measured from the bottom to the peak) by default. If the coverage ratio is larger, it tends to be easier to inspect the corresponding relationship visually, and visual ambiguity is reduced. However, it can easily mask other hyperedges at the same time. This ratio can be dynamically adjusted for maximum visual effect in our implementation. We found that the coverage ratio of 20% yields good visual feedback, while not dominantly masking other hyperedges. Once the location of each vertex of the hyperedge cover is determined on a leg, every pair of adjacent vertices (on two neighboring legs) and the peak point of the hyperedge are used as the three control points to generate the final hyperedge cover between the two legs.

Time complexity of hyperedge. As discussed earlier in this section, the time complexity of the construction of a second-order Bezier curve is $O(s)$, where s denotes the number of curve segments. Hence, the time complexity of the construction of a hyperedge with k legs without the cover is $O(ks)$. Each hyperedge with k legs has $k-1$ cover segments between a pair of legs. Each cover segment costs additional $O(s)$ operation when we use the same level of smoothness for each Bezier curve. Hence, adding the cover to the hyperedge will cost additional $O(ks)$, and the total time complexity of a hyperedge with k legs and a cover is $O(ks)$. From this analysis, we conclude that the overall complexity of the visualization of n relationships is $O(ksn)$.

Notice that the average value of k is relatively small in the real-world data when relationships obey the anti-monotone principle. In our implementation, n is the dominating factor for the scalability of the proposed approach. On the other hand, the capability of rendering a large number of relationships may bring an adversary effect, especially when the relationships are not evenly spaced out; that is, individual objects become less discernible. This issue is a system development issue and beyond the scope of this paper.

4.3 Visual cues

Visualization of relationships of arbitrary degrees would be challenging mainly due to the fact that the degrees of relationships can vary widely and the number of relationships, at least in theory, that are dealt with in data warehouses or in big data can be very large. Also, users may respond to the visual stimuli coming from a large number of visual primitives differently. For example, one user may be sensitive to variations in color but not in length, and vice versa. For these reasons, in designing a visual metaphor for relationships, we need to utilize visual cues to reinforce the meaning of each relationship in the context and to minimize any user-level distortion of the visual information.

For 3-D visualization of relationships, using multiple visual cues is generally more effective than using a single visual cue as long as they are used with consistency since viewers' responses to a particular visual cue may vary. In the proposed visualization primitive for k-relationships, multiple visual cues are used to maximize the discriminative power of the metaphors: shape, color, illumination, height, and thickness. These visual cues are demonstrated in the figures throughout this paper.

Relative location Since the peak point of each component Bezier curve of a hyperedge is a function of its associated control points, hyperedges tend to be spatially clustered when hyperedges are rendered on the same screen. For example, the four 6- and 7-relationships in Figure 13c form a clump. This tendency will increase toward the center of the screen as the degree of relationships increases (in other words, the distribution of the objects becomes more even on the base circle).

Color The hue of the legs representing a k-relationship r is determined by the statistical significance of the relationship using the following formula:

$$hue(r) = \frac{\max - weight(r)}{\max}$$

where max is the maximum significance in the dataset, and $weight(r)$ is the statistical significance of the corresponding relationship r. With this color scheme, the most significant legs are rendered in red and the least significant ones in blue, with yellow and green edges in between.

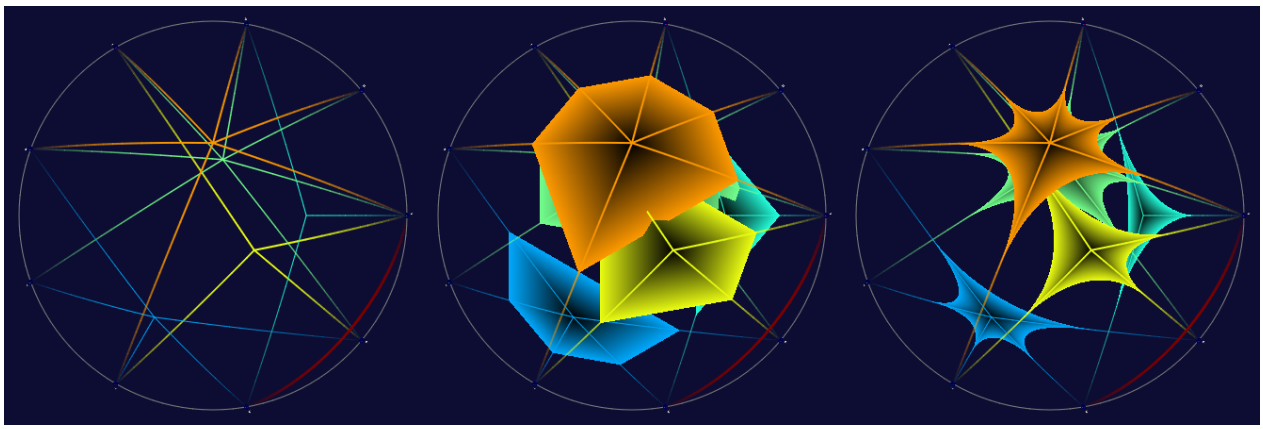
Illumination Shading is a natural phenomenon to real 3-D objects under illumination. We add a pseudo-shading effect to hyperedges to augment their 3-D look by applying varying illumination rather than uniform illumination.

The leg illumination is defined as a function of $t \in [0,1]$

$$illumination(t) = -\frac{(t-0.5)^2}{0.5^2} + 1$$

where t denotes a curve segment.

The above formula guarantees a leg to be the brightest at the vertex point (i.e., peak point) and gradually darker toward both end points, as illustrated in Figure 13.

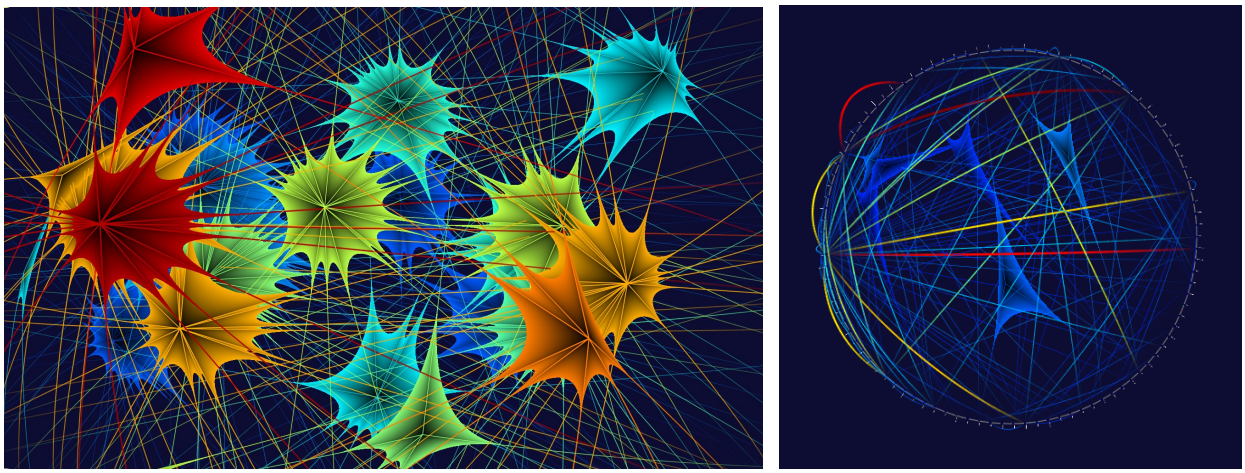


(a) Hyperedges with spherical edges only.

(b) Hyperedges with spherical edges and polygons with straight sides.

(c) Hyperedges with spherical edges and polygons with convex sides.

Figure 13: Implementation of hyperedges for 3-, 4-, 5-, 6- and 7-relationships.



(a) Hyperedges of various degrees and statistical significance from an artificial dataset. Each distinctive geometric shape with multiple visual cues help viewers visually inspect the overall and individual trend in the underlying relationships.

(b) Frequently co-occurring words in the first four books of the New Testament. The three outstanding ternary relationships are ("elders," "priests," "chief"), ("priests," "scribes," "chief"), and ("son," "man," "jesus").

Figure 14: Hyperedges rendered for artificial and real datasets.

Thickness The thickness of a leg is also proportional to the statistical significance of the corresponding relationship in our approach.

5 Implementation and Demonstration in Action

Implementation of the proposed visualization primitive. The proposed primitive is implemented in two different 3-D graphics programming environments, one in Java using the Java 3d library and the other in C using the C OpenGL library. Both libraries provide comparable 3-D graphics programming features. In our development, it took much longer time and effort to arrive at the current design from the idea of hyperbolic geometry than actual implementation.

Hyperedges in action. Figure 14a shows that highly significant relationships are in red and tall (over other hyperedges), whereas less significant ones are in blue and short. Note that the figure is generated from an artificial dataset to demonstrate the capability of the proposed visual primitive of various visual cues employed in our approach.

Figures 14b and 15 are generated using real-world datasets. Figure 14b shows frequently co-occurring words in the first four books of the New Testament. Overall, the visualization tells us that there are only a few word sets in which 3 or more words occur together at a statistically significant level. This is a natural phenomenon because frequently occurring words obey the principle of anti-monotone. In fact, among the 165 sets of co-occurring words with a minimum support of 0.35%, only ("elders," "priests," "chief"), ("priests," "scribes," "chief"), and ("son," "man," "je-

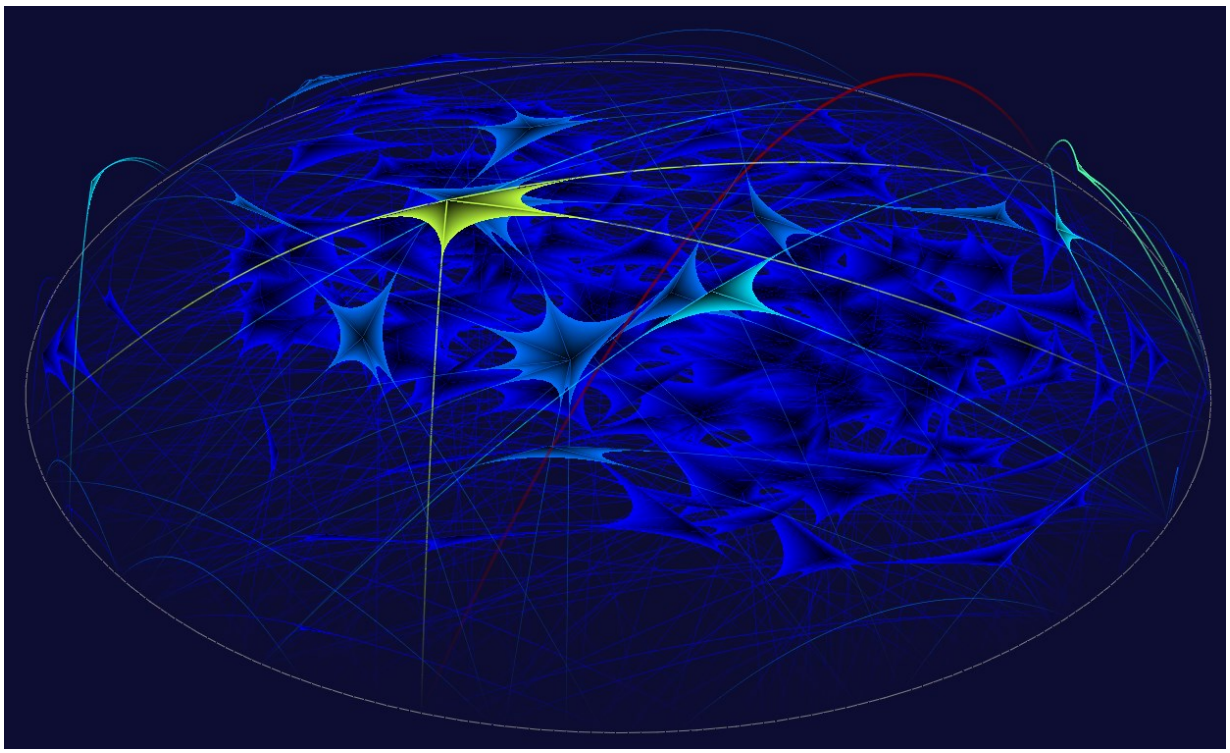


Figure 15: Interpersonal interactions found in the book of Genesis. The visualization shows that most interactions of more than 2 persons occur at a relatively low frequency. The binary interaction (God, Noah) shown in red is the most significant. The interactions between Noah and his three sons shown in yellow is one of the few outstanding interactions involving more than 2 persons.

sus") occurs more frequently than the threshold.

Figure 15 shows 402 persons along the circumference of the disc and the maximal interactions discovered from the book of Genesis. As these maximal interactions also obey the principle of anti-monotone, only a handful of relationships of higher degrees stand out in the visualization. The most significant relationship is the binary interaction between God and Noah (the red and tall arc). The most significant 4-relationship in yellow in the figure is between Noah and his three sons.

6 Conclusion

A 3-D visual metaphor for many-to-many relationships is presented in this paper. The proposed visualization primitive accurately conveys the degree of participation of a relationship with its statistical significance using multiple visual cues. Each relationship of ternary or higher degree of participation is modeled as a novel hyperedge having as many legs as the degree of the relationship and a cover at the junction point of the legs. The metaphor is implemented as visual primitives of high-quality graphical objects and shows a good separation of different degrees of participation.

The effectiveness of our model with respect to information communication is generally demonstrated through a handful of experiments in this paper. At the same time, we forewarn the reader that efficiency in terms of CPU cycles could be a concern in comparison to 2-D multivariate visualization techniques since we render information as high-quality 3-D objects. In the future, we plan to evaluate the effectiveness of the proposed visual primitive using quantitative usage statistics and a user study to assess how well our visualizations improve information processing, communication, and decision making as suggested in [13].

ABSTRACT

Recent task scheduling algorithms for a generalized workflow job in heterogeneous system adopt list-based scheduling. In those algorithms, the response time cannot be effectively reduced if the given workflow job is data-intensive. If the workflow job is computationally intensive, an attempt is made to assign tasks to many processors, which can lead to resource starvation. To this end, a task scheduling algorithm that is based on clustering tasks, called CMWSL (Clustering for Minimizing the Worst Schedule Length) has been proposed. In CMWSL, the lower bound of the assignment unit size for each processor is derived in order to suppress the total number of executing processors for effective use of processors. After the lower bound is derived, the processor as a assignment target is determined and then the assignment unit as a task cluster is generated. As a final phase of CMWSL, task ordering is performed for every assigned task. In this paper, we compare several task ordering methods in CMWSL in a real environment to find the best task ordering policy.

1 Introduction

Recent household computers have high-performance processing schemes, e.g., multi-core, hyper-threading technologies and so on. Such parallel processing schemes enable the expansion of conventional applications to scientific and large amount of data processing applications in household computers. This transition increases the needs for parallel and distributed processing schemes, e.g., grid computing[1], utility computing and cloud computing[2]. These computing models require an appropriate execution method to acquire the optimal value in terms of the response time or the schedule length, energy consumption, the economic cost and throughput. However, to obtain the optimal schedule length has been an *NP*-complete problem. In a heterogeneous system where each processing speed and communication bandwidth is arbitrary, a task assignment method as well as a task scheduling method are needed because the actual processing time and communication time are determined after each task is assigned to a processor.

In various application models, especially for work-flow type application, called Directed Acyclic Graph (DAG) is one of currently studied task scheduling fields, also known as a DAG scheduling problem. DAG scheduling is classified into two approaches, i.e., list-based scheduling[3, 4, 5, 6] and clustering-based task scheduling[7, 8, 9, 10, 11]. In HEFT (Heterogeneous Earliest Finish Time)[3], which is the most famous list scheduling for DAG applications in heterogeneous systems, a scheduling priority is assigned to each task by using the average processing time and the average communication time. Then each task is assigned to a processor by which its completion time is minimized. Though the critical part of a list scheduling is how to define the priority for ready tasks, list-based scheduling models such as HEFT, PEFT[4] and CEFT[5] apply averaged processing time and communication time for deriving a priority value for each task. As a result, a good schedule length cannot be obtained if the job is data-intensive or has a large dispersion among task sizes and data sizes. On the other hand, in task clustering for heterogeneous systems, each task belongs to a task cluster. Each task cluster is assigned to a processor and each task is scheduled in order to minimize the schedule length. Though a task clustering method is known as one of the promising methods in homogeneous systems, a good schedule length cannot be obtained in heterogeneous systems because it assumes a temporal homogeneous system for deriving each clustering priority.

We proposed a task clustering method for heterogeneous systems for effective use of processors in [12], the

https://dx.doi.org/10.25046/aj0203192

objective of which was to minimize the schedule length using a small number of processors. The method proposed in [12] firstly derives the lower bound of the total execution time of tasks in a cluster to regulate the number of processors. Then each task is clustered in order to minimize the schedule length by reducing the Worst Schedule Length (WSL). According to the literature in [13], minimizing WSL leads to the reduction of both the lower bound and the upper bound of the schedule length. Then each task is ordered by Ready Critical Path (RCP) scheduling[14] on each assigned processor. However, there is no criteria to minimize WSL in the task scheduling. In this paper, we propose a task scheduling to minimize WSL after the task clustering proposed in [12] has been finished. Experimental results in a real environment show that the proposed task scheduling outperforms the method in [12] in terms of the schedule length. This paper is an extension of work originally presented in the 19th International Conference on Advanced Communications Technology(ICACT2017)[15].

2 Assumed Model

2.1 Job Model

An assumed job is expressed as a Directed Acyclic Graph (DAG), which is known as workflow type job. Let $G = (V, E)$, where V is the set of tasks and E is the set of edges (data communications among tasks). An i-th task is denoted as n_i. Let $w(n_i)$ be the workload of n_i, i.e., $w(n_i)$ is the sum of unit times taken for being processed by the reference processor. We define the data dependency and direction of data transfer from n_i to n_j as $e_{i,j}$. And $c(e_{i,j})$ is the sum of unit times taken for transferring data from n_i to n_j over the reference communication link.

One constraint imposed by a DAG is that a task cannot be executed until all data from its predecessor tasks arrive. For instance, $e_{i,j}$ means that n_j cannot be started until the data from n_i arrives at the processor that executes n_j. And let $pred(n_i)$ be the set of immediate predecessors of n_i, and $suc(n_i)$ be the set of immediate successors of n_i. If $pred(n_i) = \emptyset$, n_i is called START task, and if $suc(n_i) = \emptyset$, n_i is called END task. If there are one or more paths from n_i to n_j, we denote such a relation as $n_i \prec n_j$.

2.2 System Model

We assume that each computer is completely connected to others, with non-identical processing speeds and non-identical communication bandwidths. The set of processors is expressed as $P = \{p_1, p_2, \ldots, p_n\}$ and let the set of processing speeds in p_i be α_i. As for data communication among computers, let the communication bandwidth of p_i be β_i. Since the actual communication speed depends on the bottleneck in the network path, suppose the communication speed is the minimum value in the two bandwidths among p_i and p_j, i.e., $L_{i,j} = min\{\beta_i, \beta_j\}$, where $L_{i,j}$ is the communication speed among p_i and p_j.

The processing time in the case that n_k is processed on p_i is defined as

$$t_p(n_k, \alpha_i) = w(n_k)/\alpha_i. \tag{1}$$

The data transfer time of $e_{k,l}$ over $\beta_{i,j}$ is defined as

$$t_c(e_{k,l}, L_{i,j}) = c(e_{k,l})/L_{i,j}. \tag{2}$$

This means that both processing time and data transfer time are not changed with time, and suppose that data transfer time within one computer is negligible. In general, the communication setup time for the preparation, denoted by O_k occurs before p_k sends the data. If $c(e_{i,j})$ is sent from p_k to p_l, the communication time is defined by O_k and the communication speed $L_{k,l}$; in particular, $L_{k,l} = \min\{\beta_k, \beta_l\}$ and the communication time is given by

$$t_c(e_{i,j}, L_{k,l}) = O_k + c(e_{i,j})/L_{k,l}. \tag{3}$$

We assume the communication setup time is negligible, i.e., $O_k = 0$ for $\forall p_k \in P$.

3 Related Work

In this section, we discuss existing methods for Directed Acyclic Graph (DAG) scheduling in heterogeneous systems. We also clarify their disadvantages when they are applied to systems with a large number of processors and when not all processors are used for execution. DAG scheduling for heterogeneous systems is categorized into two classes in terms of the task assignment policy: list-based heuristics [3, 4, 5, 16, 17] and task clustering [7, 8, 9, 10, 11].

For list-based heuristics, both HEFT[3] and Predict Earliest Finish Time (PEFT)[4] use the average processing time and average communication time to derive the scheduling priority for each free task whose predecessor tasks have been scheduled. According to the HEFT algorithm, the scheduling priority of task n_k is based on the path length from n_k to the END task, which is denoted by $rank_u^*(n_k)$ as follows:

$$\begin{aligned} rank_u^*(n_k) &= t_p(n_k, \alpha_i) + t_c(e_{k,l}, L_{i,j}) \\ &+ \max_{n_l \in suc(n_k)} \left\{ rank_u^*(n_l, \alpha_j) \right\}. \end{aligned} \tag{4}$$

In the set of free tasks, the task with the maximum $rank_u$ value is chosen and assigned to the processor to minimize the completion time of the task using an insertion-based policy. PEFT[4] uses an Optimistic Cost Table (OCT); the OCT value of task n_k assigned to p_p is the longest path from n_k to the END task in the set of paths starting from n_k, provided that each path length assumes the minimum length in the processor assignment combinations when n_k is assigned to p_p. The scheduling priority of n_k in PEFT is the average OCT value of n_k through all of the processors in P. One difference between HEFT and PEFT is whether the actual processor assignment is considered during the prioritizing phase. Another difference is that PEFT uses the average value. In Constrained Earliest Finish Time (CEFT)[5], the pruning phase is performed first. In the pruning phase, the longest path, called the Constrained Critical Path (CCP), which is derived from the average processing time and average communication time, is pruned from the DAG. Then, the pruned DAG is traversed, and the new CCP is pruned. Pruning continues until all of the tasks are pruned. Tasks in a CCP are assigned to the same processor

where their completion times are minimized. The Minimizing Schedule Length (MSL) algorithm[16] uses Mean Execution Time (MET) and Total Communication Time (TCT) for the scheduling priority derived by MET+TCT. They are calculated based on the average processing time and the average communication time. The Heterogeneous Selection Value (HSV) algorithm[17] derives $rank_u^*$ values for all processors for each task. Then the average $rank_u^*$ value is calculated as $hrank_u$. The scheduling priority in HSV is derived by the out degree times $hrank_u$, which reflects the idea that a task having larger out degree can have great effect on the schedule length. Since HEFT, PEFT, CEFT, MSL, and HSV use the average value calculated from all processor information, each scheduling priority is not accurate for minimizing the schedule length. Longest Dynamic Critical Path (LDCP)[6] uses the actual processing time and communication time for each scheduling priority and outperforms HEFT in terms of the schedule length. However, LDCP requires a set of DAGs for all processor assignment patterns, and thus, a high space complexity is required if the system has a large number of processors.

4 Overview of CMWSL Algorithm

In this section, we present an overview of the clustering-based task scheduling, called CMWSL (Clustering for Minimizing Worst Schedule Length)[12]. CMWSL consists of: (i) the lower bound of the total processing time is derived to the processor by which the maximum worst schedule length (defined as WSL (Worst Schedule Length) in Section 4.1) is obtained. (ii) several tasks on WSL path are clustered until the total processing time exceeds the lower bound in order to minimize WSL. (iii) the execution order for each task on a processor is decided according to the scheduling priority. In the following sections, the definition of WSL, the lower bound, the task clustering procedures, and the task ordering procedures are presented. For more details, see the literature in [12].

4.1 WSL (Worst Schedule Length)

Since CMWSL assumes WSL, we present the basics of WSL. Intuitively, WSL is the maximum execution path length when each task is executed as late as possible in a node, provided that there is no data waiting time for each task once the node starts executing; that is, WSL is the upper bound of the schedule length if no data waiting time occurs for each processor.

Fig. 1 shows an example of WSL derivation. In this figure, (a) is the state after four tasks have been clustered, (b) is the meaning for each items in (a), and (c) is the given system information, where three processors exist, i.e., p_1, p_2 and p_3. At (a), a virtual processor having the maximum processing speed (=4) and the maximum communication bandwidth (=4) is assumed to be assigned to a task. From this state, WSL is derived by $A \to C \to F \to E \to G \to H$, i.e., the longest execution path length is obtained when E is scheduled as late as possible on p_2.

If a processor assignment can make WSL smaller, both the upper bound and the lower bound of the actual schedule length can be made smaller[13]. The schedule length cannot be obtained until every task execution order is determined. Thus, at the task clustering phase as a task assignment, the objective is to minimize WSL, not to minimize the actual schedule length.

4.2 Lower Bound of Total Execution Time for each Processor

In general, the more tasks are assigned to a processor, the more data communications can be localized on one processor. However, to increase the number of assigned tasks on a processor can lead to the reduction of the degree of parallelism. The balance between localization of data communication and parallelism should be considered for minimizing the schedule length. Furthermore, imposing the lower bound can reduce the number of assigned processors, thereby effective use of computational resources can be achieved. In CMWSL, the lower bound of the total processing time on a processor p_p is defined as follows (for more details, see the literature in [12]):

$$\delta_{opt}(\alpha_p,\beta_p) = \sqrt{\frac{1}{\alpha_p}\left\{\varepsilon\lambda + \frac{w_{min}}{\alpha_p}\sum_{i=1}^{N}\sum_{n_k\in seq_{s-1}^{<}(i)} w(n_k)\right\}}, \quad (5)$$

where

$$\varepsilon = \sum_{n_k\in seq_{s-1}^{<}} w(n_k) - \sum_{i=1}^{N}\sum_{n_k\in seq_{s-1}^{<}(i)} w(n_k),$$
$$\lambda = \left(\frac{c_{max}}{\beta_p} - \frac{c_{max}}{\beta_{max}} + \frac{w_{min}}{\alpha_{max}} + \frac{c_{min}}{\beta_{max}}\right),$$

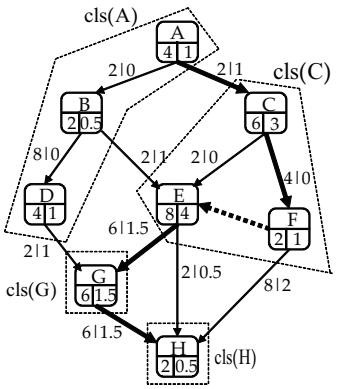
where $seq_{s-1}^{<}$ be the set of tasks in a path from a START task to the END task in the WSL sequence at the workflow after $(s-1)$ tasks have been clustered. In $seq_{s-1}^{<}$, let $seq_{s-1}^{<}(i)$ be the set of tasks that belong to the i-th cluster. In addition, c_{min} and c_{max} are the minimum and maximum data sizes in $seq_{s-1}^{<}$, and w_{min} is the minimum task size. Finally, α_{max} and β_{max} are the maximum processing speed and maximum communication bandwidth, respectively.

$\delta_{opt}(\alpha_p,\beta_p)$ means the value when the upper bound of WSL is minimized. That is, both the lower bound and the upper bound of the schedule length is minimized by applying $\delta_{opt}(\alpha_p,\beta_p)$ for each cluster.

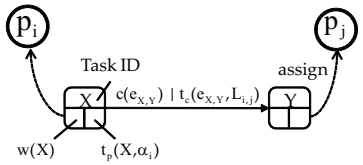
Next, we present how the processor to which an assignment unit (we call it as "cluster") is determined. CMWSL tries to find WSL path for each clustering procedure. On WSL path, there are two sub-paths, i.e., clustered path and unclustered path. Since tasks on a clustered path cannot be clustered anymore, the only set of tasks by which WSL can be varied is the unclustered path. Thus, on the unclustered path, the number of clusters whose total execution time exceeds δ (the variable for the lower bound), is defined as

$$N(\delta) = \frac{1}{\alpha_p\delta}\left(\sum_{n_k\in seq_{s-1}^{<}} w(n_k) - \sum_{i=1}^{N}\sum_{\substack{n_k\in seq_{s-1}^{<}(i),\\ cls_{s-1}(i)\notin UEX_{s-1}}} w(n_k)\right), \quad (6)$$

where $\delta = \delta(\alpha_p,\beta_p,G^s)$, G_s is the DAG after s tasks have been clustered, and $\alpha_p\delta$ is the task cluster size of p_p. $N(\delta)$



(a) State after 4 tasks have been clustered.



(b) Meanings of assigned values.

Task Cluster	Processor (p_i,α_i, β_i)
cls(A)	(p_1,4,2)
cls(C)	(p_2,2,4)
	(p_3,2,3)

(c) Processor Assignment at (a).

Figure 1: Example of WSL Derivation

is derived by taking the total workload of tasks on the unclustered path. Then, the increase of WSL by generating clusters by more r clustering steps on the unclustered path, is defined by

$$\begin{aligned} & \Delta WSL^*(M(G^{s+r})) \\ \leq & \sum_{i=1}^{N(\delta^*)-y} \Delta LV^{up}_{lnr}(cls_{s+r}(i)) + \sum_{i=N(\delta)-y+1}^{N(\delta)} \Delta LV^{up}_{nlnr}(cls_{s+r}(i)) \\ & + \sum_{\substack{e_{k,l} \in seq^{<}_{s-1}, \\ e_{k,l} \notin seq^{<}_{s+r}(i)}} \left(\frac{c(e_{k,l})}{L_{p,q}} - \frac{c(e_{k,l})}{\beta_{max}} \right) \\ \leq & \Delta WSL^*_{up}(M(G^{s+r})), \end{aligned} \tag{7}$$

where $\Delta LV^{up}_{lnr}(cls_{s+r}(i))$ is the increase of WSL by generating one linear cluster, i.e., all tasks in the cluster $cls_{s+r}(i)$ has dependencies each other. $\Delta LV^{up}_{nlnr}(cls_{s+r}(i))$ is the increase of WSL by generating one non-linear cluster, i.e., one or more tasks in the cluster $cls_{s+r}(i)$ has no dependency with others. $WSL^*_{up}(M(G^{s+r}))$ is the upper bound of the increase of WSL, i.e., $\Delta WSL^*(M(G^{s+r}))$. δ_{opt} in (5), it is obtained by differentiating $\Delta WSL^*_{up}(M(G^{s+r}))$ with respect to δ. Then $\Delta WSL^*_{up}(M(G^{s+r}))$ takes the local minimum value when δ equals to δ_{opt} defined at (5).

From the set of unassigned processors, the processor having the minimum value of $\Delta WSL^*_{up}(M(G^{s+r}))$ is selected as the next assigned target. In this phase, both the lower bound and the processor to be assigned to a cluster is determined.

4.3 Clustering Tasks

In the clustering phase, let the selected processor by the previous section be p_p. Then the actual lower bound, i.e., $\delta_{opt}(\alpha_p, \beta_p)$ is derived. The unclustered task on WSL path becomes the start point for clustering. From such a task, the successor tasks are included in the same cluster until the total processing time exceeds $\delta_{opt}(\alpha_p, \beta_p)$ in order to minimize WSL.

Fig. 2 shows an example of the task clustering phase in CMWSL. In this figure, (a) is the state after four tasks have been clustered, which is the same state as (a) at fig. 1. (b) in fig. 2 is the path on WSL path, i.e., A, C, E, G, H. In this path, the clustered path is $A \rightarrow C \rightarrow E$, and the unclustered path is $G \rightarrow H$. Thus, G becomes the start point for the next task clustering and p_3 is selected as the next assignment target, because only p_3 remained as the unassigned processor. From this state, the lower bound, i.e., $\delta_{opt}(\alpha_3, \beta_3) \approx 3.96$. Then at (c), G and H are clustered as a cluster $cls(G)$. Since the total processing time is 3+1 > 3.96, no more task are included at $cls(G)$. The clustering phase is finished if all clusters are generated with exceeding each lower bound.

5 Task Ordering

In this section, we present two list-based task ordering criteria in CMWSL. One of the objectives of this paper is to determine which one is better for minimizing the schedule length. Thus, the task ordering phase is performed after the task clustering phase presented in Section 4.3. In this phase, determining the actual execution order for each task is performed. Since the assigned processor for each task is known, the objective in this phase is to minimize the schedule length, not WSL. According to the literature in [18], a list-based task ordering method was proposed, where the task in the current WSL sequence is selected from the free list. Here, "free list" is the set of tasks, whose all immediate predecessor tasks have already been scheduled. We shall call the task ordering method as "List_maxLV". The fundamental idea behind List_maxLV is that the task in WSL

cls(G)	(p_3,2,3)

(d) Processor Assignment at (c).

Figure 2: Example of Task Clustering in CMWSL

sequence can have an effect on the worst schedule length, i.e., such a task can prolong the actual schedule length depending on the execution ordering. Thus, such a task must be scheduled as early as possible. The task ordering method in CMWSL is quite different. The task ordering in CMWSL selects the task having the minimum DRT (data ready time) from the free list. DRT of task n_j on p_q is defined as

$$DRT(n_j, p_q) = \max_{\substack{n_i \in pred(n_j),\\ p_p \in P}} \left\{ t_f(n_i, p_p) + t_c(c(e_{i,j}), L_{p,q}) \right\}, \quad (8)$$

where $t_f(n_i, p_p)$ is the finish time of n_i on p_p, and n_j on p_q is supposed to reveive the data from n_i on p_p. We shall call the ordering method as "List_minDRT".

Fig. 3 demonstrates behaviors of both List_minDRT and List_maxLV. In this figure, A, B, and C are supposed to have been already scheduled. Thus, the content of the free list is $\{E, F, G\}$. In List_minDRT, DRTs of E, F, G are supposed to be 14, 16, and 6, respectively. Then G, having the minimum DRT is selected for assigning an idle time slot. In List_maxLV, the priority is defined as "level", which is the longest execution path length when the task is scheduled as late as possible. In this case, level values of E, F, and G are supposed to be 24, 12, and 23, respectively. Thus, E is selected because its level value is the maximum.

6 Experiment

In this section, we present the comparison results in terms of the response time as the speed-up ratio in a realistic environment. The objective of this paper is to confirm the performance of CMWSL in the real environment for practical use of CMWSL, as well as which list-based task ordering policy is better in List_minDRT and List_maxLV. We adopt Gaussian Elimination DAG and FFT (First Fourier Transform) DAG as target DAGs.

6.1 Comparison Target

As for task ordering methods in CMWSL, we adopt List_minDRT and List_maxLV. We name List_minDRT in CMWSL as "CMWSL_DRT", and List_maxLV in CMWSL as "CMWSL_LV". As other comparison targets, HEFT[3], CEFT[5], HSV[17], and PEFT[4] are adopted, because these heuristic algorithms are known to derive a good schedule length with low time complexity, i.e., they are applicable in a real situation.

6.2 Gaussian Elimination DAG

In this comparison, we prepared 20 nodes that were connected in the local network as a heterogeneous cluster. Ta-

ble 1 presents the specifications of the environment in terms of processing and communication performance for Gaussian elimination DAGs. In this table, t_{proc} represents the time taken to process one arithmetic operation, and t_{comm} is the time taken to send one byte from the node to the router in the local network. In particular, t_{comm} was derived by $RTT/(\sharp\, of\ bytes * 2)$ of pinging.

As for the DAG structure, we consider one task as a second inner loop, i.e., **for**$(j = k + 1; j \leq N; j++)$ at the kji Gaussian elimination without pivoting. That is, the same as the one in Section 5.5.1. Fig. 4 presents one example of Gaussian elimination DAG at $N = 6$. According to the study in [19], the processing time of a task $n_{k,j}$ and the communication time of a data point $c(e_{(k,j),(k+1,m)})$ are defined as follows:

$$\begin{aligned} w(n_{k,j}) &= (2(N-k)+1)t_{proc}, \\ c(e_{(k,j),(k+1,m)}) &= O_p + (N-k+1)t_{com}, \end{aligned} \tag{9}$$

where O_p is the setup time of p_p performed before sending data, t_{proc} is the processing time for one arithmetic operation, and t_{com} is the communication time per byte. This model was proved to be asymptotic to a real environment[19]. Then, we can rewrite (9) using $t_c(n_{k,j}, \alpha_p)$ and $t_c(c(e_{(k,j),(k+1,m)}), L_{p,q}))$, as follows:

$$\begin{aligned} t_p(n_{k,j}, \alpha_p) &= \frac{(2(N-k)+1)t_{proc}}{\alpha_p}, \\ t_c(c(e_{(k,j),(k+1,m)}), L_{p,q}) &= O_p + (N-k+1)\frac{t_{com}}{L_{p,q}}, \end{aligned} \tag{10}$$

where t_{proc} and t_{comm} are the values obtained by the reference processor. α_p is the processing speed ratio when that of the reference processor is equal to one, and $L_{p,q}$ is the communication bandwidth ratio when the reference communication bandwidth is equal to one.

First, we executed the simulation using the information listed in Table 1.[1] We obtain the mapping of a task and a processor through the results of the simulation. Then, we implemented the parallelized MPI (MPICH2[20]) program with non-blocking communication in the C language by hand-coding each algorithm. For each algorithm, the program was executed 100 times, and we averaged the speed-

[1] O_p depends on many factors, including the program coding style and the processor status at the execution. This makes it difficult to specify O_p for each processor. We fixed the setup time O_p=0 in the simulation.

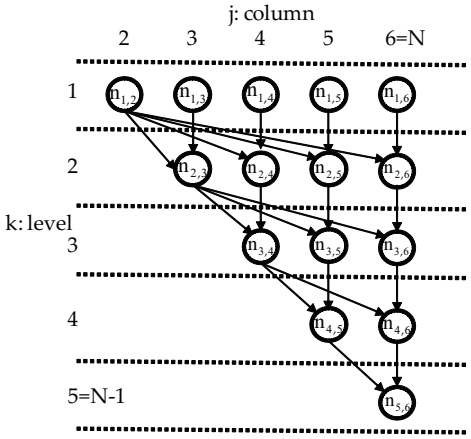

Figure 4: Gaussian Elimination DAG at $N = 6$.

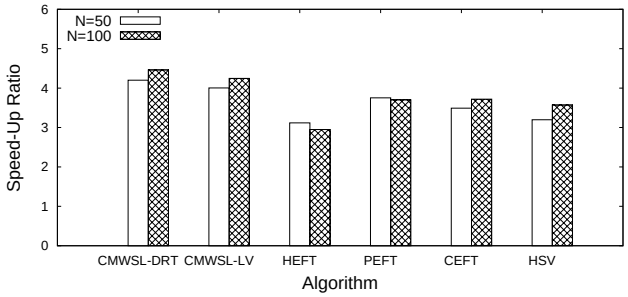

Figure 5: Comparison of Speed-Up Ratio for Gaussian Elimination DAGs in a Real Environment.

up ratio defined by the schedule length of "node 20" in Table 1, divided by that of each algorithm.

Fig. 5 presents the results in cases of $N = 50$ and $N = 100$. CMWSL-DRT and CMWSL-LV outperform the other algorithms in both cases ($N = 50$ and $N = 100$). We can see that PEFT, CEFT, and HSV output a smaller schedule length than HEFT. In the real environment, the setup time is nonzero for each processor, and therefore the communication time can have a greater effect on the schedule length than in the simulation. Even in such a case, both CMWSL-DRT and CMWSL-LV have a smaller schedule length than the other algorithms. As for the comparison between CMWSL-DRT and CMWSL-LV, it is observed that CMWSL-DRT outputs better speed-up ratio. In CMWSL-LV, a task, e.g., n_k by which WSL is obtained if it is scheduled as late as possible, is selected from the free list. However, even if n_k is selected, the actual schedule length cannot be made smaller if n_k is not a critical task, i.e., n_k does not belong to the actually dominating execution path in terms of the schedule length. In CMWSL-DRT, selecting a task having the minimum DRT can lead to the actual schedule length; that is, scheduling a task, e.g., n_k having the minimum possible start time can reduce the data waiting time from n_k. As a result, the total idle time for each processor can be suppressed.

6.3 FFT DAG

In FFT DAG, every task size is equal and every data size is equal. The FFT DAG used in this comparison contains $m \log m$ butterfly operation tasks, where m is the matrix size, as in Section 5.5.2. Each task contains the following operations:

$$\begin{aligned} y(k) &= y_e(k) + \omega^k * y_o(k), 0 \le k \le m/2 - 1, \\ y(k + m/2) &= y_e(k) - \omega^k * y_o(k), 0 \le k \le m/2 - 1, \end{aligned} \tag{11}$$

where y_e is the FFT of even points and y_o is the FFT of odd points. That is, every task involves the same number of operations. Although the data size among all tasks is the same, it contains both the real and imaginary parts as double type variables. Thus, we define each data size as 16 bytes.

Table 2 presents the specification of the environment in terms of processing and the communication performance for FFT DAGs. In this table, the "Task Size" is measured by executing (11) for each processor, while the "Data Size" is defined by multiplying t_{comm} from Table 1 by 16. From this information, α_p and β_p are derived for the simulation. Similar to the case of Gaussian elimination DAGs, we obtain the mapping of each task and each processor from the results of the algorithms in the simulation. Then, we implemented the parallelized MPI program with non-blocking communication in the C language.

Fig. 6 presents the comparison results in cases of $m = 128$ and $m = 256$, in terms of the speed-up ratio. In both cases, both CMWSL-DRT and CMWSL-LV outperform the other algorithms. However, the differences of the speed-up ratio between CMWSL (CMWSL-DRT and CMWSL-LV) and the other algorithms are not large compared with the case of Gaussian elimination, as seen in Fig. 5. As for the comparison between CMWSL-DRT and

Table 2: Specification of the Experimental Environment for FFT DAGs.

Node ♯	CPU Freq.	Task Size (μs)	α_p	Bandwidth	Data Size(μs)	β_p

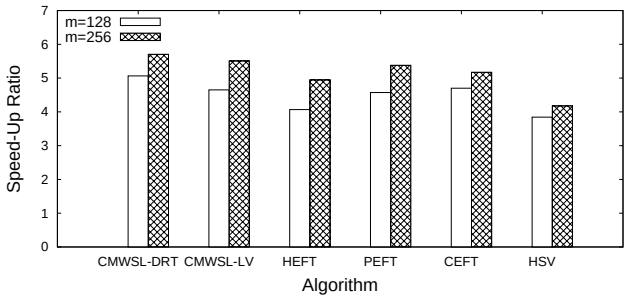

Figure 6: Comparison of Speed-Up Ratio for FFT DAGs in a Real Environment.

CMWSL-LV, CMWSL-DRT outputs better results in both cases ($m = 128, 256$). Similar to the result obtained in Section 6.2, selecting a task having the minimum possible start time can contribute to reduce the data waiting time for each processor. In general, the data size among tasks in FFT DAG is smaller than that in Gaussian Elimination DAG. This means that the effect of the communication delay is smaller in case of FFT DAG. Thus, the difference of schedule length among algorithms is also small.

From these results, we can infer that CMWSL can be applied to the FFT in a real environment.

7 Conclusion and Future Works

In this paper, we confirmed the performance and behaviors of CMWSL in a real environment using Gaussian Elimination and FFT program. According to the obtained results, CMWSL outperforms other list-based task scheduling algorithms in terms of the speed-up ratio, i.e., the schedule length. We also presented the comparison results among two task ordering methods, i.e., List_minDRT and List_maxLV for CMWSL. In CMWSL, List_minDRT was proved to output a better result than List_maxLV. That is, we can say that the task having the minimum possible start time should be selected for scheduling.

ABSTRACT

When two robot systems can share understanding using any agreed knowledge, within the constraints of the system's communication protocol, the approach may lead to a common improvement. This has persuaded numerous new research inquiries in human-robot collaboration. We have built up a framework prepared to do independent following and performing table-best protest object manipulation with humans and we have actualized two different activity models to trigger robot activities. The idea here is to explore collaborative systems and to build up a plan for them to work in a collaborative environment which has many benefits to a single more complex system. In the paper, two robots that cooperate among themselves are constructed. The participation linking the two robotic arms, the torque required and parameters are analyzed. Thus the purpose of this paper is to demonstrate a modular robot system which can serve as a base on aspects of robotics in collaborative robots using haptics.

1. Introduction

The Perception of robot motions is really important. In recent years, there has been in increasing interest in distributed robotic systems. In such a system, a task is not completed by a single robot but instead by a team of collaborating robots. Team members may exchange sensor information, may help each other to scale obstacles, or may collaborate to manipulate heavy objects. A team of robots has distinct advantages over single robots with respect to actuation as well as sensing. When manipulating or carrying large objects, the load can be distributed over several robots so that each robot can be built much smaller, lighter, and less expensive. As for sensing, a team of robots can perceive its environment from multiple disparate viewpoints. A single robot, on the other hand, can only sense its environment from a single viewpoint, even when it is equipped with a large array of different sensing modalities. There are many tasks for which distributed viewpoints are advantageous: surveillance, monitoring, demining, plume detection, etc.

The word "cobot". "Co" stands for "collaborative". We can find it in "co-working", "co-design", "co-development", and the list goes on. Work together, find better solutions together, and produce faster together. Here's the idea. Together. With new technologies coming up fast and better ways of communication, people and companies start to handle resources and skills in a better way. Make people work in open spaces, encourage them to interact with different background and culture individuals, try new flexible organization processes, are parts of this new collaborative mind. The idea is simple: work smarter together for better results. Cobots can have many roles — from autonomous robots capable of working together with humans in an office environment that can ask you for help, to industrial robots having their protective guards removed as they can react to a human presence under EN ISO 10218 or RSA BSR/T15.1.

Comparing the motions of a robot is very censorious activity. Elaborating some motions may be arduous as the operator should manage the overall motion; for example, these questions include: " The robots which are designed are with respect to the environment. Will the robot work with the same efficiency?", "Is

[*]Correponding author: Pawar Mansi Shailendrasingh, C-613, VIT University, Vellore,Tamil Nadu, India-632014, +91 9629773352, mansipawar29@gmail.com

the operator getting the same outcome?", "Are the motions of the robot constrained to specified trajectories?", "Will both the geometric specifications of the path as well as the velocity at which the robot traverses the path be followed?, "What are the control issues in the robotic control?" or "What are the fundamental problems in mobile robotics?"

When two robot systems can share understanding using any agreed knowledge, within the constraints of the system's communication protocol, the approach may lead to a common improvement. This has persuaded numerous new research inquiries in human-robot collaboration. We have build up a framework prepared to do independently following and performing table-best protest object manipulation with humans and we actualize two different activity models to trigger robot activities. The idea here is to explore collaborative systems and to build up a plan for them to work in a collaborative environment which has many benefits to a single more complex system. In the paper, two robots that cooperate among themselves are constructed. The participation linking the two robotic arms, the torque required and parameters are analyzed. Thus the purpose of this paper is to demonstrate a modular robot system which can serve as a base on aspects of robotics in collaborative robots using haptics. The primary aim is to design an actively articulated robotic arm and dynamically control its orientations i.e. yaw, pitch and roll using negative feedback to assure stability or the desired orientation at all times.

The collaborative robots seen so far are based on hard coding and are run with respect to each other. This barrier may create some issue during the interaction of the robot like if the time gives to robotic arm is different than the other after several cycles the robot will stop working in a synchronize mode and could create a problem. We are planning to an interactive platform that could create not only human-robot interaction as well as robot-robot interaction. This could reduce the barrier and could work in synchronized mode. Even we are able to make the system open source that it could be used by the college student and work on the background rather working on the fabrication part. We are using detailed simulation software only for the simulation, so the student could work on the developed CAD model to test the respective operation without direct using the provided hardware. This could reduce the risk of damage to the fabricated hardware.

2. Literature Review

In the previous paper [1], we had introduced how autonomous robots would benefit from improvements in haptic intelligence and overview of telerobotics systems. In the real world, we want robots to help to perform tasks in the remote environment. We have demonstrated the design and manufacture of a touch robotic arm that is inspired by a motive to increase efficiency. A multi-robot system can investigate an unknown domain speedier than a single robot system, even with the imperative of performing meeting to permit correspondence. In [2], the author has demonstrated the issue of how two heterogeneous robots can mastermind to meet in an obscure domain from obscure beginning areas. In [3], the author has ideated another approach for two-sided control in delta robot which has been proposed so as to lessen gravity impact [4]. In [5], [6], the author portrays the advancement of automated innovations that empower another vision of shared versatile assembling by groups of robots. In [7], the author. concentrates on the improvement and combination of the sensor arm used to convey a spectrometer from a multi-meter scale robot to centimeter scale rocks. The sensor arm joins off the rack equipment for movement control, activation, and detection. In [8], the author has tended to the inquiries of whether and when a robot ought to step up with regards to joint human-robot undertaking execution by contrasting three activity models with trigger robot activities: human-started help, robot-started receptive help, and robot started proactive offer assistance. In [8], [9], the author has clarified a review on participation between two master-slave modular robots in the paper. Kinematics of the system is contemplated. A tri-dimensional estimation arrangement of Optotrak 3020 is utilized to input the end position of the two robots. He tended to [9] the undertaking of organizing the movements of different controllers when either their directions or their ways are given. By exploiting a principal time scaling law for controllers in light of their elements, we distinguish adequate conditions for crash free coordination of the robots when the velocity profiles can be consistently time-scaled and the robot begins times can differ. [10] The demonstration of the transportation of numerous things to stations that make ask. The collaborative collection technique can outperform the individual accumulation strategy with up to 15.4% diminishment in maximum traveling cost. At that point [11] proposed scientific models for these surmisings in view of streamlining cost, attracting the similarity to the guideline of objective activity. In [12] and [13], the respective authors presented a robot control system which has been particularly intended for a subjective robot which offers space and undertaking with a human. The approach is productive in light of successful individual and collective abilities. In [14], the author looked into tactile sensing applications incapable robot hand control. The fundamental sorts of material sensors and their reconciliation with robot hands are discussed. Tactile data processing techniques and its applications are displayed.

3. Design

3.1. Specifications

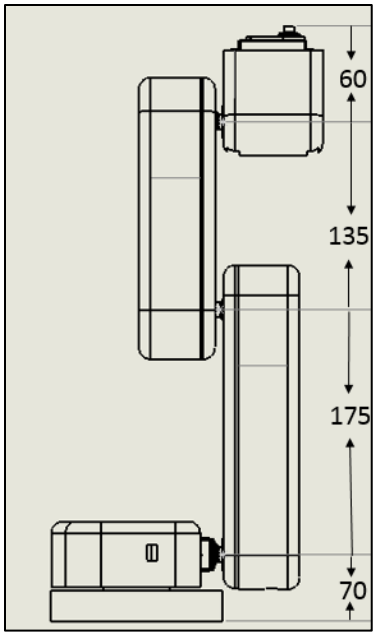

Figure 1: Robotic Arm Structure (dimensions in mm)

Table 1: Specifications of Robotic Arm

Sr. No.	*Parameters*	*Specification*
1	DOF	5 axes
2	L1	175mm
3	L2	135mm
4	L3	60mm
5	Height	440mm
6	Joint-1	180 degrees
7	Joint-2	180 degrees
8	Joint-3	180 degrees
9	Joint-4	180 degrees
10	Joint-5	180 degrees

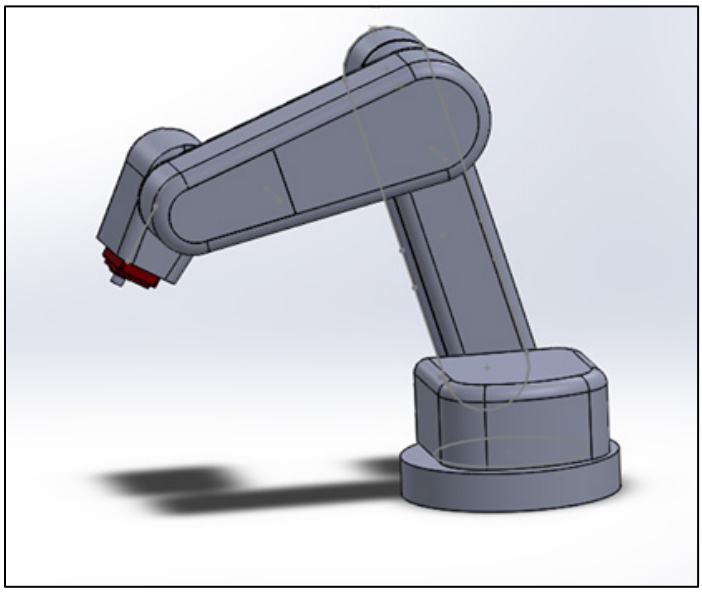

Figure 2: The redefined robot imported from the 3 D model into Solidworks model.

The aim was to build a collaborative robot system that could work with a single control unit. The primary aim was to develop a single system that could help the robot to communicate with each other and work together. There are five degrees of freedom (DOF) robotic arm. The entire robotic system was designed in Solidworks and manufactured using 3D printing process. The goal was to make the control system which could be easily operated and understood by the operator. A robot with the same dimension that is going to be manufactured is imported in the V-REP software. In this method, the robot is made to follow defined paths that are plotted using path planning function. The robot is programmed to follow the plotted path. Inverse kinematics helps the robot to follow the specified path. Individual joints calibrate their own angle and the end effector tries to reach the defined path. While following the path the robot joint angle values differ from joint to joint. Absolute joint values are obtained in V-REP during operation and even the XYZ values of the end effectors can be generated.

Figure 3: 3D printed Hardware model

4. Math

4.1. DH Parameters

The 5-DOF manipulator kinematic parameters are derived using Denavit Hartemberg formulation:

```
                % theta   d     a    alpha
L (1) = Link ([θ   70  -22.2  -pi/2     0]);
L (2) = Link ([θ  -70.0  175    pi      0]);
L (3) = Link ([θ  -4.0   135    0       0]);
L (4) = Link ([θ   0.1    60    pi/2    0]);
L (5) = Link ([θ   0.80    0    pi      0]);
L (6) = Link ([gripper    0]);
```

All measurements are in centimeters.

```
q0 =[0 -pi/3 -pi/3 pi/2 0 0 ];
```

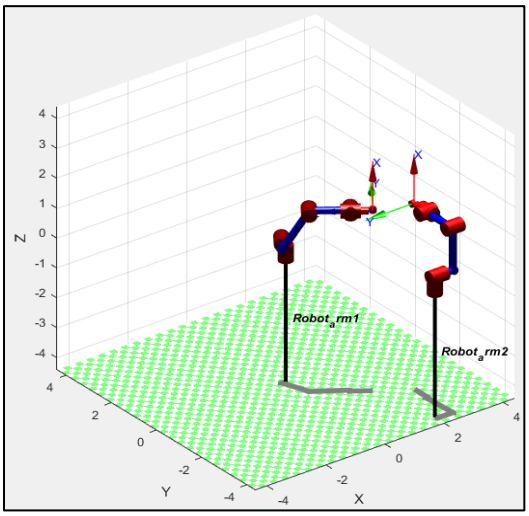

Figure 4: Sequential Robot movements of the Collaborative robotic arms for the required path.

The workspace of the end-effector relies on upon the physical furthest reaches of the five joints point, i.e. on the off chance that the point scope of the robotic arm joints is changed the workspace of the robot changes. So it is critical to consider the precision in deciding the edge scope of the robot joints to get the required workspace which covers the working range.

The general form of the Homogeneous Transformation Matrix is:

[cos(θ) -cos(a)*sin(θ) sin(α)*sin(θ) A*cos(θ)

sin(θ) cos(α)*cos(θ) -sin(α)*cos(θ) A*sin(θ)

0 sin(α) cos(α) d

0 0 0 1]

A1 = [1.0000 0 0 -22.2000

0 0.0000 1.0000 0

0 -1.0000 0.0000 70.0000

0 0 0 1.0000]

A2 = [0.5000 -0.8660 -0.0000 87.5000

-0.8660 -0.5000 -0.0000 -151.5544

0 0.0000 -1.0000 -70.0000

0 0 0 1.0000]

A3 = [0.5000 0.8660 0 67.5000

-0.8660 0.5000 0 -116.9134

0 0 1.0000 -4.0000

0 0 0 1.0000]

A4 = [0.0000 -0.0000 1.0000 0.0000

1.0000 0.0000 -0.0000 60.0000

0 1.0000 0.0000 0.1000

0 0 0 1.0000]

A5 =[1.0000 0 0 0

0 -1.0000 -0.0000 0

0 0.0000 -1.0000 0.8000

0 0 0 1.0000]

The link transformations matrix can be given as:

$^{0}T_{5}$ = A1*A2*A3*A4*A5

$^{0}T_{5}$= [0.0000 0.0000 -1.0000 201.0970

0 1.0000 0.0000 -66.1000

1.0000 -0.0000 0.0000 281.5501

0 0 0 1.0000]

4.2. Working

The flowchart representing the sequence of generating the CODE of the link transformations matrix is shown in Figure 5.

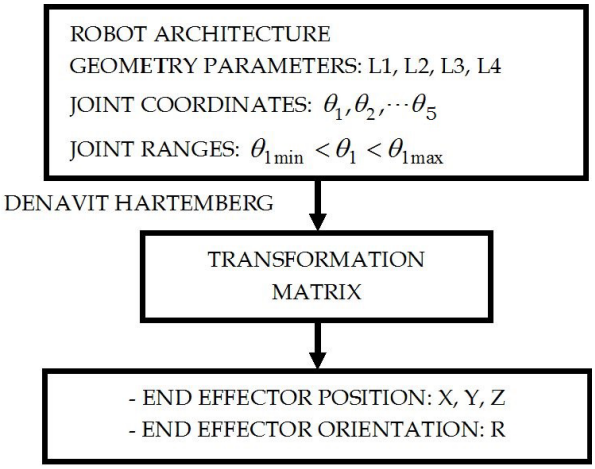

Figure 5: The flow chart of link transformation matrix.

There are four distinct strategies which are derived from figuring the direction arranging of the robot utilizing the code. The direction planning in the four techniques requires two parameters, specifically the joint point run and the last time required to finish the procedure. The first was chosen from the workspace expected to finish the procedure. For any situation, this subject to the sort of surgical applications and can without much of a stretch be distinguished. The final time needed is a vital parameter to determine the trajectory of the robotic arm. As every one of the outcomes that have been construed from the introduction, acceleration speed and torque of the robotic arm depend on this parameter. In the event that the time expands the speed needed declines and increasing speed i.e. the inertia of the arm connect therefore diminishes unintentionally regardless of the techniques utilized. The introduction must be seen precisely inspected and the conduct ought to increment step by step with the time from the underlying edge to the final point. The final time needed to finish the procedure for every technique ought to be improved and this is referred to as optimal planning. In this study, the trajectory planning has been derived and after that, correlation of the outcomes a particular joint is made. The best possible time which gives tasteful outcomes is obtained.

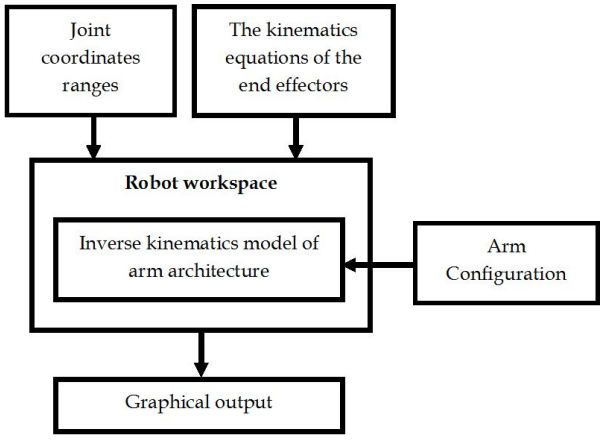

Figure 6: The flowchart for Robot workspace.

4.3. Electronics

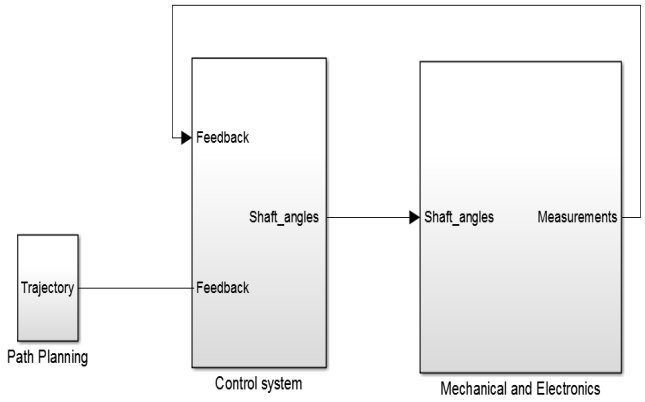

Figure 7: Simulink model of the Robot System.

These Simulink models are created in MATLAB using the robotics toolbox. The mechanical and electronic system contains the hardware as well as the electronics part. In this, the electronic components are the motors. The amount of rotation is given by the control system with the means of shaft angle. This shaft angle is provided by the robotics toolbox blocks. The motor tries to achieve the given shaft angle and provides the feedback to the control system. Then the control system provides the proper angle again reducing the error. The path planning is done and as shown in Figure 7 and the robot tries to move with respect to it. These types of feedback make the robot to easily achieve the respective position.

Figure 8: Coordination of Robotic arm in V-REP obatined from importing simulink model.

There are two lines appeared in the Figure 9. The blue one informs the movement of the end effector joint for the Robot arm 1 and the other line notifies the movement of Robot arm 2 regarding the z-axis. The movement of both the end effectors as for z-axis and time. The simulation done was the sample study of pick and place for corporative manipulators. As shown in the graph the robot one end effector moves with respect to z-axis move down practically to ground level. The robot tries to pick the object and remains there for 20 seconds. The robot picks the object and move to the upper level and move linearly in the XY plane. The robot achieves a specific position and the other robot arm which was very still going to a same position of the Robot arm1 yet the other robot is at a lower level to get the object and proceed with the cycle. As the robot arm1 drops the question from the gripper the haptic feedback recognizes the other robot and makes the other robot to get the object as the Robot arm 2 end effector is at a similar z-axis. The Robot arm 2 completes the movement. In this system, one robot arm communicates with the other robot arm with the sensing of the gripped object in the end effector as the object from the gripper tries to slip the other robot gripper tries to hold the object.

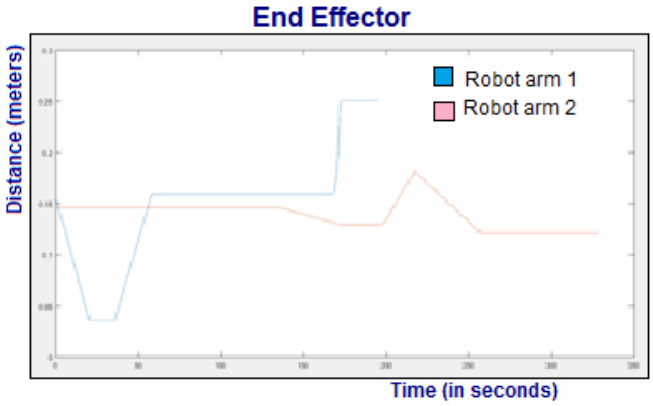

Figure 9: Position control of end effector with respect to z-axis. X axis is time in seconds and Y axis is distance in meters.

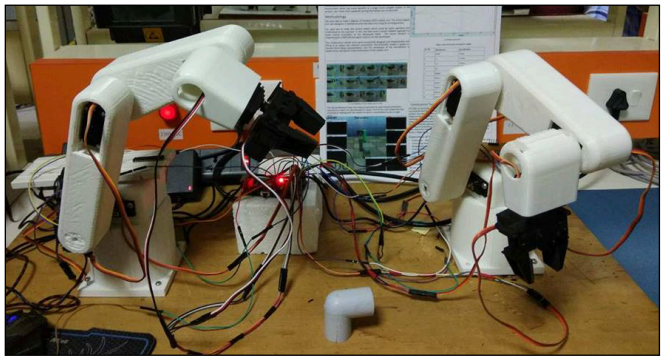

Figure 10: Hardware model of Robot System.

In order to conclude about the project execution, the project was carried out successfully and the desired output was obtained. Talking specifically about the project, the development of two robotic arms was successfully done and our main objective about making a single brain that could command both the arm was developed. Both the arms receive a command decently and behave as a single system.

4.4. Force Sensitive Resistor for Haptic Feedback

A force-sensing resistor is a material whose resistance changes when a force or pressure is applied. Figure 10 shows a demonstration of how to construct an Arduino-based pressure sensor that displays the measured pressure on a small LCD screen. With a minor adjustment to the code, one can just read the FSR values in the Arduino serial window. In that case, none of the LCD/potentiometer stuff is needed. Force Sensing Resistors (FSR) is a polymer thick film (PTF) device which exhibits a decrease in resistance with an increase in the force applied to the active surface. Its force sensitivity is optimized for use in human touch control of electronic devices. With a minor adjustment to the code, one can just read the FSR values in the Arduino serial window. In

that case, none of the LCD/potentiometers is needed. The Force Sensitive Resistor (FSR) with a sensing area of 0.5" diameter is attached to the gripper. The sensor uses a voltage divider. The FSRs get a 10k resistor, and the flex resistor gets a 22k resistor. The voltage divider works with the changing resistance of the sensors. When the resistance is higher for the variable resistor, there is a larger voltage drop across the variable resistor. The voltage dividers are supplied with +5V, and that drop in 5V is split between the two resistors. The Arduino measures the voltage between the resistors and returns value between 0 and 1023 based on the voltage reading (0 being 0V and 1023 being 5V).

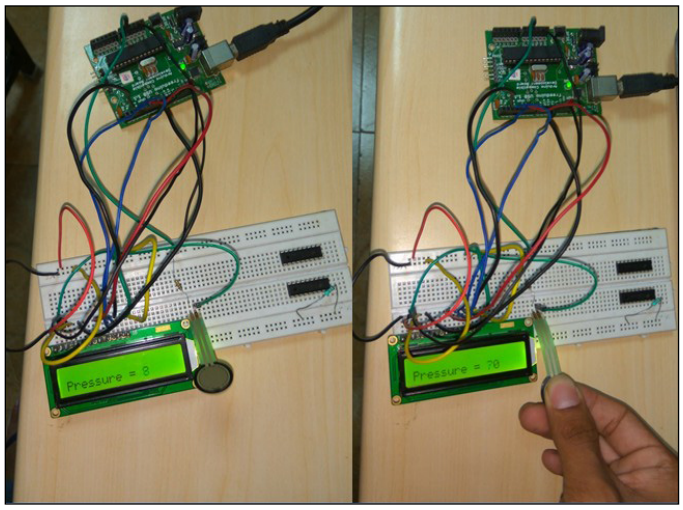

Figure 11: Display variance in pressure.

Figure 11 shows the interface of FSR with MATLAB. This figure demonstrates the calibration of a Force Sensitive Resistor (FSR) using the Arduino UNO board and MATLAB. Additionally, the UNO board logs real-time FSR data. The input and output data is as follows:

Force: [133g 175g 185g 250g 490g]

Voltage 1= [0.3955 1.0693 0.69 1.2793 1.330]

Voltage 2= [0.48 0.87 1.82 1.29 1.48]

Voltage 3= [0.65 0.94 1.015 1.15 1.41]

Average voltage= [0.5085 0.9597 1.048 1.406]

Therefore, plot between Force and Voltage:

Force_Xaxis= [133,175,183,250,490]

Voltage_Yaxis= [0.5085,0.9597,1.048,1.2397,1.406]

The Linear model Polynomial equation:

J(x) =Ax3+Bx2+Cx+D where, A=1.562x 10-7

B=-0.000152

C=0.04677

D=-3.391

5. Results and Discussion

Through the processes of conceptualization, design, assembly, and final coding, we were required to complete tasks ranging from needs assessment, static and dynamic load analyses, design for manufacturing, machining, troubleshooting, and finally microcontroller coding, to name but a few. Therefore following the earlier paper we studied human-machine interaction and works in a similar way as the body goes in specific direction or manner and shows sensation at the same time. The collaborative robotic arms were successfully designed and implemented and lifting of an object was attained successfully. The kinematic model is based on Denavit-Hartenberg representation and the workspace of the end-effector is explained by solving the inverse kinematics of the robotic arm. It plainly appeared in this work the best technique for trajectory planning that gives the smooth set trajectory planning and best execution of the robotic arms under examination was the delicate movement trajectory planning on the grounds that the most vital explanation behind this choice was the torque history that has the least number ever of shooting and the shooting was dispersed frequently over the timeframe, unlike alternate strategies which have a long number of shootings and were circulated arbitrarily.

The collaborative robotic arms are capable of handling various varieties of applications in mining, agriculture, and defense. It is a platform provision for various autonomous assignments in agriculture comprising cultivation, chemical spraying, and mowing. Because of its robustness, in the mining sector, the vehicle is operated to survey and map mines. As for military use, it can transport autonomously materials to support the soldiers. This paper also accentuates the synergy between the human operator and a robot and has various applications in healthcare, medicines, entertainment, education, graphic arts, the industry as well as space. A high level of precision was observed in the movement of the robotic arm due to the generation of accurate control signals for the servo motors. In collaboration with the visual display, haptics can be exploited by people for tasks involving hand-eye coordination, essentially Space-ship maneuvering, and Robotic Tele- Surgery. It can also be used for games in which you feel and at the same time see your Interactions with images. The information regarding the different touch forces supports the approximation of the contact accomplished by the

sensor mounted on the gripper and permit the experiencing the slipping of an object.

6. Future Work

The machine learning calculations enhance and different advances, for example, neuromorphic chips, empower more brilliant robots, we'll be seeing them do tasks that no one but people can do until now, with the exception of, by and large, they will have the capacity to improve. They will have the capacity to get to incomprehensible databases, perceive individuals, machines and parts, have the capacity to determine bits of knowledge and follow up on them. That implies that robots will soon have the capacity to do short work, as well as analyze issues and devise arrangements. They'll have the capacity to do schedule, highly monotonous work like the quality affirmation, assessing parts and completed items. Likewise, the cost of all that capacity will probably descend significantly as innovation advances and the cost of parts decreases.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to thank Dr. Vivekananda Shanmuganathan for his long-standing support of this work. We would also like to thank the Robotics Laboratory, of School of Mechanical Engineering and Vellore Institute of Technology University for providing scientific guidance, field expertise and excellent logistical support.

ABSTRACT

Education is the raising of the thinking process and developing the mind in a broader perspective. However, education that is comprehensive and appropriate to the individual according to its potential, ability and skill is too hardest to describe. Thus, matching and referral institutions, including education model that suits the person's behavior has been receiving attention. The purpose of this research is to study and develop the applications that support the development of the learner's education process with the highest degree of achievement. The material and method are consisting of five main processes, including 1) requirement definition, 2) system and software design, 3) implementation and unit testing, 4) integration and system testing, and 5) operation and maintenance. The data collection were collected from 431 samples, which divided into 4 targets; 186 high school students at Phadungnaree School, Maha Sarakham province, 191 university students at Rajabhat Mahasarakham University, 12 head of institutions at Phadungnaree School and Rajabhat Mahasarakham University, and 42 secondary teachers and university lecturers at Phadungnaree School and Rajabhat Mahasarakham University. According to the results of research, it is indicated that the total satisfaction toward the application are highest, which is equal to 4.32, and the groups with the highest levels of satisfaction are university students, which is equal to 4.43. It can be concluded that the application is appropriate and it is advisable for students who wish to study at university.

1. Introduction

Nowadays, scientific and technological progress than in the past, it seems that everything around them with the facilities and the living is easy. Technology can provide support and resolve problems in every field of knowledge. Transferring of technology and know-how is fast and comprehensive for various purposes and reasons.

Even so, justice and equality in accessing development and knowledge of the individual remain questions. According to the Sustainable Development of the United Nations (UN), it mentioned that the need for "A world with equitable and universal access to quality education at all levels, to health care and social protection, where physical, mental and social well-being is assured [1]". Many questions arise from this mission, such as how to achieve the goals, what are the main hurdles, where to solve the problem, who to deal with, and many more.

One of the ways to achieve this, the international community has focused on health, education and social reforms involving individuals, systems and information enormously. The 2015 World Education Forum held at Incheon, South Korea, been shown that the future education vision is fully taken up with an offer of equal and fair quality to educational institutions as well as the promotion of lifelong learning opportunities for all learners [2].

[*]Correponding author: Wongpanya Nuankaew, Rajabhat Mahasarakham University, Thailand | Email: wongpanya.nu@rmu.ac.th

These two ideas discuss the relationship with Goal 4 of the United Nations Sustainable Development Goal, which is quality education and ensures that quality in education is equal and promotes equality. Everybody's lifelong learning opportunity [3, 4]. Based on the importance of the above, the research team studied the components of the recommendations for selecting the right university for the right student, and developed it as an application on the device, which is the intention of the international community, as shown in Figure 1.

Figure 1. The importance of the research

Figure 1 illustrates the importance and relevance of research development to the goals of the international community, which is a complex problem when attempting to match the most appropriate student to the institution. Moreover, this research is an extension of Nuankaew's research [5], which reflects the research problem as shown in Figure 2 and Figure 3.

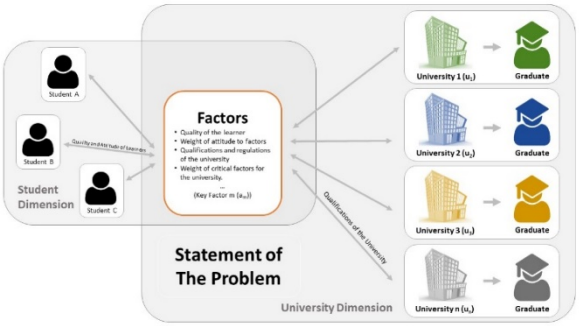

Figure 2. The Research Problem [5]

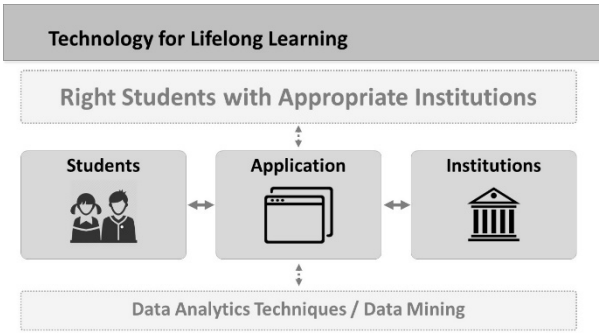

Figure 3. Using Modern Technology for Lifelong Learning

Once the research is done, the final step before publishing the application to the public is known and applied, the team has evaluated the performance and satisfaction of the application, which consists of five parts: 1) requirement definition, 2) system and software design, 3) implementation and unit testing, 4) integration and system testing, and 5) operation and maintenance as demonstrated in Figure 4. The details of each topic are clearly described in the material and methods sections.

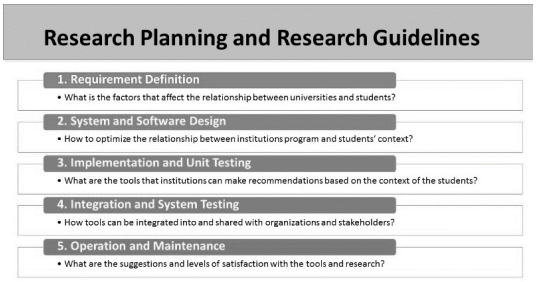

Figure 4. Research Planning and Research Guidelines

To complete the research work, the structure of the document is as follows: Literary review is compiled and presented in Section II. Section III defines and describes the variables, including a summary of all operational procedures. Section IV presents the results of the operation and discusses. Finally, Section V provides conclusions and future works, respectively.

2. Literature Review

Research and development tools for educational application consist of a combination of disciplines, including science, social sciences, education, engineering, and technology that can develop potential and success. From the research problem needed to solve the problem of matching learners to appropriate institutions. The research team summarized and collected relevant literature to present the ideas in the following topics.

2.1. Students' Academic Achievement

Measurement of student success can be done in several ways and factors. According to the research of Dougherty and Sharkey [6], it was found that factors contributing to the improvement of student achievement were three parts: grade point averages (GPAs), emotional competence, and social support. It offers a model of path analysis for mediation models with social support and emotional ability that reflects students' impact on GPA and achievement.

While the invisible academic relationship between students and institutions is contributing to academic achievement [7]. It clearly demonstrates that attitudes toward academia, along with their academic achievements, contribute to institutional decision-making and academic success. Another example of research related to academic achievement are dimension of learning styles and students' academic achievement [8]. It is suggested that an appropriate learning style could help students to achieve a good academic record in any subject they learned.

Therefore, it is concluded that the development of students to attain academic achievement must be in every dimension including the students, the learning environment, the education system and the stakeholders [9-11].

2.2. Educational Technology and Students' Performance

Students' performance refers to the academic performance of a student, which encompasses the processes that promote student success in education. While technology enables life and education is easy. Various tools and methods are used consists in teaching and learning in the classroom, including using of a mobile learning management system with online students [12], an applications on

the mobile to introduce the appropriate institution [5], prediction of students' academic failure [13], and using an educational computer program to enhance student performance [14].

No matter what tools or technologies are used to support education. Educational measurement and educational standards are still needed as a basis for the student's developmental and educational success. Therefore, the choice of tools must take into account the learning goals and achievement that will occur with the students.

2.3. Education System and Limitations

It cannot be denied that education is not only in the classroom, although education is attempting to develop a structure or form that is appropriate for the learner's age and environment. But, the out-of-class study and self-learning are surprisingly remarkable. Meanwhile, getting the knowledge and answers from the Internet can be easy and convenient. But there are few percent verified and accepted. Therefore, the education system must integrate modern technology and limit the scope of finding the correct and appropriate knowledge for the learners.

Some researches offer a dimension of education related to the education system in Thailand. Based on the research report of Sitthipon Art-in [15], it was found that the current situation and need in learning management for developing the analytical thinking of teachers in basic education of Thailand as overall in the high level. The problem with the lowest level of performance is that teachers have the ability to design and create learning plans to develop students' analytical thinking.

While research on patterns and methods of education affecting students has been discussed [16]. It is concluded that the students should be allowed to construct the body of knowledge by themselves through the Open Approach, which they are interested in and motivated to face of the problem situation. Therefore, in order to understand Thailand's education system and education structure, the following topics are divided into 2 main themes: 1) Thailand's formal education system, and 2) lifelong learning style.

2.3.1. Thailand's Formal Education System

In the public domain of Thailand, the education system is free and takes 12 years to complete. The study structure follows the "6-3-3" project, with 6 years of primary education, 3 years of lower secondary level and 3 years of upper secondary level. As displayed in Figure 5, elementary education is classified as Prathom 1-6, which correlates to Grades 1-6. While, secondary education is classified as Matthayom 1-6 and correlates to Grades 7-12.

<table>
<tr><th colspan="2">Stage</th><th colspan="2">Level / Grade</th><th>Typical Age</th><th>Notes</th></tr>
<tr><td rowspan="18">Basic Education</td><td rowspan="3">Early Childhood (Kindergarten)</td><td colspan="2" rowspan="3">Variable (Typically Anuban 1-3)</td><td>4</td><td rowspan="3"></td></tr>
<tr><td>5</td></tr>
<tr><td>6</td></tr>
<tr><td rowspan="12">Elementary</td><td colspan="2">Prathom 1</td><td>7</td><td rowspan="15">Compulsory Education</td></tr>
<tr><td colspan="2">Prathom 2</td><td>8</td></tr>
<tr><td colspan="2">Prathom 3</td><td>9</td></tr>
<tr><td colspan="2">Prathom 4</td><td>10</td></tr>
<tr><td colspan="2">Prathom 5</td><td>11</td></tr>
<tr><td colspan="2">Prathom 6</td><td>12</td></tr>
<tr><td rowspan="3">Lower-Secondary</td><td colspan="2">Matthayom 1</td><td>13</td></tr>
<tr><td colspan="2">Matthayom 2</td><td>14</td></tr>
<tr><td colspan="2">Matthayom 3</td><td>15</td></tr>

</table>

Figure 5. Thailand's Formal Education System

2.3.2. Lifelong Learning Style

In view of its success, to learn what love is one of the factors. It can be supported by Cabi's research [17]. It is recommended that students find out their own learning styles and choose the most effective strategies for their learning. It is important to learn for lifelong learning. In the definition of learning style, it is a set of techniques that make it easy for individuals to learn about yourself and learn to make the learning process information in a manner that is stable.

Theories of learning styles are continually evolving from the past. One popular theory is that Kolb's learning model, in which individual learning styles are cyclical [18]. There are four learning style in this cycle, including Abstract Conceptualization (AC), Active Experience (AE), Concrete Experience (CE), and Reflective Observation (RO). The student learning model is represented by four basic types of learning, and the individual's score indicates the most appropriate learning style as shown in Table I.

Table I. Four basic types of learning styles

Types	Elements	Meaning
Accommodating	AE and CE	Engage in real experiences and enjoy learning from exploration and application and search. They are open for strange thoughts.
Assimilating	AC and RO	They like structured and systematic knowledge. The knowledge presented must be detailed, structured and include visual and audio components.
Converging	AC and AE	The details are very important for those individuals and they are trying to understand by studying each section first. They learn to new knowledge first, then use it and not be afraid to make mistakes while learning.
Diverging	CE and RO	They like learning by observing real experiences instead of joining them. Need systematic presentation of knowledge on various topics. These individuals will be successful from the perspective of real cases.

Learning styles have a significant relationship to the nature of teaching and learning [18]. Therefore, teaching and learning management has an impact on the educational system. Laal, et al. [19] summarizes a group of lifelong learning and education systems, consisting of three main groups: formal learning, non-formal learning, and informal learning as details are shown in Table II.

Table II. Education systems

Categories	Definitions and Examples
Formal Learning (Formal Education)	It is learning that takes place in an organized and structured context. **Examples:** • Study in school or academic institutions • Training in a workplace or through an expert • Learning with curriculum or structured courses
Non-Formal Learning (Non-Formal Education)	It is driven by activities that are not clearly defined. **Examples:** • Short course training • Training in communities • Groups of adjustment according to students' needs.
Informal Learning (Informal Education)	It relates to learning from the daily activities of family and work. It is often called experiential learning. **Examples:** • Family activities • Education to improve individuals

2.4. Technology Support and Solutions

This section provides information and literature about applying technology related to education in three topics: 1) Data mining in education, which refers to the use of data mining technology for educational research. 2) Mobile web application technology, which offers technology to support and develop research tools. 3) Software development methodology, which is a process and step to develop an effective and complete application.

2.4.1. Data Mining in Education

Data mining technology is searching for patterns and processes that have values from a large number of data. In the education system, vast amounts of information being analyzed and synthesized for the main purpose is to develop the capacity of students and learners' potential, to achieve the academic achievement of the learner.

Examples of research such as Costa's research, which presents the results of evaluating the effectiveness of educational data mining techniques for early prediction of students' academic failure [13]. Natek's research demonstrates the application of data mining technologies to the analysis and development of decision models for planning and management in higher education institutions [20]. And the important example is an institution recommender system based on student context and educational institution in a mobile environment [5] that extends to this research. This work has been carried out to complete the process of the System Development Life Cycle (SDLC), which consists of seven steps: problem recognition, feasibility study, analysis, design, construction, conversion, and maintenance.

2.4.2. Mobile Web Application Technology

Nowadays, access to information and the internet is easy with the communication device everyone has. It is a mobile phone. Many applications have been developed and used to support educational systems.

For example, Briz-Ponce's research [21], which presents research findings on different drivers and factors that may affect student needs with mobile technology for learning. Yoo and Lee's research [22] uses a mobile application technology to develop knowledge and teaching for nursing students. Simonova and Poulova's research [23] applied mobile technology for learners' preferences in mobile-assisted higher education.

From the examples that bring mobile computing technology into use in various fields. As well as, the research team was interested in developing tools to support education, it developed a mobile for introducing appropriate institutions to students [5]. The research was extremely interesting, and the research team further developed the research that was proposed to assess application satisfaction and efficiency, which is presented in the next section.

2.4.3. Software Development Methodology

In software engineering, software development methodology is software development. It is a different procedure which consists of activities that are intentionally planned and managed better. It is often perceived as a subset of the development life cycle. Such methods may include predefined definitions of deliverables and inventions defined by project teams to develop or maintain programs. There are several software development methodology such as waterfall, prototyping, iterative and incremental development, spiral development, rapid application development, extreme programming and various types of agile methodology.

In this research, the waterfall model is used to assemble processes to develop applications and software for quality and performance, which consisting of five components: requirements engineering, design and implementation, testing, release, and maintenance as shown in Figure 6.

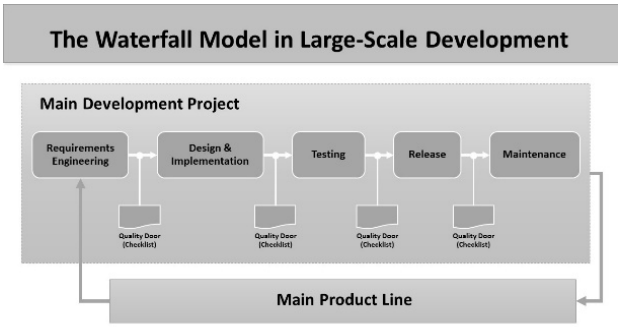

Figure 6. The Waterfall Development

2.4.3.1. Requirements Engineering

At this stage, the needs and significance of the problem are identified and documented at the abstract level. After that the specifications will be refined so that they can be used for design and operation. Specifications are stored in the required repository, and the requirements to be applied are selected from the repository. A number of requirements, depending on the resources available for the project. The quality will check that all terms are understood and agreed upon and documented. It also requires monitoring relevant stakeholders and solutions to support strategies and objectives.

2.4.3.2. Design and Implementation

At the stage of architectural design was created documented. After that, system development started. Developers also perform basic unit tests before code development during the testing phase. The quality checklist verifies that the architecture has been evaluated for deviation from the specifications compared to predetermined quality decisions.

2.4.3.3. Testing

In this period, integration has been tested on quality and functionality. In order to decide whether the system is usable, it will measure performance in the lab such as throughput. Because the goal is to solve the problem perfectly, then the test will be performed on a variety of different configurations. Phase results will be reviewed according to a checklist to track whether the system has been validated.

2.4.3.4. Release

In the release phase the product is returned into a shippable state. The release documentation is the final step, which contains documentation for installation and usage for the user. In addition, creating instructions for the system must be programmed. The build guide can be used to enable and disable features of the main line product to customize the system to meet the specific needs of the target. Quality must ensure that the response meets the needs of the target. The final result is delivered for the intended purpose and meets the quality requirements.

2.4.3.5. Maintenance

After the product has been released, it must be maintained. That is, if the user encounters a problem in the product, the report is developed and encouraged to solve the problem. If the problem is due to an error in the product package, the system update will be sent to the user.

3. Material and Methods

After gathering the literature and scope of the research area, this step details the material and the method. It consists of five main stages: 1) requirement definition, 2) system and software design, 3) implementation and unit testing, 4) integration and system testing, and 5) operation and maintenance as shown in Figure 7.

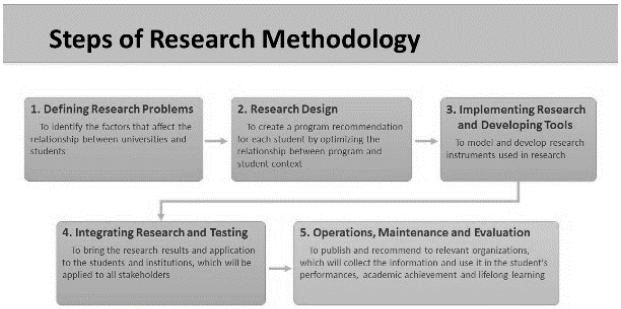

Figure 7. Steps of Research Methodology

3.1. Defining Research Problems

The objective of this step is to identify the factors that affect the relationship between universities and students [24]. This process was conducted by designing a questionnaire asking for opinions and attitudes from 256 students at two universities: University of Phayao and Rajabhat Maha Sarakham University. After receiving information from the respondents, the text mining process was analyzed to model and identify factors that are important to students and institutions.

The results show that the performance of the model employs two important factors; education system and interested in study, which are used to predict student's interest in higher education. While, the decision tree model with two depth levels was most appropriate with 81.46% accuracy as shown in Figure 8.

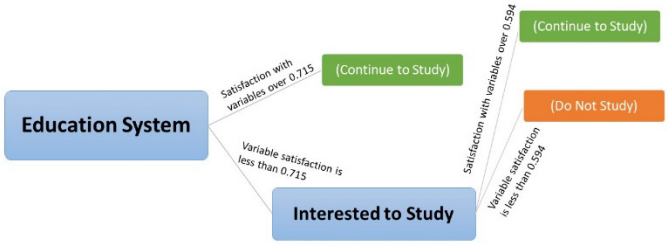

Figure 8. Decision Tree Model to Predict Student's Interest [24]

3.2. Research Design

After discovering that the education system and student interest have a bearing on the decision to study in higher education, the research team studied the characteristics of attitudes that resulted in the selection of educational programs, as well as educational institutions. Based on the data collected from 885 students of three higher educations, including Rajabhat Mahasarakham University, Mahasarakham University, and University of Phayao and the results of model analysis, the accuracy points out 19 significant factors; 15 factors of student context and 4 factors of program context, which is appropriate used to introduce institutions for the style and attitude of the students as show in Table III.

Table III. Summary of significant factors

Characteristics	Features
Student's Interests	• Interest in studying • Career path • Identity of the University • Obtained knowledge • Education system
Student's Characteristics	• Ability • Skills • Knowledge • Learning style
Student's Environment	• Social capital and Economic • Trust in institutions • Personal decision • Family income • Community • Purpose of study
Programs' Context	• The popularity of the University • Curriculum • Education standard • Quality assurance

In addition, the model has 76.50 % accuracy, showing that the generated model represents the appropriate relationship between student's context and programs' context for the proposed program recommendation, with 53 rules as shown in Figure 9.

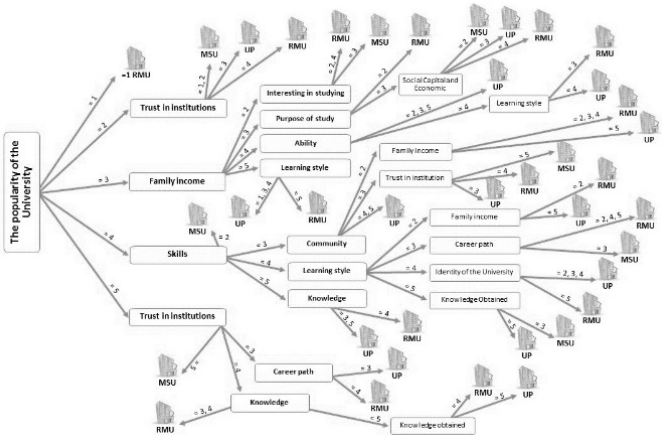

Figure 9. Decision Tree Model to Introduce Institutions

3.3. Implementing Research and Developing Tools

After knowing and discovering the factors that can be used to predict an interest in further education and behavioral characteristics that are consistent with, and appropriate educational programs and institutions. The application for introducing educational institutions based on student's context and educational institution in a mobile environment has been developed, which using the mobile web apps function [5]. It was applied to 1,109 students from 3 campuses; Rajabhat Mahasarakham University, Mahasarakham University, and University of Phayao to conduct and test the application, which the interface of the application is shown in Table IV.

Table IV. Application interface

Interface	Function
	This page aims to clarify the purpose and explain the details of the research.
	This page store user information and ask for feedback on the educational system.
	This page requests the level of satisfaction to study at university.
	This page shows the results of interest analysis of users who wish to study at university.

Interface	Function
	This page aims to gather attitudes towards additional factors in predicting the appropriate university for respondents.
	This page shows results and universities that fit the respondents.
	Thank you page

3.4. Integrating Research and Testing

To bring the application to the students, institutions and all stakeholders. The research team applied the application to the university's public relations activities and curriculum promotion activities. At the same time, the research team collected the survey data on attitudes and academic achievement of students in the upper secondary school that represent the academic relationship between academic achievement and institutions [7].

The survey found that the Grade Point Average (GPA), and school types had an impact and affects the attitudes toward the

selection institutions, which is consistent to student's attitude, their academic achievement and research's factors.

3.5. Operations, Maintenance and Evaluation

This step is the final stage of the research process, which is a key topic in the research process. The goal of this step is to publish and recommend to relevant organizations, which will provide the application and use it in the student's performances development, development of learning achievement and promoting lifelong learning.

The process at this stage consists of promoting the application and evaluation of applications in all dimensions, including finding the level of satisfaction toward the application, and evaluate the performance of the application, as elements as shown in Figure 10.

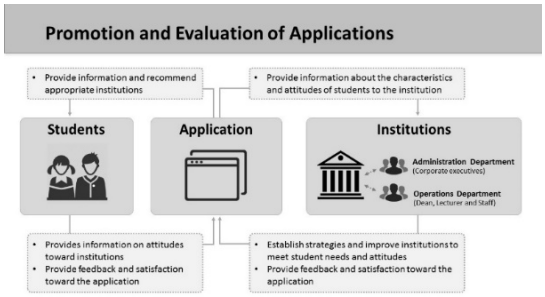

Figure 10. Process of Promotion and Evaluation of Applications

From Figure 10, it shows the process of promotion and evaluation of applications, which consist of two dimensions, including the student dimension and the institution dimension.

To carry out the full procedure as planned, the research team had planned operation consists of four stages: 1) promoting and introducing the application, 2) providing results and information from the application, 3) collecting feedback and satisfaction from the users, and 4) summary of suggestions and analyze the level of satisfaction. The details of each step is explained in the next section.

3.5.1. Promoting and Introducing the Application

The samples were selected to promote the application consists of 4 groups, including 186 high school students at Phadungnaree School, Maha Sarakham province, 191 university students at Rajabhat Mahasarakham University, 12 head of institutions at Phadungnaree School and Rajabhat Mahasarakham University, and 42 teachers and lecturers at Phadungnaree School and Rajabhat Mahasarakham University.

3.5.2. Providing Information from the Application

After presenting and introducing the application, when the user provides information, attitudes, and level of satisfaction to the application. The application performs data synthesis and presents all results to the user.

For example, students enter the attitude toward the key factor. After that, the application calculates the predictive function and introduces the appropriate institution to the student. Another example is that the application provides an overview of the user feedback to the university, each of which factors the institution can use to improve its potential. At the same time, the research team was able to gather information, attitudes and opinions to further improve and develop the research.

3.5.3. Collecting feedback and satisfaction

Gathering feedback and satisfaction levels on the application, the research team has designed and constructed a questionnaire to evaluate and ask satisfaction, which consists of four key areas to ensure compliance with software quality including 1) functional requirement test, 2) functional test, 3) usability test, and 4) security test.

However, user and volunteer participation is strictly voluntary. Apart from the results and the predictions of the application, the participants do not receive any compensation or items for participation. Participants were asked to honestly score statements on a 5-point Likert scale, ranging from 1 to 5, with 1 indicating little to no agreement and 5 indicating high agreement with statements.

3.5.4. Analyze the Level of Satisfaction

At this stage, data analysis from the sample is based on simple statistical analysis, which includes the average and standard deviation. Then analyze the results and summarize key points from the recommendations and suggestions.

4. Results and Discussion

According to the research team has designed the research protocol into five parts, The process has been completed in four stages [5, 7, 24]: 1) defining research problems [24], 2) research design, 3) implementing research and developing tools [5], and 4) integrating research and testing [7]. There is still another important step, the final step is operation, maintenance and evaluation.

Therefore, this section is divided into two parts: reporting on the results of the final stage of the research methodology and discussion topics.

4.1. Results of operations, maintenance and evaluation

The reported results of operations are presented survey results were compiled from four sample groups: 1) high school students, 2) university students, 3) head of institutions, and 4) secondary teachers and university lecturers. It has a variety of views and opinions as summarized in Table V.

Table V. Summary of sample groups

Sample Groups	Number and Source
Gender	228 female (52.90%) and 203 male (47.10%)
High School Students	186 students (43.16%) from Phadungnaree School, Maha Sarakham province, Thailand
University Students	191 students (44.32%) from Rajabhat Mahasarakham University, Maha Sarakham province, Thailand
Head of Institutions	12 school administrators (2.78%) from Phadungnaree School and 10 administrators, department heads and deans from Rajabhat Mahasarakham University.
Secondary Teachers and University Lecturers	42 teachers (9.74%) from Phadungnaree School and lectures from Rajabhat Mahasarakham University.
Total:	**431 Samples**

From Table V, it shows the details of the sample and the data collected. The data obtained from the survey is based on a

questionnaire with questions on four main perspectives as shown in Table VI.

Table VI. Four main perspectives of the questionnaire

Perspectives and Functions	Sub-topics and Details
Functional Requirement Test	• Stage 1: The system's ability to predict and recommend institutions • Stage 2: System capabilities in service and user management • Stage 3: System capabilities in data management • Stage 4: System capabilities in reporting and performance
Functional Test	• Stage 5: The accuracy of the results of the processing • Stage 6: The speed of processing of the application • Stage 7: Reliability of the program • Stage 8: Coverage of programs developed for the enterprise
Usability Test	• Stage 9: Ease of use and user friendliness • Stage 10: Appropriateness of color, size and font of the application • Stage 11: The appropriateness of using text to describe and convey meaning • Stage 12: The appropriateness of using the symbols or images • Stage 13: Standards and design criteria for the user interface • Stage 14: Appropriateness of interaction with users
Security Test	• Stage 15: Controlling access to systems, authorizing, and data access control • Stage 16: System failure prevention and data entry

After designing the questionnaire and conducting the survey on selected samples, survey results are analyzed and summarized in Table VII.

Table VII. Overview of application satisfaction

Perspectives and Functions	Sample Groups				Total:
	High School Students	University Students	Head of Institutions	Teachers and Lecturers	
Functional Requirement Test					
• Stage 1	4.36 (0.51)	4.55 (0.65)	4.33 (0.49)	4.31 (0.52)	4.44 (0.58)
• Stage 2	3.55 (0.57)	4.23 (0.76)	4.00 (0.60)	3.74 (0.59)	3.91 (0.74)
• Stage 3	3.62 (0.55)	4.42 (0.68)	4.00 (0.60)	3.83 (0.58)	4.00 (0.72)
• Stage 4	3.95 (0.28)	4.35 (0.74)	3.83 (0.39)	3.93 (0.51)	4.12 (0.57)
Functional Test					
• Stage 5	4.24 (0.44)	4.42 (0.60)	4.50 (0.52)	4.43 (0.50)	4.35 (0.53)
• Stage 6	4.81 (0.41)	4.50 (0.66)	4.75 (0.45)	4.71 (0.51)	4.66 (0.56)
• Stage 7	3.76 (0.51)	4.33 (0.76)	3.50 (0.52)	3.91 (0.62)	4.02 (0.70)
• Stage 8	3.84 (0.42)	4.33 (0.70)	3.83 (0.39)	3.91 (0.48)	4.06 (0.61)
Usability Test					
• Stage 9	4.90 (0.30)	4.61 (0.64)	4.92 (0.29)	4.98 (0.15)	4.78 (0.50)
• Stage 10	4.59 (0.49)	4.48 (0.59)	4.67 (0.49)	4.50 (0.51)	4.54 (0.54)
• Stage 11	4.12 (0.38)	4.47 (0.60)	4.25 (0.45)	4.10 (0.37)	4.28 (0.52)
• Stage 12	4.00 (0.27)	4.38 (0.67)	4.00 (0.43)	4.14 (0.35)	4.18 (0.53)
• Stage 13	4.76 (0.47)	4.41 (0.70)	4.83 (0.39)	4.69 (0.47)	4.60 (0.61)
• Stage 14	4.54 (0.54)	4.41 (0.67)	4.67 (0.49)	4.50 (0.51)	4.49 (0.60)
Security Test					
• Stage 15	4.18 (0.51)	4.43 (0.66)	3.92 (0.52)	4.17 (0.49)	4.28 (0.59)
• Stage 16	4.21 (0.50)	4.52 (0.64)	4.17 (0.72)	4.19 (0.55)	4.35 (0.60)
Total:	**4.22 (0.61)**	**4.43 (0.67)**	**4.26 (0.63)**	**4.25 (0.60)**	**4.32 (0.65)**

From Table VII, it can be seen that the overall satisfaction of the application is at a high level (4.32). The highest satisfaction level was the student in the University, with the satisfaction level at 4.43. The second highest satisfaction level was the group of head of institutions, with the satisfaction level at 4.26. And the lowest level of satisfaction was high school student's satisfaction, at 4.22.

However, the recommendations from the survey can be summarized as important issues, such as how to publish the information to the stakeholders, how to use of data and the results of research into concrete action, future research will be carried out commercially or not, and how to monitor and evaluate learners in the long term.

4.2. Discussion

Refer to research process and research objectives, this research has completed all the stages from problem study to research evaluation. At every stage, the research team publishes the results in a step-by-step manner. All the published research, it has been expertly investigated and reviewed by a specialist. So the research results are truly qualitative, beneficial and useful. However, in the research discussion, the results were based on recommendations from experts who had received research feedback and comments from the participants from the survey to the discussions.

From the feedback and comments, it was found that the recommendations of the experts encouraged the research team to develop in-depth research that related to the research in education data mining. Because, most educators use knowledge-based learning processes for learners, there is a lack of tools that support and track student achievement. While the viewpoint of the general user, it is consistent with the ideas of the experts who need the tools and technology that can support, monitor, and predict students' achievement.

In future research, the research team clearly recognizes the required for substantial studies and development into concrete actions. Research focused on tracking the educational achievement of students at all levels, including the connections and relationships between the boundaries of each education level, resolving dropout rates during education, and increasing the promotion and development of lifelong learning.

5. Conclusions

After the research team has implemented and completed five main processes, including 1) the process of requirement definition, 2) the process of system and software design, 3) the process of implementation and unit testing, 4) the process of integration and system testing, and 5) the process of operation and maintenance.

The information that has been used in the research is composed of four groups: 186 high school students at Phadungnaree School, Maha Sarakham province, 191 university students at Rajabhat Mahasarakham University, 12 deans at Phadungnaree School and Rajabhat Mahasarakham University, and 42 secondary teachers and university lecturers at Phadungnaree School and Rajabhat Mahasarakham University.

The results indicated that the total satisfaction are highest, which is equal to 4.32, and the group with the highest level of satisfaction is group of university students, which is equal to 4.43. It can be concluded that the application is appropriate and it is advisable for students who wish to study at university.

By referring to the purpose of the research, the team can conclude that this research has been very successful. The developed applications are appropriate and should be widely disseminated. In the future, the research team has the idea to use this application to promote sustainable learning that is consistent with the personality of the individual.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This article has received financial support, research information, experts and resources from Phadungnaree School, Rajabhat Mahasarakham University, the University of Phayao, and Siam Crystal Consulting Co., Ltd. Bangkok, Thailand. The authors would like to thank the researchers, participants, and technicians for their efforts toward the completion of this research.

ABSTRACT

The full service life of a technical product or system is usually not completed after an initial failure. With appropriate measures, the system can be returned to a functional state. Availability is an important parameter for evaluating such repairable systems: Failure and repair behaviors are required to determine this availability. These data are usually given as mean value distributions with a certain confidence level. Consequently, the availability value also needs to be expressed with a confidence level.

This paper first highlights the bootstrap Monte Carlo simulation (BMCS) for availability demonstration and inference with confidence intervals based on limited failure and repair data. The BMCS enables point-, steady-state and average availability to be determined with a confidence level based on the pure samples or mean value distributions in combination with the corresponding sample size of failure and repair behavior. Furthermore, the method enables individual sample sizes to be used. A sample calculation of a system with Weibull-distributed failure behavior and a sample of repair times is presented.

Based on the BMCS, an extended, new procedure is introduced: the "inverse bootstrap Monte Carlo simulation" (IBMCS) to be used for availability demonstration tests with consideration of confidence levels. The IBMCS provides a test plan comprising the required number of failures and repair actions that must be observed to demonstrate a certain availability value. The concept can be applied to each type of availability and can also be applied to the pure samples or distribution functions of failure and repair behavior. It does not require special types of distribution. In other words, for example, a Weibull, a lognormal or an exponential distribution can all be considered as distribution functions of failure and repair behavior.

After presenting the IBMCS, a sample calculation will be carried out and the potential of the BMCS and the IBMCS investigated.

1. Introduction

This paper is an extension of work originally presented in the course of the Annual Reliability and Maintainability Symposium (RAMS 2017) [1].

Availability is an important parameter for describing a repairable system. This system metric shows the quality of both of its major influences: reliability and maintainability. High availability is typically demanded from the customer, e.g., if capital goods are concerned. The required availability target is frequently specified in combination with a certain confidence level. The confidence level defines the probability that the actual population availability is at least the specified availability.

To demonstrate that the system or product will operate at a certain performance level under specified operating conditions, a demonstration test is required. Several reliability demonstration tests have been proposed, such as in [2] or [3]. For the demonstration of a repairable system's quality, an availability demonstration test needs to be carried out. This test shows that the system or product will operate with the stated level of availability.

Descriptions of failure and repair behavior, in addition to their demonstration through tests, are important topics for specifying

availability. Reliability and maintainability are usually demonstrated on the basis of limited sample sizes within a reliability test. The evaluation of the test thus yields a mean-value failure or repair distribution with a certain confidence level. The availability based on this limited information also includes a confidence level. Consequently, the confidence level of availability also needs to be considered within the course of an availability demonstration test.

Several methods which allow for the availability inference with confidence level have been published. Relatively recent approaches can be found in [4] and [5]. However, these works either require special types of distribution, or are restricted to steady-state availability. In [6], the author published three methods for availability prediction with confidence level which are not restricted to special distribution types and which allow for the prediction of time-dependent and steady-state availability with a confidence level.

Many different reliability demonstration tests have been proposed to demonstrate that a system will operate with a certain reliability [2]. However, only limited work has been conducted to develop an availability demonstration test. As a first publication, Coppola [7] provided an overview of the topic of availability demonstration. In [8], the authors proposed confidence limits on availability for exponentially distributed failure and repair times and a non-parametric approach. The approach put forward by [9] also requires exponentially distributed failure and repair times. In [10], the researcher present an initial procedure for conducting an availability demonstration tests under the assumption that the failure and repair behavior are both exponentially distributed. However, all of these works require special distribution types, e.g., exponential distribution, or they only allow for the demonstration of steady-state availability. Ref [1] provided initial concepts and methods for the availability demonstration of time-dependent and average availability with confidence level. In [11], [12], the authors provided further approaches for availability assessment based on Monte-Carlo simulation. These works does not require confidence levels and the number of samples are not predefined in advance.

To the authors' knowledge, no complete procedure has been published so far concerning the availability demonstration test with consideration of confidence levels for a specific point in time or time interval that provides a test plan. The known methods only demonstrate availability based on a predefined number of given failure and repair times or do not include confidence levels at all.

In this paper, we present a new procedure named the "inverse bootstrap Monte Carlo simulation" (IBMCS) which facilitates the availability demonstration with consideration of confidence levels, which is based on the basic concept for availability demonstration published in [1]. The procedure yields a test plan consisting of the required number of failures that must be observed in order to demonstrate a certain availability value for a point in time or as an average value for a specific time interval. Furthermore, the ratio of total observed repair times to total observed failure times will be provided. The new procedure is not restricted to special distribution types and has the potential to be applied to general availability scenarios.

Firstly, several methods for calculating availability are briefly introduced: the Markov process as an analytical method, the renewal process as a numerical method and the Monte Carlo simulation which provides approximate solutions. Several methods for determining confidence levels are also briefly outlined. Furthermore, the bootstrap Monte Carlo simulation (BMCS) for availability inference and the availability demonstration are described in greater detail. The bootstrap Markov process (BMP) and the bootstrap renewal process (BRP) are also named briefly. A sample calculation of BMCS is presented for a system with Weibull-distributed failure behavior and a given sample of repair times. All three methods are in the field of simulation-based methods like the Monte Carlo simulation based approaches.

After this, the new procedure for conducting availability demonstration tests with consideration of confidence levels is presented on the basis of the BMCS. The procedure yields a test plan comprising the required number of failures that must be observed in order to demonstrate a certain availability value. The availability value can be given as a specific availability for a point in time or as an average availability – specified in combination with a confidence level. Furthermore, the procedure yields the required ratio of total observed repair times to total observed failure times.

Finally, a sample availability demonstration test is presented that takes confidence levels into consideration. In the presented example, the failure behavior conforms to a Weibull distribution, whereby the repair times are lognormally distributed. Finally, the potential of the BMCS and the IBMCS alike is investigated.

2. Fundamentals of Reliability Engineering

In this section, several fundamentals of reliability engineering are summarized. Firstly, the basic definitions of statistics and probability theory are presented before the most common lifetime distributions for a reliability description are outlined.

2.1. Reliability and Failure Probability

The failure probability $F(t)$ is the complement of the reliability with $F(t) = 1 - R(t)$. The reliability $R(t)$ of a component or system is defined as the probability that the component or system will not fail prior to time t when operating under prescribed functional and environmental conditions [13].

Besides the reliability and the failure probability as the cumulative distribution function (cdf), the probability density function (pdf) $f(t)$ and the failure rate $\lambda(t) = f(t)/R(t)$ are often required. The mean lifetime $MTTF$ (Mean Time To Failure) is defined as the expected value of lifetime τ [13]:

$$MTTF = E(\tau) = \int_0^\infty t\, f(t)\, dt = \int_0^\infty \big(1 - F(t)\big)\, dt \quad (1)$$

Equation (1) yields the $MTTR$ (Mean Time To Repair) if the distribution is based on repair times instead of failure times.

2.2. Lifetime Distributions

Several lifetime distributions are available in reliability engineering for describing the reliability or failure behavior of a system or component. In the following section, the most commonly used lifetime distributions are described: the exponential distribution and the Weibull distribution.

The exponential distribution is often used for electronic components [13]. Its pdf is defined as [14]:

$$f(t) = \lambda \cdot e^{-\lambda \cdot t},\ t \geq 0 \text{ and } \lambda > 0 \quad (2)$$

The only parameter of the exponential distribution is the constant failure rate λ. Starting from an initial value, the density of the exponential distribution decreases constantly according to an inverse exponential function. The mean lifetime described is given as [13]:

$$MTTF = 1/\lambda \tag{3}$$

The Weibull distribution is the most common lifetime distribution used in mechanical engineering. The pdf for the three-parameter Weibull distribution is defined as [14]:

$$f(t) = \frac{b}{(\eta - t_0)}\left(\frac{t-t_0}{\eta-t_0}\right)^{b-1} e^{-\left(\frac{t-t_0}{\eta-t_0}\right)^b}, t \geq t_0 \geq 0 \tag{4}$$

Here, b is the shape parameter and η the scale parameter (characteristic lifetime). The failure-free time t_0 determines the point in time from which failure occurs. It is called referred to as a two-parameter Weibull distribution, if $t_0 = 0$. The failure rate $\lambda(t)$ of a Weibull distribution is a function in time.

3. Maintenance and Availability

The following section outlines the fundamentals of repairable systems. Firstly, the basic definitions of availability and repairable systems are summarized. Afterwards, three methods for calculating repairable systems are presented: the Markov process, the renewal process and the Monte Carlo simulation. Whereas the Markov process provides an analytical solution, the renewal is a numerical method. The Monte Carlo simulation as a simulation-based method provides approximate solutions.

3.1. Availability and Repairable Systems

Availability is an important parameter for evaluating repairable systems. A repairable system can be returned to a function state following a failure. Considering a stochastic point process with two possible states, the operational state is assigned number 1. If the system fails, the state is assigned number 0. A state indicator can be established with these definitions:

$$c(t) = \begin{cases} 1 & \text{if the system is "operational" at time } t \\ 0 & \text{if the system is "failed" at time } t \end{cases} \tag{5}$$

Here, the pdf $f(t)$ describes the transition from 1 to 0 (failure) and the pdf $g(t)$ the transition from 0 to 1 repair. Table 1 presents further descriptions of the failure and repair behavior.

The availability is defined as the probability that the system will operate satisfactorily at time t [13]. The time-dependent or point-availability is defined as the expected value of the state indicator according to (5). The following applies [13]:

$$A(t) = P(c(t) = 1) = E(c(t)) \tag{6}$$

Table 1. Description of the failure and repair behavior.

Failure behavior		Repair behavior	
Failure density	$f(t)$	Repair density	$g(t)$
Failure probability	$F(t)$	Repair probability	$G(t)$
Failure rate	$\lambda(t)$	Repair rate	$\mu(t)$
Reliability	$R(t)$	-----	
Expected lifetime	$MTTF$	Expected repair time	$MTTR$

The asymptotic value A_∞ with

$$A_\infty = \lim_{t\to\infty} A(t) = \frac{MTTF}{MTTF+MTTR} \tag{7}$$

is referred to as steady-state availability. Finally, the average availability $A_{Av}(t)$ can be calculated using [13]:

$$A_{Av}(t) = \frac{1}{t}\int_0^t A(x)dx \tag{8}$$

3.2. Markov Process

The Markov method (also called Markov model) is a method for analyzing repairable systems. It provides as an analytical method exact calculation results. The objective of the model is to determine the availability of the repairable system or component. The method is subject to a number of requirements [15]. These assumptions limit modelled maintenance actions and simplify calculations [13]:

- The unit to be observed switches continually between the states of "operational" and "repair", i.e., the state of the system or component can only be "operational" or "repair".
- After each maintenance action or repair, the repaired unit is as good as new.
- The times required for operation and repair for each unit observed are continuous and stochastically independent.
- The influence of any switch devices is not taken into consideration.

The Markov method is based on the Markov process [15], a stochastic process with a limited number of states. As a direct result of the Markov property, only systems whose elements possess constant failure and repair rates can be investigated. Thus, the failure and repair behavior need to be exponentially distributed.

For an individual system or component with the failure rate λ and repair rate μ, the availability $A(t)$ can be determined as the probability that the item assumes the state "operational". The following applies [13]:

$$A(t) = \frac{\mu}{\mu+\lambda} + \frac{\lambda}{\mu+\lambda} \cdot e^{-(\lambda+\mu)\cdot t} \tag{9}$$

If t tends to infinity ($t \to \infty$), the availability converges with the steady-state availability A_∞:

$$A_\infty = \lim_{t\to\infty} A(t) = \frac{\mu}{\mu+\lambda} = \frac{MTTF}{MTTF+MTTR} \tag{10}$$

3.3. Renewal Process

One additional method for evaluating repairable systems is the renewal process. If the time for renewal, i.e., the repair duration, is not disregarded, it is termed an alternating renewal process. In this case, the life and repair time succeed each other alternately (see Figure 1). The associated graph of the state indicator of an alternating renewal process of a single item switches alternately between 1 (operational) and 0 (repair) [13]. At time $t = 0$, the item begins operating in a new condition. When the lifetime $\tau_{1,i}$ comes to an end, it is called the point of failure $T_{1,i}$. In the ensuing repair status, the component is either repaired or replaced. The point of renewal $T_{0,i}$ ends the repair duration $\tau_{0,i}$. All points of failure constitute the embedded 1-renewal process and all points of renewal the embedded 0-renewal-process [15].

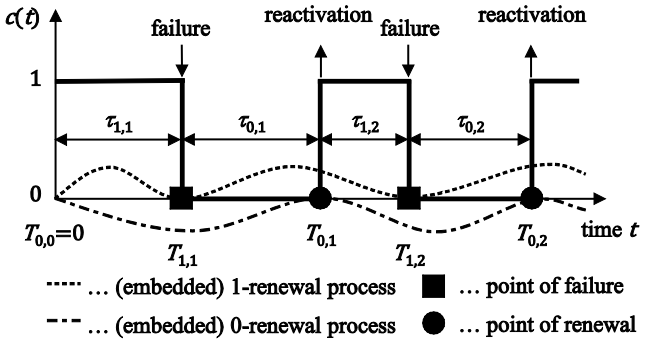

Figure 1. Alternating renewal process [13].

The renewal density function (rdf) $h_0(t)$ and $h_1(t)$ for the renewal points described by $T_{0,i}$ and $T_{1,i}$ are given as [16]:

$$h_0(t) = f * g(t) + \int_0^t f * g(t-t')h_0(t')dt' \qquad (11)$$

$$h_1(t) = f(t) + \int_0^t f * g(t-t')h_1(t')dt' \qquad (12)$$

Here, the operator $*$ denotes convolution. The renewal functions can be determined by integration of the rdfs [17]:

$$H_0(t) = F * g(t) + \int_0^t f * g(t-t')H_0(t')dt' \qquad (13)$$

$$H_1(t) = F(t) + \int_0^t f * g(t-t')H_1(t')dt' \qquad (14)$$

There are several possibilities for describing availability with the aforementioned definitions [17]. The time-dependent availability can be determined as:

$$A(t) = 1 + H_0(t) - H_1(t) \qquad (15)$$

The difference between the renewal functions is equal to the unavailability. The steady-state availability can be determined according to (7) by applying the expected values $MTTF$ and $MTTR$ of the life and repair distributions.

The alternating renewal process has no restrictions with regard to the failure and repair rates. Both constant and time-dependent failure or repair rates, e.g., with Weibull- or lognormally distributed failure and repair times, are allowed. In general, the point-availability can only be calculated numerically based on the renewal process. An analytical solution can only be derived for special types of cdfs like the exponential or Erlang distribution [16].

3.4. Monte Carlo Simulation

Besides the Markov process and the renewal process, the availability of a system or component can be calculated with the help of the Monte Carlo simulation. The Monte Carlo simulation is based on the principle of random sampling. It is a numerical method for the approximate solution of an analytical problem [18]. Thus, no exact values can be determined by Monte Carlo simulation but approximate values. The Monte Carlo simulation is frequently used for reliability analysis and facilitates the calculation of reliability parameters of very complex systems. In contrast to the Markov process, the Monte Carlo simulation has no restrictions with regard to the distribution functions or parameters [19]. The basic principle for calculating the point-availability with the help of the Monte Carlo simulation is illustrated in Figure 2 based on [20].

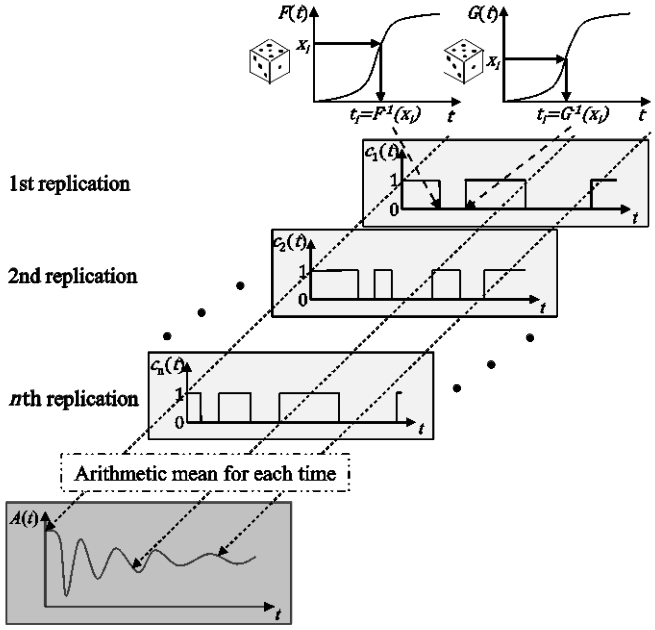

Figure 2. Monte Carlo simulation of (point-) availability [20].

Firstly, random failure and repair times are generated based on the given cdfs of failure and repair behavior. Correspondingly, pseudorandom numbers within the bounds 0 and 1 are generated. These random numbers are interpreted as the failure $F(\xi)$ or repair $G(\xi)$ probabilities. The failure and repair times t^* can subsequently be determined based on these random failure and repair probabilities and using the inversion method [21]:

$$t^* = F^{-1}(\xi) \text{ o}\rho\ t^* = G^{-1}(\xi) \qquad (16)$$

By alternatively selecting one of the randomly generated failure and repair times t^*, one trajectory of the state indicator is established. As for the renewal process, the starting condition $c(t=0) = 1$ is assumed: The component is thus starting in a new condition at time $t = 0$.

After establishing one state indicator throughout the entire observation time, the procedure is repeated n times. n is given as the number of Monte Carlo replications. As a result, n trajectories of the state indicator are calculated. Finally, the time-dependent availability $A(t)$ can be derived as the arithmetic mean of all generated state indicators for each time.

It should be mentioned that the calculated availability represents an approximate solution. The statistical quality of the values determined by means of the Monte Carlo simulation can be estimated. According to the central limit theorem [21], (17) is valid for the random number $\bar{\tau}$ according to (18) [22].

$$\lim_{n\to\infty} P\left(\left|\bar{\tau} - E(\tau) \le \frac{x\sigma}{\sqrt{n}}\right|\right) = \frac{1}{\sqrt{2\pi}}\int_{-x}^{+x} e^{-\left(\frac{u^2}{2}\right)} du \qquad (17)$$

where $-\infty < x < \infty$

$$\bar{\tau} = \frac{1}{n}\sum_{i=1}^{n}\tau_i \qquad (18)$$

This means that the estimated random number normally follows an asymptotic distribution, with the expected value $E(\tau)$ and the variance σ^2/n. Based on this thesis, the statistical quality of the mean value determined with the help of the Monte Carlo simulation can be specified as a level of statistical quality.

4. Confidence Intervals

Selected fundamentals for determining confidence levels are presented in this chapter. After the basic definition, the bootstrap method is presented in greater detail.

4.1. Basic Definition of Confidence Level

The confidence level P_A of availability A_L can be determined in an analogous manner to the reliability [23]. According to (19), it can be calculated using the integral of the density with the considered value A_L as a lower limit:

$$P_A = P(A_L \leq A \leq 1) = \int_{A_L}^{1} f(A')dA' \qquad (19)$$

The calculation is based on the density $f(A)$ of the availability. The confidence level describes the fact that a minimum availability value A_L is reached with a probability of $P_A = 1 - \alpha$. One inherent part of a certain confidence level is the specification of the probability P_A. As a sample, the 95% confidence level implies that the observed value is at least the certain value A_L in 95 out of 100 cases. Usually, a confidence interval lies symmetrically to the median. This means that a 90% confidence interval is bounded by the 5% and 95% confidence level.

There are several methods for determining the confidence intervals of a distribution function. Table 2 shows the most commonly used methods, which can be divided into "analytical methods", "approximate methods" and "simulation-based methods". The table itself is based on [24].

An analytical description of the availability function is required in order to determine a confidence interval with analytical or approximate methods. However, if general scenarios are considered or the Monte Carlo simulation is used, this analytical description is not present or modelled implicitly into an algorithm. Even in the case that the analytical formulation is absent, the bootstrap methods are suitable for determining confidence levels of availability. However, the confidence level determined by bootstrapping is also an approximate solution.

Table 2. Most commonly used methods for determining a confidence interval.

Analytical methods	Approximate methods	Simulation-based methods
• Beta-binomial distribution • Likelihood ratio Interval • Bayes confidence interval	• Fisher matrix • Wald method • Wilson score interval	• Bootstrapping: Non-parametric bootstrapping Parametric bootstrapping

4.2. Bootstrapping

Bootstrapping [25] is a method of resampling and suitable for statistical evaluation, especially if the parameters of a given sample cannot be determined using other analytical methods [26]. The method was first introduced by Bradley Efron [27]. There are two different types of bootstrapping according to Figure 3: non-parametric and parametric bootstrapping.

Non-parametric bootstrapping starts with a given sample $T = \{t_1, t_2, ..., t_n\}$ with sample size n. First, a bootstrap sample $\tilde{T}$ is established by drawing n random numbers from T with replacement and without regard to the order. Afterwards, using well-known standard parameter estimators such as the Maximum Likelihood Method (MLE) [13], the parameters θ of the bootstrap sample are estimated so that the cdf obtained by bootstrapping $\tilde{\Phi}(t)$, named as realization, can be identified.

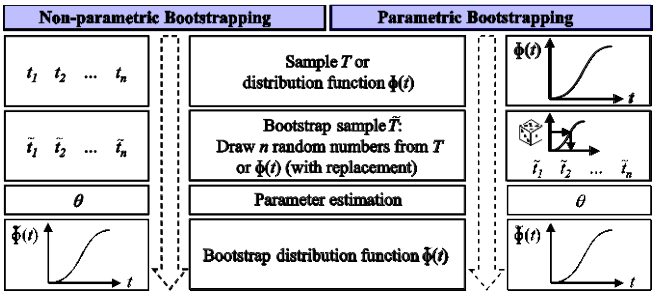

Figure 3. Non-parametric (left) and parametric (right) bootstrapping [28].

In contrast to non-parametric bootstrapping, the parametric bootstrap method is based on a given distribution function $\Phi(t)$. If this cdf is not given in advance, it can be estimated using well-known estimators such as the MLE or by employing the non-parametric bootstrap method. The first step of parametric bootstrapping is to generate n random failure times from the given distribution function. This is performed in the same manner as for the Monte Carlo simulation: with the help of pseudorandom numbers and the inversion method. The distribution function by means of bootstrapping $\tilde{\Phi}(t)$ will subsequently be determined in the same manner as non-parametric bootstrapping, i.e., using standard parameter estimators.

Several bootstrap confidence intervals are available for analyzing the confidence level by bootstrapping [2]. The evaluation can be carried out as [29]:

- An empirical bootstrap confidence interval
- A standard bootstrap confidence interval
- A percentile bootstrap confidence interval
- A bootstrap-*t*-confidence interval
- A BCα confidence interval
- etc.

Irrespective of the type of bootstrap confidence level, the bootstrap method needs to be carried out B (number of bootstrap replications) times. As a consequence, B realizations of the distribution function $\tilde{\Phi}_i(t)$, $i = 1(1)B$ can be identified. This array of trajectories subsequently has to be evaluated. Figure 4 shows the procedure for determining a confidence level using the bootstrap method.

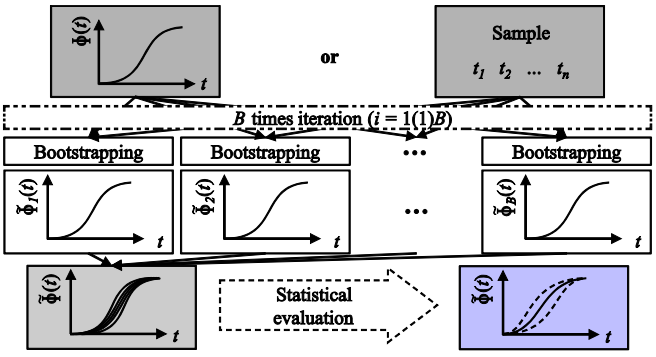

Figure 4. Determining a confidence level using bootstrapping.

In the following, only the "empirical bootstrap confidence interval", the "standard bootstrap confidence interval" and the "percentile bootstrap confidence interval" are presented in greater detail. If an empirical bootstrap confidence interval is calculated, the trajectories are evaluated by performing an empirical bootstrap density function $\varphi\left(\tilde{\Phi}(t_j)\right)$ for each time t_j. Based on the percentiles of these density functions, the confidence level of the original distribution function can be determined.

It is likewise possible to calculate a "standard bootstrap confidence interval". Under the assumption that the realizations $\tilde{\Phi}_i(t)$ are roughly normally distributed, the upper and lower confidence limit of the 100(1-2α)% standard bootstrap confidence interval can be calculated for each time t_j as:

$$\left(\hat{\Phi}(t_j) - z_\alpha \cdot sd\left(\hat{\Phi}(t_j)\right), \hat{\Phi}(t_j) + z_\alpha \cdot sd\left(\hat{\Phi}(t_j)\right)\right) \quad (20)$$

$\hat{\Phi}(t_j)$ is the arithmetic mean value of the B realizations $\tilde{\Phi}_i(t)$, where $sd\left(\hat{\Phi}(t_j)\right)$ is given as the standard deviation of these realizations. z_α is the αth quantile of the standard normal distribution.

On the other hand, the percentile bootstrap confidence interval can be selected based on the given B realizations $\tilde{\Phi}_i(t)$. They have to be sorted in ascending order. Consequently, the $\Phi_i^*(t_j)$ is the ith smallest element. Afterwards, the 100(1-2α)% percentile bootstrap confidence interval can be determined according to (21). Here, $[x]$ equals the largest integer less than or equal to x.

$$\left(\Phi^*_{[\alpha\cdot B]}(t_j), \Phi^*_{[(1-\alpha)\cdot B]}(t_j)\right) \quad (21)$$

In general, the input parameters of the bootstrap parameter can be variously interpreted as failure or repair times. As an example, the given cdf $\Phi(t)$ can either be a failure or a repair distribution function. The confidence interval calculated using the bootstrap method can thus be the confidence interval for a failure distribution function or a repair distribution function. The confidence level of a reliability function or other distribution functions using the bootstrap method is calculated in the same way.

5. Bootstrap Monte Carlo Simulation

This section presents the bootstrap Monte Carlo simulation as a new method for availability inference and demonstration with a confidence level. Using this highlighted method, the confidence level of point-availability as well as the confidence level of average and steady-state availability can be determined.

5.1. Basic Concept

The bootstrap Monte Carlo simulation (BMCS) combines bootstrapping as a method for determining confidence levels with the Monte Carlo simulation. Figure 5 shows the basic principle of BMCS for calculating point-availability with a confidence level. With this basic principle, it is possible to use the information concerning the confidence level of the input data, i.e., of the failure and repair distributions.

The BMCS can be carried out based on pure samples or on the distribution functions (cdfs) of failure and repair behavior. It is also possible to shuffle both types of input data, such as by providing the failure behavior as a cdf and the repair behavior as a sample of repair times or vice versa. The basic procedure also facilitates individual sample sizes for lifetime and repair data. In other words, the sample sizes do not have to be equal.

In the first step of the BMCS, one realization $\tilde{F}_i(t)$ of the failure behavior and one realization $\tilde{G}_i(t)$ of the repair behavior are generated using the bootstrap method and based on the input data. Depending on the type of input data, non-parametric or parametric bootstrapping is employed. After this, these realizations are used to calculate one realization of the point-availability $\tilde{A}_i(t)$ using the Monte Carlo simulation, according to Figure 2. After repeating the entire calculation B times, B realizations of point-availability $\tilde{A}_i(t)$, $i = 1(1)B$ can be calculated. B corresponds to the predefined number of bootstrap replications. Finally, this array of trajectories of point-availability subsequently has to be evaluated.

As shown in the previous chapter, it is possible to determine an empirical bootstrap confidence interval, a standard bootstrap confidence interval, a percentile bootstrap confidence interval or another type of bootstrap confidence interval. If an empirical bootstrap confidence interval is chosen, an empirical bootstrap probability density function $\varphi_j(\tilde{A}(t_j))$ is derived from the individual function values of the realizations of point-availability.

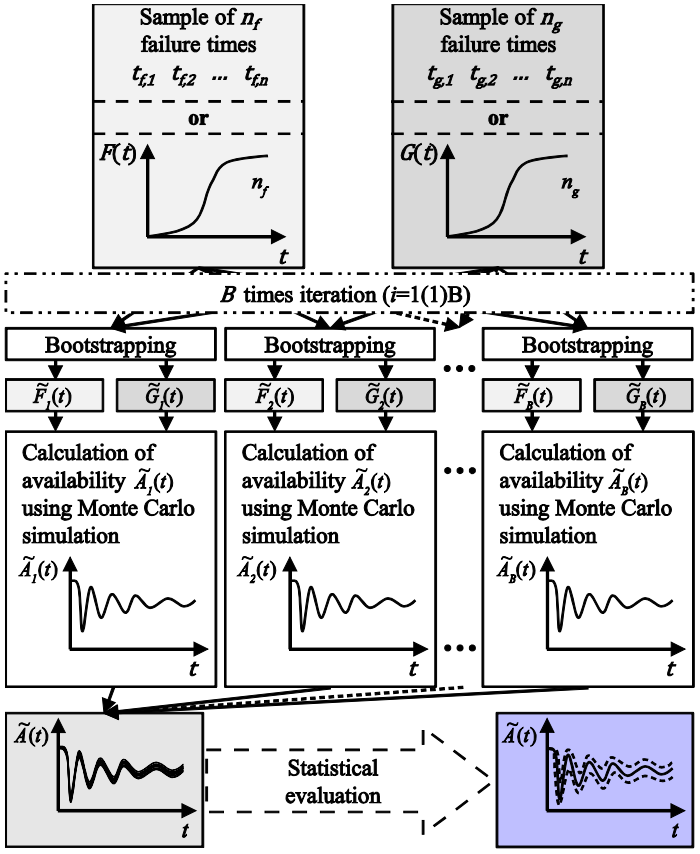

Figure 5. Basic procedure of bootstrap Monte Carlo simulation (BMCS) for calculating point-availability with a confidence level.

The confidence interval can be derived based on the percentiles of these density functions. Figure 6 illustrates this step of the statistical evaluation. On the other hand, the standard bootstrap confidence interval can be determined according to (20) or the percentile bootstrap confidence interval according to (21).

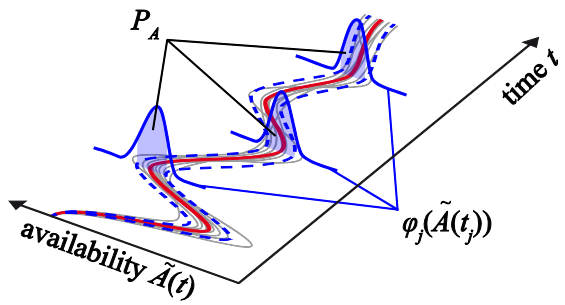

Figure 6. Statistical evaluation of the realizations of point-availability.

The BMCS is an approximation method as the Monte Carlo simulation is used: The calculated confidence interval is thus also an approximation. The BMCS can only provide accurate approximations from a certain threshold number of replications. As shown in [28], the number of bootstrap replications should not be fewer than 200. If at least 200 bootstrap replications are carried out, the approximation of the BMCS is very thorough. On the other hand, the number of Monte Carlo replications should be chosen in the range of 1,000-10,000 Monte Carlo replications. Generally speaking: The higher the numbers of replications, the better the approximation of BMCS. It should be mentioned that the simulation time increases sharply in line with higher numbers of replications.

If the Markov process is used in place of the Monte Carlo simulation to calculate point-availability within the basic procedure according to Figure 5, the bootstrap Markov process (BMP) is established (see [1] or [6], for example). The BMP combines the bootstrap method with the calculation of availability using the Markov method. The BMP therefore has the same restrictions as the Markov process. In other words, the failure and repair behavior needs to be exponentially distributed.

Besides the BMCS and the BMP, the bootstrap renewal process (BRP) [6] combines the bootstrap method with the renewal process [1]. In other words, the availability calculation of the basic procedure according to Figure 5 is carried out using the alternating renewal process. All three methods – the BMCS, the BMP and the BRP – facilitate the availability prediction and demonstration with confidence level, whereby the BMCS has the highest potential to be extended to more general scenarios of availability prediction and demonstration.

5.2. Steady-State and Average Availability with Confidence Level

It is likewise possible to estimate a confidence interval for steady-state and average availability using the bootstrap Monte Carlo simulation provided in Figure 5. The basic concept needs to be amended so that steady-state or average availability is determined for each bootstrap replication i with $i = 1(1)B$, as opposed to point-availability. The calculation of steady-state availability is performed using (7), whereas the average availability is calculated according to (8). In total, B realizations of the value of steady-state availability $\tilde{A}_{\infty,i}$ or B realizations of the curve of average availability $\tilde{A}_{Av,i}(t)$ are generated.

Exactly as with point-availability, both the B realizations of steady-state availability and the B realizations of average availability are evaluated statistically. An empirical, standard or percentile bootstrap confidence interval can thus be constructed.

5.3. Sample Calculation

In the following section, a sample calculation using the BMCS is presented. The sample calculations determine point-availability, steady-state availability and average availability with a 90% confidence level. The availability values are calculated with a 90% confidence interval for the sample failure and repair behavior listed in Table 3.

Table 3. Sample failure and repair behavior.

Failure behavior $F(t)$	**Repair behavior $G(t)$**
• Weibull-distributed • $b = 3.0$ • $\eta = 1{,}119.85$ h • $MTTF = 1{,}000$ h • $n_f = 10$	• Sample ($n_g = 20$) of repair times [h]: 154.0 209.5 246.0 291.5 171.5 217.0 254.0 304.0 183.0 224.0 262.0 320.0 193.0 231.0 271.0 342.5 201.5 239.0 280.5 382.0

The failure behavior $F(t)$ is given as a cdf, whereby the repair behavior $G(t)$ is based on a given sample. As shown in Table 3, the sample sizes of the failure and repair behavior are not equal. The BMCS is carried out with 200 bootstrap and 10,000 Monte Carlo replications. Within the last step of the BMCS, an empirical bootstrap confidence interval is determined.

To begin with, Figure 7 shows the $B = 200$ realizations of the point-availability calculated during the BMCS. Furthermore, the mean availability and the 90% confidence interval of the time-dependent availability are illustrated. Some empirical density functions $\varphi(\tilde{A})$ of the confidence interval are also plotted on the graph. The color of the pointed density functions clarifies the frequency n_B. In other words, this color illustrates the number of availability curves going through the point $(t_i, A(t_i))$ in absolute terms.

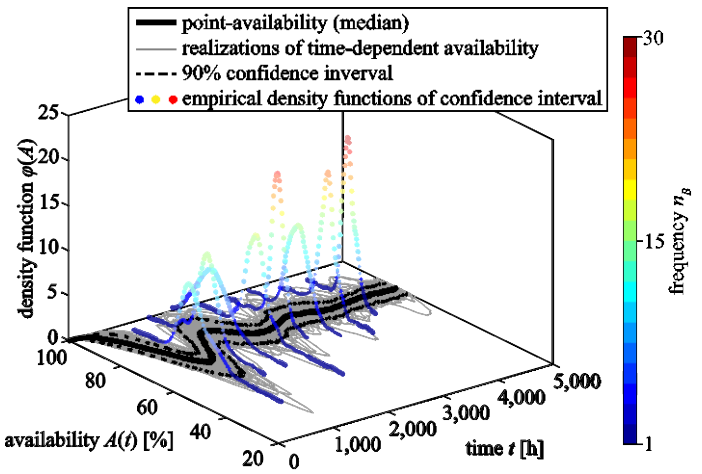

Figure 7. Point-availability with 90% confidence interval and selected density functions of confidence level.

Figure 8 builds on Figure 7 to show the steady-state availability as well as the average availability. Both availability graphs are clarified with a 90% confidence interval. The confidence interval of all graphs expands slightly with shorter durations and converges to a constant range at longer ones. For long operation times, the confidence intervals of all types of availability coincide with each other and lead to a constantly wide range.

Although it is not necessary to carry out this investigation because non-parametric bootstrapping is applied to the sample of the repair behavior, the analysis of the repair times using the Maximum Likelihood method provides a lognormally distributed repair behavior ($\mu = 5.4902$, $\sigma = 0.25$, $MTTR = 250$ h).

As shown in [1] and [6], the confidence interval of all types of availability becomes narrower or smaller as the sample sizes increase. Independently of the sample sizes, the confidence interval of point-availability, steady-state availability and average availability harmonizes very well within a constantly wide range for long operation times. A first verification of the BMCS as well as an investigation about the accuracy of the BMCS is provided by Müller et al. [30]. If the numbers of bootstrap and Monte Carlo replications are high enough, the BMCS provides acceptable results as an approximate method. First parameter studies of the input parameters of the BMCS are carried out in [1], [20] or [30].

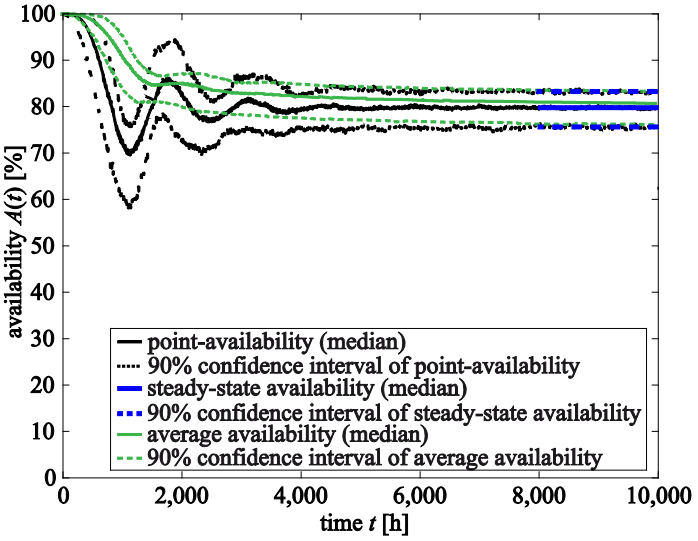

Figure 8. Point-availability, steady-state availability and average availability with 90% confidence interval.

6. Availability Demonstration Test with Consideration of Confidence Level

In this section, the inverse bootstrap Monte Carlo simulation (IBMCS) as a new procedure is presented. The IBMCS enables an availability demonstration test with consideration of confidence levels to be conducted. Firstly, the basic concept of IBMCS is presented in detail before a sample calculation is carried out.

6.1. Inverse Bootstrap Monte Carlo Simulation

An availability demonstration test needs to be carried out in order to demonstrate the quality of a repairable system. This test provides the demonstration that the system will operate with a stated level of availability. As a consequence of the availability description with confidence level using the BMCS, the availability demonstration tests also need to be specified with a confidence level. The inverse bootstrap Monte Carlo simulation (IBMCS) enables such availability demonstration tests with consideration of confidence levels. The new procedures provide a test plan comprising the required number of failures that must be observed to demonstrate a certain availability value $A(t^*)$ at a specific point in time t^*. The IMBCS can be seen as the inversion of the BMCS.

Figure 9 shows the basic concept of the inverse bootstrap Monte Carlo simulation.

The procedure begins by defining the input data. The objective is to determine the required number of observed failure and repair times, i.e., the required sample size n_f and n_g of failure and repair behavior to demonstrate the availability value $A_{objective}(t^*)$ at time t^* with confidence level $P_{A,objective}$. It is assumed that the failure behavior $F(t)$ and repair behavior $G(t)$ of the repairable system or product is known, but not its corresponding sample sizes. Furthermore, the ratio of sample sizes of failure and repair behavior is predefined:

$$n_{ratio} = \frac{n_f}{n_g}$$

Besides the ratio of the sample sizes, the minimum $n_{f,min}$ and maximum number of observed failure time $n_{f,max}$ are also predefined. These numbers correspond with the minimum and maximum number of reliability tests that could be carried out. Frequently, the maximum number of possible tests is fixed by other limitations, e.g., the number of available test benches. The minimum number is usually fixed by the corporate strategy or normative rules. These requirements frequently require a certain minimum number of reliability tests to be carried out.

Finally, the calculation parameters B (number of bootstrap replications of the BMCS) and n_{MC} (number of Monte Carlo replications of the BMCS) are required.

In the first step of the IBMCS, a BMCS is carried out based on the input data. In other words, an availability value $A_{min}(t^*)$ with confidence level $P_{A,objective}$ is calculated using the BMCS and under the assumption of the minimum sample size of failure behavior $n_{f,min}$. The same calculation is carried out under the assumption of the maximum sample size $n_{f,max}$, so that the availability value $A_{max}(t^*)$ with confidence level $P_{A,objective}$ can be determined.

It should be noted that the corresponding sample size of the repair behavior can be calculated for each step of the IBMCS using the predefined value of ratio n_{ratio} according to (22) using the actual sample size of failure behavior.

After determining both values $A_{min}(t^*)$ and $A_{max}(t^*)$, it must be verified whether the objective availability value $A_{objective}(t^*)$ lies within these ranges. In other words, a check is conducted as to whether (22) is valid or not.

$$A_{min}(t^*) \leq A_{objective}(t^*) \leq A_{max}(t^*) \qquad (22)$$

There is no solution if (22) is not valid, since the objective availability value does not lie within the interval of possible availability values $[A_{min}(t^*), A_{max}(t^*)]$. Values which are not included in this interval cannot be achieved with the predefined limitations of minimum and maximum failure time figures.

If the calculation can be advanced further, as (22) is valid, a binary search is performed to determine the required number of observed failure and repair times. Therefore, in the first step, a new sample size number is chosen according to (23), where $n_1 = n_{f,min}$ and $n_2 = n_{f,max}$.

$$n_{f,new} = \frac{n_1 + n_2}{2} \qquad (23)$$

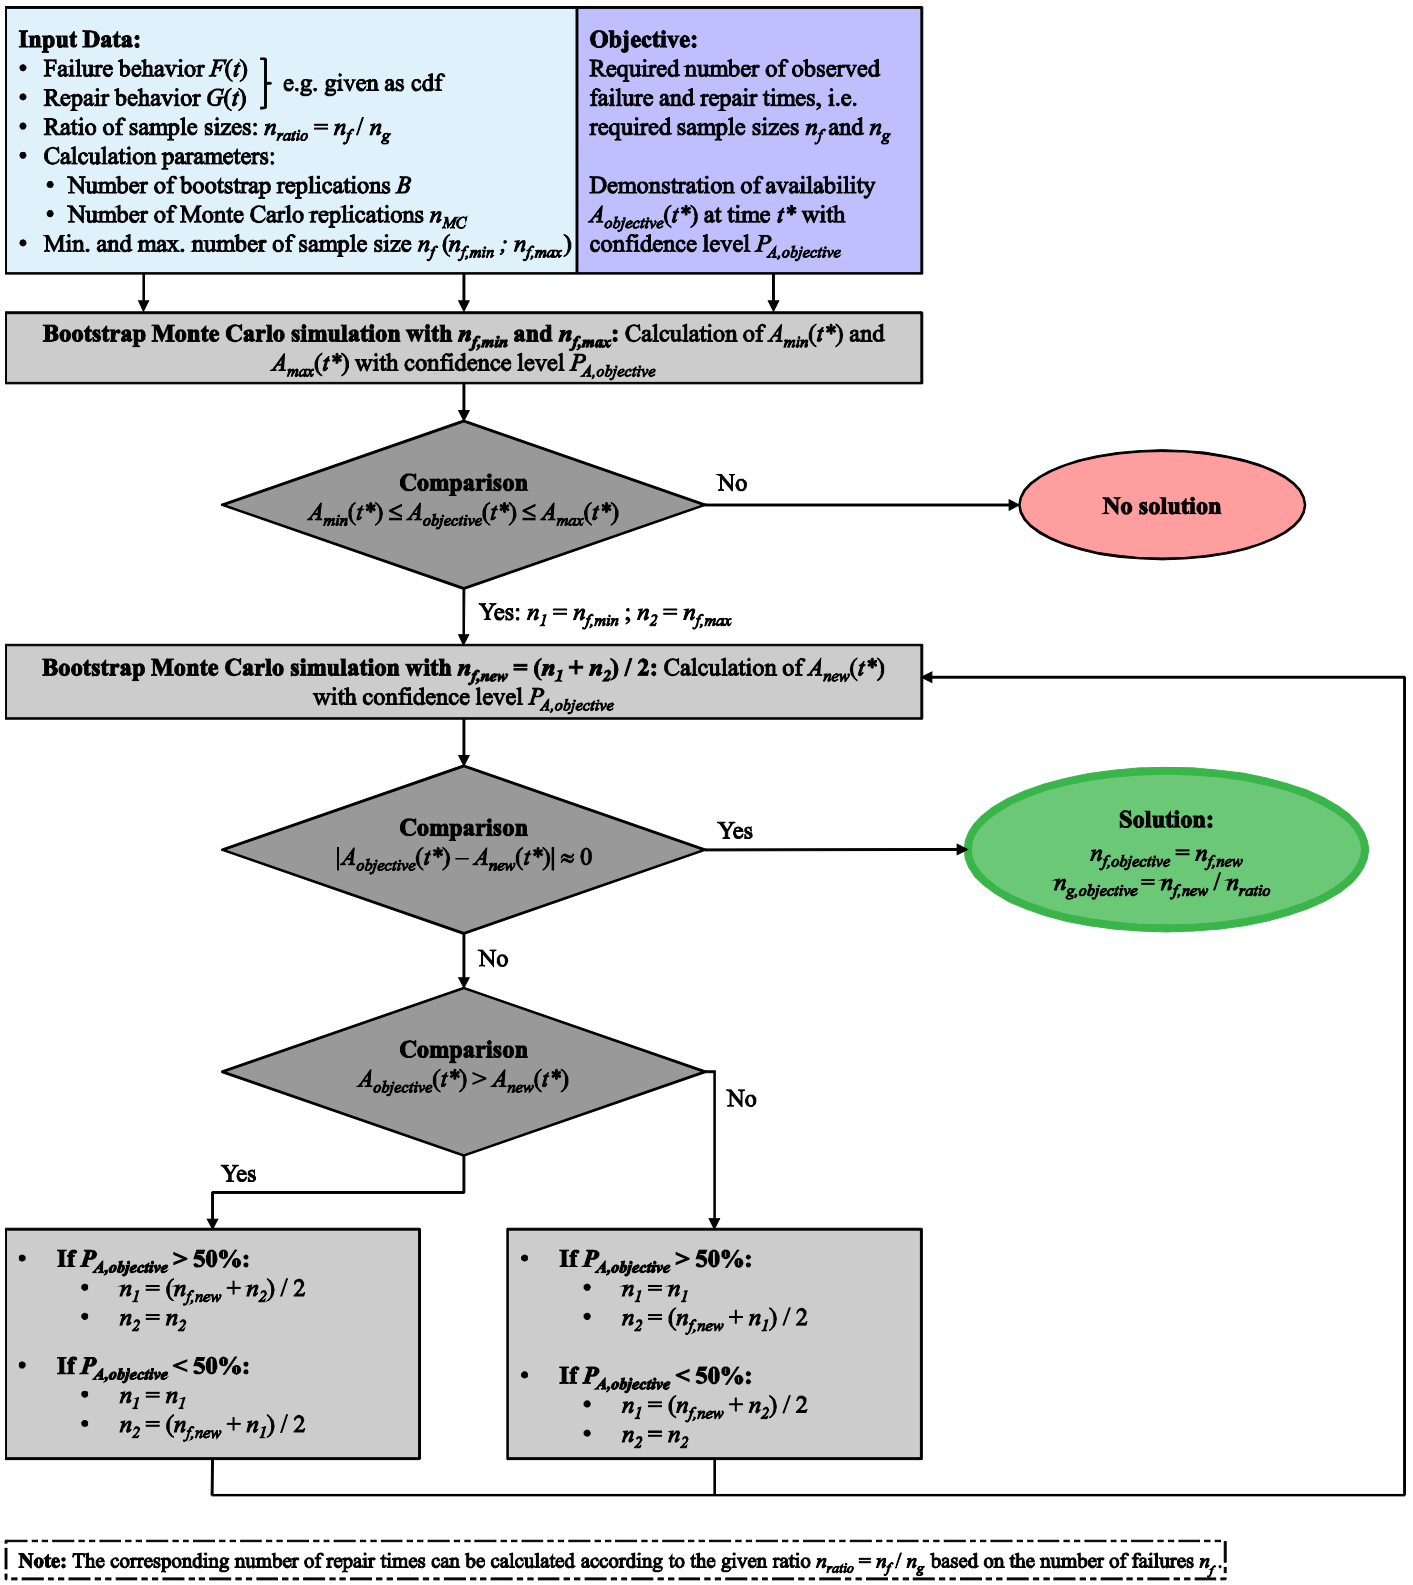

Figure 9. Basic procedure of the inverse bootstrap Monte Carlo simulation (IBMCS).

The new value $n_{f,new}$ is derived as the mean of the previous sample sizes due to the binary search. After this, a new calculation using the BMCS gives the availability value $A_{new}(t^*)$ with confidence level $P_{A,objective}$ based on the new sample size $n_{f,new}$. If this value is not approximately equal to the required demanded availability value $A_{objective}(t^*)$, the sample size requires further adaptations. Therefore, two case distinctions have to be made. One distinction investigates if the objective availability value

$A_{objective}(t^*)$ with confidence level $P_{A,objective}$ is greater than the actual calculated availability value $A_{new}(t^*)$ with confidence level $P_{A,objective}$.

Furthermore, the second distinction has to be made with regard to the demanded confidence level $P_{A,objective}$. As shown in Figure 10, the availability value with a constant confidence level increases in line with increasing sample sizes if the confidence level is lower than 50%. On the other hand, if $P_A > 50\%$, the availability value decreases as sample size n increases.

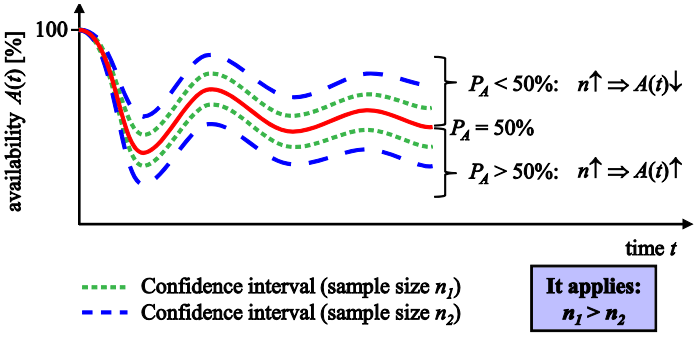

Figure 10. Confidence intervals with varying sample sizes.

After performing both case distinctions, the sample size of the failure behavior is adapted according to the equations shown in Figure 9. The corresponding number of observed repair times is calculated according to (22). A new availability value $A_{new}(t^*)$ with confidence level $P_{A,objective}$ based on the new sample sizes is subsequently determined using the BMCS.

These calculation steps are repeated until the actual determined availability value $A_{new}(t^*)$ with confidence level $P_{A,objective}$ and corresponding sample sizes $n_{f,new}$ and $n_{g,new} = n_{f,new}/n_{ratio}$ is approximatively equal to the objective availability value $A_{objective}(t^*)$ with confidence level $P_{A,objective}$. If this is the case, the required number of failures and repair actions that must be observed in order to demonstrate a certain availability value is determined as:

$$n_{f,objective} = n_{f,new} \tag{24}$$

$$n_{g,objective} = \frac{n_{f,new}}{n_{ratio}} \tag{25}$$

As a derivation of the IBMCS, it is possible to conduct an availability demonstration test with consideration of the confidence level. It is therefore possible to demonstrate a specific availability value for a point in time and a given confidence level. The procedure yields the required number of failures as well as the required number of repair actions that must be observed within a reliability test of the investigated repairable system or product with a known failure and repair behavior type. The availability test plan can subsequently be conducted and several availability requirements can be demonstrated with a confidence level.

The IBMCS can be adapted further so that it is not the value of point availability $A_{objective}(t^*)$ at time $t^*$with confidence level $P_{A,objective}$ is demanded within the objective, but rather the value of average availability $A_{Av,objective}(t^*)$ at time $t^*$with confidence level $P_{A,objective}$. In this case, the point-availability value is not calculated, but rather the average availability value within the inherent steps of BMCS. The IBMCS procedure is carried out in the same manner.

If the BMP or BRP is used within the basic procedure according to Figure 9 as opposed to the BMCS, the inverse bootstrap Markov process (IBMP) or the inverse BRP (IBRP) are established.

6.2. Sample Calculation

In the following section, a sample calculation of the IBMCS is presented. The procedure is applied to the system already investigated in the previous sample calculation. In other words, the failure behavior of the system is given from previous investigations as being Weibull-distributed with $b = 3.0$, $\eta = 1{,}119.85$ h and $MTTF = 1{,}000$ h. The repair behavior is given as being lognormally distributed with $\mu = 5.4902$, $\sigma = 0.25$ and $MTTR = 250$ h.

The IBMCS is carried out with 200 bootstrap replications and 10,000 Monte Carlo replications. It is assumed that an availability of 75% should be present at an operating time of 5,000 h. The availability should be indicated with a confidence level of 95%. It is possible to carry out a maximum of 100 reliability tests. In other words, the maximum number of sample sizes for the failure behavior is 100. The ratio between both sample sizes is predefined as 2, i.e., the sample size of the repair behavior should be half of the sample size of the failure behavior.

On the basis of the IBMCS, it is possible to determine the required sample size of failure behavior to $n_f = 16$ and the sample size of the repair behavior $n_g = 8$. Assuming that the failure behavior is known and constant as given, 16 failures need to be observed during the reliability test in order to demonstrate the demanded availability of 75% with a 95% confidence level at a time of 5,000 h. In other words, the analysis of the given failure behavior must be based on 16 failure times. Conversely, the analysis of the repair behavior must simultaneously be based on 8 observed repair times.

Figure 11 shows point-availability with a 90% confidence interval. The confidence interval is determined with input data from $n_f = 16$ and $n_g = 8$. As illustrated in this figure, the requirements of 75% availability with a 95% confidence level at an operating time of 5,000 h can be demonstrated with the given sample sizes.

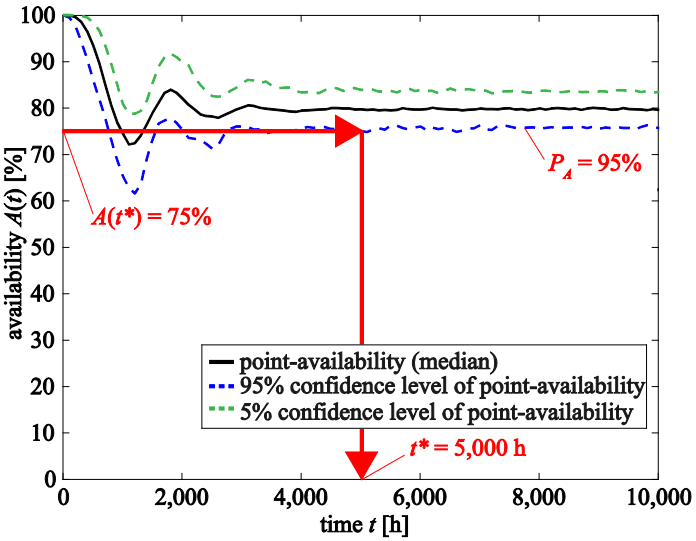

Figure 11. Point-availability with 90% confidence interval based on 16 failure and 8 repair times.

7. Potential of the Bootstrap Monte Carlo Simulation and the Inverse Bootstrap Monte Carlo Simulation

Both the bootstrap Monte Carlo simulation (BMCS) and the inverse bootstrap Monte Carlo simulation (IBMCS) have a high potential to be applied to more general availability scenarios. Beyond the consideration of preventive maintenance, the BMCS and the IBMCS are not restricted to selected maintenance strategies. It is possible to investigate technical systems with general maintenance strategies.

As given in [31], different maintenance strategies are conceivable. In general, the maintenance strategy defines the type and planning of the intended maintenance activities [31]. Possible strategies include corrective, preventive or condition-based maintenance actions. Furthermore, combined strategies are possible. Besides the aspect of maintenance, the BMCS and IMBCS have a high potential to take system aspects, failure dependencies or limited maintenance resources into consideration.

The BMCS and the IBMCS are very innovative in terms of the possibility of applying them to more general scenarios. This also includes transferring the procedures to predict and demonstrate reliability with a confidence level, e.g., for systems with periodical maintenance (see [28] or [30]).

8. Summary & Conclusions

In this paper, the bootstrap Monte Carlo simulation (BMCS) is highlighted as a new method for availability inference and demonstration with a confidence level. Besides the BMCS, the bootstrap Markov process (BMP) and the bootstrap renewal process (BRP) are briefly outlined. The BMCS facilitates analysis based on a sample of failure and repair times or on a mean value distribution with corresponding sample sizes of failure and repair behavior. The BMCS has no restrictions concerning the distribution function.

The inverse bootstrap Monte Carlo simulation (IBMCS) is presented in detail alongside the BMCS. The IBMCS enables the planning of availability demonstration tests with consideration of confidence levels. The procedure is based on the BMCS. Using the IBMCS, it is possible to determine the required number of failures and repair actions that must be observed in order to demonstrate a certain state of availability with a predefined confidence level.

Firstly, the fundamentals of reliability engineering and a basic definition of repairable systems and availability were given. After this, the bootstrap method for determining a confidence level of a distribution function was shown in more detail. After describing the BMCS in detail, a sample availability calculation with a confidence level was carried out. Based on the BMCS, the IBMCS was derived. The basic procedure was outlined on the basis of a sample calculation, too. Finally, the potential of the BMCS and the IBMCS was investigated.

The BMCS and the IBMCS have high potential for application to more general scenarios concerning general systems. Besides corrective maintenance actions, other maintenance strategies can be included within the procedure. Both the BMCS and the IBMCS are very innovative. In addition to availability with a confidence level, further parameters of reliability engineering, e.g., reliability, can be integrated into the BMCS and IBMCS.

Conflict of Interest

The authors declare that there are no conflicts of interest.

ABSTRACT

Recent standards, legislation, and best practices point to data center infrastructure management systems to control and monitor data center performance. This work presents an innovative approach to address some of the challenges that currently hinder data center management. It explains how monitoring and management systems should be envisioned and implemented. Key parameters associated with data center infrastructure and information technology equipment can be monitored in real-time across an entire facility using low-cost, low-power wireless sensors. Given the data centers' mission critical nature, the system must be reliable and deployable through a non-invasive process. The need for the monitoring system is also presented through a feedback control systems perspective, which allows higher levels of automation. The data center monitoring and management system enables data gathering, analysis, and decision-making to improve performance, and to enhance asset utilization.

1. Introduction

There is significant room for improvement in current practices that address data center performance relative to benchmarks. A novel data center infrastructure monitoring approach was introduced in a paper originally presented at the 7th IEEE Annual Computing and Communication Workshop and Conference (CCWC) in 2017 [1], for which this work is an extension.

A data center is defined as a facility with all the resources required for storage and processing of digital information, and its support areas. Data centers comprise the required infrastructure (e.g., power distribution, environmental control systems, telecommunications, automation, security, fire protection) and information technology equipment (e.g., servers, data storage, and network/communication equipment). Data centers are complex and highly dynamic. New equipment may be added, existing equipment may be upgraded, obsolete equipment may be removed, and both prior and current generation systems may be in use simultaneously. Increasing reliance on digital information makes data centers indispensable for assuring data is permanently available and securely stored.

Data centers can consume 40 times more energy than conventional office buildings. IT equipment by itself can consume 1100 W/m^2 [2], and its high concentration in data centers results in higher power densities. By 2014, there were around 3 million data centers in the U.S., representing one data center for every 100 people [3]. These data centers consumed approximately 70 billion kWh, or 1.8% of total electricity consumption [4]. Data center energy consumption experienced a nearly 24% increase from 2005-2010, 4% from 2010-2014, and is projected to grow by 4% from 2014-2020. In 2020, U.S. data centers are projected to consume about 73 billion kWh [4]. Emerging technologies and other energy management strategies may reduce projected energy demand.

Technical issues and human errors may threaten a data center. Power and environmental issues are especially important, and might affect performance. Human errors can be diminished through monitoring, automation, and control systems. Intangible losses, such as business confidence and reputation are difficult to

Email: mlevy2015@fau.edu

quantify. When problems arise, data centers may shut down for a period of time. The cost of downtime depends on industry, potentially reaching thousands of dollars per minute. The average cost associated with data center downtime for an unplanned outage is approximately $9,000 per minute, an increase of 60% from 2010 to 2016 [5].

According to legislation, standards, best practices, and user needs, data centers must satisfy stringent technical requirements in order to guarantee reliability, availability, and security, as they have a direct impact on asset utilization and data center performance. In order to comply with such requirements, equipment needs continuous monitoring, control, and maintenance to assure it is working properly. A data center infrastructure management (DCIM) system can be summarized as collectively comprising a suite of tools that can monitor, manage, and control data center assets [6].

The emerging Internet of Things (IoT) makes it possible to design and implement a low-cost, non-invasive, real-time monitoring and management system. IoT can be understood as a global infrastructure enabling the interconnection of physical and virtual "things" [7]. Gartner forecasts more than 20 billion connected things by 2020 [8]. According to Cisco, 50 billion devices will be connected to the internet by 2020, and 500 billion by 2030 [9]. Each device includes sensors collecting and transmitting data over a network. These new trends help to reevaluate how to monitor and manage data center infrastructure and IT equipment. IoT makes it possible for a data center monitoring and management system to be deployed rapidly through a non-invasive process, helping to establish an integrated strategy towards performance improvement, while lowering risk.

2. Background

Since the deregulation of telecommunications in the U.S. (Telecommunications Act of 1996), a number of standards and best practices related to telecommunications, and more recently to the data center industry have emerged. Appropriate standards are essential in designing and building data centers, including national codes (required), local and country codes (required), and performance standards (optional). Governments have enforced regulations on data centers depending on the nature of the business. Different entities have also contributed to generate standards, best practices, and recommendations for the industry. These organizations include: U.S. Department of Energy; U.S. Environmental Protection Agency; U.S. Green Building Council; European Commission; Japan Data Center Council; Japan's Green IT Promotion Council; International Organization for Standardization; International Electrotechnical Commission; American National Standards Institute; National Institute of Standards and Technology; the Institute of Electrical and Electronics Engineers; National Fire Protection Association; Telecommunication Industry Association; Building Industry Consulting Service International; American Society of Heating, Refrigerating and Air-Conditioning Engineers; the Green Grid; and the Uptime Institute.

Recent standards for data centers make general recommendations that should be taken into consideration for data center infrastructure management. The ANSI/BICSI 002 standard "Data Center Design and Implementation Best Practices" [10] provides a chapter for DCIM with general recommendations for components, communication protocols, media, hardware, and reporting. The ISO/IEC 18598 standard "Information Technology - Automated Infrastructure Management (AIM) Systems - Requirements, Data Exchange and Applications" [11] includes a section on DCIM. Intelligent Infrastructure Management systems comprise hardware and software used to manage structured cabling systems based on the insertion or removal of a patch (or equipment) cord. This standard should increase operational efficiency of workflows, processes, and management of physical networks, helping to provide real-time information related to connectivity from cabling infrastructure (e.g., switches, patch panels).

Legislators have been increasingly concerned about how data centers perform. Federal data centers alone consume about 10% of total U.S. data center consumption. The Energy Efficiency Improvement Act of 2014 (H.R. 2126) [12] forces federal data centers to review energy efficiency strategies, with the ultimate goal of reducing power consumption and increasing efficiency and utilization. Likewise, in 2016, the Data Center Optimization Initiative required federal data centers to reduce their power usage below a specified threshold by September 2018, unless they are scheduled to be shutdown as part of the Federal Data Center Consolidation Initiative. To help data centers comply with legislation faster and more effectively, manual collection and reporting must be eliminated by the end of 2018. Automated infrastructure management tools must be used instead, and must address different metric targets, such as energy metering, power usage effectiveness, virtualization, server utilization, and facility monitoring [13]. The U.S. Data Center Usage Report of June 2016 [4] highlights the need for future research on performance metrics that better capture efficiency. Most recently, the Energy Efficient Government Technology Act (H.R. 306) [14] of 2017 required the implementation of energy efficient technology in federal data centers, including advanced metering infrastructure, energy efficient strategies, asset optimization strategies, and development of new metrics covering infrastructure and IT equipment.

Data center infrastructure management systems have been driven mainly by private industry. Previous experience in building automation systems, building management systems, energy management systems, facilities management systems, and energy management and control systems have enabled private industry to deploy similar solutions for the data center sector. However, these are not solutions explicitly designed for data centers. The leading companies who offer data center infrastructure management tools include Nlyte Software, Schneider Electric, and Emerson Network Power [15]. In addition, there are several reports from private industry with general guidelines and recommendations [16-24].

Academic work in data center infrastructure management includes research for specific areas, such as energy management systems [25]; distribution control systems [26]; modeling and control [27]; power efficiency [28-29]; power consumption models [30-31]; power management [32]; data center networks [33]; wireless network optimization [34-36]; thermal and computational fluid dynamics models [37-38]; wireless sensors for environmental monitoring [39]; power monitoring [40]; corrosion detection [41]; and improvement strategies, such as big data [42], genetic algorithms [43], and machine learning [44]. No previous work presents guidelines to develop a comprehensive data center monitoring and management system, considering recent advances in technology and the mission critical nature of this highly dynamic sector.

3. Data Center Monitoring and Management

3.1. Concept of Operations

This section describes quantitative and qualitative characteristics and objectives of the data center monitoring and management system. The system is envisioned to be reliable, non-invasive, wireless, sensor-based, low-cost, and low-power. It provides real-time measurements that enable the creation of a real-time data map for each parameter. It measures power usage across equipment, environmental and motion parameters across the physical space of the data center, and IT resource usage. This underscores the need for developing innovative approaches to reliable and non-invasive real-time monitoring and management.

Data center performance analysis requires understanding of facilities and IT equipment. Table 1 outlines the main components of a data center, categorized by power delivery and power consumption (e.g., IT equipment, environmental control systems, and other).

Table 1: Components of a data center

Component	Description
Power delivery systems	Different sources of energy Generators Switch gear Automatic transfer switches Electrical panels UPS systems Power distribution units Remote power panels Distribution losses external to IT equipment
IT equipment	Servers Storage systems Network / communication equipment
Environmental control systems	Chillers Cooling towers Pumps Ventilation Computer room air handling units Computer room air conditioning units Direct expansion air handler units
Other	Structured cabling systems Automation systems Lighting Security Fire systems

Real-time data collection can add value in several areas, including data center infrastructure control and management; performance optimization; enhancement of availability, reliability and business continuity [45]; reduction of total cost of ownership [46]; optimization of asset usage; and predictive analytics. A real-time monitoring and management system can highlight areas to reduce energy consumption, increase efficiency, improve productivity, characterize sustainability, and boost operations. The practice may also help to avoid or defer expensive facility expansion or relocation, via optimization of the current facility.

At least two classes of sensing devices are needed for data gathering: power sensing devices and environmental / motion sensing devices. For power sensing, we focus on non-invasive methods. Environmental data such as temperature, humidity, airflow, differential air pressure, lighting, moisture, motion, vibration, and cabinet door closure measurements are also required. Table 2 summarizes the requirements for these sensing devices.

Table 2: Requirements for sensing devices

Requirement	Description
Reliability	Due to the dynamic nature of data centers, the equipment shall be reliable and easy to install, relocate, or replace.
Wireless	Wireless data transmission using a radio transceiver reduces the use of cables in the data center. To avoid interference with existing equipment in the data center, wireless monitoring devices should have low-power transmissions, low data transmission rates, and non-overlapping frequency ranges [47].
Real-time	Sensing data in real-time helps to build situational awareness tools, such as reports and dashboards, which lead to immediate and more informed actions, reducing downtime and operating expenses.
Low-power	Low-power sensing devices enable an extended lifecycle before replacing batteries, reducing maintenance.
Battery operated	Battery operated devices eliminate the risk of connecting devices to an outlet, which could conflict with critical loads.
Low-cost	Low-cost microcontrollers and sensors make monitoring technologies available to all data centers.

Obtaining real-time data can be challenging, especially in existing data centers that lack adequate instrumentation [48]. For sampling purposes, several factors must be considered. If the sampling rate is too high, excessive data could be collected. Conversely, if the sampling rate is too low, relevant data for real-time monitoring and prediction may be lost. Collecting the right data and understanding its nature is more important than simply collecting more data [45]. We must ensure that required information is not lost. In many cases, new data may be required; the system should be flexible, allowing addition of new sensors and retrieval of additional data from equipment. After sensing and gathering the required data, it must be stored, locally or remotely, for real-time processing and future analysis. Data analysis leads to more informed decisions.

3.2. Data Collection and Transmission

For data collection, different classes of sensing devices are required. It is also necessary to gather IT equipment resource utilization data through processor measurements.

Power Measurements:

For power consumption measurements, all data center IT equipment and its supporting infrastructure must be considered. This task could be accomplished in many ways, but we are interested in reliable and non-invasive methods. Most data center components, such as uninterruptible power supplies, power distribution units, remote power panels, electrical panels, and cooling systems offer real-time data through existing communication interfaces. To avoid additional cabling, the use of wireless transmission must be the first option.

A standard protocol should be used to access data on remote devices, such as the Simple Network Management Protocol (SNMP) over TCP/IP. In addition, appropriate security measures must be implemented, since the data retrieval feature could create a security vulnerability. For equipment without a communication interface, one option is to install a specific power meter with the required communication interface. It will be an additive component, applicable across different device types, reducing operational risk. Another alternative is to replace existing equipment with new units that include metering and communication interfaces.

Software developed for data collection must gather and filter data collected from sensing devices and transmit the data to one or more storage devices. All monitored devices must be evaluated to define the required parameters and sampling rates.

Environmental / Motion Measurements:

The described system measures environmental and motion parameters across the physical space of the data center. Equipment cabinets, and various measurement points at different heights must be considered to capture relevant environmental variables. Different areas without equipment, such as below the raised floor, the aisles, and other points, must also be taken into consideration.

Table 3. Parameters to be monitored

Parameter	Description	Sensing
Temperature	Acceptable range required by equipment, and to optimize cooling systems and enhance efficiency.	Across the data center. In each IT cabinet: front of the cabinet (bottom, middle, and top) may be sensed for cold air inlet, and back or top for exhaust.
Humidity	Acceptable range required to reduce electrostatic discharge problems (if humidity is low), and condensation problems (if humidity is high).	Across the data center. In each IT cabinet: in the middle of the air inlet.
Airflow	Equipment and infrastructure require airflow, as specified.	Below the raised floor. Above perforated tiles.
Differential air pressure	Differential air pressure analysis could help to optimize airflow and cooling systems. If differential pressure between two areas is low or high, it indicates the airflow rate is also low or high.	Across the data center. Sensors are installed between two areas with varying air pressure (e.g., below and above the raised floor, inside and outside air plenum areas, between hot and cold aisles).
Water	Water sensing is required to prevent failures from cooling equipment, pipes, or external sources.	Near cooling system, water pipes, equipment, or potential risk areas.
Vibration	In case of earthquakes or excessive vibration, vibration sensors can trigger appropriate alerts. The sensors could also detect unauthorized installation, removal, or movement of equipment.	In each cabinet.
Lighting	Different levels of lighting according to human occupancy or security requirements.	Across the data center.
Security	Motion sensors could detect movement around cabinets. Contact closure sensors to enhance security systems. Airflow, temperature, and humidity in equipment could be affected if a cabinet door is opened, or if people are around the perforated tiles. Contact closures for access doors may be checked and tied to temperature variations nearby.	Door contact closures for cabinets and access doors, motion sensors, and surveillance cameras located nearby.
Fire systems	Fire alarms must be considered.	Data from fire system.

Each sensed parameter covers a specific range, and depending on the equipment, the range varies. Newer technologies allow a broader range of environmental parameters. ASHRAE Technical Committee 9.9 has created a set of guidelines regarding the optimal and allowable range of temperature and humidity set points for data centers [49-51]. Manufacturers have also established the environmental optimal operating ranges for their equipment, which enables a more detailed analysis of operational ranges. The standard ANSI/BICSI-002 [10] recommends three different lighting levels (level 1 for security purposes, level 2 when unauthorized access is detected, and level 3 for normal conditions).

The parameters to be monitored across the data center are described in Table 3. All parameters must be analyzed to define sampling rates. Contingent on specific requirements, additional inputs or sensors may be added.

As shown in Figure 1, after sensor data is acquired, transmitters are responsible for relaying data from all sensing devices to a storage device. The transmitter must be capable of storing data for an established period of time in case transmission problems occur, to avoid losing data.

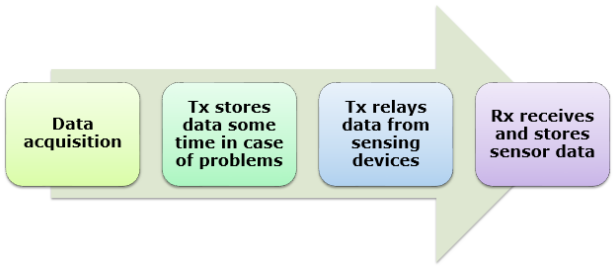

Figure 1: Data collection and transmission workflow

Given the limited (battery) energy available to each device, one data acquisition challenge is to maximize network lifetime, and to balance the use of energy among nodes. Network lifetime can be defined as the time the network is able to perform tasks, or as the minimum time before any node runs out of energy and is unable to transmit data. A multihop routing protocol should be used, ensuring there is an active path between each network device and the network's sink [52].

The following aspects associated with the wireless sensor nodes deserve attention: device location, which depends on data center layout; new device additions or relocations, where communication is not disrupted; failure diagnostics (e.g. energy problems, disconnections); and redundancy requirements across critical tasks.

Processor Measurements:

Enhancements by some IT equipment manufacturers include the ability to directly access some measurements related to power, surrounding environment, and resource utilization for each device. These measurements could include parameters such as power utilization, air inlet temperature, airflow, outlet temperature, CPU usage, memory usage, and I/O usage. Platform level telemetry helps transform data center monitoring and management, allowing direct data access from the equipment processor. Comparison of processor measurements to environmental and power measurements, as well as analysis of the IT resource usage, can improve decision-making [53].

With IT resource utilization data available, IT resource optimization through workload allocation and balancing, as well as through other control strategies, is feasible. These measurements may not be available for all equipment. Querying

this information is unlikely to interfere with IT equipment's primary tasks.

3.3. Redundancy

Redundancy can be understood as the multiplication of systems to enhance reliability. Since data center components require maintenance, upgrade, replacement, and may fail, redundancy is required to reduce downtime. Critical components of the monitoring and management system may also fail, and sensitive data could be lost. To evaluate the need for monitoring and management redundancy, several factors must be considered.

The data center monitoring and management system should be designed according to the reliability tier of the data center and its related redundancy level [54]. If the data center presents redundancy (e.g., N+1, 2N, 2N+1), the monitoring and management system should provide the same redundancy level to preserve reliability. Conversely, if a data center has no redundancy in its IT equipment and supporting infrastructure (e.g., electrical, mechanical), redundancy may not be required. In addition, for the evaluation of the required redundancy of monitoring and management devices, mission critical IT equipment in the data center should be identified.

Data centers can use thousands of sensors to gather required data. For that reason, it is convenient to have general estimations of the number of sensing devices required for a given data center. Although the best way to calculate this is to analyze each data center in detail, there are guidelines to make preliminary estimates.

The first step is to estimate how many cabinets fit in the data center layout. Initially, the data center layout and information about the equipment must be examined. Most IT equipment is installed in a cabinet or open rack, with supporting rails 19in wide (Electronic Industry Alliance industry standard); adding space required for panels, doors, wiring and airflow increases the width to between 24in and 30in. The typical depth ranges from 36in to 48in, depending on the equipment. Standalone equipment may require special cabinets, which can increase the previous estimates. Considering a raised floor grid of 24in x 24in (industry standard), the cabinet's area can be estimated as 24in x 48in, or 8 ft^2. A similar area per cabinet is required for hallways, infrastructure facilities, and other non-IT equipment. The second step is to estimate how many sensing devices are required. Based on the previous step, for each cabinet, or for each 16 ft^2, at least one environmental / motion sensing device will be required. Power sensing devices must also be considered; the total count can be estimated as the total number of elements (e.g., electrical facilities, cooling and ventilation systems) that support IT equipment. In addition, depending on spatial distribution, at least one transmitter should be in place to gather and transmit sensed data for storage and further processing. The final step is to review redundancy requirements and to estimate the total number of sensing and transmitter devices needed.

3.4. Data Storage, Processing, and Management

As shown in Figure 1, after gathering data, it is sent to the storage device, locally or remotely, to support future processing and reporting. The large amount of data collected must be organized to guarantee that it can be integrated, shared, analyzed, and maintained. A metadata management system is suggested. Metadata is understood as structured information that describes an information resource. It is, in effect, data about data. A metadata management system ensures that metadata is added correctly and provides mechanisms to optimize its use. A software interface must be developed to process and manage the information. Figure 2 shows a diagram of the different elements involved in data storage, processing, and management.

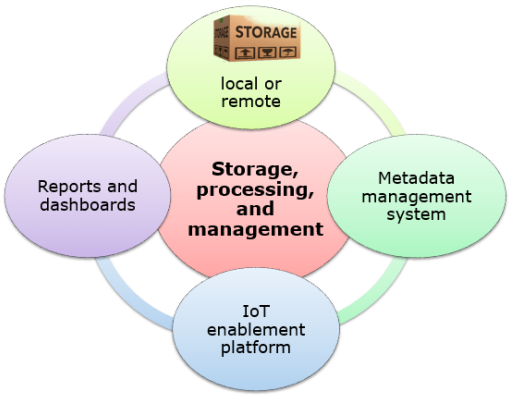

Figure 2: Storage, processing, and management

The use of an IoT enablement platform is a viable option to connect monitoring devices anywhere to the cloud. The key added value of these platforms is to simplify connectivity, data collection, and device management.

Reports and dashboards help to visualize a data center's past and present performance. Dashboards are graphical user interfaces customized to user requirements, used to display key performance indicators to make them easier to read and interpret. Visualizing results in real-time supports responsive improvement. Warnings may be used for undesirable events. Furthermore, forecast reports can be used to predict how the data center will perform in the future.

Numerous reports can be generated from the data gathered by the monitoring and management system, such as real-time data reports for existing conditions; historical reports showing behavior with baselines and trends; statistical reports; and analytical reports showing asset utilization, performance, and other key indicators. In summary, different reports and dashboards translate data into information and strategic knowledge.

Proactive strategies are more desirable than reactive actions. Strategies may be undertaken based on what has been learned. Results will be measured as the system continues to collect data, reflecting the effectiveness of prior actions. This feedback often constitutes the basis for new actions [45].

3.5. Metrics

Data centers can be evaluated in comparison to the goals established or to similar data centers through the use of different metrics, as the performance cannot be understood with the use of a single metric [48]. Inconsistencies or variations in measurements can produce a false result for a metric, and for that reason, it is very important to standardize metrics. After thoroughly reviewing existing data center metrics, four areas are identified through which data center performance can be measured: efficiency, productivity, sustainability, and operations [55]. Table 4 presents general concepts for these metrics.

Table 4. Performance measurements

Metric	Concept
Efficiency	Due to the high-energy consumption of the data center sector, efficiency has been given substantial attention. Efficiency indicators show how energy efficient site infrastructure, IT equipment, environmental control systems, and other systems are.
Productivity	It gives a sense of work accomplished and can be estimated through different indicators, such as the ratio of useful work completed to energy usage, or useful work completed to the cost of the data center. Useful work can be understood as the sum of weighted tasks carried out in a period of time, such as transactions, amount of information processed, or units of production. The weight of each task is allocated depending on its importance.
Sustainability	It is defined as development that addresses current needs without jeopardizing future generations' capabilities to satisfy their own needs [56]. Measurements for sustainability include carbon footprint, the greenhouse gas footprint, and the ratio of green energy sources to total energy.
Operations	Measurements gauge how well managed a data center is. This must include an analysis of operations, including site infrastructure, IT equipment, maintenance, human resources training, and security systems, among other factors.

The process to gather data to calculate metrics can easily be automated, as many parameters are updated automatically through the monitoring and management system. This allows some key indicators to be updated in real time. Other parameters are not easily automated. Instead, they derive from audits, human observation, evaluation, and analysis, and must be updated if and when a process changes. This is the case for some aspects of sustainability and operations. In addition, new variables will be measured, and new metrics will be created, as needs and technologies evolve.

Data center performance is the basis for designing and implementing plans aimed at improving key indicators. Asset usage is an important component of performance measurements, as it reflects how adequately the different data center assets are being used at specific points in time. Improving specific performance indicators leads to asset usage optimization.

3.6. New Tools for Data Analytics

Considering the large amount of data collected, new tools must be developed to help users employ historical and real-time data, together with know-how, to undertake assertive actions. Predictive modeling enables simulation and forecasting of how a data center will perform in the future. As shown in Figure 3, combining real-time data from the monitoring and management system, know-how, and new tools (e.g., simulation, modeling, machine/deep learning) will lead to predictive analytics for the data center and its components. Simulations show how different components could perform or fail, allowing more time to evaluate and mitigate problems.

Simulation is an important tool for model validation, and for analyzing different scenarios. Models are safer, faster, and more affordable than field implementation and testing. Simulations help to explore how systems might perform under specific scenarios, including disturbances, equipment failure, different layout configurations, or specific control strategies. Historical data must be used to validate and calibrate the models developed for each specific data center. To transform data center predictive modeling from probabilistic to physics-based, tools such as computational fluid dynamics models for airflow, temperature, humidity, and other parameters must be used. Simulations can also help to understand how adaptive and resilient a data center is. Resiliency can be understood as the ability of a data center and its components to adapt existing resources to new situations.

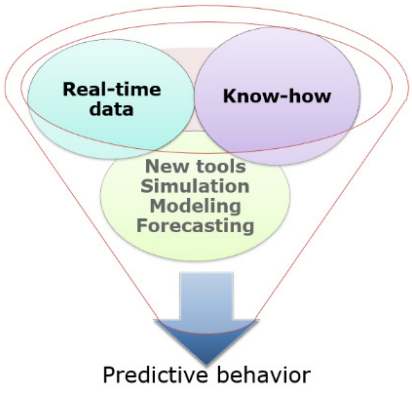

Figure 3: Predictive Analytics

To recognize new insights or predict future behavior, tools such as predictive analytics and machine/deep learning are needed. These tools involve algorithms that can learn from and make predictions about data without being explicitly programmed. Models should be constantly updated with real-time data to make predictions based on new realities. These tools lead to planned scenarios, rather than emergencies or failures, enabling more proactive decision-making.

3.7. End-to-end Resource Management

Data center optimization strategies should include all assets - power and cooling equipment, and IT equipment resources - to support end-to-end resource management. Resource management is iterative, enabling data center managers to plan and make adjustments. Examples include physical space planning for replacing, upgrading, or relocating equipment; detection of unused or idle IT equipment; capacity planning; optimization of cooling systems; power system optimization; IT resource optimization, including servers, storage, and networking equipment; workload allocation to control power and environmental parameters; workload balance among IT equipment; and virtualization. Comprehensive control strategies allow performance optimization.

4. Data Center Modeling and Control Systems

With increasing levels of automation in the data center, the role of control systems is growing. Data center monitoring systems are the main components of any such feedback control system; they deliver the required information so the control system can take appropriate actions. The control system comprises components or processes interconnected to achieve a function with multiple inputs and outputs. Optimization is a desirable objective, considering data center components are dynamic and change continuously with time, or with any other independent parameter.

From a control systems point of view, the data center can be described as a closed loop system with multiple inputs and multiple outputs, controllers and actuators, as shown in Figure 4. The desired values are generally based on standards, best practices, and/or user requirements. The system or process to be controlled is the IT equipment in the data center. Various devices and sensors are required to measure the variables to be controlled, such as power, temperature, humidity, air flow, differential air pressure, closure, motion, vibration, and IT equipment resource utilization.

The actuator represents infrastructure equipment (e.g., cooling system, ventilation, security, fire system) and IT equipment resource management (e.g. virtualization, workload transfer, load balancing). The actuator will influence the process, and by consequence, the associated outputs / controlled parameters. The controller, as its name suggests, computes the control signals. The multiple outputs / controlled parameters are compared to the multiple inputs or desired values. Based on the error signal, or the difference between the desired values and the outputs, the controller takes corrective actions, affecting the actuators, so that the output values track the reference values within a desired margin.

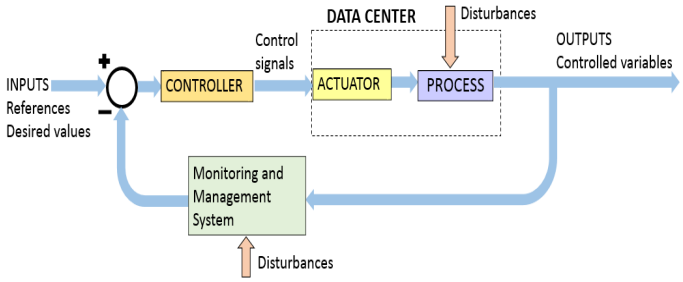

Figure 4: Data center feedback control loop block diagram

Disturbances that can affect the behavior of the processes, undesired or unforeseen, should be taken into consideration. Feedback is required for adaptive and robust control. Feedback control allows corrective action regardless of the disturbance sources and decreases the sensitivity of the controlled parameters to process changes and other disturbances.

Each of the different data center components can be modeled through a mathematical description using a macro level approach, with inputs and outputs. After identifying all the measurements and parameters required, the data center monitoring and management system must gather all data inputs and outputs from various components, from which the key indicators will be calculated. The monitoring and management system allows reliable feedback control, measuring the controlled variables to adjust the manipulated variables; and also enables validation and calibration of the proposed models.

5. Conclusions

The described data center monitoring and management approach allows rapid deployment of a reliable, real-time monitoring system to improve operations, to enhance performance, and to reduce risk of failures. Using battery operated, low-power, wireless sensing devices, and retrieving data directly from equipment, information is collected through a non-invasive, continuous process.

Collected data can be used in many ways to make more informed decisions, to reduce downtime and cost of operations, to improve performance and key indicators, to optimize asset usage, to implement more informed actions and strategies, and to develop predictive behavior models. Data center professionals must think critically to determine what data is needed for each particular case, also considering future scenarios. This practice prevents missing important measurements and helps to avoid collecting unnecessary data.

Going forward, data center monitoring and management systems must include end-to-end resource management, covering both the IT equipment and supporting infrastructure. The ability to directly access measurements related to power, environment, and IT resource utilization opens new windows for optimization. Future data centers may avoid full time on-site staff, by relying on monitoring and management systems.

Timetabling Models

ABSTRACT

Technological tools such as Semantic Web and ontologies have contributed immensely to the reduction of most managerial complexities on daily basis. However, most resolved complexities are solely dependent on the emerging issues which are not general enough to accommodate some specific domain challenges. Temporal scheduling complexities occur in several domains including timetabling, but inter-departmental courses allocation on a general institutional timetable has not been considered. This poses serious managerial concerns and threats to the academic performance of any institution. This paper is aimed at formalizing an ontology model for analyzing temporal scheduling complexities in an existing schedule and giving optimal possible time scheduling resolutions showing their reduction rates for efficient and intelligent knowledge management. Protégé was used in modeling the domain ontology described in the resulted ontograf. The semantics of the formal ontology model is described based on Allen's interval temporal relations. The use of ontologies make way for easy and intelligent reasoning with knowledge and exposes the need for such knowledge management tool to manage the influx of the numerous data.

1. Introduction

This paper is an extension of work originally presented in the Future Technologies Conference 2016 [1], where the use of ontologies in semantic web was established as an efficient and intelligent tool for managing timetabling knowledge [2]. Domain specific concepts and some complexities were presented in figures 2, 3(a) and 3(b) of the conference paper. The Allen's interval-based temporal relations [3] were considered suitable and introduced for inferencing [4] in the sample rules used to describe possible resolutions to the highlighted complexities in the conference paper. Allen's interval-based temporal relations were introduced to handle time durations and is adapted or reused for formal description of time periods for complex knowledge management as seen in the timetable domain. However, this paper extends works done in the conference paper as it aims at formalizing an ontology model for analyzing temporal scheduling complexities in an existing schedule and providing optimal possible time scheduling resolutions showing their reduction rate for efficient and intelligent knowledge management.

In recent years, the explicit formal specifications of terms in any given domain and relations among them have gradually moved from the realm of Artificial Intelligence (AI) laboratories to the desktops of domain experts. The representation of domain concepts in structural ways - definition of concepts (classes and properties) and mapping the relationships among the defined concepts, form the basis of Ontology [5]. From the computer science perspective, it is a formal naming and definition of the types, properties, and interrelationship of the entities that really or fundamentally exist for a particular domain of discourse [6] [7]. For example, in a lecture timetable domain, courses, timeslots, students, lecturers, venues and lectures are some of the concepts from which the timetabling application domain can be described. These concepts and their meanings together constitute ontology for timetable and can be used as common knowledge for communication among educational stakeholders and provides information for the development of a timetable information system.

Ontologies exist in diverse forms - lexicons, dictionaries, thesauri, and logical models described in languages such as first order logic (FOL). Lexicons provide standard lists of words

(vocabulary) in a language with corresponding knowledge of how each word is used. Hence a lexicon can be seen as an index for mapping written form of a word with the information about that word [8]. Dictionaries can be organized to form hierarchies-taxonomies, meronomies, mereologies and merons, according to specific relations. Related terms, linguistics objects are added to any given collection of terms through thesauri. Ontologies provide standardization of the terms used to represent knowledge about a domain in any of these forms. They can as well support inference with FOL or its subset, by deriving new facts from a collection of facts and enforcement of consistency. It also allows for sharing common understanding of the structure of information among people or software agent; reuse of domain knowledge; making domain assumption explicit; separating domain knowledge from operational knowledge; and analyzing domain knowledge. These considerations are clearly useful for knowledge management, especially when large amounts of knowledge are being processed. Ontology is increasingly used in various fields such as Knowledge Engineering, Artificial Intelligence(AI) and computer science, in applications related to knowledge management (KM), natural language processing.

KM involves the acquisition, creation, use, representation, organization and advancement of knowledge in its many forms. As a requirement for effective KM, an understanding of how individuals, groups and organizations use knowledge is needed. One major aspect of an organization that require effective management of knowledge is timetable scheduling. This is because an organization's general timetable exhibit different levels of temporal scheduling complexities depending on the available resources. The threats posed by these complexities ranges from poor organization performance as seen in the domain of discourse (poor academic performance). Knowledge management is thereby required in attempt to reduce these complexities. Automation of timetabling process as seen in existing systems [9] [10] [11] does not resolve these complexities. This paper demonstrates the application of ontologies in timetable KM. It is aimed at analyzing any existing temporal schedule to discover all complexities and providing possible temporal schedules with reduced complexities (in time and space requirement) that tends towards optimality. This is achieved by utilizing Allen's temporal interval relations described in the following sections and evaluating the resulting optimal temporal schedule for proof and the need for adoption.

2. Formal Ontologies and Temporal Interval Relations

The time ontology has been considered by several authors with unique contributions to issues relating to temporal (time) representation and reasoning among others. Hobbs and Pan [12] considered temporal relations (TR) involving two subclasses of time— time instant and time interval. Allen's interval relations [13, 3] centers on various time intervals and possible reasoning involving co-operating concepts. As proposed by Allen [3], a framework for temporal reasoning, and all the relations proposed dealt with the directionality of time. In his proposal, intervals are the only temporal primitives in the temporal logic. Allen aimed at illustrating natural language sentences and to represent plans. To achieve the thirteen (13) basic relations between time intervals, with six of the intervals being the inverse of the other six: before, after, finishes, finished-by, overlaps, overlapped-by, starts, started- by, during, contains, meets, met-by and equal [3]. The basic interval temporal relations (Figure 1). These temporal relations depict and relate the actions and plans described in this paper.

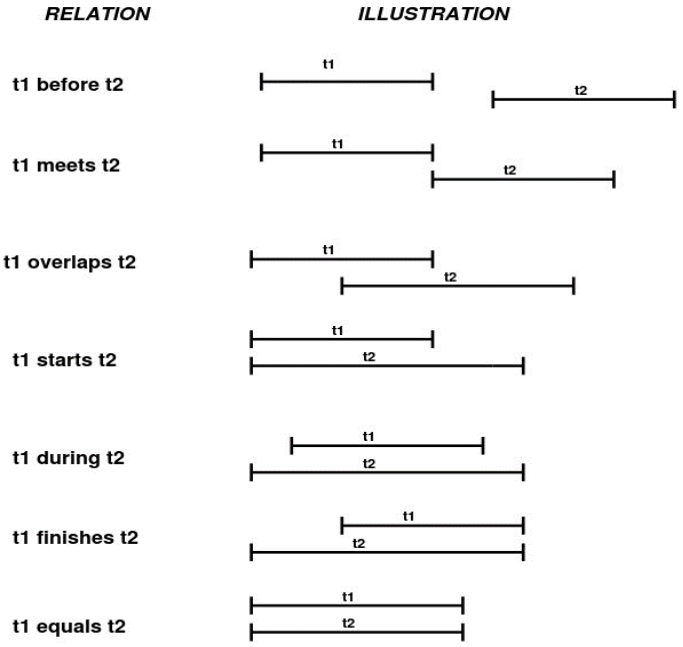

Figure 1: Allen's interval based temporal relations

This paper is targeted at formalizing the basic temporal ontology model for reasoning and inference towards an optimal time scheduling, after an analysis of an existing timetable to unravel all the complexities and evaluating feasible solutions towards achieving optimality. An illustration of how moment and point works on interval-based temporal logic is given in "moment and point in an interval based temporal logic". Moment is a non-decomposable period where the time is corresponding to instantaneous events while a point (a zero duration time) is where reasoning about the beginning and ending of event do arises. The axiomatization of the stated theory of time was done in terms of the simple relationship "meets" and subsumes the interval-based theory proposed in [3] thereby extending the theory to point-like time periods.

3. Timetabling Complexities

Timetable analysis reveals the major concepts - departments, timeslots, courses, students, venue and lecturers as objects responsible for complexities in timetable implementations. Three categories of courses exist in any typical higher institution; departmental, faculty-based and university-based courses. This paper considers the complexities arising from their inter-dependencies in scheduling the intra-departmental and inter-departmental (faculty-based and university-based) courses. Amongst other timetabling competency questions, are the following in the optimization of the general temporal scheduling ontology. They include:

i. Is the course offered by other departments, other than the host department?
ii. Are other courses for the same level in all cooperating departments allocated to the same time?
iii. Are students in higher levels in the cooperating departments also offering the course?
iv. Is the course lecturer teaching another course allocated at the same time?
v. Is the venue for course far apart from venue of the preceding or succeeding courses (courses before or after)? That is, are the respective venue for teaching the courses on different campuses? or are they within the same campus but widely separated?

Each of these concepts has peculiar attributes. These concepts relate in diverse ways and some of the relations exist in reverse form. The relations include *owns, has, can-be, offers, teaches, holds-in, lectures-in*, and *are-assigned-to*. In consideration of the fact that most resources of the university (such as lecturer, venue, and courses) are shared and in some other cases limited, departments compete for these resources. A university has a given number of programmes running on specified number of campuses. Campuses or lecture venues widely separated far apart from each other will exhibit a high level of complexity with numerous inter-dependencies. A sample model in fig. 1 with the departmental general timetable ontology for each department was described in [1] and shown in the resulting ontograf (Figure 2) from protégé. Almost all the components of the ontology are shared, making it needful for interoperability amongst relating departments. An attempt to link the ontologies for all the relating departments will make the resulting ontology cumbersome and more complicated largely because components of the ontology are not owned by a department, the number of inter-dependencies will generate some form of conflict of interest.

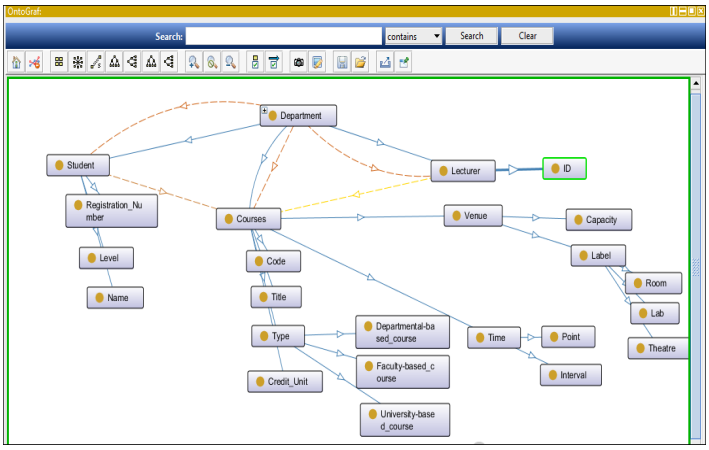

Figure 2: An Ontograf of a Departmental Timetable Ontology

Suppose course c_i is to be taught by lecturer L_l, scheduled to hold at venue v_1 at time t_i and another course c_j to be taught be the same lecturer L_l at same time t_i in another venue v_2, exposes some form of complexities. Again, suppose c_i and c_j are both scheduled to hold at v_1 at the same time t_i bring to bear another level of complexity that is predominant in the domain. That is a groups of students offering a particular course holding at time t_1 at campus U_1, and also offering another course c_j holding at time t_2 at campus U_2, where time t_1 meets time t_2. The meeting time does not give allowance for the participating students to travel from campus U_1 to campus U_2 (or from venue vi to venue v2 with campus U_i). A general model of these complexities is shown in Figure 3.

A view of the various complexities based on the Allen's interval relations results in the following temporal complexity types: overlapping time (which also includes starts, ends and during relations) for courses taught by same lecturers and offered by same level of students. Meeting time complexity also results for courses offered by inter campus students. Other complexity types, not handled in this paper, include venue-clash and carrying capacity check.

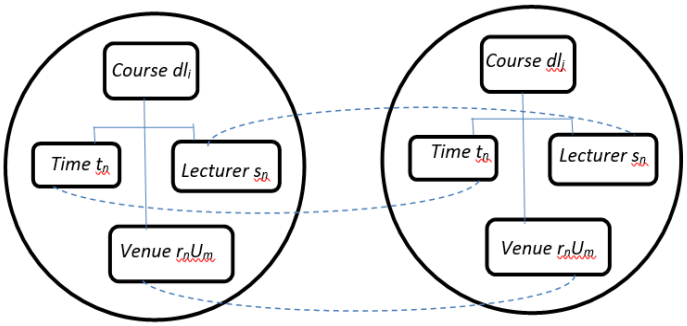

Figure 3: A course allocation complexity model

where *d* is the department's code, *l* is the level of students, t represents the timeslot, s is the lecturer, r the room number while U is the campus. *i,j,n,m>0* are instances of the various objects

From the general course allocation complexity model in Figure 3, several levels of complexity are defined to include:

- Departmental Complexity (Regular)
- Departmental Complexity (Carryover)
- Faculty-Based (Inter-Departmental) Complexity (Regular)
- Faculty-Based (Inter-Departmental) Complexity (carryover)
- Inter-Faculty/Same Campus Complexities (Regular)
- Inter-Faculty/Same Campus Complexities (Carryover)
- Inter-Faculty/Inter-Campus Complexities

A generalized timetable ontology will expand the departmental timetable ontology is obtained from a mapped departmental timetable ontology as modeled in [1]. This require the mapping of domain resources ranging from, past results, course registration list, departmental brochure for details of all level courses and lecturers, campus location (or distance apart), etc.

Table 1 gives a justification of complexities in all the cases in consideration and the possible resolution based on interval temporal relations.

4. System Framework

Figure 4 gives the architecture of the proposed Ontology-Based Temporal Scheduling Framework showing the relevant components for the achievement of its set goal of producing an optimal time schedule.

Table 1: Complexity description by type and possible time scheduling resolution

Case number	Case description	Complexity type	Resolution
1.	Carryover /repeating students in the host department.	Overlapping- Time	If carryover students are offering course c_i at time t_1, then time t_2 for course c_j (time for their level course should not overlap).
2.	Carryover / repeating students in the serviced department.	Overlapping- Time	If carryover students are offering course c_i at time t_1, then time t_2 for course c_j (time for their level course should not overlap).
3.	Regular students (students at that level) in the services department.	Meeting-Time	If course c_i is scheduled at time t_1 in campus U_1, (for e.g 10-12) and course c_j is also scheduled at time t_2 in campus U_2, where the end-time of course1 c_i meets with the start-time of course c_j, the course should be rescheduled.
4.	Assigning the same lecturer to teach at different campuses, without giving sufficient time interval.	Meeting-Time	A lecturer assigned for course c_1 at time t_1 in campus U^1, and also assigned for course c_j at time t_2 in campus U_2, where the end-time of course c_i meets with the start-time of course c_j, should be rescheduled.
5.	students at same level and carryover/repeaters student in the services department.	Starts/ Finishes	If course c_i and course c_j are of different department, then course c_j should not start at the same time with course1 and finishes after course c_i
6.	Students in their regular year of studies and carryover student of different department, but the same faculty.	During	If course c_i and course c_j are of different department , d_i and d_j respectively, but of the same faculty, then course c_i should not hold during course c_j
7.	Students (both regular students and carryover student) at another campus, offering a course holding at a different campus.	Location Campus location (distance apart)	If course c_i is scheduled for time t_1 in campus U_1, and course c_j is also scheduled for time t_2 in campus U_2, then time t_1 should not meet t_2
8.	The class size and the carrying capacity of the lecture venue.	Space (carrying capacity)	If the number of students offering course c_i is greater than the venue assigned, then course c_i should be re-scheduled for a bigger venue.

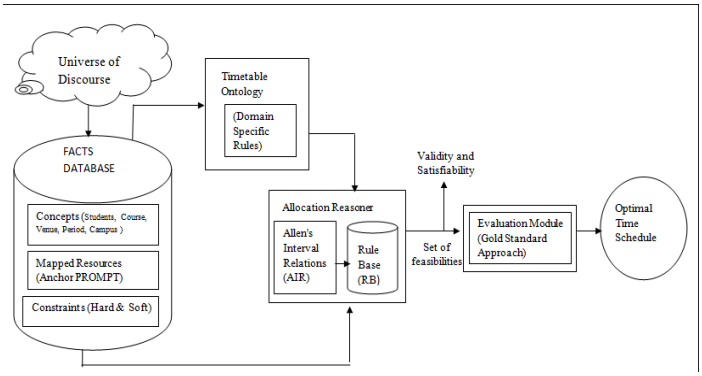

Figure 4: Architecture of the Proposed Ontology-Based Time Scheduling System

The major components of the system as depicted in Figure 4, are described as follows:

(i) Universe of Discourse: the universe of discourse where the domain knowledge under consideration is obtained. It consists of all the domain concepts — courses, venues, universities, timeslots, lecturers, students, students' status, departments, faculties, levels, campuses, locations, timetable and other aspects of the timetabling domain

(ii) Fact Database: this includes the values and instances of the domain concepts, the resources, relations and a mapping of facts to concepts and resources. It also has the hard and soft constraints.

(iii) Time Ontology; this component stores the domain specific rule (owns, has, offers etc.) which will be considered while mapping the resources.

(iv) Allocation Reasoner: this is where reasoning and inferencing take place based on the Allen's interval-based temporal relations. The sets of rules arising from the competency questions and some already established constraints, are also part of this component. the Allocation Reasoner works in collaboration with the domain specific rules.

(v) Ontology Evaluation Approach: Criteria from the gold or golden ontology evaluation standard helps in assessing the set of feasibilities obtained from the Allocation Reasoner towards optimality of the timetable.

(vi) Optimal Time Schedule: This gives the resulting possible time schedule showing the resolutions made towards optimality.

To manage the complexities called for the optimized general time schedule with an allocation reasoner with interval-based temporal relations operating in-between the cooperating departmental timetable ontologies. Shared components of the optimized general timetable ontology. The interval-based temporal relations/rules serve as the instrument for managing the identified complexities in the timetabling system. With the interval-based temporal relation allocation of courses to venues, allocation of courses to timeslots (time duration), and assignment of lecturers to courses/venues are efficiently done.

4.1 Proposed Complexity Reduction Rules

From competency questions (i) to (v) identified in section 3.0, rules R1 to R12 addresses the complexities as well as adopting the Allen's interval relations in the proposed resolutions. It is assumed that all departments within the same faculties are domicile in the same geo-location:

R1: IF student of department d_i *offers* course c_i AND department d_i NOT *owns* course c_i THEN time t_1 for course c_i **NOT *overlaps*** time t_2 for course c_j in department d_2.

R2: IF course c_i *holds* at time t_1 and course c_j holds at time t_2 AND t_1 ***equals*** t_2 AND students offer c_i and c_j THEN t_1 and t_2 ***overlaps***.

R3: IF course c_i *holds* at time t_1 and course c_j holds at time t_2 AND time t_1 is ***during*** time t_2 AND students offer course c_i and course c_j THEN t_1 and t_2 ***overlaps***.

R4: IF course c_i *holds* at time t_1 and course c_j holds at time t_2 AND t_1 ***starts*** with t_2 AND students offer c_i and c_j THEN t_1 and t_2 ***overlaps***.

R5: IF course c_i *holds* at t_1 and course c_j holds at time c_2 AND t_1 ***finishes*** at t_2 AND students offer c_i and c_j THEN t_1 and t_2 ***overlaps***.

R6: IF c_i and c_j *belongs* to the same department, d_1, THEN scheduled c_j to t_i AND c_j to t_j such that $t_i \neq t_j$ (**NOT *overlaps***).

R7: IF c_i and c_j are of different department, d_i and d_j respectively, but of the same faculty, THEN time for c_i should **NOT *overlaps*** with c_j or c_i **NOT *during*** c_j.

R8: IF t_i for c_i and t_2 for c_j ***meets***, THEN t_j for c_j will be changed and scheduled for another time (**NOT *meets***)

R9: IF c_i and c_j are courses of different faculty, THEN their time **NOT *meets*** and **NOT *overlaps***

R10: IF time for c_i and c_j are ***equals*** AND venue assigned for c_i is the same venue assigned for c_j, THEN (c_i OR c_j) should be rescheduled for different time.

R11: IF time for c_i and c_j are ***equals*** or ***meets***, AND the lecturer assigned for c*i* in campus U_1 is also assigned for c_j in U_2 within the time interval of one hour, THEN c_j should be re-scheduled for another time.

R12: IF c_i is scheduled for t_i in U_1 AND c_j scheduled for t_j in U_2 THEN t_i **NOT *meets*** tj.

R13: IF carryover/repeating students are offering c_i scheduled for time t_i THEN t_j, time for their level course, c_j **NOT *overlaps*** t_i.

R14: IF c_i in campus U_1 and course c_j in U_2, THEN time t_i for c_i and t_j for c_j **NOT *meets*** or **NOT *overlaps.***

R15: IF number of students offering c_i is greater than the venue carrying capacity, THEN re-schedule c_i.

Formally expressing the above rules in FOL results in axioms A1 to A15. Recalling from the conceptualization of the domain concepts: **student, lecturer, time**, **venue** and **campus** with domain-specific relations: *owns, has, offers, holds* and *teaches* does not resolve time scheduling complexities when considering inter-departmental course allocation. This called for the adoption of the Allen's interval relations which includes temporal relations such as ***overlaps. meets, equals, during*** and their negations for a more explicit representation. Axioms A1 to A15 constitute the core of the ontology reasoner that results in the optimal time scheduling process.

A1: $\forall$*Student, Course1, Time1, Dept1* $\exists$ *Course2, Time2, Dept2.*

A15: ∀Student, Course1,Venue1, Time1, nos, ∃Venue2, ccap.

offers(Student, Course1, Venue1) ∧ holds(Course1, Venue1, Time1) ∧ (nos > ccap) ⇒ holds(Course1, Venue2)

4.2 Weighting of Complexities

The severity levels of complexities are denoted by 0%, 50% 70% and 100% respectively based on the sources of complexity (time, space and location).

1. *Overlapping Time*:

Overlapping time complexities includes five relations in Allen's Interval-based Temporal Relations: s*tarts, finishes, overlaps, during* and e*quals*. In this paper, these five temporal relations are classified into two levels of complexities namely complete and partial. Complete overlap occurs if two or more courses offered by a group of Students begins and ends at the same time (Equals Relation – See Table 2) or the Start and End times of these course is within the start and end time of c_j (During Relation – See Table 3), then a complete overlap of weight 100% has occurred. However, the During relation will not apply in this domain since the university system does not have 4-hour lecture period. For example, instances of *equals* and *during* relations are given in Tables 2 and 3 respectively.

Table 2: equals Relation

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00–12:00 NOON
c_i			
c_j			

Table 3: during Relation

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00– 12:00 NOON
c_i			
	c_j		

A partial overlap is described using Allen's Interval-based Temporal Relations as follows; *overlaps*, *starts* and *finishes* shown in Tables 4, 5 and 6 respectively. These relations under partial overlap are assigned a complexity of 50%. Examples of partial overlaps are given in Tables 4, 5 and 6

Table 4: overlaps Relation

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00– 12:00 NOON
c_i			
	c_j		

Table 5: starts Relation

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00–12:00 NOON
c_i			
c_j			

Table 6: finishes Relation

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00– 12:00 NOON
c_i			
	c_j		

In the resolved overlap, the desired Allen's interval-based temporal relation for the resolution of overlapping time complexity is *before* in Table 7 and Table 8. When course c_i is *before* course c_j a 0% complexity is recorded.

Table 7: before Relation (A)

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00– 12:00 NOON
c_i			
		c_j	

Table 8: before Relation (B)

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00– 12:00 NOON
c_i			
			c_j

2. Meeting Time Complexity

If courses c_i and c_j hold in geographically dispersed Venues (R_nU_m, $R_{n+1}U_{m+1}$) and it takes a student time t_n to move from venue R_nU_m to $R_{n+1}U_{m+1}$, there exist a time complexity if course c_j starts immediately course c_i ends as shown in Table 9.

Table 9: Meeting Time Complexity (100%)

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00 – 12:00 NOON
c_i			
		c_j	

The 70% is for time to reach the venue and 100% is if there is additional time for the student to settle in the class before the actual lecture start time, an additional 30% weight is added. A 70% and a 100% resolution of the Meeting time complexity is as shown in Tables 10 and 11

Table 10: 70% Resolved Meeting Time Complexity

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00 – 12:00 NOON
c_i			
			c_j

Table 11: 100% Resolved Meeting Time Complexity

8:00 – 9:00 AM	9:00 – 10:00 AM	10:00 – 11:00 AM	11:00 – 12:00 NOON
c_i			
			c_j

5. Implementation Results and Discussions

The timetable showing schedules for two departments located at different campuses are used for the implementation of the proposed system.

These two departments offer common courses — CSC 211, STA 211, CSC 111. The natures of complexity are (meeting and overlapping times) clearly. Analysis of existing system shows the course under study, CSC 211 with Geo-informatics students in 300 level, who may be carrying over the course. It also handles the distance apart between the two campuses, being the venue for these two courses. Another case considers a complete overlap where CSC 211 and STA 211 from two different departments at two different venues, though in the same campus. Here, students of both departments are offering CSC 211. The analysis of these complexity levels with given assigned weights on the identified complexities is as shown in Table 12.

Table 12: Complexity weights of the existing time schedules

Case No	Complexity Type	Complexity Weight (%)
1	Meeting Time	100
2.	Overlapping Time (*equals*)	100

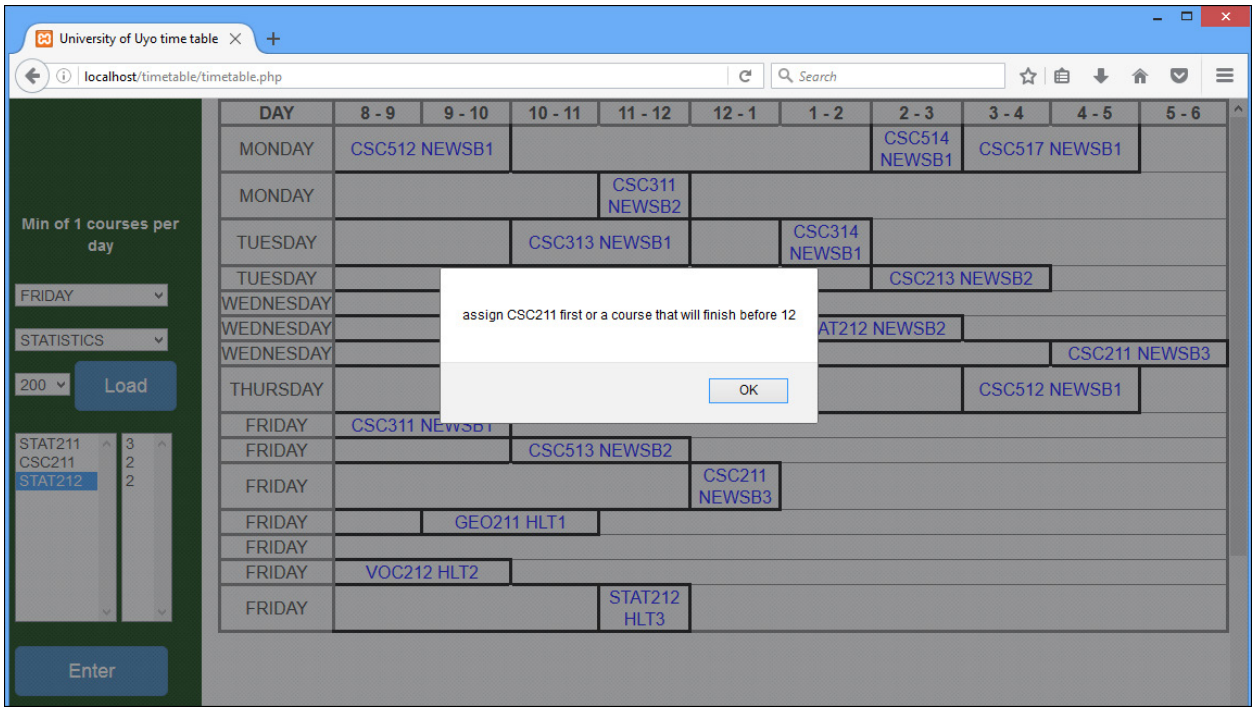

Figure. 5: Active Resolution of Meeting Time Complexity.

5.1 Resolutions with proposed Time Scheduling system

To resolve the time schedules, the complexity weights of the two cases should be 30% and 0% for meeting time and overlapping time respectively. The screen shots in Figure 5 gives the resolution of the meeting time complexity for the scheduled GEO 211 and CSC 211. The screen shot also shows a prompt to reschedule the STA 212 course as shown on the white pop-up window. That is the overlapping time complexity resolution, where the prompt calls for the relocation of the statistics (STA) course resulted. This is because CSC 211 is offered by many other departments, thereby having increased level of inter-dependency than the STA 212 course.

6. Conclusion

The proposed optimized time scheduling system analyzes any given existing time schedule and identifies the complexity types in existence. It provides the users the window to reschedule any time with identified complexity to obtain an optimized time schedule as shown in this paper. The rules in the reasoner are based on Allen's interval-based temporal relations as well the domain specific relations. Knowledge management as seen in the university timetabling complexities is possible with the mapping of the departmental timetable ontologies shown in the ontograf with all other required resources in the databases of fact. As a further work, the formal model that describes how the embedded semantics in the given rules are used for inferencing will be implemented on the ontology.

ABSTRACT

Radiation hardened devices are mostly extremely expensive. The continuously downscaling of microelectronic structures and the unavoidable presence of particle radiation on ground and in space leads to unwanted failures in electronic devices. Furthermore it is expected that in the next few years around 8000 new satellites will be launched around the world. Due to the enormous increasing need for Rad-Hard devices, there will be more focus on Commercial Of The Shelf (COTS) devices, which costs are lower. Also nowadays microelectronics for automotive systems are tested to withstand radiation especially SEU-single event upsets. It is clear that SEU cannot be ignored anymore especially in the application of unmanned autonomous vehicles and systems. Reliability testing is expensive and extremely time consuming. The use of COTS-Commercials of the shelf is the ultimate goal to reach. In this paper, an overview of radiation effects on different CMOS technologies used in COTS devices is given. These effects can be considered while selecting different functional equivalent COTS devices implemented with different technologies. Moreover, an overview of software techniques used in programmable commercial devices to reduce the radiation effects is also described.

1. Introduction

This paper is an extension of work originally presented at the SMTA Pan Pacific Symposium [1].

It is well known, that CMOS components are radiation sensitive and mostly have a variability concerning radiation response. The most commercial devices can withstand doses in the order of 5-10 krad and a minority can survive up to 100 krad [2]. To identify the more Rad-Hard Components radiation tests are needed. To get information about the radiation response especially single event upsets (SEU), the influences of the technology node, metallization scheme, new materials as well as package and shielding materials have to be investigated and evaluated. It has to be said, that concerning packaging materials, design and technology many steps were taken to avoid radiation sensitivity.

The procurement of COTS parts for use in a radiation environment is a problem. Technically the same components are produced in different foundries of the companies. A product can be changes without the knowledge of the consumer if the datasheet is not affected.

Ideally, the purchaser would like to have a homogeneous quantity for the purchase of several components, which originate from the same process line produced simultaneously. Then the characterization of the radiation behavior of a small sample of parts is representative for the whole lot. In cases where the contract volume is interesting for the trader or manufacturer, it may be possible to negotiate a better traceability with the manufacturer / trader. Another possibility is the use of qualified automotive components for space applications. Here the problem is that air and space applications have almost smaller quantities compared to automotive and the manufacturers only deliver big quantities.

The increase of high integration of chip and package influences the costs and the time-to-market in parts negatively. The system complexity results in integration of analog and digital components on a single chip and the use of new packaging concepts.

The environment as well as new materials like Pb-free solder or Platinum as metallization material, the use of organic materials

[*]Corresponding Author: Kirsten Weide-Zaage, RESRI Group, Institute of Microelectronic Systems, Leibniz Universität Hannover, 30176, Hannover, Germany | Email: weide-zaage@ims.uni-hannover.de

and new dielectrics influence the reliability and quality of the devices and systems and can yield, in the worst case, to a complete re-design (Figure 1).

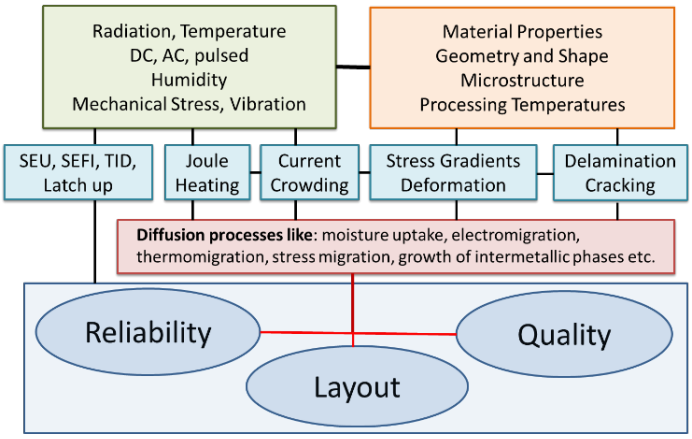

Figure 1. Reliability, quality and layout dependence of some physical failures in the devices and components.

In this paper several considerations about radiation effects are given in Section 2. After the description of the different CMOS related failures and a discussion of the different technology and materials, some simulation ideas will also be considered in the frame of high temperature application. Furthermore migration effects resulting from harsh conditions are discussed. Looking to ultra-scaled memories, it is found that the sensitivity against radiation is directly coupled with the reduction of the size and the distance between two circuits. This leads directly to a reduction of the critical charge which can induce a bit flip [3]. Then section 3 introduces different methods used in programmable COTS devices to reduce or mitigate the harsh condition effects. Finally this paper is concluded in Section 4.

2. Technology Node and Material

The quantity of products from the different technology nodes is shown in Figure 2. It is found, that a big portion of the products is still manufactured in 180 nm and 130nm technology node [4].

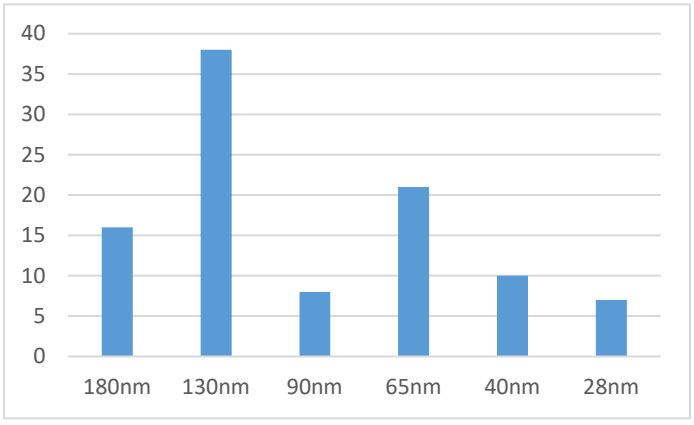

Figure 2. Quantity of products in (%) of the different technology nodes.

Generally the number of the materials used in the Front-End manufacturing of the devices is in the two-digit range. Every material and processing step can have more or less influence on the radiation sensitivity of the device. A look on the semiconductor processing as well as the materials and the packaging for the technology nodes beyond the 65nm node is necessary caused by the fact that materials etc. change. In the 22nm technology node with Hafnium as gate material new possible radiation risks may occur. ^{174}Hf is an alpha particle emitter. Materials used in the semiconductor industry with their natural occurrence are shown in Table 1. An investigation of SEU related to these materials shows that due to the high half-life there should not be a problem. However, due to the ultra-high integration the portion of these material increases drastically and therefor an SEU risk cannot be excluded anymore.

Table 1. Alpha-Emitter with half-live and natural occurrence.

Alpha Emitter	Half-live (a)	Natural occurrence [%]
^{174}Hf	2.0 x 10^{15}	0.162
^{152}Gd	1.08 x 10^{14}	0.2
^{144}Nd	2.29 x 10^{15}	23.8
^{148}Sm	7.0 x 10^{15}	11.3
^{147}Sm	1.06 x 10^{11}	15.0
^{90}Pt	6.5 x 10^{11}	0.01

2.1. Alpha Particles and Packaging

The emissivity of alpha particles in the different package materials are given in Table 2 [4-8]. Especially in Flip-Chip applications the emissivity's as well as the range in the materials are important. The highest emissivity is found in Pb based solder followed by Sn based solder material.

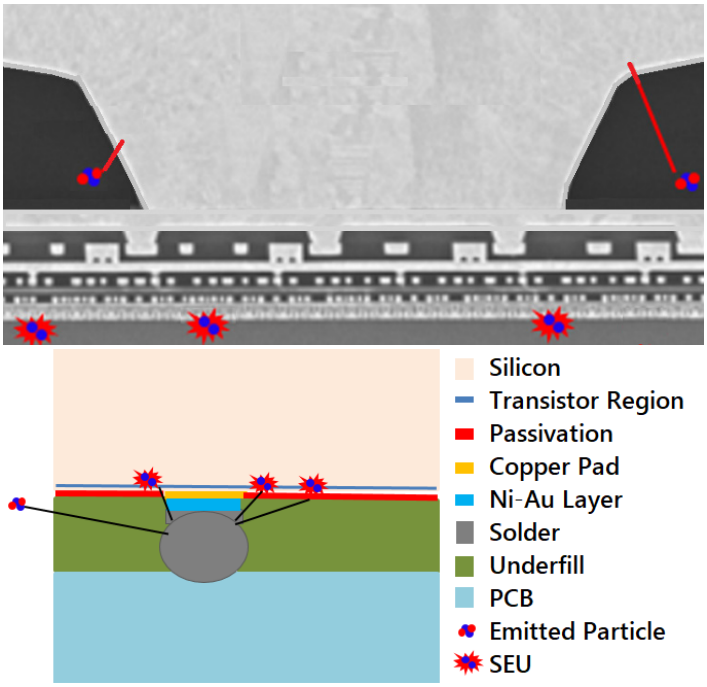

Figure 3. Schematic view of the interaction between particles emitted from the solder with the transistor level.

In Figure 3 the interaction between particles emitted from the solder with the transistor level is shown schematically. The risk for alpha emission from the Sn is not eliminated due to the fact that trace contamination of Pb in Sn occurs which cannot eliminated easily [9].

Table 2. Emissivity (α/cm²-hr) of different materials.

Material	Emissivity (α/cm²-hr)
Mold Compound	0.024→ < 0.002
Underfill Flip Chip Pb	0.004→ 0.0007
Eutectic Pb based Solder	7300→ < 0.0009
DIP Leadframe	0.00677
Alloy 42 (Hitachi)	8
Au-plated Alloy 42	4
Sn	>1000 → <1
AlSiC (Lanxide)	215
ZIP Leadframe	0.00258
256K DIP	0.00124
64K DIP	0.00109
Metal package lid	0.030
Ceramic package lid	3.10
Plastic (Epoxy)	0.00080
Ceramic DIP	0.03230
Ceramic LCC	0.02530

With concern to alpha particle induced SEU several conditions must be fulfilled so that an alpha particle causes a soft error. These are:

- An alpha particle-emitting radioisotope must be present in the packaging material and at a distance within 50µm.
- The alpha particle must be emitted in the direct direction to the active layer.
- The alpha particle must have enough energy or exceed the critical charge in order to influence the active layer in such a way that a bit flip occurs.

Alternatively, the influence of the alpha particles can be eliminated by:

- a better design, i.e. more distance to the active layer
- shielding material such as die coatings or thin polyimide films
- the choice of Ultra-Low-Alpha housing materials

There are different package categories defined related to radiation. The categories are given in Table 3 [10].

Table 3. Categories of the different packages related to radiation.

Category	Emissivity (α/cm²-hr)
Standard	10 – 0.01
Low-alpha (LA)	< 0.01
Ultra-low-alpha (ULA)	< 0.001
Hyper-low-alpha (HLA)	< 0.0005

2.2. CMOS Related Failure Mechanism

The following error mechanisms can be distinguished in CMOS devices:

- **SEU**: Single Event Upset as a singular event temporarily interfering with the system, e.g. wrong calculation information or a bit flip in a memory. If the bit is corrected, the system continues to operate normally.
- **SEFI**: Single Event Functional Interrupts occurring in control loops and bringing the system to an undefined state, a test mode, or a standstill that should be reset by a reset.
- **SEL**: In a single-event latch-up of a parasitic PNPN structure, a high-energy particle can cause a short between two transistors. This remains as long as the system is connected to the power supply. If the current is switched off and the system is restarted, the SEL is over. The energy for an SEL at the processor is 80 MeV/cm²/mg and in the CMOS-RAM 50 MeV/cm²/mg.
- **SET**: A single-event transient is a high-energy particle that induces a surge current that travels through the circuit and can disturb the module in a manner similar to an electrostatic discharge (ESD).
- **Single event snapback**, which can occur similarly to the SEL but does not require a PNPN structure.
- **TID** total ionizing can as a long-term impact on CMOS chips by trapping holes near the boundary layer between the dielectric (SiO2) and silicon.

2.3. Simulation of Iteration

A precise prediction of the radiation response in the new technologies and circuits is crucial to ensure a trouble-free operation. Simulation may support this and help to reduce the costs in terms of stress tests. Three dimensional physical simulations of ionizing radiation effects in the semiconductor structure, which are coupled to an external circuit simulator are one way to do so [11].

The reaction on a radiation event is in technology nodes beyond 100nm closely related to the structure of the device caused by the presence of interconnects, bias, and different metallization layers affecting the performance [11-13].

A physical-based modeling approach that includes detailed high-energy physics-based simulations of nuclear reactions coupled with advanced component and circuit simulators is a need here. With tools such as e.g. GEANT4, a refinement of TCAD simulations with e.g. SILVACO can be done. Approaches to this are described in [14, 15].

GEANT4 is an on C++ based open source software package composed of tools that can be used to simulate the interaction of particles with matter. This software package was developed at CERN. The calculation of decay, track, energy of the particles, elastic and inelastic bumps etc. is possible. Furthermore beside NIST (National Institute of Standards) materials user materials can be defined.

A Monte Carlo simulation using GEANT4 to determine the path of the particles through the transistor as well as the deposited energy was carried out. This data was then used to determine the generation rate for electron hole pairs (3.6 eV) and the radial distribution. The radial distribution is energy-dependent and complex analytical models can be used for their determination [16]. In the following simulation with the TCAD Tool SILVACO, the resulting characteristics can then be determined. In Figure 4 the simulation flow in terms of radiation using GEANT4 and SILVACO TCAD is shown.

It has to be remarked that GEANT4 is highly complex and requires a long training period and knowledge about the physics

and coupling. All user interfaces have to be programmed for the special needed cases. This makes it's use for a fast application uncomfortable.

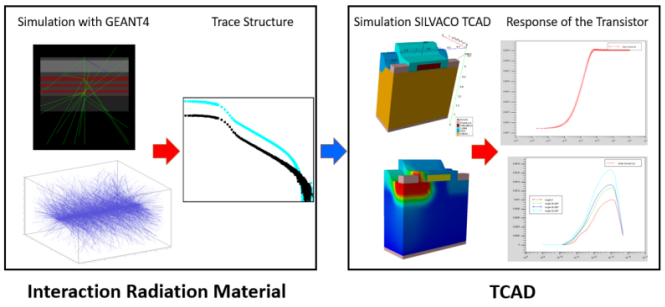

Figure 4. Simulation flow in terms of radiation.

2.4. Multilevel Metallization for Harsh Application

In CMOS devices used under harsh temperature environment tungsten metallization is used. To determine the reaction of the tungsten metallization layer on neutron radiation a metallization scheme was modeled (Figure 5). A B-doped active layer with a thickness of 100nm followed by a 500nm SiO2 including a Tungsten interconnect was positioned on the silicon substrate. The thickness of the first two Tungsten metallization and the dielectric was set to 500nm as well. The third level was set to 750nm followed by 2µm Aluminum power line covered with SiO2 passivation.

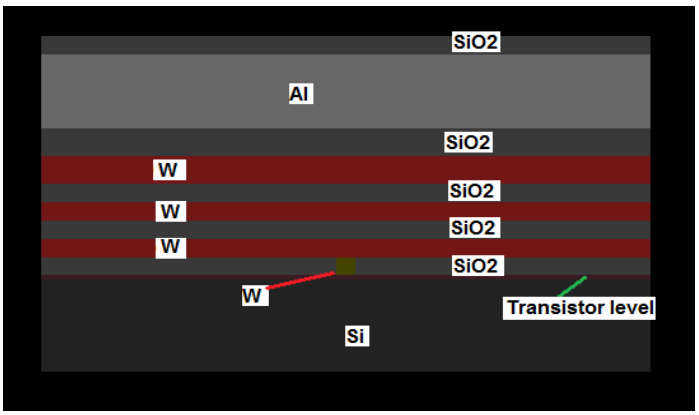

Figure 5. Model in GEANT4 with tungsten metallization and aluminum power line.

In Figure 6 the reaction after neutron radiation is shown. It was found that a lot of reactions occur in the Tungsten interconnects. This corresponds to observations in [17].

Under high temperature exposure coupled with high voltage or current, beside radiation effects migration effects also play an important rule. Depending on the stress conditions electromigration (EM) or stress migration (SM) are the main driving forces for these failures.

In the case of migration in metallization electro- and stress migration are the main failure mechanism. In the case of solder bumps thermomigration can occur as well [18, 19]. Stress migration occurs preferred at locations with high stress gradients, with a high concentration of vacancies or microstructure defects and at locations with active diffusion pathways with a low activation energy [20].

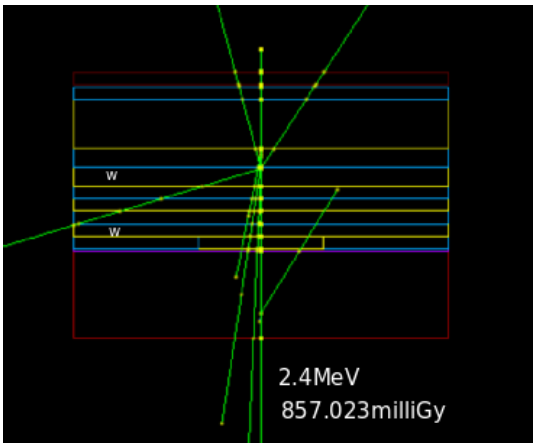

Figure 6. Reaction after neutron radiation with 2.4MeV.

It appears from the literature that the choice of relevant materials is the most discussed issue to enhance device performances as the reduction of interconnect is the "standard" evolution of all systems and cannot be prevented. In particular, the choice of the conducting material has a high influence on the specific resistance, on the homogeneity of thermal gradients, and on hot spots [18].

Migration effects are strong depending on local current densities, heating and stress gradients and the processing temperatures have to be considered [21, 22]. The mass flux describes the strength of the electromigration effect in the metallization structure. The mass flux represents the mass that flows through unit area per unit time. The mass flux of the different mechanisms are given in equation 1-3.

$$\overrightarrow{J_{el}} = \frac{D \cdot N}{k_B \cdot T} \cdot Z^* \cdot e \cdot \rho \cdot \left(\vec{j} - \overrightarrow{j_{th}}\right) \quad (1)$$

$$\overrightarrow{J_{TM}} = -\frac{N Q^*}{k_B T^2} D_0 \exp\left(-\frac{E_A}{k_B T}\right) grad\, T \quad (2)$$

$$\vec{J}_S = -\frac{N\Omega}{k_B T} D_0 \exp(-\frac{E_A}{k_B T}) \quad (3)$$

In equation 1-6, j is the local current density, j_{th} the threshold current density N is the number of the activated particles, k_B the Boltzmann constant, T the temperature, eZ* the effective charge, ρ the resistivity, D_0 the self-diffusion constant, Q* the heat of transport, grad T the temperature gradient, Ω the atomic volume, grad σ_H the stress gradient and E_A the activation energy for the specific mechanism. The resulting divergences are given in equation 4-6.

$$div\left(\overrightarrow{J_{el}}\right) = \left(\frac{E_A}{k_B T^2} + \frac{\alpha_T \rho_0}{\rho} - \frac{1}{T}\right) \cdot \overrightarrow{J_{el}} \cdot grad(T) \quad (4)$$

$$div\left(\overrightarrow{J_T}\right) = \left(\frac{E_A}{k_B T^2} - \frac{2}{T}\right) \cdot \overrightarrow{J_T} \cdot grad(T) - \frac{QND}{k_B T^2} \cdot divgrad\, T \quad (5)$$

$$div\, \overrightarrow{J_{SM}} = \left(\frac{E_A}{k_B T^2} - \frac{1}{T}\right) \cdot \overrightarrow{J_{SM}} \cdot grad\, T - \frac{D\, N\, \Omega}{k_B T^2} divgrad\, \sigma_H \quad (6)$$

For divergences bigger than zero a void can occur and for divergences smaller than zero a hillock can grow.

The different material properties for metallization materials as well as SnAgCu (SAC) as solder material are given in table y. It can be seen that the activation energy for tungsten as well as for platinum is higher compared to Al or Cu. The migration process is in the range of x magnitudes smaller compared to aluminum. The use of tungsten helps in this case to decrease migration effects due to the high activation energy for that process.

Table 4. Material properties for the different metallization materials [23-25].

Material	ρ[μΩcm]	κ[W/mK]	E_A[eV]	Z*	Q*[eV]
Al	3.16	237	0.7	-10	-0.104
Cu	1.74	395	0.9	-5.5	-0.312
W	5.5	174	1.7	12.4	0.009
Pt	10.5	73	1.0	0.3	0.677
SnAgCu	13.2	58.7	0.863	20	-0.009

2.5. SILVACO TCAD

With SILVACO TCAD the behavior of a transistor after SEU exposure with different energies as well as different LET Doses and a radius of 5nm with a cylindrical way through the transistor were calculated. In Figure 7 the dimensions of the transistor is shown.

The incidence of the SEU began at the drain vertical trough the transistor. The drain current depending on the transient time is shown in Figure 8. The higher the LET dose the sharper the profile of the drain current occurs. Once the onset of the SEU, a prompt charge collection will occur followed by the diffusion charge collection.

Electron-hole pairs with high carrier concentrations are created. If the ionization track traverses or comes close to the depletion region, carriers are rapidly collected by the electric field creating a large current/voltage transient. The 'prompt' collections phase follows, indicated in Figure 8. A funnel is created which enhances the efficiency of the drift collection by extending the depletion region deeper into the substrate. The size of the funnel is a function of the substrate doping. This phase is completed within a nanosecond and followed by a phase where diffusion begins to dominate the collection process. Additional charge is collected as electrons diffuse into the depletion region in a time scale of hundreds of nanoseconds until all excess carriers have been collected, recombined, or diffused away from the junction area [26].

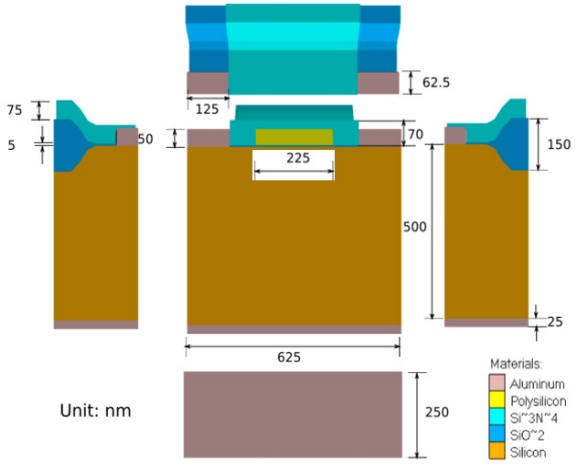

Figure 7. Dimensions of the transistor in SILVACO.

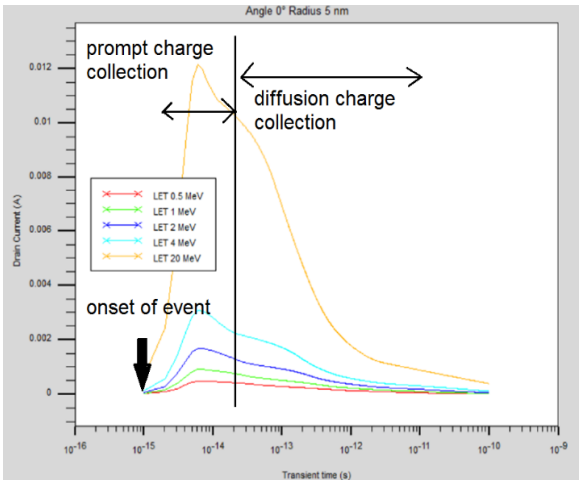

Figure 8. Drain current depending on the transient time for different LET.

2.6. Stacked Dies in 3D-Integration

In 3D integration several memories are stacked one by the other. In Figure 9 a possible scenario of a SEU interaction in 3D integration is shown. This might be an additional problem caused by the fact, that not only one silicon die (die 4) is exposed by alpha emitters from the solder. The die below (die 3) will also be affected due to the strong silicon thinning for stacking the IC's. Due to the high penetration rate of alpha particles in silicon SEU's can occur in die 3.

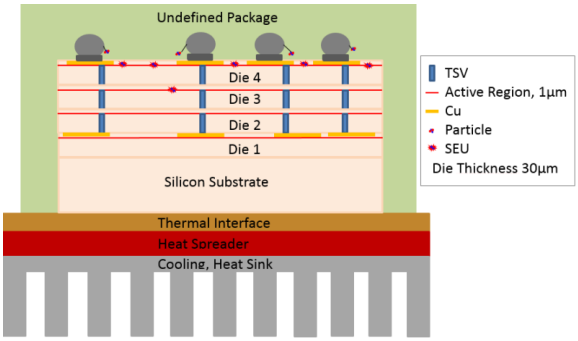

Figure 9. Scheme of stacked dies in 3D integration with possible scenario of SEU interaction.

2.7. SRAM in Different Technology Nodes

After dispensing with boron phosphorus silicate glass (BPSG) in the production processes below the 0.25µm technology node, the proportion of the soft error rate could be reduced by a factor of 10 [27]. From literature it is found that BPSG is also used for technology nodes below 250nm [28]. As a conclusion, it can be seen that thermal neutrons have an influence on the SEU even in small technology nodes. It is well known that commercial of the shelf (COTS) SRAMs were investigated regarding their radiation hardness.

The SRAMs differ concerning the transistor processing in the different technology node of 90nm and 130nm in the gate length as well as the number of the wiring planes. The neutron-induced failure on eight different SRAM components with different neutron energy was investigated and the single event upset (SEU) rate was measured. The test set up and the measurement results are described in [29]. It was found that various sources deal with the

analysis of conventional SRAMs of these technology nodes. In [30] SRAMs of the technology nodes 90nm to 350nm are reported. The components were not designated, so that a conclusion regarding manufacturers is not possible. A comparison between the different technologies with respect to their critical charge, shows no linearity between the technology nodes and the critical charge. The consideration of the cell size also shows no linearity with respect to the critical charge. This finding is relevant for the possible establishment of a standard model for checking on the basis of the critical charge.

3. Harsh Condition Effects Mitigation on Programmable COTS Devices

The use of programmable COTS devices in systems for satellites and space missions [31] implies the use of fault tolerant mechanisms at different levels (i.e., system, application, and instruction level) capable of detecting and correcting the previously mentioned (see Section 2.2.) CMOS related failure mechanisms.

In the system level, the duplication or triplication of programmable COTS devices is the most usual technique [32]. Bi-Modular Redundancy (Bi-MR) architectures are mainly used in fail-stop systems, since a duplex mechanism cannot intrinsically correct failures, requiring extra mechanisms that use time redundancy at the application level for diagnostic and recovery. The telemetry module of the Ariane 5 uses a Bi-MR based on COTS digital signal processors [31]. When results on both DSP differ, the results of one DSP are used and the second one is reinitialized. Tri-Modular Redundancy (Tri-MR) architectures also enable the correction of SEUs by reinitializing, for example, this processor which results differ. The Proton100K computer used by Space Micro [33] extended the concept of Tri-MR by applying time redundancy at the application level. The SCS750 space-qualified board [35] implements three IBM PowerPC 750FX working in triplex mode and includes a Radiation Tolerant FPGA, which is in charge of comparing the results among the PowerPC processors. Increasing the number of duplicated modules can increase even more the failure correction rate. For example, the flight control system implemented by Airbus A320/A330/A340 made use of eight computers [34]

In the application level, time redundancy is mostly used consisting in executing two consecutive times the target application on the same processor. Then, the failures are detected when the results of both executions differ. This technique is commonly used in conjunction with Bi-MR or Tri-MR architectures as it is mentioned above.

Replication techniques can also be applied at instruction level. In this case, each instruction is executed twice sequentially on the same processor, followed by a conditional branch. In case the results mismatch, the condition of the following branch instruction is true and the corresponding recovering subroutine is executed. This technique requires a huge memory and can drastically reduce the processing performance. A first software implementation of this technique was presented in [36] and tested on an Intel 8051 microcontroller. In [37], the authors present a new methodology that permits easy combination of hardware and software soft errors mitigation techniques and allows the automatic generation of protected source code, called hardened code.

4. Conclusion

Influences concerning radiation hardness on the components were discussed. The ultra-high integration with new materials and processes influences the SEU risk. For many applications the transition from Pb-free to Sn-based solder materials is done. The risk for alpha emission from the Sn is not eliminated due to the fact that trace contamination of Pb in Sn. Different metallization layers and Tungsten as local interconnect influences the radiation sensitivity. Simulation investigations with tools such as e.g. GEANT4 with a refinement of TCAD simulations e.g. SILVACO can help to understand the radiation impact on the devices. The availability as well as the utilization of such a tool is difficult. BPSG should be history below the 250nm nodes. It is reported, that in 250nm and beyond BPSG is still or again present.

In the case of high temperature and high voltage or current, application migration effects can occur in the metallization or solder material. Migration effects are strong depending on local current densities, heating and stress gradients and the processing temperatures have to be considered by simulation.

Finally examples how to mitigate harsh condition effects on programmable COTS devices are presented on three different design levels.

ABSTRACT

In this paper, a secure elevator handling system is presented to enable a flexible movement of wheeled mobile robots among laboratories distributed in different floors. The automated handling system consists mainly of an ADAM module which has the ability to call the elevator to the robot's current floor and to request the destination floor. The LPS25HP pressure sensor attached to an STM32F411 microcontroller is utilized as a height measurement system to estimate the robot's current floor inside the elevator. The ultrasonic sensor is used to recognize the elevator's door status. Many challenges have to be solved to realize a stable height measurement system based on pressure sensor readings. The difference of the pressure sensor readings before and after soldering is realized by comparing the reading after soldering with an accurate barometric reading. In addition, the sensor output signal shows oscillation and wide variation of the same floor pressure sensor readings at different times. The oscillation in the output signal has been handled using a first order FIR smoothing filter. The first order filter was selected to balance between the stability and the elapsed time to receive the updated values. An auto-calibration stage is established to maintain the wide variation in the atmospheric pressure readings by calibrating the sensor readings with the robot's current floor before entering the elevator. An error handling management system is utilized to guarantee a stable automated elevator management system performance. Many experiments to assess and verify the performance of the automated elevator management system and robot's current floor estimation are reported. The experimental results show that the proposed methods and sub-systems developed for the mobile robot are effective and efficient in providing a transportation service in multiple-floor life sciences laboratories.

1. Introduction

This paper is an extension of work originally presented at the International Conference on Mechatronics - Mechatronika (ME 2016) [1].

Over the last years, mobile service robots have played critical roles in many applications, including (but not limited to) medical [2, 3] and cleaning services [4, 5], agriculture [6, 7], operations in hazardous environments [8, 9], construction and demolition [10], space [11] and military applications [12], materials transportation [13], support services for the elderly and handicapped [14], and entertainment [15]. In contrast to certain service mobile robots used for surveillance and cleaning services, which can utilize random movement in performing their tasks, the majority of mobile robot applications requires a sophisticated navigation ability in order to move in the desired manner. Thus, an autonomous navigation system is a fundamental functional requirement. Mobile robots in automated laboratories are usually used for the transportation of samples and other material between sub-systems located in different places. The mobile robot has to solve four basic problems in order to achieve highly effective autonomous navigation, which are mapping, localization, path planning, and action. The mobile robot must either climb stairs or use an elevator to deal with complex building structures with

multiple floor working environments. Legged robots and special designs of wheeled mobile robots [16] can climb stairs. However, climbing stairs during transportation tasks adds further challenges to the robot movement related to load capacity and balance preservation. Thus the elevator offers a suitable solution to this problem. An elevator handling system (EHS) includes many operations which must be accomplished in order to travel successfully on an elevator. The elevator entrance door and its status (open or closed) need to be recognized, the entry button must be detected, the destination floor button distinguished, and the current floor identified. Chen et al. presented a mobile service robot which has the abilities to both plan its own path as well as to call the elevator at each floor[17]. For the elevator calling operation, wireless control was designed. An Xbee module is employed to control the servo motor to push the elevator entry button. An RFID is utilized to approximate the current floor when the robot is inside the elevator. Experimental results demonstrated that the proposed mobile robot can ride the elevator and complete delivery tasks. This technique has many constraints, which would prevent its employment in life sciences laboratories. Firstly, each floor requires an electronic circuit consisting of an Xbee module, servomotors, microcontroller and power supply positioned beside the elevator for the call button pressing operation. Also, an RFID antenna would be required on each floor for current floor estimation, and finally this technique does not handle destination floor calling. Maneerat et al. presented a simple method for current floor estimation [18]. It is based on received signal strength (RSS) which is acquired from the number of wireless network sources installed on every floor. The main limitation of this method is the costs since it requires at least four wireless network sources on each floor to realize an acceptable success rate. Chen et al. presented a height measurement system using the MS5534B pressure sensor [19]. This sensor was attached to an LPC1114 microcontroller with the necessary peripherals attached to build the hardware platform. An experiment was conducted in a hotel covering 37 floors to examine the stability of the proposed system. However, this system does not take into consideration the wide variation in pressure sensor readings for one location at different times. Xia et al. presented a pedestrian floor estimation for smartphones [20]. A multi-reference barometer floor positioning method used multiple barometer sensors in each floor to determine a floor reference, and then the smartphone reading was compared with the floor reference to identify the current floor accurately. The method can overcome the problem of daily changes in pressure but the system will be expensive since it needs extra sensors for each floor, especially when applied with the highest number of floors and Floor-positioning servers. Frank et al. developed a motion estimation system to identify motion types, including walking, elevator, escalator, and stairs [21]. They use a Bayesian network to classify motion based on IMU and pressure sensors. The system estimates the kind of movement with value from 73.8 for falling detection to 95.5 for jumping. At CELISCA, researchers are working to develop the automated life science laboratory of the future. For a facility such as a laboratory, a system consisting of several H20 mobile robots has been established which allows samples, labwares and materials to be transported between individual automated sub-systems as support for laboratory staff or to replace them outside of working hours. In multi-floor transportation systems for mobile robots, the elevator aspect is a major topic to be handled. Two different working strategies are developed to guarantee secure glass elevator handling using automated and vision detection algorithms. Orders are sent to the elevator over Wi-Fi signals using the former, while the latter deals with the detection of entry and internal buttons and elevator door status, and controls the kinematic arm for the button-pressing operation. A pressure sensor is utilized as a stable floor estimation approach for both the automated and vision-based elevator handling.

In this paper, a new method is presented to provide a transportation mobile robot with a secured elevator facility to move in a multi-floor building environment. The automated elevator with its management system uses a Wi-Fi signal for data transmission (order/status exchange). The automated elevator management system translates the number of the called floor into a specific pin and port. Then the pin and port number with the “on” order are sent to the ADAM module. After 100ms, an “off” order is sent. The selected ADAM module has four digital inputs and four relay outputs. The module is connected to the elevator entry button of four floors in a laboratory building. The main limitation of the automated elevator is that it does not provide any feedback about the elevator's current floor or its door status, and thus pressure sensor based current floor estimation and an ultrasonic sensor based elevator door status reader are used. To utilize pressure as a current floor reader, many challenges must be considered. Firstly, differences in pressure sensor readings may occur before and after soldering. This problem is solved by applying a one-point calibration technique. Secondly, readings of the same floor pressure sensor vary at different times. A smoothing filter with an FIR structure is utilized to overcome small variations in sensor readings, while an adaptive calibration method handles wide variations during the week. Finally, the integration of the proposed elevator operation handling system in a real mobile robot transportation system in life sciences laboratories is initialized. Figure 1 shows the installed pressure sensor with its microcontroller board on the H20 Mobile robot.

Figure 1 Installed Pressure Sensor with its Microcontroller board

This paper is organized as follows: the system structure is described in section 2, while section 3 explains the automated elevator management system, floor estimation based on the pressure sensor and the related smoothing filter, calibration stages,

and integration into a real transportation system. The hybrid method to select a suitable elevator handling method is detailed in section 4. Section 5 describes four experiments conducted for system validation. The final section summarizes the results.

2. System Structure

At celisca, Rostock, Germany researchers have been developed a hierarchal management system to handle the processes of establishing a fully automated life science laboratories. This system has four control layers. The first layer has been divided into the Transportation and Assistance Control System (TACS), and Process Control Adapter System (PCAS). The TACS has a middle control layer which is the Robot Remote Center (RRC). This layer was established to manage the transportation tasks of mobile robots. It manages the robot by receiving a transportation order from the TACS then forwarding it to the Robot Board Computer (RBC) of an available robot which has the highest battery voltage. The Multi-Floor System (MFS) is the core component of the RBC level, and was developed to perform transportation tasks in multiple floor environments. As shown in Figure *2* the MFS is established to realize the functions of a multiple floor navigation system with a Robot Arm Kinematic Module (RAKM), Elevator Handling System (EHS), and Collision Avoidance System (CAS).

A multiple floor navigation system including mapping, indoor localization, path planning, an Internal Management Automated Door Controlling System, as well as the communication system, and Internal Battery Charging Management System has been reported earlier [22]. The MFS is integrated with the Elevator Handling System (EHS) to control elevator operation. The EHS consists of two sub-systems to handle the elevator operation as follows: elevator handling based computer vision [23] with kinematic arm solution for pressing operation [24]; and an automated elevator management system (AEMS). The Automated Elevator (AE) utilizes a WISE 4060 ADAM socket to call the elevator. An LPS25HB pressure sensor and STM32F411 microcontroller are used in the current floor estimation system hardware platform and are configured and programmed to overcome the inability of the AE to give any feedback about elevator's current floor. The LPS25HB sensor is employed to measure the atmospheric pressure and the STM32F411 microcontroller to receive the raw data from the pressure sensor board, to filter them, and to send them to the MFS over USB cable.

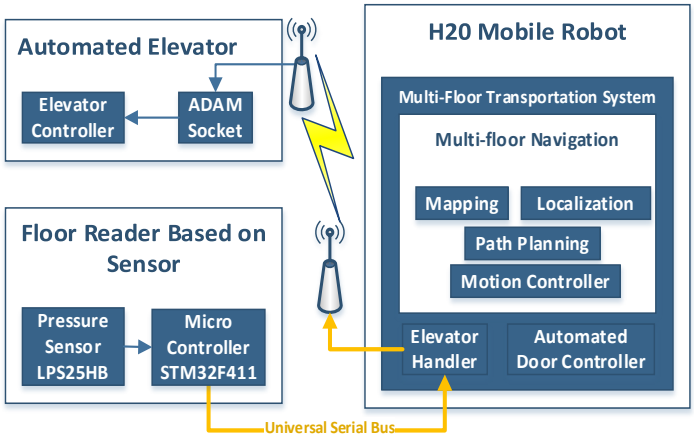

Figure 2 System Structure

3. Method Description

3.1. Automated Elevator Management System

The elevator is the key for the wheeled mobile robot to move among laboratories distributed on different floors in a complex building structure. Thus, it is necessary to establish a secure system to deal with the elevator. The system developed earlier was based on computer vision to deal with elevator operations (entry button detection, internal buttons recognition, and current floor estimation) [22], and the H20 arm solution [24] was developed for the button pressing operation. The weakness of the H20 arm joints can decrease the usability of this system. Thus, the AEMS is developed as a secure solution. This system controls the AE over Wi-Fi socket. The AE consists mainly of an ADAM module for calling the elevator and requesting the destination floor. WISE 4060 ADAM socket is a digital acquisition and control system over a computer network. It has the ability to collect data, and to remotely control the devices required to accomplishing integration between automated and enterprise systems through network technology. The ADAM mmodule consists mainly of a microcontroller, power circuit, Wi-Fi adaptor, four insulated digital inputs and four insulated high-speed relay outputs, and two watchdog timers (one for communication and the other for the system). It can be accessed using the IEEE 802.11b/g/n WLAN network either directly to the device (outdoor coverage area: 110m) or through a router/repeater to extend the coverage area. This module is embedded inside the elevator cabin and is connected directly to the elevator controller of the required floors to establish the AE as demonstrated in Figure 3. The AEMS is developed to connect the MFS with the AE. It translates the required elevator destination floor into a specific hardware port and pin numbers.

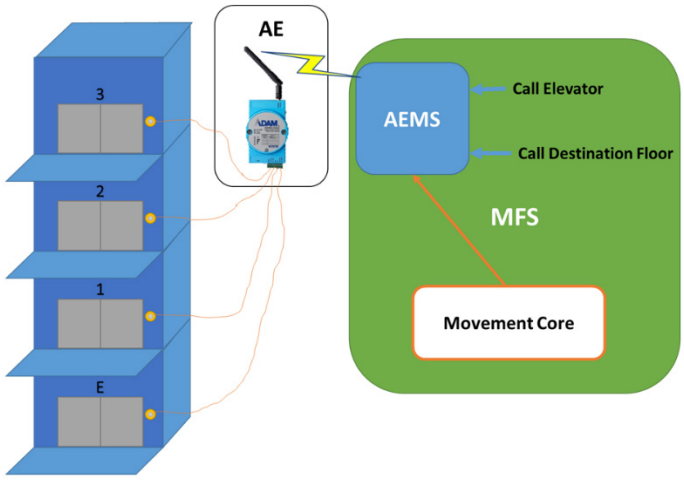

Figure 3 Automated Elevator with Adam Socket and Automated Elevator Management System

The AEMS calls the elevator to the robot's current floor when the mobile robot needs the elevator to move to another floor during a transportation task. To identify the robot's current floor outside the elevator, the indoor localization system developed earlier is utilized [22]. Inside the elevator, the MFS needs a logical solution to specify the destination floor. At this level, the movement core depends on the transportation task status (Grasp Position Done, Place Position Done, and Charge Position Done) to determine the current destination. When the robot enters the elevator, the movement core checks the current destination floor based on the current intermediate goal, as clarified in Table 1. For example, if

the grasping operation has been completed, the placing operation floor has to be requested. Then the elevator is directed to go to the required destination.

Table 1 Destination Floor Selection Strategy.

Grasp Position Done	Place Position Done	Charge Position Done	Entry Button	Internal Button
Not yet	Not yet	Not yet	Current Floor	Grasp Floor
Done	Not yet	Not yet	Current Floor	Place Floor
Done	Done	Not yet	Current Floor	Charge Floor

The reconnection function is developed to handle the weakness of the Wi-Fi signal which connects the AEMS with the AE. As mentioned above, the AE is embedded in the elevator passengers cabin while the AEMS is a part of MFS which is the core of the RBC. Thus, the weakness in the Wi-Fi signal is related to the mobile robot's large navigation area. This function starts to receive the updated elevator status. In case of missing data, the function closes the socket to AE and then initializes the connection again till a stable connection is realized.

3.2. Current Floor Estimation

The elevator is shared with human users in the building. Many people can use it simultaneously, and the elevator controller will respond to all requests based on the priority for moving direction (up/down).

For mobile robots, the current floor estimation technique is a topic aspect to consider. This technique is employed to inform the robot about its current floor inside the elevator. Earlier a vision system is utilized to recognize the current floor number. This was installed in the glassy elevator shaft for each floor to estimate the current floor [23]. This method has a high success rate in recognizing the correct floor in cloudy weather conditions. However, in some situations (such as a human forming an obstacle between the robot and the floor number indicator, or the disability of the vision sensor to recognize the floor number indicator at some times of the sunny day because of sunlight reflecting over the number mark) the robot completely fails to estimate its current floor. These limitations make this method an inappropriate solution for multiple floor transportation task since incorrect current floor estimation can make the robot lose its way to the destination. Thus, a new innovative method based on a height measurement system is developed to estimate the elevator current floor for mobile robot applications to enable a secure navigation system.

As a hardware platform for the height measurement system, the LPS25HB pressure sensor and STM32F411 microcontroller were configured and programmed to sense the environment and detect the current floor position. Many challenges have to be solved to use the pressure sensor as a floor estimation system. A soldering drift, which is defined as the difference between the accuracy of the sensor before and after soldering, appeared when the pressure sensor was attached to the STM32F411 microcontroller. A one-point calibration technique was used to solve the soldering drift problem by comparing the pressure sensor readings after attachment with a precision barometer. The difference was calculated and added as an offset to each pressure sensor reading. In addition, absolute digital barometer (pressure sensor) readings at the same floor of the building keep changing during the day due to various weather conditions. The oscillation in the output signal and the wide variations in barometric readings would reduce the applicability of this technique for floor detection. Two methods were applied to deal with the variations in pressure. Firstly, a smoothing filter with a finite impulse response (FIR) structure was used to solve the problem of small variations in pressure sensor readings. The FIR design diagram is shown in Figure 4, and equation (1).

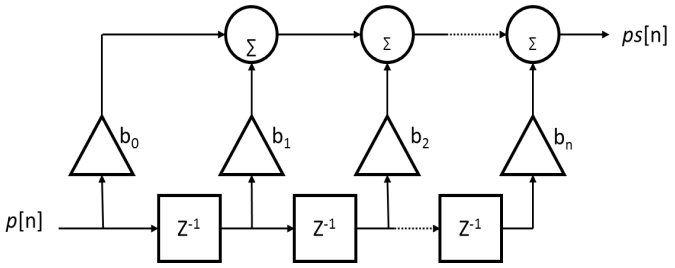

Figure 4 Finite impulse response filter

$$Ps[n] = b_0 p[n] + b_1 p[n-1] + ... + b_n p[n-N] \quad (1)$$

Where:

p[n]: is the input pressure reading.

Ps[n]: is the output smooth pressure value after the filter.

b_i: Filter coefficient.

N: Filter order.

The FIR filter waschosen due to its stability, linearity, and simplicity. A practical analysis was performed to choose the filter in order to achieve a balance between the time required and the stability of pressure readings. While the stability of the sensor readings is enhanced by increasing the filter order, the time required to complete the smoothing filter is also increases. In real transportation task applications, the elapsed time to estimate the current robot's floor is an essential aspect to manage since the robot must estimate its current floor, distinguish the elevator door status, and leave the elevator before the elevator door closes. Thus, a first order smoothing filter has been selected. The smoothing filter is embedded inside the microcontroller and the MBED development environment is used to program the microcontroller using the C language. Figure 5 shows the implemented flowchart for a microcontroller which starts by initializing it with the necessary setting, then collecting the pressure sensor data, applying the smoothing filter to these data with a special procedure on the first occasion to stabilize the output, and finally sending it over USB to the robot computer every 1s. Secondly, an adaptive calibration method is used to calibrate the sensor readings to the robot's current floor before entering the elevator in order to overcome the wide variations in daily pressure readings. According to an experiment conducted over one week (the second experiment reported in the results section), the variation can reach up to approximately one hundred meters. The indoor localization method developed earlier, which is based on passive landmarks for a multi-floor environment, was utilized to identify the robot's current floor number outside the elevator.

The calibration value is calculated as follows. Firstly, the multiple floor localization method developed earlier is used to find the current floor information outside the elevator based on the landmark ID located near the elevator. Then the pressure sensor reading is converted into the height using equation 2. The extracted

height is calibrated with the current floor height to realize a constant number which is the calibration value. Then the calibration value is added to current floor height. Finally, the extracted height is compared with the height range of each floor to identify the current robot's floor (see Figure 6). The reconnection function is developed to maintain a stable connection to the sensor board by continuously checking the incoming message. In the case of missing data, the serial port will close and initialize again till receiving the updated data.

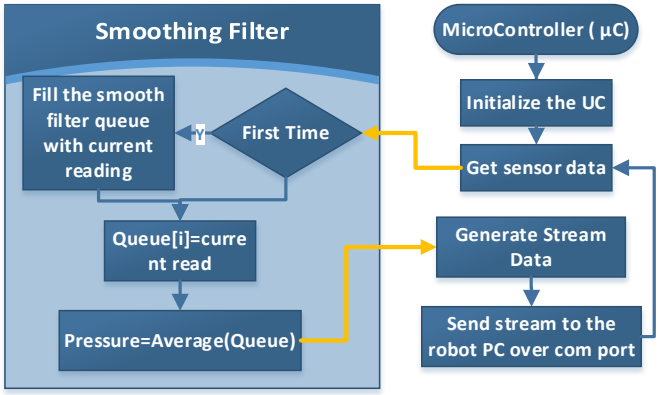

Figure 5 Microcontroller flowchart

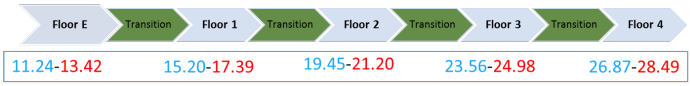

Figure 6 The Range of Height Measurements for each Floor

The MFS is embedded with the required GUI and coded with C# to handle the connection to the microcontroller; the incoming data and calibration stage are shown in Figure 7.

During a multi-floor transportation tasks, the ultrasonic sensor is used to recognize the elevator door's status. When the destination floor matches the estimated robot's current floor and the elevator's door status is recognized as "open", the robot leaves the elevator to complete the transportation task process.

$$Height(p) = \frac{1-\left(\frac{p}{1013.25}\right)^{0.190284} * 145366.45}{3.2808} \quad (2)$$

4. Elevator Handling Error Management System

The proposed detailed robot-elevator interface control strategy is illustrated in Figure 8. The EHS classifies the error according to its appearance space as either outside or inside elevator error handling. The elevator handling system has two methods for handling outside elevator errors. If the mobile robot fails to reach the required elevator button pushing area accurately which is usually due to wheel slip, the position and orientation correction function checks the robot's position after movement and tries to correct it three times. Next, the elevator handling system based on computer vision and an arm solution starts. After the robot has found the button's position as X, Y, Z coordinates, the values are then passed to the robot arm kinematic module for button pressing operation. The ultrasonic sensor is then utilized to distinguish the elevator door status. If the door is recognized as closed, the EHS controls the robot kinematic arm again to press the detected button. If previous attempts have failed, the EHS selects the AEMS over the Wi-Fi socket to open the door. If the functions listed above have failed in handling the elevator correctly, the MFS reports to the higher level controller RRC, terminates the current transportation operation, and directs the robot to the charging station.

The error handling system inside the elevator starts by monitoring whether or not the destination floor has been reached by continuously checking the current floor reader. If it does not reach the destination floor after a specified number of attempts, the MFS sends a warning alarm to the RRC to initiate the appropriate procedures. After finding the destination floor, the next stage of error handling is enabled to check the elevator door status, and another warning alarm is sent to the RRC if the door is still closed after a defined number of attempts. The final error handling maneuver is to check if the floor reached matches the required destination floor based on the landmarks installed outside the elevator. If the landmark is missing or a wrong floor number landmark is read, the error handling system returns the robot back to the elevator and chooses the destination floor again. Finally, if the robot fails to reach the destination floor after reaching the maximum allowed number of attempts, an error message is sent to the RRC. These steps are arranged as a flowchart in Figure 9.

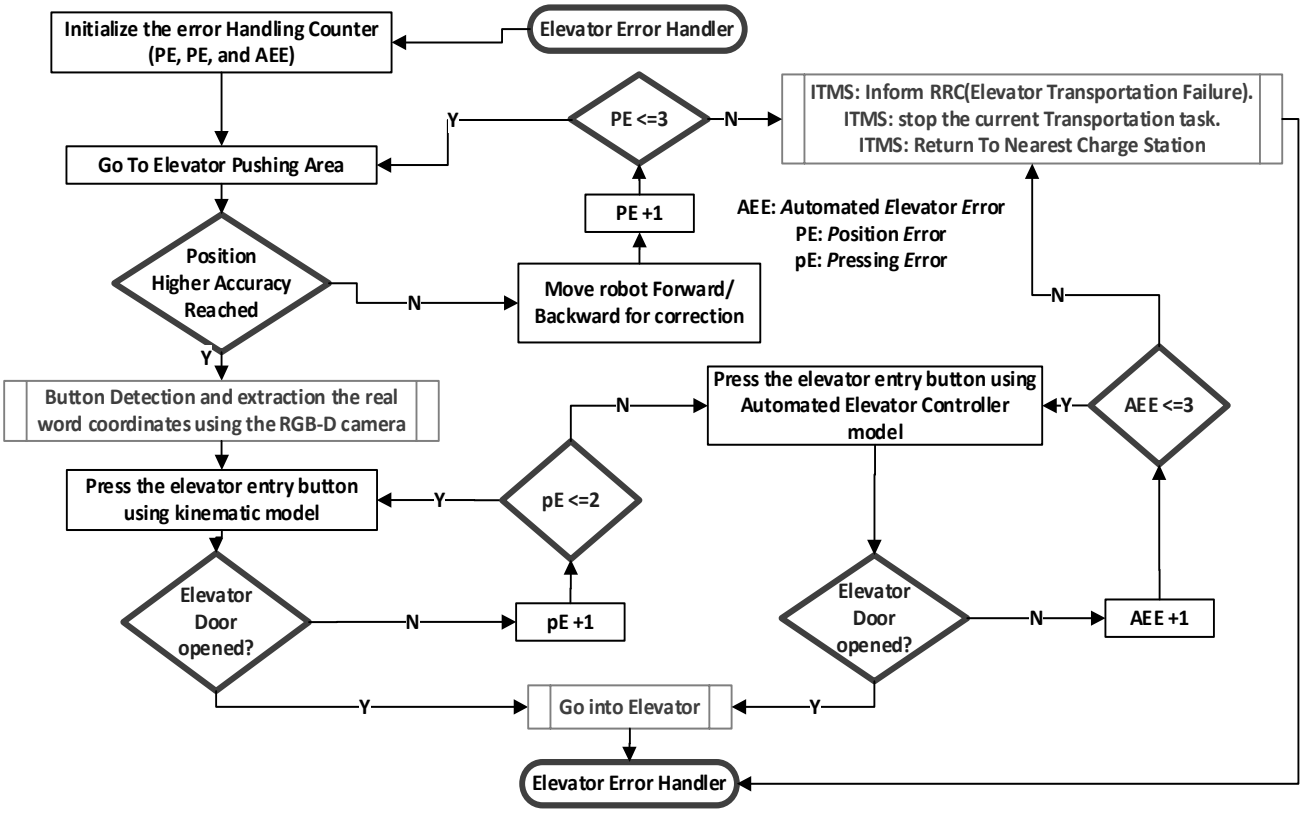

Figure 8 Outside Elevator Error Handling Flow Chart.

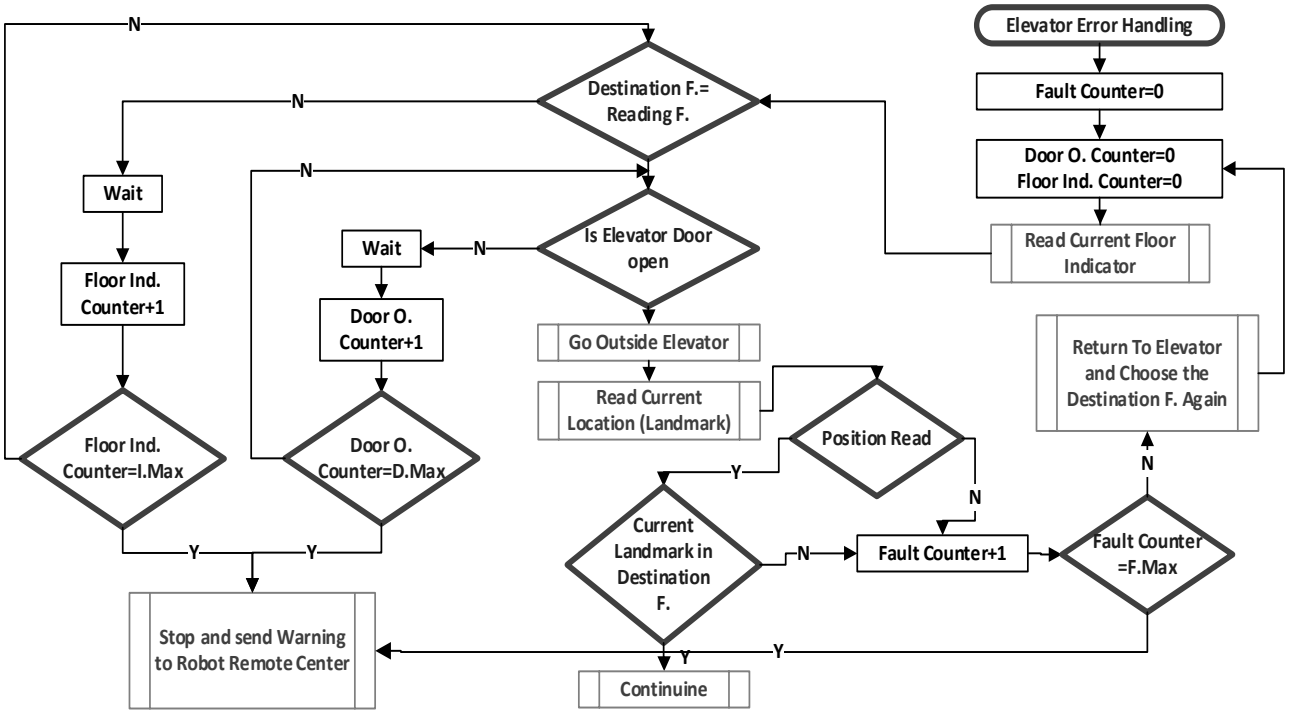

Figure 9 Inside Elevator Error Handling Flowchart

5. Results

Four sets of experiment have been performed to prove the efficiency of the developed system. The first experiment was conducted to check the stability of the pressure sensor before and after smoothing filter application. The smoothing filter was applied with different parameters to find an acceptance performance level to achieve a balance between filter performance and elapsed time. The second experiment was executed to validate the stability of atmospheric pressure readings over time. Then the integration into a real mobile robot-based transportation system was examined, and finally the system's extension for multiple robots was verified as follows.

The IKS01A1 MEMS inertial and environmental sensor board has the pressure sensor LPS25HB. This board was attached to the STM32F411 microcontroller board as shown in Figure 10, and the developed system for data acquisition was written in the C# language. Pressure sensor readings were collected from five floors with one hundred pressure readings for each floor. The pressure sensor data before applying smoothing are shown in Figure 11. Next, the smoothing filter with first order was applied to the acquired pressure sensor readings (see Figure 12), and finally the second order smoothing filter was applied to the collected data to validate performance (see Figure 13). Table 2 shows the average and possible tolerance for pressure sensor readings before and after smoothing filter application. From Table 2, it can be seen that the oscillation of the pressure sensor readings for the same floor at different times can exceed the distance between two floors, which makes decisions about floor identification impossible. Thus, the acquired data has to be filtered, and the second order filter gives higher smoothing performance than the first order smoothing filter, but the required time can cause the robot to miss the destination. Thus the first order smoothing filter was chosen to determine the floor within an acceptable time.

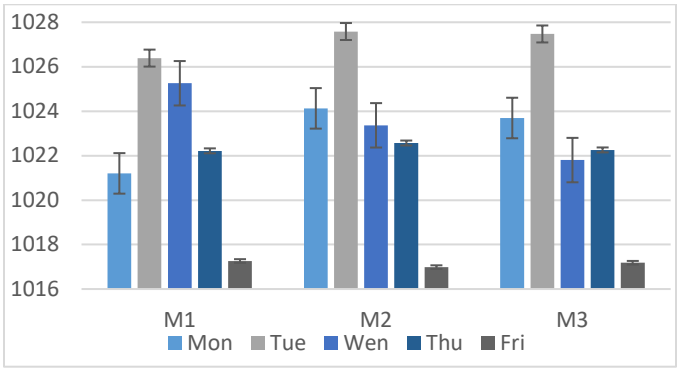

Figure 14 Daily Pressure

The second experiment was conducted to check the variance in daily pressure and the possibility of using the developed floor estimation method directly. During five working days, pressure sensor readings were taken and recorded. Three hundred readings were taken each day distributed equally among three times (morning, midday, and afternoon). From Figure 14, it can be noticed that the pressure sensor gives wide variation even on the same day, and thus the pressure data require an adaptive calibration stage.

The third set of experiments was conducted in order to evaluate the performance of the AEMS and current floor estimation technique based on the height measurement system. A transportation task between laboratories located on the second and third floors was executed one hundred times in the CELISCA building. The transportation task started from the second floor, moving to the third floor for placing and finally returning to the second floor for charging. The AEMS calls the elevator to the robot's current floor for it to move to the third floor.

(g) Wrong Floor (h) Leave the elevator at 2nd floor

Figure 15 Transportation Experiment

Inside the elevator, the ground floor was chosen by another passenger before the robot called the 3rd floor. This stage was included to examine the current floor estimation method. At first, the elevator controller directed the elevator to the ground floor and the elevator's door opens. At this stage, the robot stays in the elevator since the detected current floor estimation does not match the destination floor. The robot waits until the detected current floor matches the destination floor and the elevator's door is recognized as open. Also, the same procedures were repeated when the robot had to return to the 2nd floor for charging, where the 4th floor was selected by another passenger before the robot called its destination. Each time, the robot succeeding in leaving the elevator at the correct floor. The developed system's stability and reliability is proven with a 100% success rate. Figure 15 demonstrates the experiment steps in detail.

The final experiment was executed to validate the possibility of extending the method of current floor estimation based on the height measurement system to other mobile robots. The same kind of sensor board with the same processing stages (a one-point calibration stage, first order FIR smoothing filter, and an adaptive calibration stage) was embedded for three other mobile robots. The procedures used in the third experiment were repeated ten times for each robot to validate their ability to estimate the current floor. Each robot succeeded in estimating its current floor inside the elevator without any change needed in the sensor board or the processing stages.

6. Conclusion

In this paper, a secured method for the elevator handling system based automated elevator is presented. To handle the elevator, four main operations should be considered which are elevator requesting, destination floor calling, current floor estimation, and elevator's door status recognition. The automated elevator handling system mainly consists of WISE 4060 ADAM modules. A Wi-Fi socket is established to connect the automated elevator management system with the ADAM module. This module can call the elevator to the current floor and request the current floor when the robot enters the elevator. However, this module does not provide any feedback about the robot's current floor inside the elevator which may make the robot lose its way to the destination. Thus, an innovative and stable current floor estimation based on a height measurement system is presented. The height measurement system consists of the LPS25HB pressure sensor attached to the STM32F411 microcontroller. To utilize the pressure sensor as a height measurement system many aspects must be considered which as follows: firstly, a soldering drift,

which is defined as the difference between the accuracy of the sensor before and after soldering. A one-step calibration stage is employed to solve this problem. This technique compares the pressure sensor reading after soldering with a precision barometer. The difference is added to each pressure reading. Secondly, the oscillation of the output signal and the wide variations in barometric readings during the week. The first order FIR smoothing filter is employed to overcome the oscillation in the pressure sensor output signal while an adaptive calibration stage is used to handle the wide variation. The ultrasonic sensor is used to recognize the elevator's door stats. An error management system is developed to guarantee a secured elevator handling system. A series of experiments has been conducted to evaluate the variation in the pressure sensor readings and to validate the performance of the presented systems. The results of the experiments prove the efficiency of the automated elevator management sensor and robot's current floor inside the elevator with a success rate reaches to 100% for each.

ABSTRACT

The Cognitive Radio usage has been estimated as non-emergency service with low volume traffic. Present work proposes an infrastructure based Cognitive Radio network and probability of success of CR traffic in licensed band. The Cognitive Radio nodes will form cluster. The cluster nodes will communicate on Industrial, Scientific and Medical band using IPv6 over Low-Power Wireless Personal Area Network based protocol from sensor to Gateway Cluster Head. For Cognitive Radio-Media Access Control protocol for Gateway to Cognitive Radio-Base Station communication, it will use vacant channels of licensed band. Standalone secondary users of Cognitive Radio Network shall be considered as a Gateway with one user. The Gateway will handle multi-channel multi radio for communication with Base Station. Cognitive Radio Network operators shall define various traffic data accumulation counters at Base Station for storing signal strength, Carrier-to-Interference and Noise Ratio, etc. parameters and record channel occupied/vacant status. The researches has been done so far using hour as interval is too long for parameters like holding time expressed in minutes and hence channel vacant/occupied status time is only probabilistically calculated. In the present work, an infrastructure based architecture has been proposed which polls channel status each minute in contrary to hourly polling of data. The Gateways of the Cognitive Radio Network shall monitor status of each Primary User periodically inside its working range and shall inform to Cognitive Radio- Base Station for preparation of minutewise database. For simulation, the occupancy data for all primary user channels were pulled in one minute interval from a live mobile network. Hourly traffic data and minutewise holding times has been analyzed to optimize the parameters of Seasonal Auto Regressive Integrated Moving Average prediction model. The blocking probability of an incoming Cognitive Radio call has been assessed as a function of instantaneous occupancy and the blocksize of trunk servers.

1. Introduction

The mobile communication network is faced with serious challenges to ensure optimum Quality of Service (QoS). In order to survive in this present economic situation, the network operators must put into consideration that the available resources must be effectively used with optimum QoS. This leads to design of effective network and effective network planning. It can be achieved through parameters like call arrival rate, optimum holding time, blocking probability, etc. These parameters are based on available resources and traffic load in the mobile communication network. The proposed work is aimed at developing a traffic model that will predict blocking probability for voice calls in Global System for Mobile Communication (GSM) network.

To have interference free communication, it is imperative that the SUs are able to distinguish between the channels those are currently occupied by PUs and transmit result to Cognitive Radio-Base Station (CR-BS). The CR-BS predicts the availability of vacant channels depending on the past sensing results which directs a channel requesting Secondary User (SU) to associate

*Corresponding Author: Neeta Nathani, G.H.R.C.E. Nagpur, Maharashtra, India, +919300986070, E-mail: neeta_nathani@yahoo.com

with vacant channels accordingly. The proposed model shall assess daily traffic pattern based on monthly observation, hourly traffic pattern based on daily observation and minutewise traffic pattern based on hourly traffic observation particularly in and around Primary User (PU) busy minutes when scarcity for PU channels are at peak.

Assume the SUs in the area are covered through ISM band and available with sufficiently high Carrier-to-Interference and Noise Ratio (CINR) so that this part of the network is not a bottleneck. The procedure for initial selection of channel is described as follows:

(a) The Gateway (GW) node scans the area where SU allocation is to be made. It informs to CR-BS about the PU's activities in the area along with their activities like idle/dedicated and since when it was dedicated.

(b) Listing of all the GWs under the CR-BS is done.

(c) The coverage of the GWs is estimated from different CR-BS's and is updated in the CR-BS table. The coverage, signal strength, signal quality, etc. are also to be noticed in the table.

(d) Hourwise prediction of weekly occupancy is done at day = dd, hour = hh using static database from dd = 1 to (dd-1) that holds occupancy records of PU on monthly basis. The estimated value of occupancy obtained at hour = hh helps to estimate minutewise occupancy of PU at time t, i.e., at minute = mm.

(e) A dynamic database for minutewise occupancy of PU is obtained and updated. Whenever SU initiates a call request at an instant, the computation of blocking probability is done for each channel.

(f) The list of channels are available for use by the SU at minute = mm+1 which have blocking probability < 0.5.

Blocking probability (BP) at a moment of call demand can be assessed by channel occupancy rate amid last clock hour, e.g., 9am-10am for call request at a moment between 10am-11am, and so on, as in traditional teletraffic hypothesis. This estimation has been additionally enhanced through expectation models taking 9am-10am hour information for a few earlier days. The CR-BS might keep up and occasionally refresh database of channel occupancy during (a) every hour of a day, and (b) minutewise channel occupancy during each hour. Spectrum detecting is a key capacity of intellectual radio to keep the unsafe impedance with PUs and recognize the accessible range for improving utilization of spectrum use. However, the performance in detection techniques is regularly traded off with multipath blurring, shadowing and recipient instability issues. To alleviate the effect of these issues, cooperative spectrum sensing (CSS) has been appeared to be a viable technique to enhance the detection performance by exploiting spatial diversity [1,2].

The CSS is grouped into three classifications as; centralized, distributed, and relay-assisted [3]. In the centralized CSS, the master node collects the sensing information from all the other nodes within the network and the information is shared with all the CR nodes. In distributed CSS, each CR node acts as an independent node for sharing information between various users. Relay assisted nodes are helpful for extending the coverage area of the network.

In all the three detecting techniques listed above, the agreeable CR nodes with fusion centre takes decision about vacant channels. It doesn't unequivocally specify which SU might get benefit from which CR node in its physical range. Likewise, CR node takes choice of channel accessibility relying upon the then circumstance which may not be sane. Further, CR nodes are not anticipated that would keep up a database for choice support on the selected channels. To comprehend these restrictions in the adhoc CSS, a CR-BS design is proposed. In the CR-BS engineering, a Cognitive Radio- Base Station Controller (CR-BSC) is provisioned which is relied upon to pronounce the channel accessibility in view of the present channel occupancy and the previous history of occupancy of the channels. In this architecture,

(i) SU works as probe for occupied primary and secondary channels accessible in the environment with location data through GPS and transmit to CR–BS for intermittent updation of channel status database.

(ii) To decide if a channel is involved or not, a filtering recurrence is set and for all useful purposes, this examining recurrence is set as one minute. Consequently, when a SU makes a channel demand to CR-BS, CR-BS surveys the accessibility of each channel as a combination of current occupancy in addition to expected vacant time in future from its occupancy history. In this way, occupancy history is atomized in minutes.

(iii) A database is set up in CR-BSC which stacks information in minutes, collected in hours and in days.

A thorough forecast model is utilized to assess the normal vacant time from the time of demand by SU. This count is done at CR-BSC for all accessible vacant channels and the best one is chosen for allocation to the SU.

Several researchers have recommended methods for spectrum sensing, filtering and dynamic spectrum access for use in CR. Probability of channel availability, duration etc. has also been modeled. These models do not identify individual channels available for cognitive radio use effectively. These aspects have been discussed in section 2 viz. Literature Survey. The CR network architecture modeled in the present work is based on observation of 50 cells data for 36 days of PU network. The background study for present work include channel occupancy during a typical day and holding time distribution and has been discussed in Section 3. Section 4 discusses about architecture for infrastructure based CR. Collection of PU data and its call arrival rate prediction has been discussed in Section 5 followed by the blocking probability in Section 6. The relevance of the proposed work is concluded with results in Section 7 followed by the future work in Section 8.

2. Literature Survey

Cognitive Radio SUs accesses unallocated channels to PUs in licensed bands. Secondary users need to dynamically detect and access unused channels of PUs. Spectrum sensing consumes considerable energy, and hence, predictive methods for concluding gross availability of spectrum holes and idle channels can be used to schedule scan frequency and optimize energy consumption of secondary users.

The authors of the paper [4] propose a CR network architecture made out of an arrangement of SUs with or without a secondary Base Station in which CSS is utilized. At the point when environment is highly dynamic, the detected data may not be valuable because of user's mobility, channel blurring, and so on. The CSS is not an ideal strategy, as individual sensor nodes may encounter heterogeneous false alarm and missed detection because of their diverse locations.

Xiukui Li and Seyed A. (Reza) Zekavat [5] have accepted that different channels which are licensed to PUs, from which SUs can choose any idle channel for correspondence. A method is recommended that empowers SUs to assess direct accessibility in cognitive radio systems when SUs exist together with PUs. The call arrival s of PUs is monitored by the SUs. The simulations are done with the PU data to study the effect of the proposed prediction technique on the communication and have been compared with Seasonal Auto Regressive Integrated Moving Average (SARIMA) model. This model does not specify about the channel updation technique.

The author in [6] discusses about an infrastructure-based CR network architecture integrated in a PU network operating in licensed spectrum band where, the CR network has a centralized network entity such as a base station and associated CR nodes. The proposed architecture overcomes the drawbacks of the Poisson's modeling.

A two phase joint power and spectrum allocation scheme for a Cooperative Cognitive Radio Network (CCRN) has been discussed in [7]. The PU leases unused licensed spectrum to various SUs utilizing Frequency Division Multiple Access (FDMA) technique. This paper considers the design with respect to PU-SU. This paper lacks spectrum sensing and is, thus, not a pure CR situation.

The authors [8,9] have presented different traffic forecast procedures and have discussed about the process of assessing channel accessibility through predicting traffic patterns of PUs for cognitive radios in an infrastructure of CR network as clarified in [5] above. In this model, SUs can forecast the call arrival rate and call holding time of primary users that utilized this channel. At that point, as per the prediction as well as estimation results, secondary users can assess the probability that the channel would be accessible for a given time period or not. By comparing the assessed probability with some threshold, secondary users can choose whether to utilize this channel. This model doesn't unequivocally express the need of infrastructure. The sensing, computation and prediction needs high processing ability and more power and are thus hard to implement in practice.

An infrastructure based CR network that empowers cooperative spectrum sharing over different service providers by means of static CR nodes have been proposed in [10,11]. At the point when all the channels of a service provider are accessed or it is over-burden, it can utilize the available channels that are authorized to the service providers that are under loaded. This is not a pure CR subject.

In this manner, it is seen from above literature surveys that no document is sufficiently complete to quantify the availability of vacant channels with adequately free holding time to accommodate a secondary user call. In the present work, the prediction of availability of vacant channels for the proposed holding time of the secondary user is done. These aspects have been incorporated into the present review and results are required to be very helpful to CR building architects.

3. Background Studies

3.1 Daily Traffic Pattern of PU

Conventionally, a telecom operator analyzes the total traffic on hourly basis and identifies the busy hour where total traffic is maximum. Hourly data arranged on weekly basis does not give a clear picture of the peak hour as it contains many peaks. The traffic variations within a clock hour are not predictable in weekly analysis. Thus, data arranged on daily basis is taken to estimate the behavior of hourly traffic. The minutewise collected occupancy data was taken on hourly basis for 50 cells of different channel numbers. Figure 4.3 depicts daily occupancy pattern for the locations with 60 channels (8 RFs) and differently loaded at various traffic places. The results are similar for other Radio Frequency (RF) counts also. The figure indicates double heaps in the channel occupancy. The heap pattern shows near parabolic nature from 05:00 to 15:00 hours and 19:00 to 23:00 hours.

In this analysis, minutewise gathered occupancy information was figured on hourly basis for 50 cells of varying channel numbers, e.g., each cell with 7channels/14 channels/28 channels/60 channels for 1/2/4/8 Radio Frequencies (RFs) of GSM framework. Channels with same number of RFs are some where lightly loaded and highly loaded in some different areas. Areas with 8 RFs (60 channels) and distinctively stacked at various activity areas are shown in figure 1. The outcomes shown are comparable for other RF counts also. The figure shows double heaps in the channel occupancy. The heap design appears near to parabolic in nature from 07:00 to 15:00 hours and 17:00 to 22:00 hours. An observation of instant occupancy together with last two observations might show peak time location along with the occupancy at peak time. This will help to regulate scanning frequency to optimize battery life of the SU. Based on the channel occupancy pattern, SU shall work in three scan states for power consumption optimization given below:

(i) State-I: This is part of the day during which primary traffic is too low, hence any SU request for channels can be serviced by CR-BS system without blockage. The State-I is depicted in figure 1 from 00:00 to 05:00 hours (from points A to B), and from 15:00 to 19:00 hours (from points D to E). During these periods the occupancy is very less and hence, the SU can save

its battery power as no scan (scan frequency =0) is required. The SUs may go to sleep mode keeping only its receiver active for receiving paging message from CR-BS system only. In this state, SU RF is active in paging Listen mode from CR-BS but scanner remains inactive. GPS remains inactive while SU is static but restarts when SU is in motion. Manual interrupt is active for switching to dedicated mode for SU.

(ii) State-II: This is part of the day during which primary traffic goes on increasing, hence any SU request for channels can be serviced only when vacant PU channels as are sufficient. As depicted in Figure 1, from 05:00 to 11:00 (from points B to C) and from 19:00 to 20:00 hours (from points E to F), the channel occupancy shows a positive slope at the beginning which requires SUs to periodically scan the environment and update to CR-BS at highest rate to support channel hopping to active SUs.

(iii) State-III: In this state, the scanning frequency becomes active after every few seconds as specified by CR-BSC. The State-III is depicted in figure 1 from 11:00 to 15:00 hours (from points C to D) and 20:00 to 23:00 hours (from points F to G).

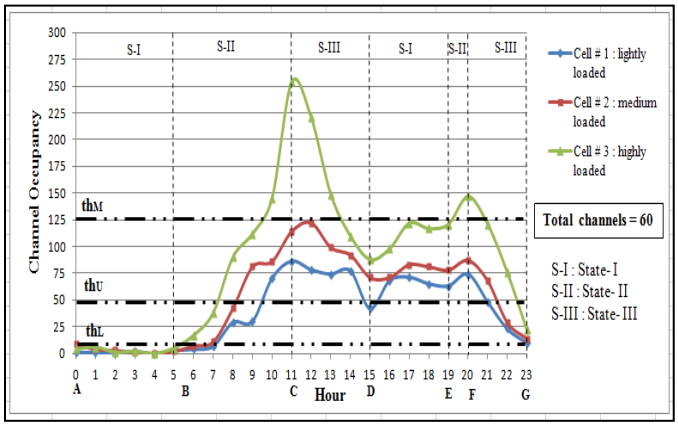

Figure 1. Daily Channel Occupancy Pattern for Three Cells With 60 Channels

(iii) State-III: In this state, the scanning frequency becomes active after every few seconds as specified by CR-BSC. The State-III is depicted in figure 1 from 11:00 to 15:00 hours (from points C to D) and 20:00 to 23:00 hours (from points F to G).

3.2.Holding Time Distribution

The data was collected at busy hour for 60 channels and minutewise occupancy was computed. An analysis of 60 minutes calls is practically taken for calculation purpose. The holding time distribution is shown in figure 3. It is observed that 58.5% calls are lying within 1 minute, 75% calls within 2 minutes, 82.9% calls within 3 minutes and 86.4% calls within 4 minutes 90.3% calls within 5 minutes. It is observed that holding time is nearly zero for a large number of calls which are due to transaction of Short Message Service (SMS) and Unstructured Supplementary Service Data (USSD) calls.

Study of figure 2 reveals that holding time of 86.4% calls are 4 minutes and the peak occupancy is 173. So, traffic carried is 173*(8/60) = 23 Erlangs, whereas total traffic maximum traffic carrying capacity is 60 Erlangs, i.e., actual loading is (23/60)*100 = 38.4%. Hence, there is enough vacant space to accommodate SU calls even in busy hour.

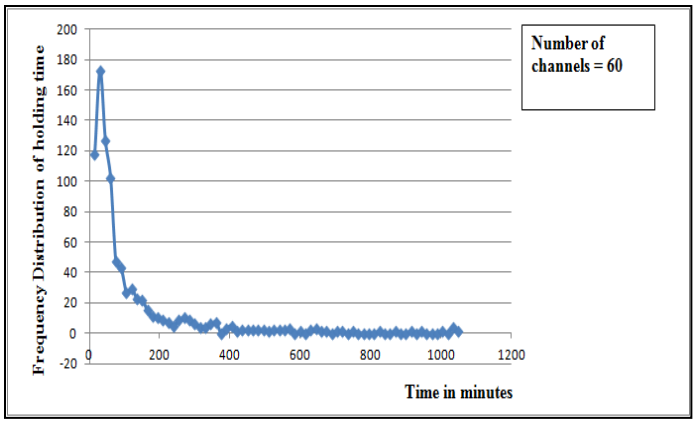

Figure 2. Holding Time Distribution Pattern in Busy Hour

4. CR Architecture and Model

The present document shall use the SU and Cognitive Radio-User Equipment (CR-UE) interchangeably. In previous study [12,13], it has been established that more than 20% of the completely licensed bandwidth is practically vacant in a saturated market environment. This is well above the requirement of 1/8th part of the band to get access to the whole of the bandwidth at a time and adequate to take additional Media Access Control(MAC) level overhead required for C. There is no immediate necessity of these channels by the licensed operators which can be safely deployed as common control channel for cognitive radio purpose. This paper also assumes that the communication shall take place in licensed band channels only so that the UEs can be used as SUs with little modification in access protocol.

The evolved network architecture as shown in figure 3 contains CR nodes which may be combined in exclusive clusters or Personal Area Networks (PANs). The clusters will have a Cluster Head (CH) or GW. The CR-GW shall internally coordinate with sensor nodes using standard 6LowPAN based protocols and CR-MAC protocol for GW to CR-BS communication where it will use the vacant channels of licensed band. The GW will be able to handle multi channel multi radio for communication with BS. It will also have a dedicated RF scanner for monitoring licensed channels and inform channel status change to BS. Unique code will be assigned to all CR-BS. According to capacity of CR-BS in radio side, CR-BS can control number of SUs. In the backbone side, it provides interface to Mobile Switching Center (MSC) through Media Gateway (MGW).

At the time of access for traffic data, GW-SU transmitter ensures that the access of PU channel do not interfere with PU functioning and CINR at BS. Network operators define various traffic accumulation data counters at BS. These parameters are polled at regular intervals for dynamic record of various RF parameters usually on hourly basis (T) and stored in Operations and Maintenance Center for Radio (OMC-R) [fusion centre in present case]. One hour time is too long for critical ON/OFF activity observation. Hence, channel status acquisition information need to be polled and updated at fusion centre at rate >> λ (call arrival rate) of the channels, or, in other words, polling time (τ) <<1/ λ, i.e. channel occupancy repetition time. In addition to periodic polling, both (i) the status of the channel change from free state to occupied state and, (ii) SU channel

allocation request should be interrupt driven and get instantly registered in Fusion Centre. Channel allocation shall be made by fusion centre from available list of channels for each channel based on: a) instantaneous channel status i.e. free state; b) amount of time passed since the channel was free; c) channel free time behavior prediction during the hour from data warehouse and d) User call holding time prediction during the hour from data warehouse. Eligible list of channels is thus prepared in order of merit and allocation is made by the switching centre depending upon the user service type request and QoS eligibility of the user.

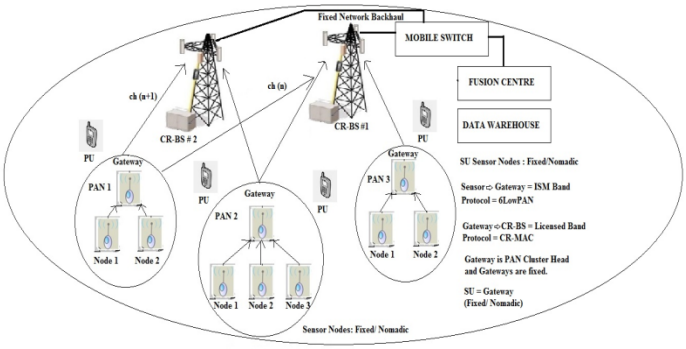

Figure 3. Cognitive Radio Cellular and Sensor Network

The proposed architecture also assumes that the communication shall take place in licensed band channels only so that the UE can be used as SUs with little modification in access protocol. PUs will communicate through BSC whereby SUs are located in between different PUs. The SU shall communicate through CR-BSC. The CR-BSC contains transceiver assembly based on Software Defined Radio (SDR) architecture, an exclusive wideband RF receiver and a Global Positioning System (GPS). Also it is expected that every SUs need to have in built GPS facility. The job of SU transceiver is to monitor channel occupancy information and the signal levels for all PUs. The CR-BS receiver collects the information such as channel occupancy from SUs. Thus the CR-UE shall take the role of static CR node for cooperative sensing with exception that it is mobile. On the other hand, the idea of swapping the dynamic database among CR nodes is missing. Instead, the database acquired by an SU during a specific duration is sent to a central node i.e., CR-BSC through CR-BS.

Secondary infrastructure might stay associated with CR-BSC for cognitive call handling function. CR-BSC shall hold the tables and decision logic for allocation of channels to SUs. In like manner, the spare channels and the assigned frequencies are distributed by CR framework in order to have minimum interference.

5. Call Arrival Rate Prediction

CR infrastructure and CR users are same as licensed user framework with the exception of that CR frameworks needs to follow the mandatory guideline that: (a) exclusive vacant channels of PU are to be utilized and returned when PU is active on this channel, (b) it won't cause any noise to PU framework. In this way, SU design might contain some extra logic than PU framework; else they are basically the same. Accordingly, it is basic to examine altogether the PU behavior for drawing conclusions about CR traffic handling effectively.

A review was completed for 42 days for 7 channels of various geographic and business significance of the city e.g., local location, market, play area and so forth, out of which 35 days (7 weeks) information was utilized for development of the model and one week (7 days) information was forecasted and verified with actual days information from 36th day to 42nd day to guarantee goodness of fit.

In this analysis, 35 days information of every cell was gathered and arranged on hourly basis and one specific hour was chosen. It was expected that hourly information might follow a weekly pattern and then a period of 7 days was taken after. SARIMA model was applied to forecast 7 days information for that specific hour in view of 35 days observed information of that hour. The prediction of traffic pattern for a week follows the following relationship:

Forecast Occupancy = $F_i = S_i * T_j$

where, i = 1 to 7 as one week is considered as a seasonal unit,

j = 1 to n,

n= number of days of observation = 35 in present analysis.

$T_i = \{A_0 - A_1 * D_j\}$,

S_i = Seasonal Coefficients;

A_0& A_1= Intercept Coefficients obtained from SARIMA modeling.

A lag of 7 was observed to be ideal fit for predicted data with actually obtained result. In this way SARIMA model of (7,7,7) was found to be best fit after application on 7 channels. Such perception for an estimated busy hour has been plotted in Figure 4.

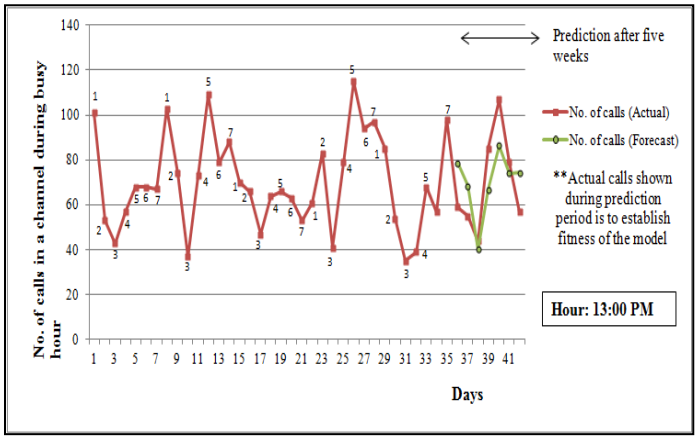

Figure 4.Forecast of Channel Availability during Busy Hour: 13:00 PM of Each Day of Five Weeks Observation Using SARIMA Approach

Investigation of the plots for week after week observation demonstrates reliable conduct from week to week as shown by digits 1 to 7 in the figure 4. This information is stored and updated in data warehouse of the CR-BSC for long term forecast.

The prediction of availability of vacant primary channels or in other words, occupancy of primary channels during the holding time of SU is essential, in particular, in and around peak occupancy. Despite the fact that, the parabolic model gives an idea of peak occupancy time and peak occupancy count from static perception however it can't be completely depended upon [14]. Thus,

prediction mechanism is essential about busy hour and at least for the duration of the holding time.

The probability that no call arrives ($P_i(0)$) during the holding time of SU (τ) was calculated using the relation:

$P_i(0) = \exp -[(\lambda/60)* \tau]$

where, λ = call arrival rate of PU,

τ = holding time of SU

It is found in figure 5, even if we assume that call arrival rate of PU = 8 with τ = 3 minutes, the SU call will mature with probability of 0.67.

6. Blocking Probability

The determination of QoS provided by a particular network configuration is required for an efficient design of communication networks [15]. Whenever a customer makes a telephone call, the routing equipment will decide to reroute the call to alternative equipment, to receive the call or to reject it entirely. Call rejection is occurred because of heavy traffic loads (congestion) on the system which results in either call being delayed or lost. The blocking probability is defined as the probability that the call attempts cannot be handled successfully due to unavailability of the radio resources (i.e. unavailability of free circuits or other switching equipments).

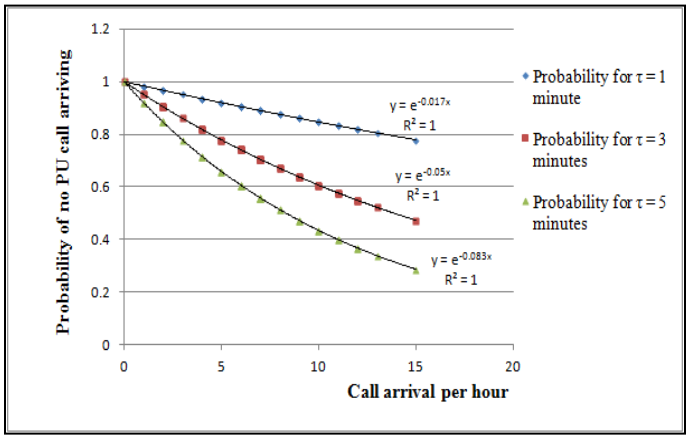

Figure 5. Graph of Probability of No Call Arriving Of PU, $P_i(0)$ vs Number of Vacant Channels with Different Holding Time Of SU (τ)

Efficient design of communication networks requires the ability to determine the quality of service provided by a particular network configuration. A common quality of service measure is the blocking probability, which is the probability that a new call will not be admitted to the network due to insufficient network resources [16].

Using the Poisson theorem, the probability that a call will be blocked can be calculated as:

$$P(c,a) = 1 - \sum_{k=0}^{c-1} \frac{a^k}{k!} e^{-a}$$

where, P(c,a) = the proportion of offered load that is blocked using the Poisson model given "c" servers and "a" offered load.

For a Lost Call system, the Grade of Service (GoS) for CR shall be measured by using modified Poisson's Model, as proposed in this work is given by the equation:

$$P(c,N) = 1 - \sum_{k=0}^{c-1} \frac{N^k}{k!} e^{-N}$$

where, k = 0 to (c-1) with c = total number of trunked channels, $N=N_p+N_s$, N_p = Count of PUs in the system, $N_s = \sigma N_p$ + offset = Count of SUs in the system, where, $0 < \sigma \leq 1$. A portion of the PU, σ (known as SU factor) can be considered for the calculation of the blocking probability of a secondary call combined with PUs traffic in the system. Also, 0<offset<1 such that N_s is an integer of higher value. These values of GoS help to determine whether the channel allocation to SU shall be successful or fail.

At the point when a cellular system is planned, the blocking probability P should be less than some pre-determined value. An observation for varying channels was made with c= 60 servers and is depicted in figure 6.

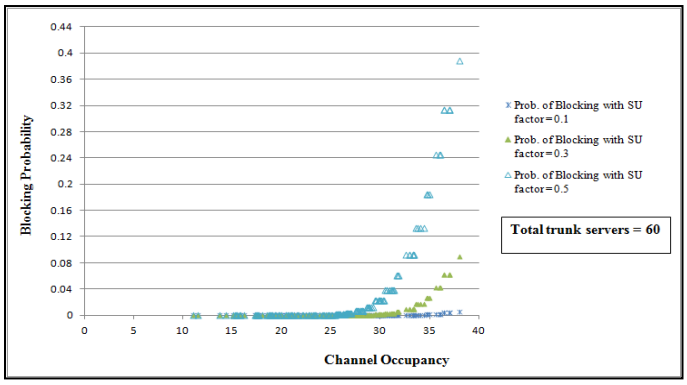

Figure 6.Call Blocking Probability with Trunk Servers (c) = 60 using Poisson's Model

7. Discussions on Results and Conclusion

The study establishes that there are scanty occupancy of PU channels about 16 hours of a day during which large quantum of SU can be allocated without problem. The performance of SU can be further improved in case, the traffic holding time is less than 1 minute. The SARIMA prediction model with a periodicity of 7 ideally fits the predicted data. It is also established that when the PU channel occupancy is 50%, the CR-BS shall provide voice channel to SU with blocking probability ≤ 0.02, where industry standard for blocking is 0.02.

8. Future Work

The SARIMA method is a better method for prediction of channel occupancy rate which takes into account the auto regression and moving average method along with the seasonal parameters. But still there is a scope of further improvement in the results of prediction by including three exponential smoothening

factors viz. (a) the level (or mean) that can be smoothed to give a local average value for the series of data, (b) the trend that can be smoothed, and (c) each seasonal sub-series (i.e., all the values of Monday, all the values of Tuesday, etc. for weekly data) that can be smoothed separately to give a seasonal estimate for each of the seasons. Some other methods like Holt-Winters (HW) additive technique may provide more predictive results.

ABSTRACT

The increased motivation (by service providers) to offer user-centric and seamless communication services – that satisfies users' quality of experience (QoE), has manifested a myriad of challenges in the field of wireless communication; and given the increased traffic capacity and sudden explosion of cellular devices, communication systems are constantly threatened by performance related issues – including soft handoff. Although intelligent techniques have evolved to provide solutions to these issues, they are yet to flourish in the area of soft handoff. This contribution therefore proposes a framework that integrates two components: (i) machine learning methodologies: self-organizing map (SOM) and pattern classification – for robust performance evaluation of available soft handoff data; (ii) multiple attribute decision making mechanisms (MADM): the Analytical Hierarchy Process (AHP) – which result feeds the Technique for Order of Preference by Similarity to the Ideal Solution (TOPSIS) – for efficient access network selection.

Implementation of component one of the design revealed that SOM enabled a precise visualization of handoff features that influenced the system performance; and the error levels of training, validation and test dataset, with number and percentage of correct and incorrect classifications, were obtained from our pattern classifier.

Implementation of component two of the design for four heterogeneous (access) networks indicated that although network two (N2) was selected as best access network by TOPSIS and network three (N3) by Synthetic Extent Analysis (SEA) – a method adopted in a related paper, for a particular application; both TOPSIS and SEA selected N1 as second best alternative access network and network four (N4) as third best alternative network, despite the issue of ranking abnormality in TOPSIS. Further, AHP and TOPSIS can effectively be applied as MADM algorithms in handoff decision framework for selecting the best available network for handoff.

1. Introduction

Handoff is an essential element of cellular communications, as efficient handoff algorithms are a cost-effective way of enhancing the capacity and quality of service (QoS) of cellular systems. Traditional handoff mechanisms are mostly based on received signal strength (RSS) from current access point (AP) or base station (BS). The method to decide handoff based on RSS is considered as the simplest method to handoff decision [1], but on the other hand, it may not have sufficient reliability because of RSS fluctuation [2]. Further, each network in a heterogeneous network has different RSS threshold; hence, RSS-based method results in inefficient handoff, unbalanced load, and frequent service interruption. The heterogeneous network concept was introduced to satisfy the demands of network traffic capacity and data rate [3], and consists of multiplatform networks with various radio access technologies. Conventionally, a mobile user may roam and accomplish handoff using single criteria such as RSS, but the co-existence of different networks with different RSS thresholds degrades the network performance. As such researchers exploit other parameters such as signal to interference and noise ratio (SINR), current location of mobile user, and network conditions for initiating handoffs.

The integration of diverse but complementary cellular and wireless technologies in the next generation wireless networks requires the design of intelligent handoff decision algorithms to enable mobile users equipped with contemporary multi-interfaced mobile terminals to seamlessly switch network access and experience uninterrupted service continuity anywhere and anytime. Recently, various schemes have been implemented to enhance the quality of multimedia traffic [4], but such schemes are yet to offer good estimates of the traffic load and throughput.

The continuous developments and evolving generations of the cellular network technologies are influenced heavily by increased traffic capacity; high data consumption; and demand for better service quality – sufficient to satisfy end-users' quality of experience (QoE), but, state-of-the-art solutions are yet to parallel these challenges. Next generation cellular systems are expected to leverage the challenges of previous generations and provide ubiquitous connectivity, zero latency and high-speed connection. It is also expected (in the future) that devices should integrate heterogeneous radio access technologies (RATs) in order to improve the network performance as well as satisfy users' quality of experience.

Vertical handoff which occurs between base stations (BSs) with diverse wireless network interfaces, enables mobile subscribers to seamlessly make connections with the new BS before terminating with the previous BS. Network selection for subscribers with multiple connection interfaces however, creates a huge challenge for heterogeneous wireless environment. This raises the concern for innovative approaches to access network selection to ensure: seamless and always best connected (ABC) service to mobile subscribers, maximized resource utilization, and increased revenue to network operators. One promising solution is the use of multiple attribute decision making (MADM) methodology to handle the multiple attribute requirements of each access network for efficient handoff.

In this paper, we engage the prioritization of various handoff decision variables – to improve on the overall network performance. The current work is an extension of our FTC'16 paper [5]. First, we subject the available (handoff) input data to two machine learning procedures: (i) unsupervised analysis of inherent patterns; and (ii) supervised classification of the system performance. We then proceed further to demonstrate the use of two MADM techniques – analytic hierarchy process (AHP) and Technique for order of Preference by Similarity to the Ideal Solution (TOPSIS) – for the network selection problem. The AHP is used to determine the weights of decision criteria, which are later fed into TOPSIS and used to assist the network to rank the access networks. Our focus is on the handoff decision phase and aimed at satisfying mobile subscriber through the ABC concept. Further, the performance of TOPSIS in network ranking is compared with the synthetic extent analysis using decision criteria values obtained in [5].

This paper is structured as follows: A critical review of literature on related works is done in section 2; Section 3 presents the materials and methods required for accomplishing the study; Section 4 discusses the results obtained; and Section 5 offers conclusion to the study.

2. Related Works

Macro-diversity can change the transmission power required to service a mobile station with regards to its location. Although this contributes to improving the system performance, it can also cause unexpected call-dropping after handoff. For multimedia traffics which require high data rates, macro-diversity is necessary. In [6] an analytical soft handoff model considering macro-diversity effect was developed. Using analytic and simulation method, a performance evaluation of blocking probability, handoff failure probability and the region-transition failure probability was carried out. Their results were also compared with previous analytic models to illustrate the effect of macro-diversity on the system performance. The system was found to be useful for managing the determination of optimal resource allocation, cell configuration, and admission strategy. In a similar research, Chung and Cho [7], had proposed an analytical model of soft handoff when multimedia services are served in CDMA based intelligent transport system (ITS). They evaluated the performance of soft handoff scheme using analytical and simulation method, and considered key performance metrics such as blocking probability, handoff failure probability and carried traffic – obtained for the system management parameters considered in [6]. Ma, Cao, Liu and Trivedi [8] investigated the features of cellular geometry in CDMA systems with soft handoff, which distinguishes the controlled area of a cell from the cell coverage area. Important characteristics of the cellular configuration were used to propose a new design for efficient call admission control (CAC) in CDMA systems and the construction of a continuous-time Markov chain (CTMC) model for CAC in CDMA with soft handoff queue. Closed-form solutions were also obtained with algorithms that provide stability in loss probabilities computation and the determination of the optimal number of guard channels. To apply the loss formulas, their proposed modelling techniques were used to evaluate and compare the performance of conventional and proposed soft handoff schemes. Numerical results showed the effectiveness of the proposed Markov chain models as well as benefits of the new soft handoff scheme. A neural network (NN) approach was proposed in [9] to optimize the operation of cellular networks, where an analytical equation was derived to establish the effect of essential handoff contributory factors, with data obtained from base stations of an operational network carrier, and trained using a back-propagation NN algorithm. Their results showed that the network performance improved with large data size. A self organizing map was then used to visualize the existing system for the purpose of improving further, its performance.

Heterogeneous multi-radio networks are emerging with architectures that compromise hierarchical deployments of increasingly smaller cells [10]. These deployments may employ multi-radio access technologies to communicate with the network infrastructure, and calls for a dynamic access network selection. Various schemes have been implemented for access network selection during handoff in heterogeneous wireless networks, but most of them are usually optimization procedures and only useful for the reduction of handoff latency instead of improving QoS. One of the important aspects of seamless communication for ubiquitous computing is the dynamic selection of best access network. Ajuja, Singh and Khanna [11] considered bandwidth availability as the dynamic parameter for network selection in heterogeneous environments. A bootstrap approximation based algorithm is deployed in temporal and spatial domains to check its robustness. Numerical results showed that their algorithm reduced the estimation error, overhead, and improved reliability, compared to the existing algorithm.

To assure the required QoS for various applications run by the mobile user (MU) and avoid frequent handoff errors in heterogeneous networks, an AHP method for network selection was introduced in [12]. AHP performs decision selection on the basis of different handover parameters such as QoS, communication cost, availability and reputation of a network, etc, and combines the average of each criterion to decide an appropriate network for handoff. The AHP method has been employed by different researchers for efficient network selection in WLANs, but the method has not achieved the desired success in cellular networks [12]. A similar scheme was proposed to enhance the QoS of a network through the optimization of different handoff parameters such as data rate and handoff latency [1], and the decision for handoff was performed using a hybrid of fuzzy logic and analytic hierarchy approaches. A hierarchal scheme for discovering network selection rule based on media independent handoff (MIH) optimization has been proposed in [13]. In their experiment, a number of APs/BSs in a particular zone were connected to a zone media independent information system (MIIS) server attached to both the local and global MIIS servers. The energy consumption rate of a MU directly depends on the available networks scanned during a handoff process. Different schemes based on the energy efficient network selection for multimedia based applications have been proposed in [14, 15]. The schemes adopted the concept of adapt-or-handoff for balancing the multimedia traffic during a handoff process, thereby saving energy consumed due to the insignificant degradation in quality. Hence, energy consumption during the selection of networks is important and should be considered carefully. In order to optimize the energy consumption of multiple interfaces, Doppler, Ribeiro and Kneckt [16] have proposed a two-step scanning mechanism for obtaining band/channel information within a specific area. In their scheme, the MU scans highly reachable channels and provides each MU with the network density information as it enters a new area.

One major issue in handoff is how to optimize the decision time in selecting the access network with the best signal quality among the available one at the exact time needed by the mobile users. It is therefore necessary that mobile network operators provide good control and decision-making algorithms that optimize the soft handoff process – to avoid false initiation alarm, and select the best available network. Various MADM techniques for handoff decision optimization abound in the literature (c.f. [17-20]). However, no one technique is superior as there exist drawbacks in them such as ranking abnormality, subjective experts' judgment, uncertainties in human preference and penalizing behaviour towards poor attributes. In this paper, AHP and TOPSIS are combined for performance evaluation of network selection in heterogeneous wireless environment during handoff. Furthermore, the selection of these models is based on the following evaluation criteria [21]: internal consistency and logical soundness, transparency, ease of use, data requirements are consistent with the importance of the issue being considered, realistic time and manpower resource requirements for the analytical process.

The idea with AHP is to form a comparison matrix for each pair of criteria or alternatives such that the paired comparisons produce weighting scores that measure how much importance the criteria or alternatives have with each other. It begins by decomposing a complex decision problem into a hierarchical structure comprising the goal to be achieved at the top of the hierarchy, followed by criteria needed to achieve the goal and possibly the alternatives for each criterion at the bottom of the hierarchy. The major steps in AHP hierarchal structure are presented in [22-23]. The method tries to optimize decision making when decision makers are faced with conflicting qualitative and quantitative data. It optimizes decision making by enabling decision makers, in its final ranking, to choose the best solution among several alternatives across multiple criteria to attaining a specific goal. The ability of the method to capture both subjective and objective data in a quantitative manner for evaluation as well as the provision of a mechanism for checking the consistency ratio of the evaluation measurements makes it a veritable tool for decision making. The use of TOPSIS as a classical MADM algorithm is aimed at identifying an alternative that will have the shortest distance from the positive ideal solution and the farthest distance from the negative ideal solution [24]. The algorithm calculates positive and negative ideal solutions based on the attribute values available for each alternative.

In [25] a modified ''ELECTRE'' algorithm that provides complete ranking of the networks in application scenarios where the utility of some attributes is non-monotonic was presented. In [26], they compared the performance of "PROMETHEE" with "AHP" in terms of consistency, ranking abnormality, robustness, and accuracy. In [27], a comparison among different decision making techniques was made to check their pros and cons in terms of selection of network for sensor based applications. Results indicate that AHP appears more stable, less prone to risk and penalizing judgment behaviour. Also, more than 80-85% of the time, the results made by AHP, TOPSIS, Simple Additive Weighting (SAW) and Multiplicative Exponent Weighting (MEW) were the same. In [28], an access network selection algorithm that uses AHP and TOPSIS was proposed, but crucial QoS parameters such as RSS and available bandwidth resources were not considered in the selection process. However, it has been shown that the available bandwidth, received signal quality, battery life of the MT, security level, cost of service per byte, and distance between MT and BS are important parameters when considering vertical handoff decisions [29-31].

A QoS mechanism was proposed in [5] for improved handoff decisions in mobile communication networks. The proposed design adopted a hybrid channel perception tool to train observed key performance channel characteristics for system channel behaviour discovery. A HMM framework was adopted to ensure that the available channels were not completely consumed during handoffs. Estimates obtained from the training were then passed to a Fuzzy-based model to select the appropriate access network or base station. Their results showed that the proposed system could sustain handoffs at an average of 80%, compared to the empirical system, which average gave 50%. Further, two multiple attribute decision making (MADM) methods: fuzzy AHP and synthetic extent analysis (SEA) were used to assign weights to certain criteria influencing handoff decision, and the alternative access networks ranked based on weight priority scores in order to select the most optimal access network for a particular application.

3. Materials and Methods

The methodology adopted for the soft handoff evaluation integrates two machine learning tools. The self organizing map (SOM) – an unsupervised classifier is first used to cluster the input data in order to observe the inherent patterns exhibited by the existing system. The stipulated threshold for handoff success rate set by the Nigerian Communications Commission (NCC) – the communication regulatory body in Nigeria, was then used to

generate the target class. Both data classes (input and target) are later fed into a (supervised) feed-forward pattern classifier, to explain the performance of the classification algorithm. The system framework is shown in Figure 1.

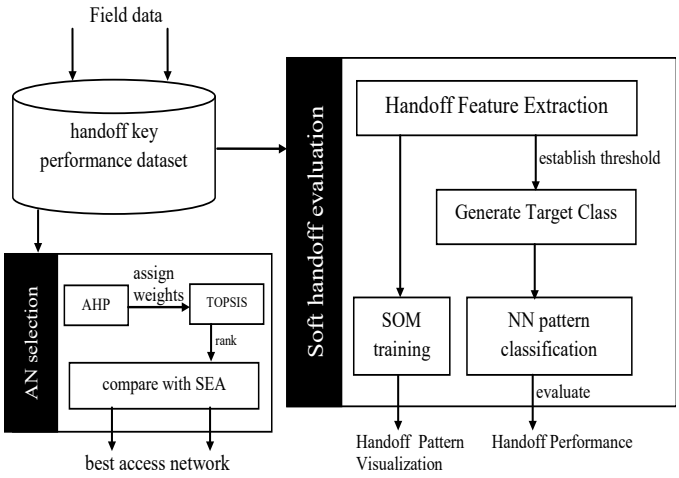

Figure 1. Proposed system framework

To ensure effective comparison between SEA and TOPSIS, the most promising values generated from the membership functions of the triangular fuzzy numbers in the fuzzy-AHP method in [5] were used to construct the AHP pair-wise comparison matrix for the considered criteria necessary for handoff decision. The AHP process in the end assigns weights to criteria which are used by the TOPSIS method to perform final ranking of the access networks. The alternative access network is the one with the highest value of relative closeness to ideal solution. We also compare the access network selection results of SEA technique – obtained in [5] with TOPSIS, to evaluate the efficiency of both selection techniques, in selecting the best access network for handoff.

3.1. Key Performance Dataset

Dataset for the soft handoff evaluation experiment consists of the input class and the target class. Sample data points for the input and generated target classes are presented in Table 1. The input data are real-time measurements acquired from 49 base station controllers (BSCs) of an operational cellular network carrier, at busy hours. These data were gathered over a period of one month, and are required for evaluating the existing system.

The input data extracted for this experiment include: drop call rate (DR); cell availability (CA); base station controller availability (BSCA); carried traffic (CT); block call rate (BR); up-link throughput (UL_TH); down-link throughput (DL_TH); and handoff success rate (HOSR). The target class is made up of three features namely, not satisfactory (C1: class 1); satisfactory (C2: class 2); and very satisfactory (C3: class 3). Data for the target class were obtained through the following classification rule: (if HOSR<90, C1=1, else, C1=0); (if 91≤HOSR≤95, C2=1, else, C2=0); (if 95≤HOSR≤100, C3=1, else, C3=0).

After generating the target class, 7 samples (about 14% of the data) were not satisfactory (fell into class 1), 42 samples (about 86% of the data) were satisfactory (fell into class 2), and none (0% of the data) was very satisfactory (fell into class 3). The analysis indicates that the handoff performance of the existing system was not optimal, as no data fell into the third class.

Table 1. Sample input data points and generated target classes

	Input class								Target class		
SN	DR	CA	BSCA	CT	BR	UL_TH	DL_TH	HOSR	C1	C2	C3
1	1.1200	99.8700	93.3800	402.0800	0.1200	11.7000	33.8100	88.6600	1	0	0
2	0.9000	99.8900	97.5900	569.1900	0.2100	11.3200	30.3200	91.2100	0	1	0

3.2. SOM Methodology

One major feature of artificial neural networks (ANNs) is its ability to adapt to an environment by learning to improve its performance at emulating behaviourial characteristics of an object in an unsupervised manner. The basic SOM is as a nonlinear, ordered, smooth mapping of high-dimensional data manifolds onto the elements of a regular, low-dimensional array, and the mapping is implemented as follows:

(i) define the set of input variables x_j as a real vector, $x_j = \{x_1, x_2, \dots, x_n\}^T \in \mathbb{R}^n$;
(ii) associate with each element in the SOM array a parametric real vector: $m_i = \{m_1, m_2, \dots, m_n\}^T \in \mathbb{R}^n$ – also called a model;
(iii) define a distance measure between x and m_i, denoted as $d(x, m_i)$.

In this paper, we adopt the incremental SOM algorithm with a rectangular map topology, as shown in Figure 2.

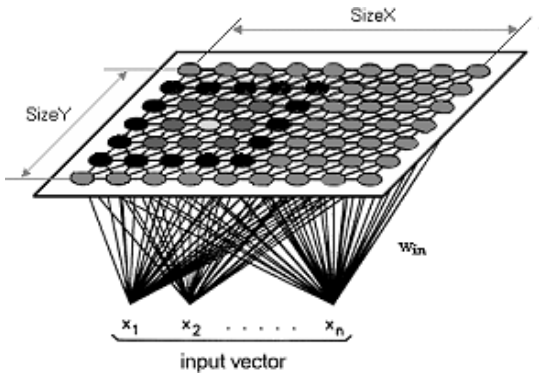

Figure 2. SOM topology; Source [32]

The image of an input vector x on the SOM array is then defined as the array element m_c that best matches with x, where the index $\arg min_i\,(d(x, m_i))$. The main task here is to define mi in such a way that the mapping is ordered and descriptive of the distribution of x. The process in which such mappings are formed is defined by the SOM algorithm. This process is then likely to produce asymptotically converged values for the models mi, the collection of which will approximate the distribution of the input samples $x(t)$, even in an ordered fashion. Vector x may be compared with all the m_i in any metric. In many practical applications, the smallest of the Euclidian distance $|x - m_i|$ can be made to define the best matching node (BMN), defined by the subscript:

$$c = \arg min_i ||x - m_i|| \equiv \big||x - m_c|\big| = |min_i|.$$

3.3. Pattern Recognition Methodology

Pattern recognition is the process of classifying input data into classes based on key features. Two classification methods to pattern classification are identified in the literature and include: supervised and unsupervised classification. This paper adopts the supervised method to pattern classification. The need for pattern recognition in handoff algorithms is essential for evaluating the robustness of communication systems. Pattern recognition application to the handoff process assumes that mobile users travel along same paths within the radio coverage area, and their movements follow the topological structure of the road infrastructure or the architectural structure of the environment. These patterns are then exploited to make handoff decisions and to define the locations where handoff executions are desirable through training of the network – to identify such locations. Pattern recognition can be implemented in a variety of ways and algorithms, and the setting up of a complete pattern recognition based handoff decision system should consider the following tasks:

(i) *Handoff location determination:* defining the location depends on the choice of criteria for what an optimal or good enough position a handoff should occur;
(ii) *Pattern formation:* generating pattern trace of the street, path, etc., with the collected metric samples. The components of the pattern trace are feature matrices associated with the surrounding BSs/APs, which are often referred to as class representatives.
(iii) *Data sample collection:* using data samples of a chosen metric around the chosen handoff location to train and validate the recognized patterns.

In this paper, a two-layer feed-forward network, with sigmoid transfer function in the hidden layer, and a soft-max transfer function in the output layer is proposed. The number of hidden and output neurons are set to 10 and 2, respectively, and the number of elements in the target vector (the number of categories or classes) is 3 (see Table 1). The input data were randomly divided such that 70% of the samples were for training, 15% for validation, and 15% for testing. The neural network architecture showing the pattern recognition components is presented in Figure 3.

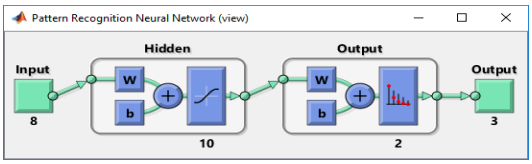

Figure 3. Pattern recognition network architecture

3.4. AHP Methodology

The application of the AHP method to a complex problem usually involves the following major steps [22-23]:

(i) Define the unstructured problem by describing the hierarchy with the goal at the top, followed by criteria at the lower levels and then alternatives at the bottom.
(ii) Construct a set of pair-wise comparison matrices among decision elements (criteria and alternatives) by establishing priorities among them based on a preference scale of 1 to 9 as shown in table 2.

Table 2. AHP preference scale

Scale	Definition
9	Extreme importance
7	Very strong importance
5	Strong importance
3	Moderate importance
1	Equal importance
2, 4, 6, 8	Intermediate values

(iii) Estimate the relative weights (w_k) of the decision elements using eigenvector method; where $w_k = \frac{GM_k}{\sum_{k=1}^{n} GM_k}$, where GM_k is the geometric mean of the kth row.
(iv) Aggregate these relative weights and synthesize them for the final measurements of the decision alternatives.

(v) Compute the consistency ratio (CR) to determine the acceptability or otherwise of the chosen criteria or alternative; where $CR = \frac{CI}{RI}$ (CI is the consistency index, and RI is the random index).

3.5. TOPSIS Methodology

The final weight measurements from AHP are used by TOPSIS for ranking of alternatives. In the TOPSIS method two artificial alternatives are hypothesized, i.e. the positive and negative alternatives. The basic rule behind these hypotheses is that the chosen alternative should have shortest distance from positive ideal solution and longest distance from negative ideal solution. TOPSIS makes the decision of alternative that is very near to the best result and very far from pessimistic alternative. The first step transforms attribute dimensions into non-dimensional attributes, which allows comparisons across criteria. The following steps describe the TOPSIS algorithm for network selection.

(i) Compute root of sum of squares to standardized the overall decision matrix of weights of criteria d_{ij} obtained from AHP method;

(ii) Normalize the decision matrix of criteria d_{ij} acquired from the four candidate networks as listed in Table 1 using (1).

$$z_{ij} = d_{ij} / \sum_{i=1}^{n} d_{ij} \quad (1)$$

(iii) Generate the weighted normalized matrix by multiplying the normalized decision criterion z_{ij} with its assigned weight w_k as in (2)

$$r_{ij} = z_{ij} w_k \quad (2)$$

(iv) Determine the positive ideal solution V^+ and the negative ideal solution V^- as in s (3) and (4)

$$V^+ = (R_1^+, R_2^+, \dots, R_n^+) \quad (3)$$

$$V^- = (R_1^-, R_2^-, \dots, R_n^-) \quad (4)$$

However, for beneficial criteria, $R_i^+ = \max(r_{ij})$ and $R_i^- = \min(r_{ij})$ while for non-beneficial criteria, $R_i^+ = \min(r_{ij})$ and $R_i^- = \max(r_{ij})$.

(v) Determine separation from ideal solution by calculating the similarity distance as expressed in (5) and (6),

$$S_j^+ = \sqrt{\sum_{j=1}^{n} \left(R_i^+ - r_{ij}\right)^2}, j = 1,2, \dots, n \quad (5)$$

$$S_j^- = \sqrt{\sum_{j=1}^{n} \left(r_{ij} - R_i^-\right)^2}, j = 1,2, \dots, n \quad (6)$$

(vi) Determine the relative closeness to the ideal solution by calculating C_j^* as in (7)

$$C_j^* = S_j^- / \left(S_j^+ + S_j^-\right), \; j = 1,2, \dots, n \quad (7)$$

(vii) Rank the access networks according to the descending order of C_j^*.

4. Results

4.1. SOM Visualization

We visualize the feature component planes of the SOM in Figure 4. The component planes show which features has a significant influence on the clustering results. Dark colors represent relatively small values while light colors represent relatively large values. Hence as expected, CA, BSCA, CT and HOSR have high range values, whereas DR, BR, UL_TH, and DL_TH have low range values, as predicted. Interestingly, (DR and BR); (UL_TH and DL_TH); and (BSA and HOSR); exhibit similar patterns, and thus signifying strong correlation between the component planes. In practice, we can say that these variables occur in sequence. For instance, block calls usually occur before drop calls, uplink transmission must occur before downlink transmission, and base station controller availability determines the handoff success rate. Cell availability and carried traffic show dissimilar patterns, indicating in practice that one component cannot determine the other – i.e., the carried traffic does not determine cell availability, or vice versa.

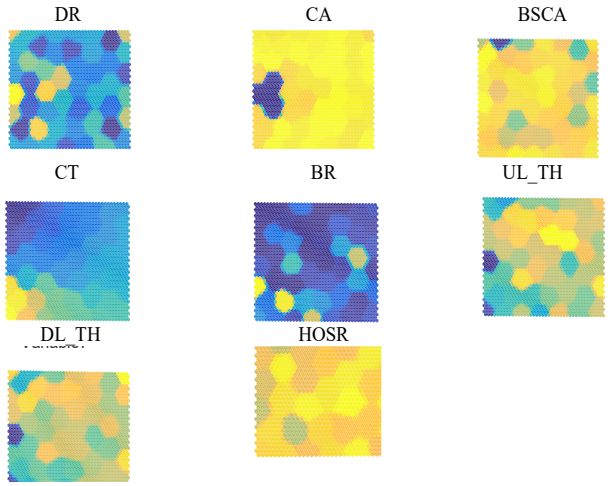

Figure 4. SOM component planes for selected features

4.2. Pattern Classification

Figure 5 shows the performance plots of the neural network for training, validation and test data. We observed that although the error reduced rapidly after the third epoch of training, the validation and test errors were still high even up till the ninth epoch. But the degradation did not cause an over-fit in the training data, and the best validation performance was 0.0559.

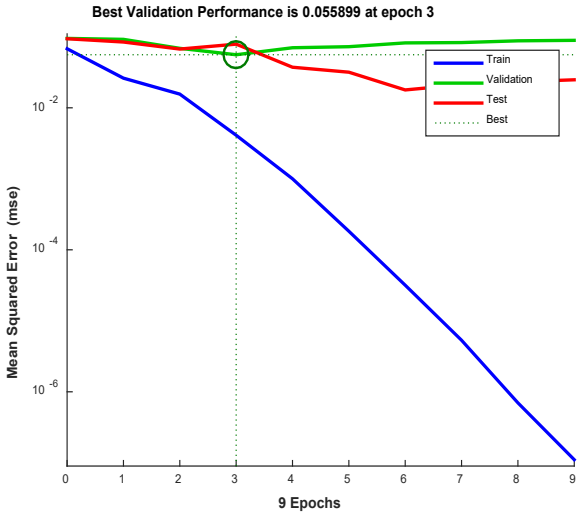

Figure 5. Neural network performance plot for handoff feature data

In Figure 6, the confusion matrix plots for training, validation and test performances of our classifier are shown. We observed that the data were well trained, but some validation and test errors were noticed, as evidenced in Figure 5. The first three diagonal cells in Figure 6 show the number and percentage of correctly classified observations. We concentrate on the overall confusion matrix that takes into account the overall performance of the training, validation and test cases. Hence, 5 BSCs were correctly classified as not satisfactory, corresponding to 10.2% of the overall BSCs within the study area. Similarly, 42 BSCs were correctly classified as satisfactory, corresponding to 85.7% of all BSCs under study. None of the satisfactory cases were incorrectly classified as not satisfactory, 2 of the not satisfactory cases were incorrectly classified as satisfactory – representing 4.1% of all BSCs. Now, out of the 7 not satisfactory predictions, 100% were correct. Also, out of 42 satisfactory predictions, 95.5% were correct, while 4.5% were wrong. Out of 7 not satisfactory cases, 71.4% were correctly predicted as not satisfactory, and 28.6% were predicted as satisfactory. Out of 42 satisfactory cases, 100% were correctly classified as satisfactory and none as not satisfactory. The overall prediction was 95.9%, with 4.1% wrong classifications.

The Receiver Operating Characteristic curve (or ROC curve) shows the tradeoff between sensitivity and specificity (any increase in sensitivity will be accompanied by a decrease in specificity), and is presented in Figure 7. It plots the true positive rate against the false positive rate for the different possible cut-points of the classifier. As can be seen, the distortion in the test data plot is not unconnected with the high total misclassification of not satisfactory cases as satisfactory (see Figure 7). Even with this distortion which came as a result of validation and test errors (see Figure 6), the overall ROC seems a more accurate test, as evidence in the closeness of the curves to the left hand border are noticed, except for the third class (C3) which had no recorded data.

Figure 6. Confusion matrix plots for evaluating our pattern classifier

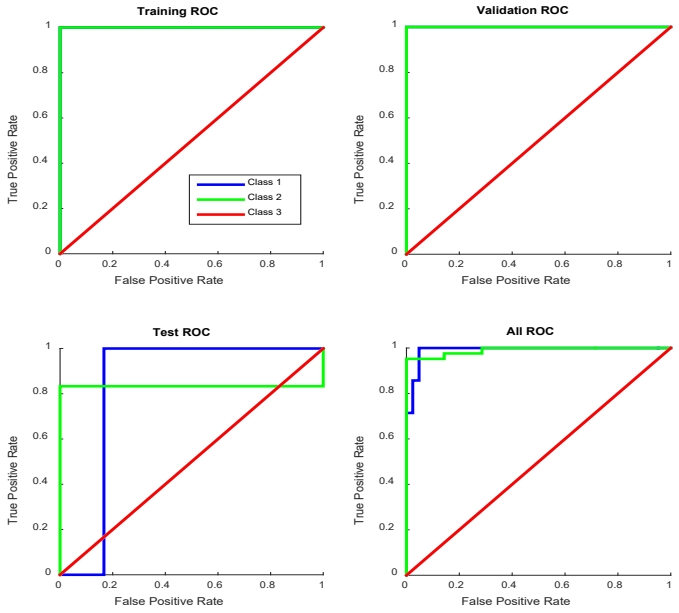

Figure 7. ROC curves showing sensitivity and specificity tradeoffs

4.3. AHP Analysis

To evaluate the performance of synthetic extent analysis and TOPSIS algorithms in network selection, an application scenario of four heterogeneous networks N1, N2, N3, N4 is considered which typically denotes 4G-LTE, 3G-UMTS1, 3G-UMTS2, and WiFi. In such a scenario a MS is assumed to be connected to N1 network and is traversing through an area overlapped by three more networks N2, N3, and N4. So, four networks are available simultaneously to the MS. The MS has to select the best network from the available networks for handoff. For selection process, AHP and TOPSIS algorithms are applied using the most promising values in the membership function of the triangular fuzzy numbers of the Fuzzy AHP method in [5], as AHP values for assignment of weights to criteria. The essence is to comparatively evaluate the performance of synthetic extent analysis with TOPSIS in terms of best network selection. Decision is based on assessing various criteria from each network: Quality of Service (QoS), Available Bandwidth (AB), Security, Cost, Battery Life, Distance between Mobile Node and Base station (DMNBS. The overall decision matrix for the criteria values for network selection are shown in Table 3.

Table 3. Decision matrix showing criteria values

Criteria	N1	N2	N3	N4
QoS	0.29	0.12	0.41	0.18
AB	0.45	0.18	0.27	0.09
Security	0.40	0.13	0.20	0.27
Cost	0.33	0.17	0.39	0.11
B. Life	0.12	0.41	0.18	0.29
DMNBS	0.33	0.13	0.20	0.33

Assignment of Criteria Weights by AHP

Weights are measures of relative importance of criteria. Most of the existing network selection algorithms have employed AHP methodology for assigning weights to the criterion. In AHP, weights are assigned according to the knowledge and perception

of the decision maker. It performs measurement through pair-wise comparisons and relies on the judgment of experts to derive priority scales. The AHP procedure for weight determination consists of the following steps:

(i) Construct pair-wise comparison matrix for the criterion at each level. For each pair, within each criterion award a score, on a scale between 1 and 9 to the better option, and a reciprocal of this value to the other option in the pair. The pair wise comparison matrix of the criteria for handoff calls is shown in Table 4.

Table 4. Citeria-by- criteria pair-wise comparison matrix

Scale	5	7	4	2	3	4
Criteria	QoS	AB	Security	Cost	B.Life	DMNBS
QoS	1.00	0.71	1.25	2.50	1.67	1.25
AB	1.40	1.00	1.75	3.50	2.33	1.75
Security	0.80	0.57	1.00	2.00	1.33	1.00
Cost	0.40	0.29	0.50	1.00	0.67	0.50
B.Life	0.60	0.43	0.75	1.50	1.00	0.75
DMNBS	0.80	0.57	1.00	2.00	1.33	1.00
Total	5.00	3.57	6.25	12.5	8.33	6.25

(ii) Determine the geometric mean of each row for each matrix and normalize the results to obtain the weights for each criterion. This results in table 5.

Table 5. Normalized criteria-by-criteria comparison matrix and weights

	QoS	AB	Security	Cost	B.Life	DMNBS	Weights (w_k)
QoS	0.20	0.20	0.20	0.20	0.20	0.20	0.20
AB	0.28	0.28	0.28	0.28	0.28	0.28	0.28
Security	0.16	0.16	0.16	0.16	0.16	0.16	0.16
Cost	0.08	0.08	0.08	0.08	0.08	0.08	0.08
B.Life	0.12	0.12	0.12	0.12	0.12	0.12	0.12
DMNBS	0.16	0.16	0.16	0.16	0.16	0.16	0.16

(iii) Check the consistency of the pair-wise comparison in the normalized matrix. The original comparison matrix is considered not consistent if the columns in its normalized matrix are not identical. Ideally, if CR is less than or equal to 0.1, the pair-wise comparison is considered acceptable; otherwise the subjective judgment is revised. TOPSIS algorithm requires weights to be assigned to each criterion for further computation of positive and negative ideal alternatives, where the positive ideal alternative is considered to be one with the best value for all attributes.

4.4. TOPSIS Analysis

From the steps in TOPSIS method (see section 3.4), the following results were obtained:

Step 1: Root of sum of squares computation (see Table 6)

Table 6: Root of Sum of Squares for each Criteria

Criteria	N1	N2	N3	N4	RSS
QoS	0.29	0.12	0.41	0.18	0.46
AB	0.45	0.18	0.27	0.09	0.56
Security	0.40	0.13	0.20	0.27	0.54
Cost	0.33	0.17	0.39	0.11	0.55
B. Life	0.12	0.41	0.18	0.29	0.55
DMNBS	0.33	0.13	0.20	0.33	0.52

Step 2: Decision matrix normalization (see Table 7)

Table 7. Normalized decision matrix of criteria

Criteria	N1	N2	N3	N4
QoS	0.63	0.26	0.89	0.39
AB	0.80	0.32	0.48	0.16
Security	0.74	0.24	0.37	0.50
Cost	0.60	0.31	0.71	0.20
B. Life	0.22	0.75	0.33	0.53
DMNBS	0.63	0.25	0.38	0.63

Step 3: Weighted normalized decision evaluation (see Table 8)

Table 8. Weighted normalized decision matrix

Criteria	N1	N2	N3	N4
QoS	0.13	0.52	0.18	0.08
AB	0.22	0.09	0.13	0.05
Security	0.12	0.04	0.06	0.08
Cost	0.05	0.03	0.06	0.02
B. Life	0.03	0.09	0.04	0.06
DMNBS	0.10	0.04	0.06	0.10

Steps 4 and 5: Determination of/and separation from positive and negative ideal solutions (see Tables 9 and 10)

Table 9. Separation from positive ideal solution

Criteria	N1	N2	N3	N4
QoS	0.15	0.0	1.16	0.19
AB	0.0	0.02	0.0081	0.03
Security	0.00	0.0064	0.0036	0.0016
Cost	0.0001	0.0009	0.0	0.0016

	$\sqrt{(0.0423)}$	$\sqrt{(0.1989}$	$\sqrt{(0.0189)}$	$\sqrt{(0.0061)}$
S_j^-	0.2057	0.4459	0.1375	0.078

Step 6: Computation of relative closeness (see Table 11)

Table 11. Relative closeness to ideal solution

Criteria	N1	N2	N3	N4
S_j^+	0.392	0.176	1.084	0.473
S_j^-	0.2057	0.4459	0.1375	0.078
$S_j^+ + S_j^-$	0.5977	0.6219	1.2215	0.551
$S_j^-/(S_j^+ + S_j^-)$	0.344	0.717	0.113	0.142

Step 7: Access network ranking (see Table 12)

Table 12: TOPSIS Ranking of the access networks

S/N	Network	TOPSIS Rank
1	N1	2
2	N2	1
3	N3	4
4	N4	3

4.5. Performance Comparison

From [5], the SEA ranking placed the four networks in the following order as shown in table 13.

Table 13. Access Network ranking by synthetic extent analysis

S/N	Final weight	Access Network	Ranking
1	0.33	N1	2
2	0.11	N2	4
3	0.34	N3	1
4	0.21	N4	3

The results indicate that for the same set of network decision criteria values, the selected network significantly varies for some reasons. The ranking order of Synthetic Extent Analysis is different from that of TOPSIS for handoff decision in heterogeneous networks. Both methods have similar ranking results for selecting N1 access network and N4 access network as second and third best alternative for roaming by mobile subscribers. Whereas TOPSIS considers N3 as negative ideal solution since if selected presents the user with minimum benefit attributes and maximum cost attributes, synthetic extent analysis considers N2 as least network to switch connection to.

5. Conclusion

Diverse technologies deployed by individual operators in heterogeneous wireless environments require innovative network selection methodologies for provision of always best connected (ABC) services to mobile subscribers. Handling multiple attributes or parameters with different relative importance from each network during handoff decision phase is a huge challenge in such network environment. This paper has exploited two machine learning techniques to visualize the performance of handoff in an existing system; and report on the error levels experienced by the network. It also proposed the use of two multiple attribute decision making (MADM) methods – Analytic Hierarchy Process (AHP) and Technique for Order of Preference by Similarity to the Ideal Solution (TOPSIS) for access network selection and compares the performance of TOPSIS and Synthetic Extent Analysis (SEA) [5] – in ranking the alternatives after assignment of weights to network criteria by AHP.

Embedded Methodologies

ABSTRACT

This work is an extension of the Proceedings of the International Conference on Industrial Engineering, Management Science and Applications, which presented some of the phases of Reengineering applied to Bamboo Panel Company; the results were Strategic planning, Systemic Diagnosis and Performance Indicators through the Balanced Scorecard. Now, the main purpose of this article is to present a methodology that embedding Organizational Diagnosis and Reengineering, which emphasizes the incorporation of culture, context, management style, and knowledge as well as inner and outer actors. The results of the proposed methodology applied to the case study are included, up to the moment of the writing of this article. Future work consists on the development of strategies for Innovation as a strategy planned in the Balanced Scorecard and derived from the embedded methodology.

1. Introduction

This paper shows a subsequent development of the work "Systemic Diagnosis and Strategy-Based Performance Indicators. Bamboo Panel Company Case" exposed at the 6th International Conference on Industrial Technology and Management [1]. The paper came from the project called "Product Development of Modular Components with Prefabricated Bamboo, Phase II". It was part of the Program for Research Stimulation, Technological Development and Innovation of the NATIONAL COUNCIL OF SCIENCE AND TECHNOLOGY (CONACYT, in Mexico). This project was developed by the Autonomous University of Hidalgo in Mexico and a private Enterprise.

The project was carried out from March 2016 to April 2017. It included physical prototypes, procedure manuals, mapping of facilities distribution, simulation of the production systems as well as performance indicators systems, among others.

The paper focuses on the section of methodology, especially, the one that concerns Strategic Planning: Systemic Diagnosis and Performance Indicators following the basis of the Balanced Scorecard, since them conflux to the main perspectives of this stage of development: embedding organizational diagnosis and reengineering processes. Other deliverables include prototypes and development of technology, but they shall not be exposed since that is confidential information. For the same reasons, the name of the company is not disclosed. The company, in which the case study was carried out, designs and constructs structures using bamboo as a raw material. This company creates and executes innovative projects, products and services, from the perspective of sustainability, combining artisan techniques with technologies that allow low environmental impact seeking also, a high social impact. A highlight is that the tool of reengineering was followed for the development of the bamboo prefabricated panel processes.

An organizational diagnosis was performed under the systemic approach, in order to identify the problems of the organization and for the creation of performance indicators. For this, it was necessary to create the so called embedded methodology combining reengineering and organizational diagnosis tools considering the enterprise as a system.

There are many diagnostic tools, however, the methodological design for the diagnosis was the one proposed by Ortega [2], which embeds a systemic perspective and incorporates ad hoc tools according to the situation of the organization, in this case, technology, organization, production, environmental conditions and regulatory frameworks. Additionally, the diagnosis comes to be a component of the Strategic Planning that serves to make decisions.

The first step consisted on stablishing the scope of the diagnosis. For this purpose, the different areas of the organization were analyzed following the methodology proposed by Ortega [2] shown in Figure 1.

Figure 1. Dimensions and useful techniques. Source: Author's elaboration

The second step was to define the dimensions and useful techniques of the intervention which were also defined following this author (Figure 2).

Figure 2. Organizational diagnosis.Source: Author's elaboration

The resultant was a diagnostic map divided into External and Internal, aspects that were also included in the methodological proposal (Figure 3).

Then the tool of the Balanced Scorecard (BSC) was used to integrate the areas of the research process in a Strategic Map [1]. The BSC is a model that becomes a very useful tool for strategic management. It is based on the definition of strategic objectives, indicators and strategic initiatives, establishing relationships by a strategic map in four basic perspectives: financial, clients, internal processes and learning and growth, then the strategy should be translated directly into objectives; where it will be measured through indicators and aligned with initiatives. Success at implementing the BSC depends on the participation of people from different levels and areas of the organization. Kaplan and Norton [3] designed the Balanced Scorecard as an instrument to measure results, based on the establishment of financial and non-financial indicators derived from the company's vision, mission and strategy, making it a tool to manage the strategy.

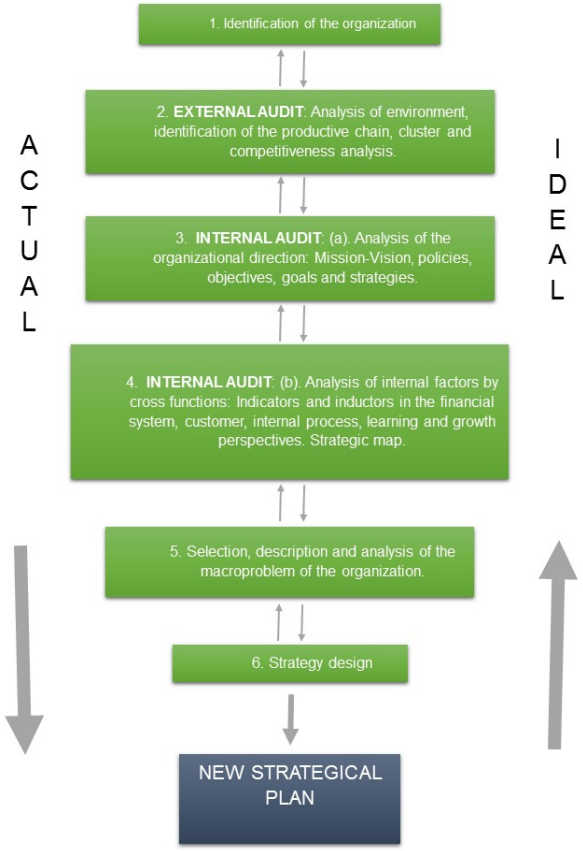

Figure 3. Diagnostic map. Source: Author's elaboration

Some of the benefits of implementing the BSC in organizations are: aligning employees to the company's vision, improving communication to all the staff and compliance, redefining the strategy based on results presented, a translation of the vision and the strategy into actions, which are oriented towards the creation of value; it is integrated with the information of all the areas of the organization and also the capacity of analysis and the decision making is improved. A strategic map as a resultant outcome [4], presents in a simple and coherent way the description of an organization's strategy, in order to establish the objectives and indicators in the financial, customer, internal processes and learning and growth perspectives.

The financial perspective describes the tangible results of the strategy in traditional financial terms, indicators such as the profitability of the investment, shareholder value, revenue growth, unit costs, among others; thus, measuring the creation of value for the organization. The customer perspective, reflects the positioning of the organization in the market, identifying the customer segments and, defines the value proposition for the target customers. Rodiles and Fuentes [5] mention the indicators which are generally considered: customer satisfaction and retention, as well as the acquisition of new customers, customer profitability and market participation where the organization participates. The

internal process perspective identifies internal processes that will have a greater impact on customer satisfaction. Some indicators of this perspective are: productivity, quality and innovation of products and services. The perspective of learning and growth is based on the fact that the formation and growth of an organization come mainly from people, systems and processes. According to Altair Consulting Group [6], the objectives of this perspective are to identify the human capital, systems and organizational climate required to support value creation processes.

Balanced Scorecard has evolved from its early use as a simple performance measurement framework to a full strategic planning and management system. Balanced Scorecard is used by many successful businesses all around the world [7], [8].

2. The Bamboo Industry in Mexico

According to Estrada [9], the Mexican manufacturing industry is investing little in Research and Development activities and the poor resultants of these investments are concentrated in few sectors as: cars, glass, cement as well as office and electronic equipment. Therefore, there is a huge need to encourage new technologies in alternate areas of the economy, so the industrial platform can take off.

In the case of the industry of Bamboo in Mexico the general situation reflects the opportunity for this sector to grow. Nowadays the use of bamboo in Mexico is not very exploited and companies that use it as raw material are limited to decorative purposes only such as walls, floors and partition panels in simple constructions. Nevertheless, there are some states in Mexico with the optimal conditions to have bamboo plantations such as Veracruz, Chiapas and Puebla. Bamboo is known as “one of the most surprising plants in nature”, known as "the plant of the thousand uses" because from it, food, clothing, construction material, pulp for paper and medicines, among others can be obtained. In Mexico, bamboo is used in the construction of rural dwellings, in the manufacture of handicrafts, furniture and home accessories, also for medicinal and ornamental purposes.

For this study, the enterprise was a local producer of Bamboo constructions such as cabins, docks, pergolas, storage rooms and specialized designs which are manufactured in this medium company. The business was created in 2011 and has participated in several government programs with the purpose of developing the technology of its processes and improving its quality and profitability. One of the supports the company received was a special funding from the Mexican National Council of Science and Technology with the participation of a public university, in order to aid the enterprise to create an innovative process for the massive production of bamboo panels. This is the framework that budgeted and allowed the development of this project, which started with an organizational diagnosis process and included a reengineering purpose, embedding both perspectives in the creation of innovative production processes.

3. Problem situation

Nevertheless the organizational diagnosis, was intended to identify the difficulties and opportunity areas of the company, there were some symptoms which pointed to specific problems: lack of a well-defined organizational structure, lack of clarity about the product benefits and its uses, an inexistent trading strategy, non-structured procedures which led the production to artisan and non-standardized products, organizational ends not clearly established, an inappropriate layout, and confusing management styles.

So, the problem statement for this study was that, at the moment of the project, the company did not have formal procedures, documents and a business strategy which allowed it to develop its operations under a quality and innovation style that responded to the requirements of its sector and market.

Therefore, it was necessary to set a way to identify, analyze and combine tools of problem solving, work improvement and processes engineering such as organizational diagnosis and reengineering. Reengineering is a methodology whose principles are used to implement other philosophies such as Total Quality Control [10].

4. Reengineering

Reengineering is “the notion of discontinuous thinking –of recognizing and breaking away from the outdated rules and fundamental assumptions that underlie operations” [11]. Reengineering processes require analysis of managerial efficiency. Welsch, Hilton, Gordon and Rivera mention that the efficiency of an entity is generally recognized as the single most important factor in long-term success. The success of the organization is measured in terms of achieving its goals. For this, it is necessary to implement the activities through the efficient use of human, material and financial resources. That is why it is important to develop and implement the process of planning, organizing, directing and controlling. “Business process improvement is about analyzing the current behavior of process execution in order to identify the process inefficiencies such as agent assignment, resource utilization, and control flow” [12].

To begin with the administrative process, the first phase is planning, which consists of defining what will be done, how to do it and who will. It implies defining the vision, mission, strategies, objectives, goals, actions and initiatives, as well as the allocation of human, material and financial resources for the implementation, monitoring and continuous improvement of the organization. In order to achieve this, it is necessary to develop the strategic plan. This document demands the consideration of the current and desired situation for its construction and defines the strategy.

The holistic view of this managerial approach was understood following the spots of organizational diagnosis.

5. Organizational diagnosis

There have been many scholars who have defined the concept; however, the following definitions were suitable for the theoretical framework of this study. According to Vidal [13], it is “the process of comparison between two situations: the present, which we have come to know through inquiry, and another already defined and supposedly known that serves as a guideline or model”. Porter [14], points out that the competency analysis consists of four diagnostic components: future goals, current strategy, assumptions and capabilities. Savall and Zardet [15] highlight that a socio-economic diagnosis aims “to make the inventory of the dysfunctions and calculate the hidden costs that they originate”, and add that the diagnosis is based on three sources of information: interviews, direct observations, and document analysis. Audirac, et. al. [16] refer that “the diagnosis consists of obtaining valid

information about the organization. It involves collecting and analyzing information about the culture, processes, structure and other essential elements of the organization". Finally, the definition of Ortega [2], established the organizational diagnosis as "the action and effect of specifying the state that an organization keeps from the identification and understanding of its signs and symptoms".

From these definitions and theoretical framework, it was possible to propose a methodological design to diagnose and reengineer the company of this study.

6. Embedded Methodology for the organizational diagnosis in the bamboo industry

The methodological design started from considering the situation of the company as a unique case study. Each case study presents its own features due to its culture, context, management style, knowledge as well as inner and outer actors, which altogether lead to the application of discerned, adjusted analyzes that incorporate these characteristics. Therefore, the methodological design was sustained by different approaches and techniques which have been successfully used in different areas. So, to describe the current conditions of the company, this research used observation, documentary revision, survey and interview, as data collection techniques, with the instruments of field diary, data sheets, questionnaire, focus groups and semi-structured guides [17]. Also, the investigation was considered non-experimental since there was no variables manipulation, and only the facts as they were developed, were observed and described [18].

Therefore, we started form a holistic methodological approach based in the general system theory and particularly in the methodology of soft systems of Checkland [19], that sets the status of a given problem situation, to be then contrasted with the ideal state though the systemic thinking. We designed the diagnostic intervention and we also used benchmarking for the contextual analysis and systemic diagnosis, in order to perform an internal and external auditing of the company. To be able to understand the problems of the organization, a Balanced Scorecard setting was useful in order to align the vision and strategy of the company with the objectives and initiatives. For the application of techniques, a team of five observers was formed, who used audio and video recording equipment as well as observation rooms. The methodological strategy considered a qualitative design applied on March 2016 at the enterprise, which is located in Mexico City, where we worked with local suppliers of this company. The actions performed were:

1. Documentary analysis to formulate a sectorial context at international, national levels through information sources such as sectorial indexes, web pages of companies and videos on internet.
2. Field work through "in situ" inspections that included the applications of the following techniques:
    - Observation guide about planning, organization, management aspects and control of the enterprise.
    - Focus group with the main suppliers of the enterprise to determine the competitiveness of an organization and its productive chain.
    - Technique of Nominal Groups for the revision of the mission and vision, creation of the policies, strategies, objectives and initiatives [20].
    - A focus group with the employees of the company, who also answered the tool of Organizational Health Checkup.
3. Cabinet study for the integration, analysis and synthesis of information collected with the following phases:
    - Design of a cluster for the enterprise.
    - Writing the mission and vision, creating policies, strategies, objectives and initiatives.
    - Drafting of the Balanced Scorecard and creation of the Strategic Map for the Company.

Following these settings, an organizational proposal of the methodology was established dividing the involved elements into endogenous and **exogenous**, considering the actions of organizational diagnosis as inner activities and the reengineering processes as strategic tasks. These, allowed us to include the perspective of intrinsic and extrinsic influence factors in the activity of the enterprise, and embed the theoretical aspects of reengineering and organizational diagnosis as shown in Figure 4.

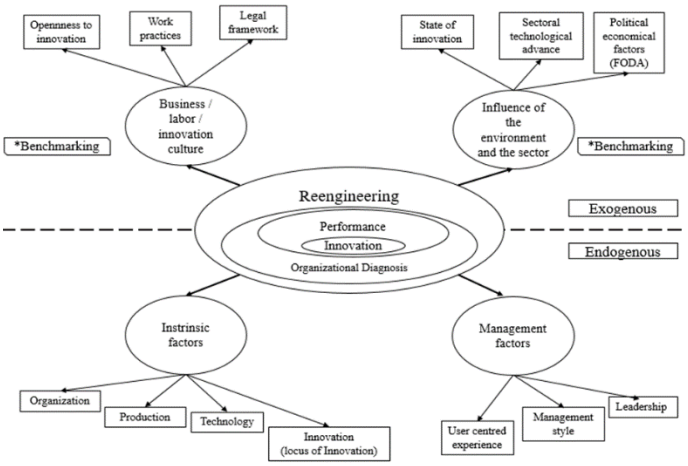

Figure 4.Embedded Methodology for the organizational diagnosis in the bamboo industry. Source: Author's elaboration

Following this design, data gathering and data analysis led us to the following results and discussion.

7. Results and discussion

7.1. Diagnostic Results

To begin with the diagnosis, an evaluation of the environment is required. Environment refers to the set of people, organizations, institutions, objects or elements of any nature, which are outside the company, have some significance for it. For this purpose, the production chain of the enterprise was identified by conducting a focal group interview where suppliers, subcontractors, distribution channels, transport, communication technologies, direct competitors, sector barriers and customers were required.

The mission of the Company is to: Minimize environmental impact and maximize social impact, taking up vernacular construction techniques and enhancing them with innovative technologies.

In general, it is observed that the mission is structured in an appropriate way, although it is to point out that the enterprise should review its geographical scope and develop strategies at local, regional or international levels. As a conclusion, it is clear they are still working in a stage of growth.

The vision of the enterprise is: *To be in 2020 a leading company in the sustainable construction market, through the fusion of vernacular techniques with innovative technological developments.*

The vision and mission were reviewed. In addition, the establishment of strategies and policies was done using a nominal group technique. This session was attended by executives and employees of the Company. The Technique of Nominal Groups allows a working group to reach a consensus on some subject, according to their level of importance and according to priorities established by the group [20].

The vision remained the same; but the mission, was adjusted as follows: *To minimize environmental impacts and maximize social impacts, taking up vernacular construction techniques and enhancing them with innovative technologies, where our employees carry out a specialized monitoring in each of the stages of the cycle life of products.*

After applying the technique of nominal groups the generic strategy for the enterprise was précised as the differentiation since it is desired to:

- Create a product and / or service that is perceived as unique.
- Work in design, brand image, technology, customer service, dealer chain, high quality, etc.
- New product design with high quality materials.
- Intense customer support by providing specialized follow-up at each stage of the product life cycle.

7.2. Balanced Scorecard results

Some specific aspects that were taken into account for the creation of the Integral Chart of the Company contemplating important aspects defined during the Systemic Diagnosis included:

- The alignment of the personal goals of all employees should have with the company's strategy [21]. So employees were asked to write their goals according to the company strategy.
- The value of intangible assets such as knowledge and technology that have a direct impact on income and profits. In this case the investment which is making innovation and technology is of vital importance. Innovation focused companies must offer products and services whose performance exceeds the competitors in which the customer values.

Since the Company is starting with mass production, in the manufacturing aspect, simple indicators such as on-time delivery, customer waiting time, number of reworks, defect rates, cycle times, etc., were presented.

The Balanced Scorecard remained for the company to align the objectives of the employees and directors with the strategy, and to carry out the plan of operation and revision. With this strategy in mind, and the important aspects to consider, the strategic map, the objectives and the initiatives of the Balanced Scorecard, the results and the initiatives developed are in [1] considering the proposal of [4].

7.3. Management style

The Pareto principle establishes a distinction between the aspects that require greater attention and that have greater impact in the organization, discriminating those with less impact. It allows to discriminate the few vital issues of the trivial many. After data gathering with surveys and interviews, a Pareto graphic was formulated showing the most important problems in the management style in Table 1 and Figure 5. This was one of the reasons why the use of Reengineering in the case study is justified because one of the strongest problems they face is organizational and this factor has been shown to have a very strong relationship with reengineering aspects [22].

Table 1. Data for the Pareto Chart, Source: Author's elaboration.

Problems mentioned	Sort Data	Number of Accumulated Defects	% Total	% Accumulated
Organization	10	10	23.80952381	23.80952381
Communication	10	20	23.80952381	47.61904762
Decisions	7	27	16.66666667	64.28571429
Time	6	33	14.28571429	78.57142857
Management of staff	3	36	7.142857143	85.71428571
Planning	2	38	4.761904762	90.47619048
Commitment	2	40	4.761904762	95.23809524
Work environment	2	42	4.761904762	100
	42			

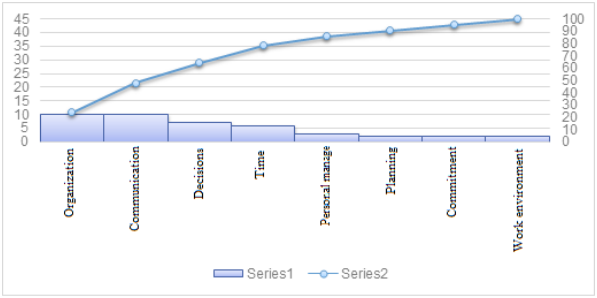

Figure 5. Pareto Chart. Source: Author's elaboration.

Thus, according to the graph of the total of problems detected and confirmed by different techniques, those of greater weight for the correct operation of the company were the organization, the communication and the decision making.

7.4. SWOT Matrix

In addition to the Benchmarking carried out in [1], the SWOT (*strengths*, *weaknesses*, *opportunities*, and *threats)*is a structured

planning method that evaluates those four elements in the organization. It was built with all the elements of the Diagnosis, in this sense 10 employees of the company were asked to vote for the most significant aspects. The results are shown below:

Table 2. SWOT Matrix. Source: Author's elaboration.

Forces	Weaknesses
1. The company is concerned about the environment, which means that it has sustainable products 2. The constant innovation in products. 3. Their products are unique in our country. 4. The architectural projects that have been carried out so far have a harmonious design. 5. The structural and seismic tests performed on constructions with bamboo panels are favorable. 6. Its management for the search of economic funds is good. 7. The presence of the company in associations dedicated to sustainable construction	1. The shared leadership and the different ideas of the owners of the organization. 2. The lack of market certainty for this type of constructions. 3. The lack of customer follow-up. 4. The company do not have defined processes, nor standardize. 5. Its processes of production are handicraft which makes massive production impossible. 6. There is high turnover in staff, which causes them to waste time in training them.
Threats	**Opportunities**
1. Supplier relationships are not narrow, making it difficult to implement some manufacturing systems. 2. The company has no market share. There is not even a market for what is intended to be commercialized. 3. There are companies that are already manufacturing other products with bamboo, especially decorative walls and floors that could venture into the design and construction of houses. 4. Creation of microenterprises with the same turnaround due to unemployment, since the unemployment rate in the country during the second quarter of 2016 was 3.9% of the Economically Active Population and although it is lower than in 2015 with 4.3% , This one is in constant dynamism. 5. The annual inflation rate, which currently stands at 2.88%, and because it is rising, makes it difficult each day to buy its inputs as well as the stability of the prices of its products.	1. The support that many institutions grant to companies that minimize environmental impact (CONACYT and public universities). 2. Currently, until the moment of the investigation, no other company located in Mexico was found on the Internet to do the same. 3. The company has strived to develop sustainable technology and products for the construction of its products. 4. Mexico in many states is suitable for planting bamboo, which could benefit the company by having high quality raw material. 5. The closeness with the United States of America that accepts well the construction with prefabricated wood panels. The possible devaluation of the peso may facilitate exports. 6. Manufacture other bamboo products that are already accepted as decorative walls, partition panels, floors. 7. Carry out a cluster with civil associations and municipal governments that carry out decent housing in marginalized areas. 8, The company is behaving adequately for the business phase in which it is: Growth, dedicating itself to the development and identification of new products and services, expanding facilities and investing in infrastructure 8. Increased demand for housing at the national level, in 2015 was 1 159,480 households and during the current year is estimated to be 1'166,872 households.

This served to evaluate if the strategy of the organization and the objectives set out in the Balanced Scorecard, are correctly defined, in addition to identifying aspects such as management style and influence of the environment.

8. Innovation

The innovation approach followed for the bamboo industry in this study was, the one proposed by Belay-Endalamaw [23], who suggests identifying at first the innovation scope, according to the following typology:

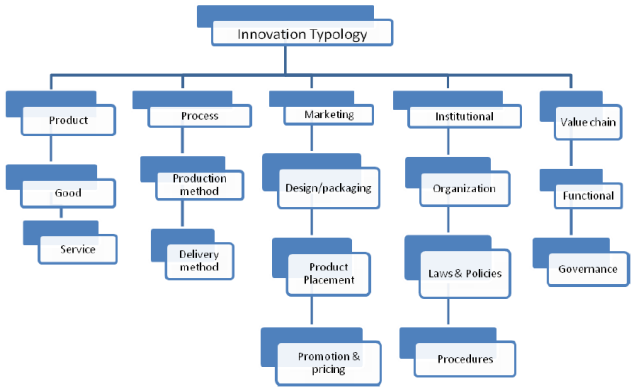

Figure 6. Innovation Typologies [24]

9. Reengineering results

Once the mission, vision, strategy and policies were defined, the organization chart and the job manual were built. Figure 8 shows the organizational chart and in Figure 2, as an example, a position of the manual: project coordinator.

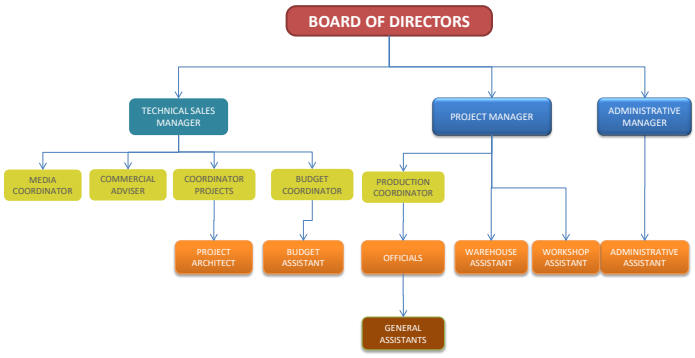

Figure 7. Organization chart of the company. Source: Author's elaboration.

Then, in order to establish the proper features of work positions and to reorganize communication flows and tasks, a manual of positions was developed.

The foregoing supports the development of manual procedures, which serves as a means of communication and coordination between different levels of a company. The procedures manual describes routine work tasks, describing the procedures used within the organization and the logical sequence of each activity, to unify and Control work routines and to avoid their arbitrary alteration. It also helps the supervision of standardization activities, avoiding duplication of functions and unnecessary steps within processes, facilitates the work of the

administrative audit, the evaluation of internal control and its monitoring.

POSITION	PROJECT COORDINATOR	DIRECT BOSS	TECHNICAL SALES MANAGER
AREA	PROJECTS	PERSONNEL IN CHARGE	PROJECT ARCHITECT

SCOPE
Coordinate the design of the projects between architecture and engineering and the operation of the building trades.

Functions and Responsibilities	Profile
1. Coordinate the design of projects 2. Coordinate with the project engineering 3. Deal with customer in design matter 4. Coordinate the building trades	EDUCATION Architect EXPERIENCE In project coordination TRAINING • Office (Word, Excel, Power Point) • Internet and tools • Design programs:Autocad, Sketchup. • Planning Programs: Project ABILITIES: • Agility in media • Capacity for planning and organization • Ability to making decisions • Compromise • Communication • Discipline • Ethics • Order • Proactivity • Responsability

Figure 8. Position of Project coordinator, in the manual of positions. Source: Author's elaboration.

The proper structuring of the manual should reflect the specific activities carried out, as well as the means used to obtain the objectives, while facilitating the execution, monitoring and evaluation of organizational performance. This should be an instrument that supports the process of updating and improvement, by simplifying the procedures that allow the proper and efficient performance of the assigned function. The manual has a general objective, the specific ones by the procedure and the norms of operation. Only the purchasing process is displayed in Figure 9 and Figure 10.

1	Warehouse assistant	Receives a copy of the purchase order	Purchase order CBW01
2		Checks copy of purchase order, identify product and verify matching purchase order, invoice and product	CBW01
4	General Assistant	Unloads and counts the products, entering the quantity on the raw material registration sheet	Raw material registration sheet PBW04
5	Warehouse assistant	Inspects that the raw material meets the required specifications, according to the raw material quality control guide	Raw material quality control guide PBW05
6		Compares the information on the raw material registration sheet with the purchase order information.	Purchase order and raw material registration sheet CBW01, PBW04
7		Do the products and quantities match?	
8		Affirmative. Go to Activity 10	
9		Negative. Return the raw material to the supplier.

So, after showing evidence of the developments and results of embedding the approaches of organizational diagnosis and reengineering, a summary a table with different approaches considering in both methodologies are shown in Table 3.

10. Conclusions

This project was carried out since March 2016 in a medium company dedicated to the development of bamboo structural panels. In the "Diagnosis", something that was observed is the company did not have a strategic plan, so they proceeded to review their vision and mission. Their policies were generated and the strategy was also determined. Another of the deliverables was the "Performance Indicators", but they were not intended to establish solely the relation to the productive process; they were indicators that really aligned the organization with its strategy to lead it to achieve its vision. The Balanced Scorecard gathers indicators from four perspectives: Customer, Employees, Internal Business Process and Finance and developed clear and measurable objectives in each of these items so that the company can achieve its vision through the differentiation of its product and service [1].

In this article an extension was discussed embedding two methodologies: System Diagnosis and Reengineering, considering exogenous and endogenous factors, innovation culture, influence of the environment, management and another intrinsic values like organization and culture. Some results in a bamboo company are shown in order to validate this methodology. The most important is the use of System Diagnosis and Reengineering to achieve innovation as performance indicator to consolidate the company strategic planning.

Some initiatives to achieve the objectives have already been worked out such as employee training in 5's, revision of the

organization chart and job profile, creation of workshops that bring the Company closer to its suppliers, creation of the manual of processes, among others. However some pending includes the development and implementation of the proper facility layout; implementation of the automated assembly machine, among others

Future work should be aimed at validating the proposal of an inner culture of innovation and its evaluation.

Table 3. Summary of Techniques. Source: Author's elaboration.

	Tools/techniques	Description for application
System Diagnosis	Organizational Health Check up	Employees of the company
	Focus group	Main suppliers of the enterprise to determine the competitiveness of an organization and its productive chain.
	Technique of Nominal Groups	Revision of the mission and vision
	Observation guide	Planning, organization, management aspects and control of the enterprise.
	Interview	Data collection techniques
	Survey	Data collection techniques
	Pareto Graphic	Shows the most important problems in the management style.
	SWOT Matrix	Serves to evaluate if the strategy of the organization and the objectives set out in the Balanced Scorecard, are correctly defined,
Reengineering	Balanced Scorecard	It is based on the definition of strategic objectives, indicators and strategic initiatives, establishing relationships by a strategic map in four basic perspectives: financial, clients, internal processes and learning and growth, then the strategy should be translated directly into objectives.
	Manual procedures	Serves for communication and coordination between different levels of a company
	Manual of positions	Define the proper features of work positions and to reorganize communication flows and tasks
	Innovation	The forms of innovation included in this study were product, process and organizational innovation.

ABSTRACT

Electroencephalography (EEG) can globally monitor neural activity in millisecond scale, which is critical for identifying causality of human brain functions and mechanisms. However, to obtain accurate EEG stimulation-response relationship one usually needs to repeat multiple-ten times of stimulation-response recording to average out background signals of other irreverent brain activities, making real-time monitoring difficult to be accomplished. In this study, we explored new approaches which don't require repeats. EEG signals were recorded from subjects doing mind tasks including image formation of motor functions or emotional subjects and mathematical calculations in mind. Time stamps in EEG recording were used to mark task completion time. Signals within 300ms or 1,000ms before task completions were analyzed. Using sLoreta 3-D tracking we found that delta-wave activities were mostly located at frontal lobe or visual cortex, isolated with each other. Theta-wave activity tended to rotate around cortex with low spatial correlation. Beta-wave behaved like inquiry types of oscillations between any two regions across cortex and was consistently correlated with each other over different areas. Alpha-wave activity looked like mixture of theta and beta activities. Together with sliding window dynamic connectivity method we confirmed beta waves play key roles in linking different brain areas together for information inquiry. Theta and low Alpha are more likely playing the role of information control, integration, and image formation. With the proposed new method we demonstrated reproducible linkages of subject behaviors with 3-D tracing characteristics along the 3 categories: emotion, math calculation, and motor functions without using event repeats.

1. Introduction

This paper is a full version of 2016 *IEEE Signal Processing in Medicine and Biology Symposium* (Wudenhe, Meng and Choa 2016) conference abstract. Electroencephalography (EEG) is one of the most important neural imaging modalities used for monitoring brain activities [1]. Its ability to achieve millisecond scale time resolution is critical for obtaining causal relationship. However, due to the dynamic nature of brain electrical activity, the same stimuli may generate different responses under different psychological setting. Interpreting EEG signals, extracting EEG biomarkers and correlating them to behaviors have always been challenging since the technique was discovered. Event related potential (ERP) technique has been one of the successful methods that is used to obtain reproducible brain responses to stimuli. However, ERP signals are intrinsically weak and are typically buried under signals produced by other brain activities. To extract ERP signal, one needs to average over many repeats to distinguish it from noises and background signals produced by other brain activities [2]. Furthermore, brain states are high dimensional and complex. Multiple origins or sources can recruit neural activities from different paths and influence the same behavior outcome. That puts serious restrictions on ERP experiment designs and applications for studying event based brain dynamics and causal relationship. So, even though ERP is a useful tool, its ability to study brain dynamics and applications coverage are limited. To eliminate the need of experimental repeats, in this work, we

*Corresponding Author Name: Qinglei Meng, Department of Computer Science and Electrical Engineering, University of Maryland, Baltimore County, Baltimore, MD, 21250, USA. Email: meng2@umbc.edu. Tel: 410-455-6553.

developed EEG 3-D signal tracking methods to monitor brain dynamics without event repeat. We also verify obtained results with EEG based functional connectivity and statistical studies as described in detail in the following.

Earlier studies have shown that EEG signals may play important roles in controlling and initiating brain functions and activities [3, 4]. For example, attention usually requires a high beta wave to synchronize brain oscillators at different locations and alpha wave is used to decouple or disengage attention [4]. Furthermore, brain reticular formation area in the brainstem has been considered where consciousness and attention control initiated [5]. Considering if these descriptions are all correct, we shall likely observe some EEG signals initiated from the brain stem region when monitoring 3-D EEG signal traces.

To investigate brain activities in deep brain region, the sources of EEG signals need to be localized by solving inverse problems. Various techniques have been proposed, such as Low-Resolution Electromagnetic Tomography (LORETA) [6], Variable Resolution Electromagnetic Tomography (VARETA) [7], Brain Electrical Source Analysis (BESA) [8], to establish procedures for source localization. However, most of these programs cannot guarantee unique solution and are not able to accurately localize the EEG sources. One exception is the standardized LORETA (sLORETA) method, which improves the source localization accuracy by reducing spatial resolution. Pascaual-Marqui reviewed different methods of EEG localization [9], in which compared multiple mathematical models and concluded that extending the good localization properties of 2D minimum norm solution to 3D solution spaces with LORETA was the greatest challenge in the development of EEG source localization but was achieved with LORETA. With the help of LORETA, Herrmann and his colleagues investigated error processing of 39 subjects engaging the Eriksen flanker task and found significantly higher brain electrical activity in medical prefrontal areas for incorrect responses and both positive and negative error related components represented different aspects of error processing [10]. An earlier study from Mientus aimed to address whether LORETA was able to detect hypofrontality in schizophrenic patients by recording resting status EEG signals from patients and normal subjects [11]. For comparison, subjects with schizotypal personality and depressive patients were also investigated. Significant increase of delta wave activity was detected in the patients over the entire cortex, while both schizotypal subjects and depressive patients showed much less delta, theta and beta activities in the anterior cingulum. Their conclusions obtained from LORETA analysis are largely consistent with findings from related literatures. Saletu's group reported application of LORETA in diagnosis and pharmacotherapy of depression [12], in which LORETA identifies cerebral generators responsible for the pathogenesis of depression and for the mode of action of antidepressants. LORETA was also used to verify the hypothesis that the highest temporal correlations between 3D EEG current source densities corresponds to anatomical Modules of high synaptic connectivity [13]. These researchers demonstrated that EEG temporal correlations between different brain areas were related to synaptic density as measured by diffusion spectral imaging.

In this study, we apply sLORETA techniques to obtain 3D EEG map, trace them in time and associate these traces with their corresponding behaviors. Since many of these vector traces are long jumps across over large brain regions in a very short period of time, the method provides a big picture about brain dynamics with the understanding that sLORETA has its limitation on spatial-resolution. The proposed method is a much simpler approach to monitor brain dynamics and function mechanism in the sense that no complex experimental arrangement for event repeats are required. It opens the door for real-time monitoring of brain natural responses under any desired psychological setting without worrying about sensory gating effects and how to experimentally set up event-repeats [14].

To verify our conclusions from the monitoring results we have also implemented EEG based sliding-window functional connectivity analysis. We use the technique to obtain correlation statistics and its implications are consistent with 3-D tracing monitoring results.

Correlation between two brain regions is studied by segmenting EEG data followed by calculating correlation coefficients between two electrode channels. Such schemes basically involve breaking down the EEG data into segments followed by extracting features (such as correlation in this case) that are henceforth used to find patterns in the EEG activity [15, 16, 17]. The segmentation approach (as described further in the methods section) has recently adopted by function magnetic resonance imaging (fMRI) researchers to analyze brain dynamics in terms of functional connectivity when subjects are performing tasks [18, 19]. To the best of our knowledge, the combined segmentation and sliding window analysis has not been done with EEG analysis. We describe the implementation methods and experiment details in section 2, report their results in section 3, and finally conclude our studies in section 4.

2. Methods and Experiments

In this section we first describe our experiment design and arrangement and then the methods used to analyze the recorded data with sLORETA and sliding window techniques.

2.1. Experimental setup and design

A 16-channel EEG system was used in this study for EEG signal recording. Figure 1 illustrates the channel locations on cortex map and A1 and A2 are the reference channels on the left and right side brain, respectively. Six subjects participated this study (4 males and 2 females, all aged between 18 and 30). We designed experiments to obtain EEG recordings when subjects were under the following tasks. Subjects were asked (a). to visualize images of some parts of their body, for example, the left and right hands and feet, nose, lips, etc; (b). to form images in their mind of faces of people they love most or they hate most; (c). to perform simple mathematical calculations in their mind (like 15 multiplies 18 or 23 plus 38). When images or calculation results were formed in their mind, they time-marked the moment by finger touching a static electrode at hand which provided an electrical pulse to the EEG recording as a time marker as shown in the bottom tract in Figure 2.

Through the mirror neuron system in human brain, the tasks we selected can activate 3 categories of brain activities: emotion,

math calculation, and motor function without generating EEG artifacts like motor evoked potential (MEP) signals, ...etc. [20]-[23].

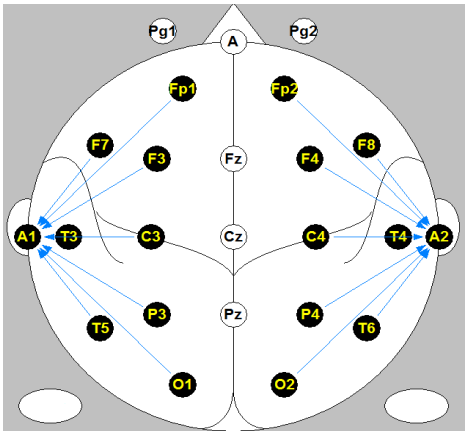

Figure: 1 16-channel EEG cortex and channel locations map

Raw EEG data was recorded by KT88, and then exported as BioSemi format for Matlab with EEGlab toolbox data processing followed by converting data into text files for sLORETA brain activity maps plotting [6]. Since the EEG system had a sampling rate of 100Hz, brain activity maps were recorded every 10ms.

2.2. Brain activity tracking by sLORETA

We processed EEG signals 300ms before the time marker since it takes that much time for human brain to process information and realize task accomplished or decision made. [24]. For example, to track dynamic trace of Delta activities during the 300ms, the filter in sLORETA was firstly set to 0-4Hz low-pass filter to extract delta waves. Then in the real-time EEG signal display in sLORETA, as shown in Figure 3, the cursor was located at the time point 300ms before the time marker (the starting point of the pulse generated in original EEG recording, for which the time was readable from KT88 EEG signals display). From this time point on, one Delta wave activity map was generated for every 10ms until the cursor reached the time marker itself. So during the analyzed 300ms, there was a series of 31 Delta wave activity maps. The same method was applied on Theta, Alpha and Beta waves by setting the filter in sLORETA to 4-8Hz, 8-13Hz and 13-30Hz, respectively.

For each sLORETA brain wave activity map, a corresponding focus point with the strongest brain activity was found (sLORETA provides this function). These focus points were connected and plotted in Matlab at a 10ms increments over the 300ms measured timespan recorded, and viewed considering both the X axis, showing left and right sides of the brain, Y axis, representing the front and back of the brain, and the Z axis representing the top and bottom of the brain. Axis distance range being set to -100 to 100 mm.

2.3. Sliding window analysis

We also analyzed functional connectivity between brain nodes (i.e. 16 EEG channels) during the above described mind imagination tasks by using the sliding window approach [18,19] for delta, theta, alpha and beta wave activity followed by standard deviation analysis as described below.

a. First, EEG data of 1000ms before the marker onset indicating task completion was extracted. This data was filtered for delta, theta, alpha and beta wave followed by processing with ICA to identify components. (We take 1000ms data because the sliding window approach requires larger sample size for computing meaningful results).

b. Then, data points within a time window of first 100ms for one of the wave activity were taken to calculate correlation among all pairs of electrodes for that one window. Next, the window was then shifted in time by 10ms of data points that overlaps between the successive windows. This resulted in 120 correlation values for each of the 91 windows as shown in Figure 4. Here, correlation between two electrodes is given by:

$$\frac{\sum_i (x_i(y_i - \overline{y}) - \overline{x}(y_i - \overline{y}))}{\sqrt{(\sum_i (x_i - \overline{x})^2)(\sum_i (y_i - \overline{y})^2)}}$$

where,

x_i = a time series data point from 1st electrode
y_i = a time series data point from 2nd electrode
$\overline{x}$ = mean of 1st electrode's time series data
$\overline{y}$ = mean of 2nd electrode's time series data
i = 10, 20, 30, … ,100ms

c. Finally, we then computed standard deviation (σ) of these correlation values over the 91 windows for each pair of channels to analyze the fluctuation in their connectivity. Here, if Ais a matrix that contains correlation values over the 91 windows then the standard deviation is defined as:

$$S = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N} |A_i - \mu|^2}$$

where,

μ is the mean of A and i = 1,2,3,…,(N = 91)

The above is done for all 120 pairs of correlated electrodes. Then, the maximum out of the 120 standard deviation values was extracted for narrowing down the analysis to most erratically correlated nodes. This was done for each wave and averaged over all experiment-tasks for that wave as plotted in Figure 5.

The above computation and analysis helps in quantification of the time-varying behavior in terms of functional connectivity and brain dynamics. From the best of our knowledge, the sliding window approach has recently adopted for fRMI data analysis to describe brain dynamics in slower scale compared with EEG signal analysis [18, 19]. Here we applied sliding-window techniques to EEG data analysis and extended the technique with maximum standard deviation analysis to help interpret EEG data. The standard deviation values indicate the degree of fluctuation that exists in the functional connectivity i.e. the correlation values. We compare the selected maximum standard deviation of all waves (Figure 5) as this enables us to test and see the correlation-consistency for each wave among their most fluctuated nodes that are erratically in and out of phase with each other. This is further discussed and analyzed in the results and discussion section.

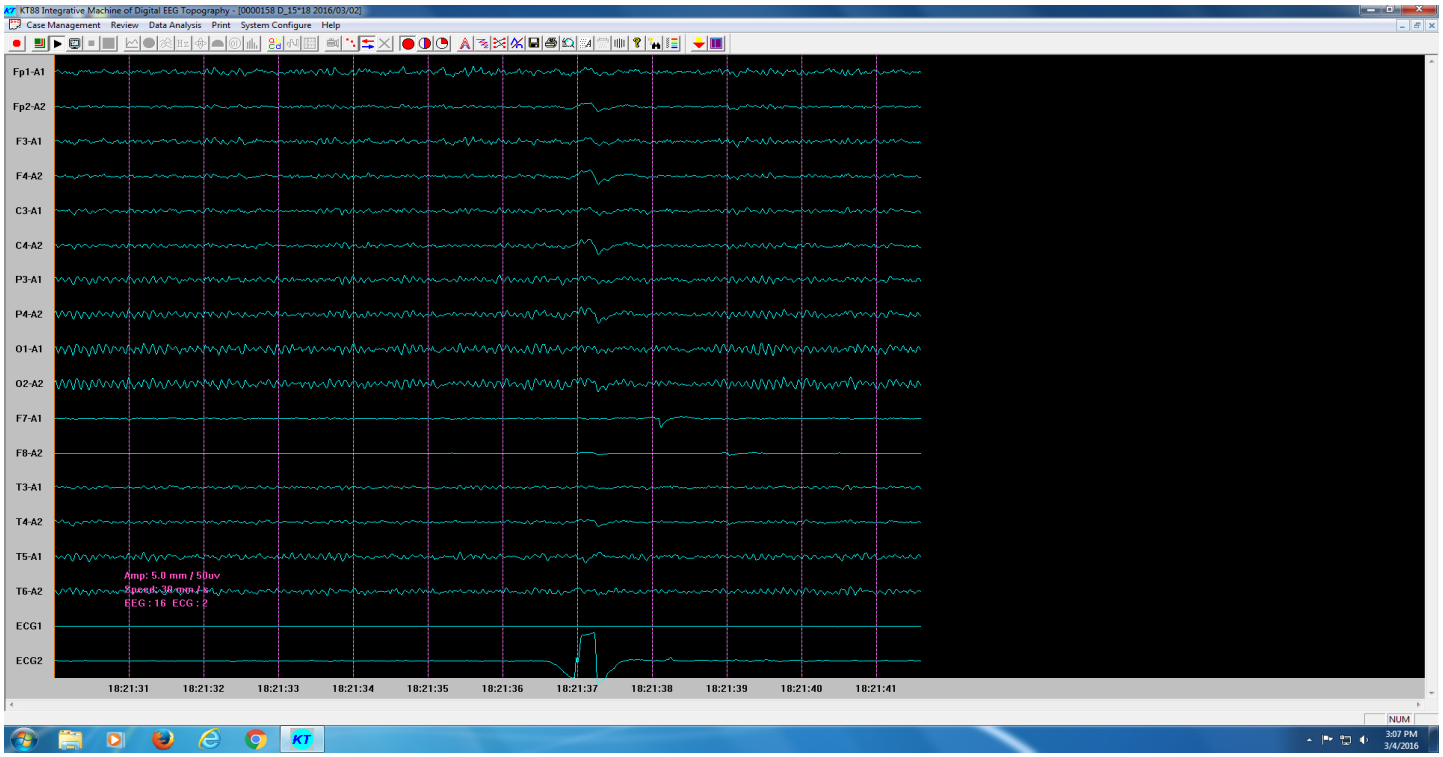

Figure 2: Example of real-time EEG signal on KT88 (The last channel was added to the EEG system as a time marker, once subjects touched the metal clip, a electrical pulse would be generated to mark the time point when images were formed in their mind.)

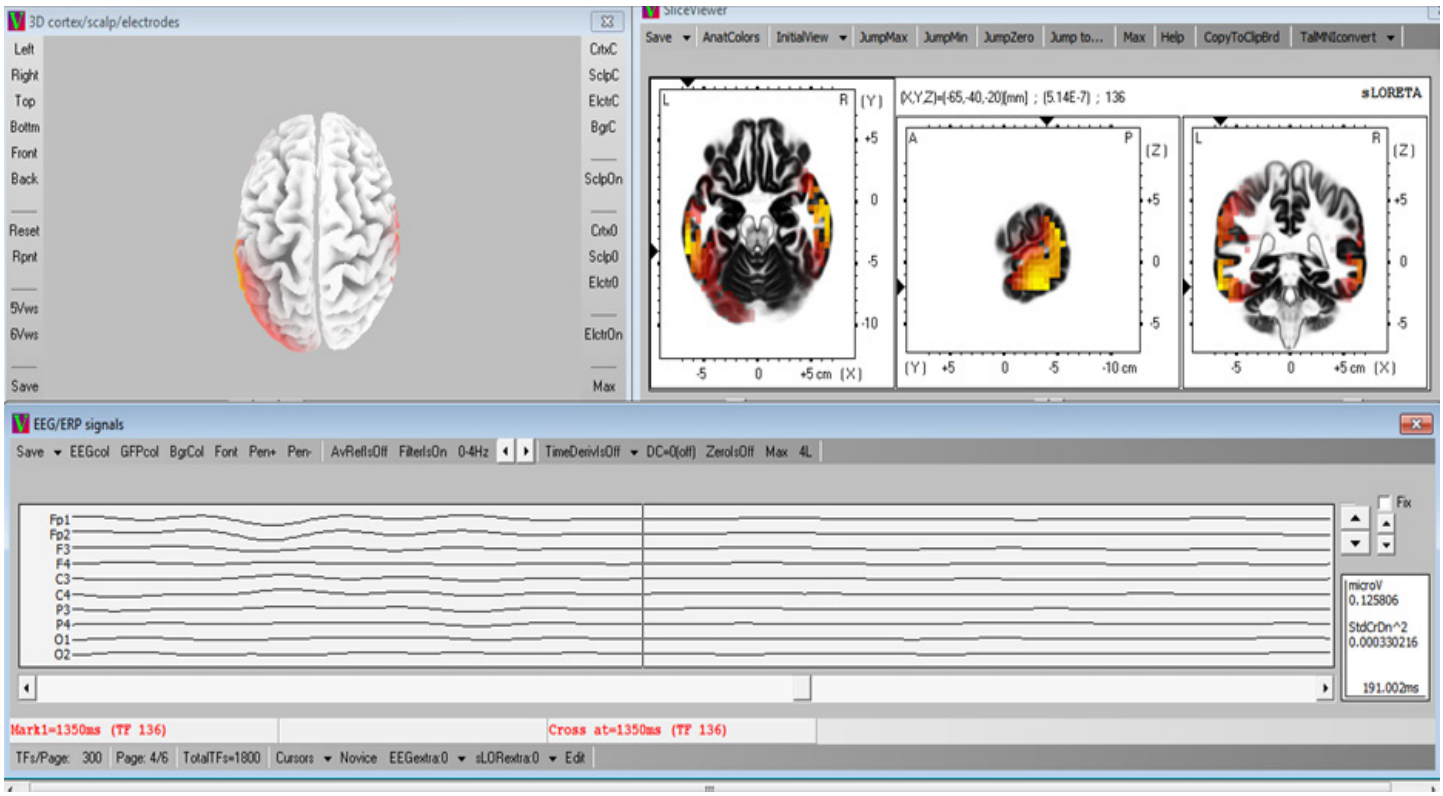

Figure 3: An example of sLORETA brain activity map (The waves under the 2D and 3D maps are EEG signal on time domain. A 0-4Hz low-pass filter was applied to analyze Delta rhythm. The maps are presenting Delta rhythm activities on the time point, where the cursor is located on the time domain signal. The 3D cortex map on the left-top corner can be rotated for different perspectives, and the 3 2D maps are the cross section views of xy, yz and zx planes in a 3D Cartesian coordinate system. They vary according to the positions of cuts, which are shown as the arrows along the x, y and z axis. By relocating these arrows, the brain activity inside the brain can be observed. Red regions represent relatively strong activities and yellow regions represent very strong activities.)

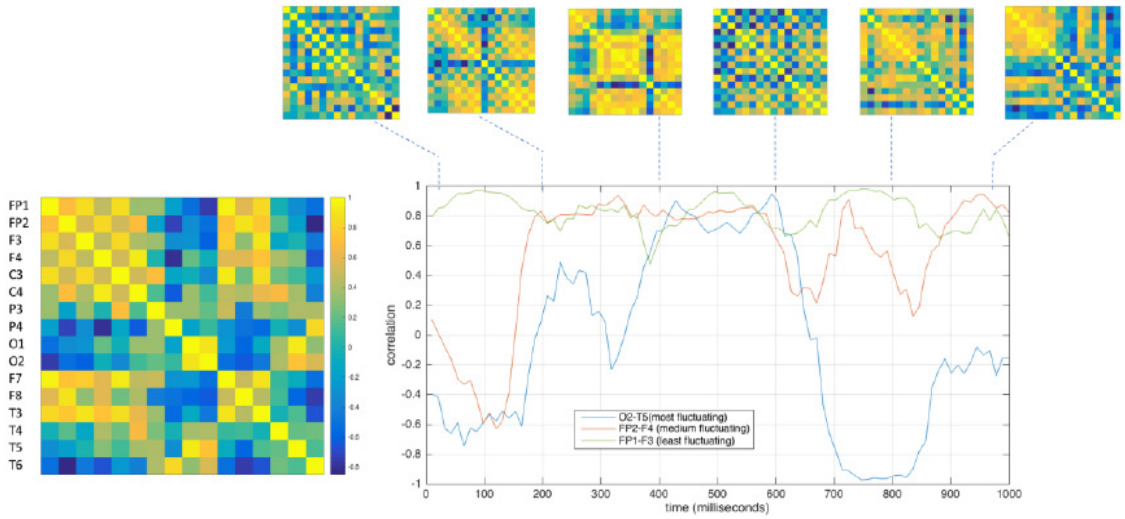

Figure 4: (left) Functional connectivity as correlation matrix between EEG channels from window of 100ms of EEG data. (right) Functional connectivity time series for connections between selected pairs of EEG channels based on maximum (O2-T5 pair in blue), medium (FP2-F4 pair in red) and least (FP1-F3 in green) deviation in their correlation values.

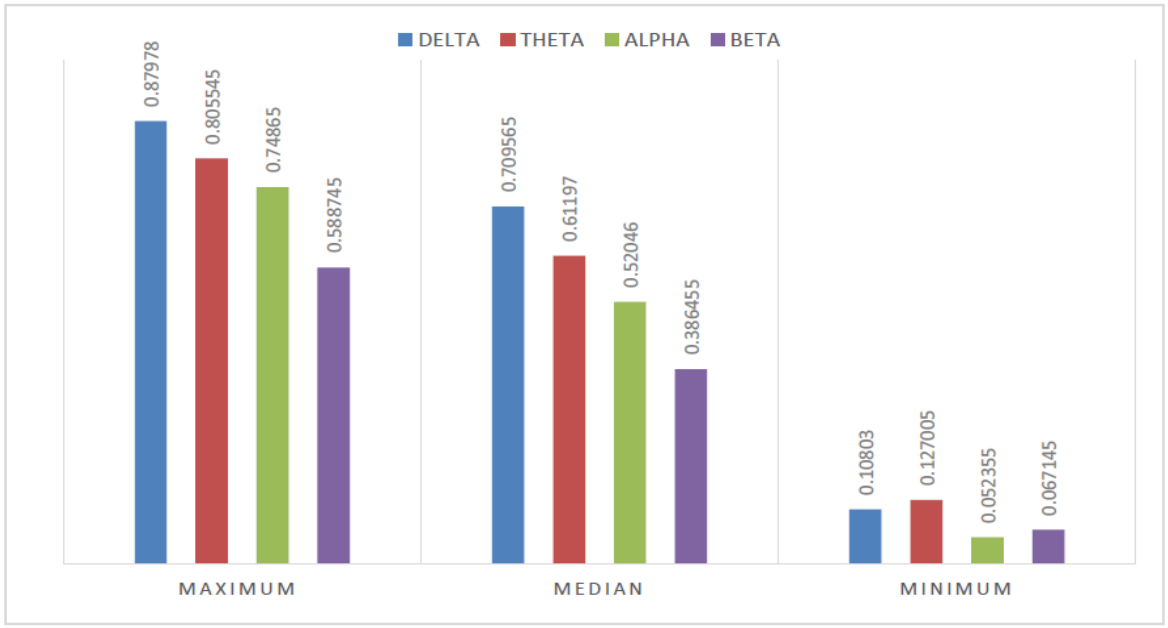

Figure 5: Mean standard deviation (σ) of correlation values that is obtained by the sliding window approach while the subject is performing imagination tasks. This is clustered as most (maximum σ), medium (median σ) and least (minimum σ) fluctuation in phase of the pair of EEG time series channels for each wave rhythm. Overall, correlation of EEG channels is the least fluctuating for Alpha and Beta wave in majority of the cases.

3. Results and Discussion

From cortex maps plotted by sLORETA we found that the Delta oscillations are not only the slowest in frequency, but also slowest in the shift or movement of activated regions within the 300ms before subjects realized image formations in their mind. For most of the time in the 300ms, Delta activities tend to arise at either frontal lobe or visual cortex. A sudden shift of activation between these regions would occur for most cases, and a duration of about 150ms to 180ms was observed between two shifts in the analyzed period. A group of plots in Figure 6 presents such Delta wave activities. We also found that the maximum and medium standard deviation of correlation (deduced from sliding window approach as described in the methods section) was highest for the delta wave. This indicates that the brain regions are not consistently correlated and less interactive with each other for the delta wave activity (Figure 5).

Cortex maps plotted by sLORETA also indicate that the Beta oscillation activities show up at frontal and visual cortex as well for most of the sampled time points, but the spatial shifts can be detected every 10ms as shown in Figure 7, which is much faster than that of the Delta oscillation. This is to say for one certain activity map in the 300ms sampled time series, the excited region is different from both 10ms before or after itself for Beta wave. Since the sampling rate of the EEG system is 100Hz, the Beta activity spatial shifts present a frequency of at least 50Hz,

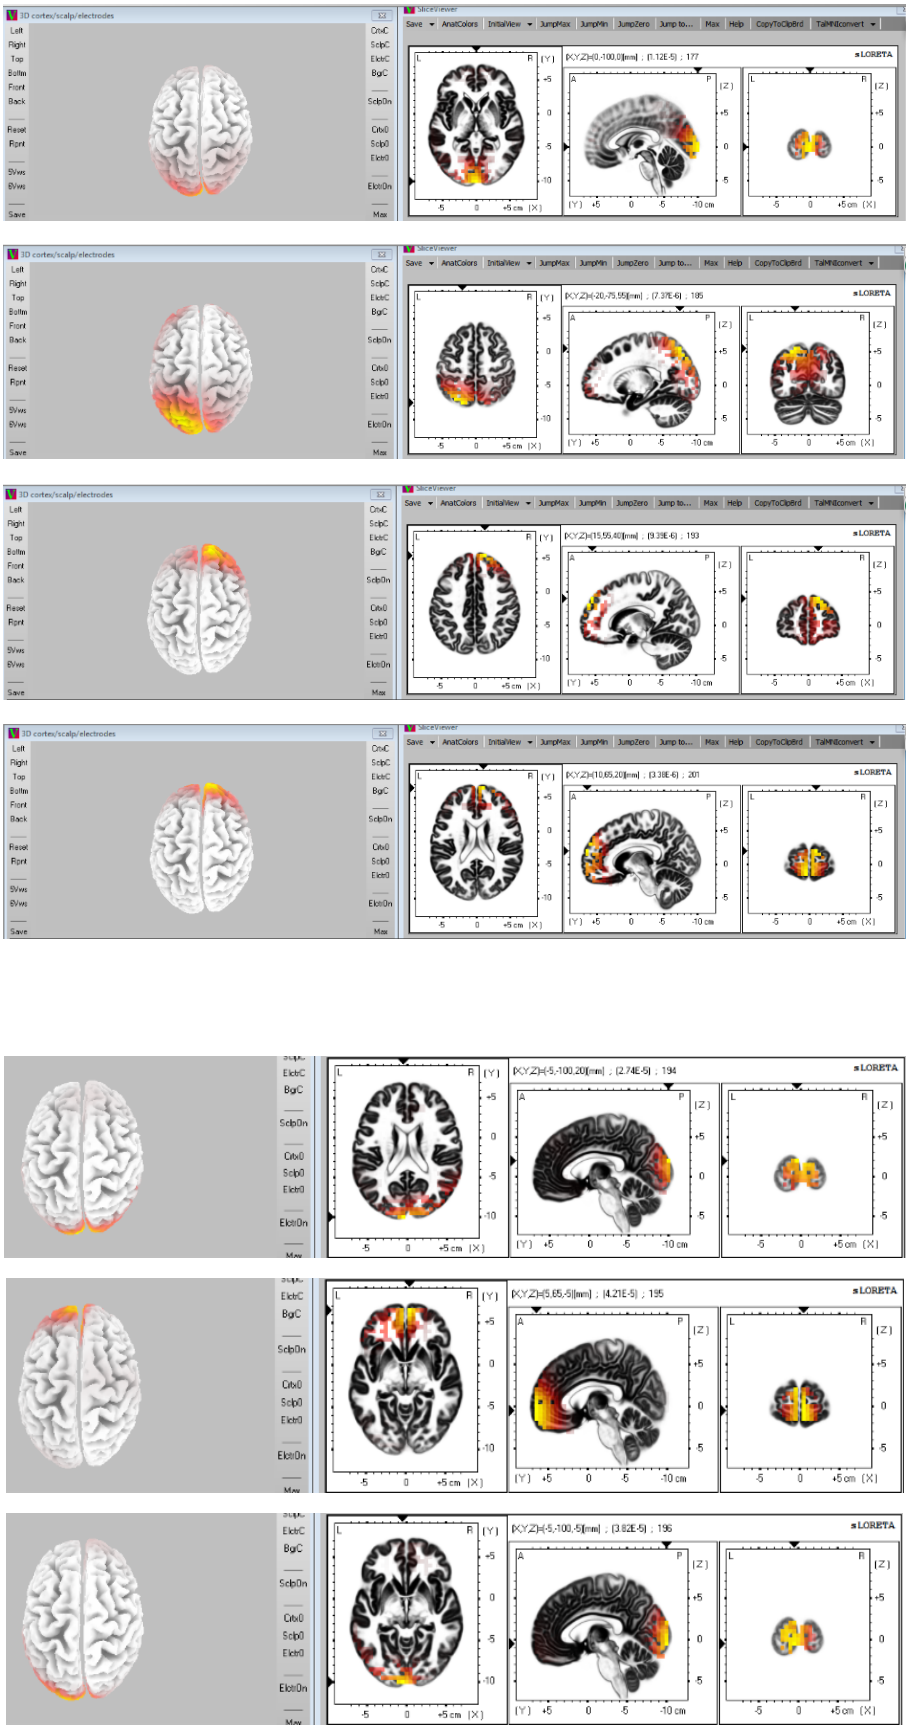

Figure 7: Performance of Beta rhythm activities (From upside to down side, the plots present Beta rhythm activities 80ms, 70ms, 60ms and 50ms before the subject realized the image formation.)

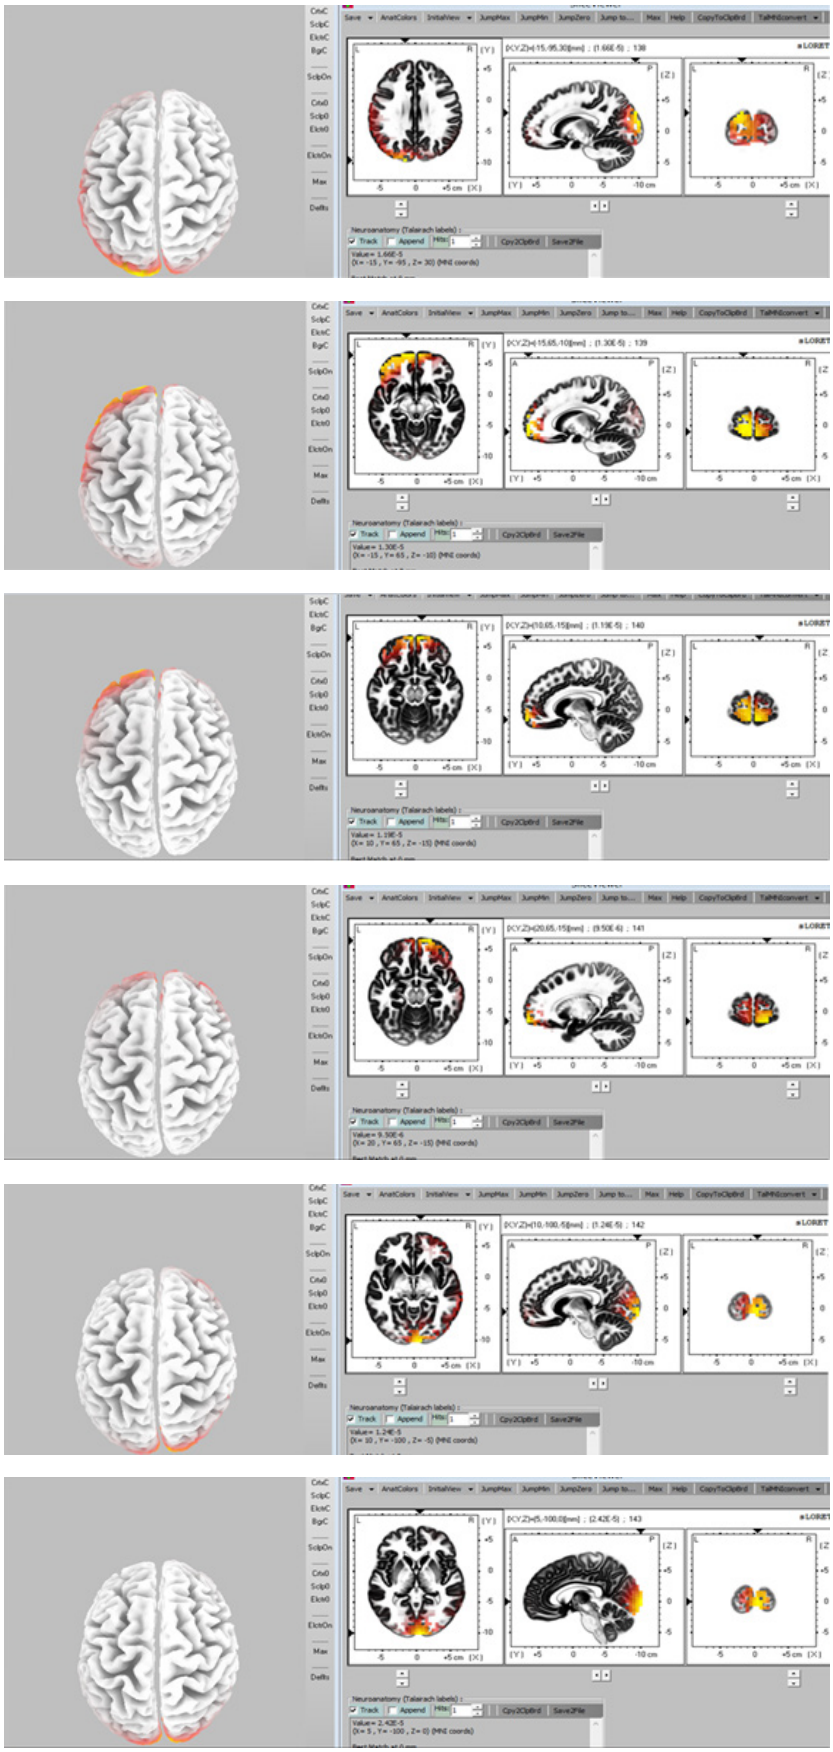
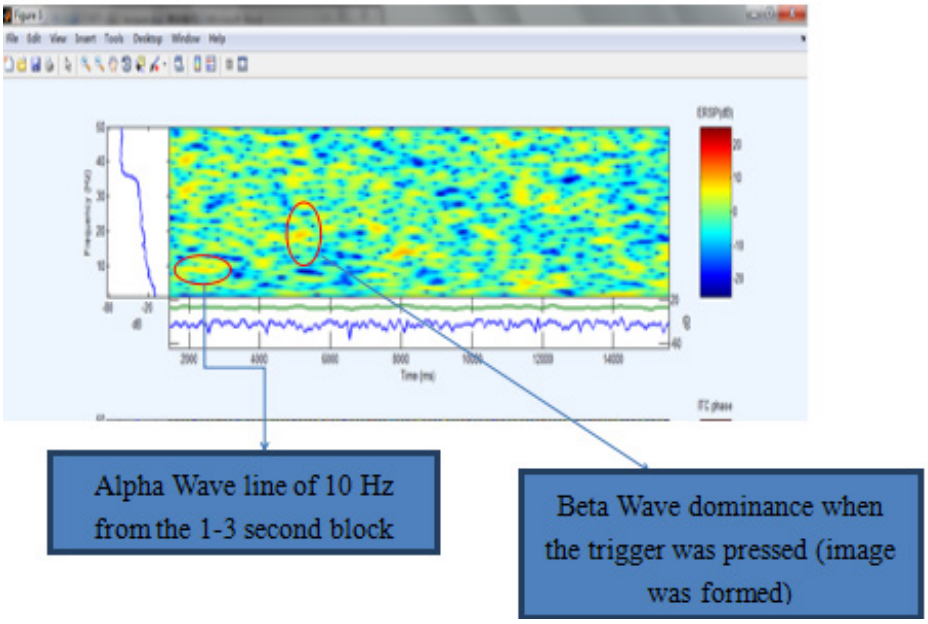
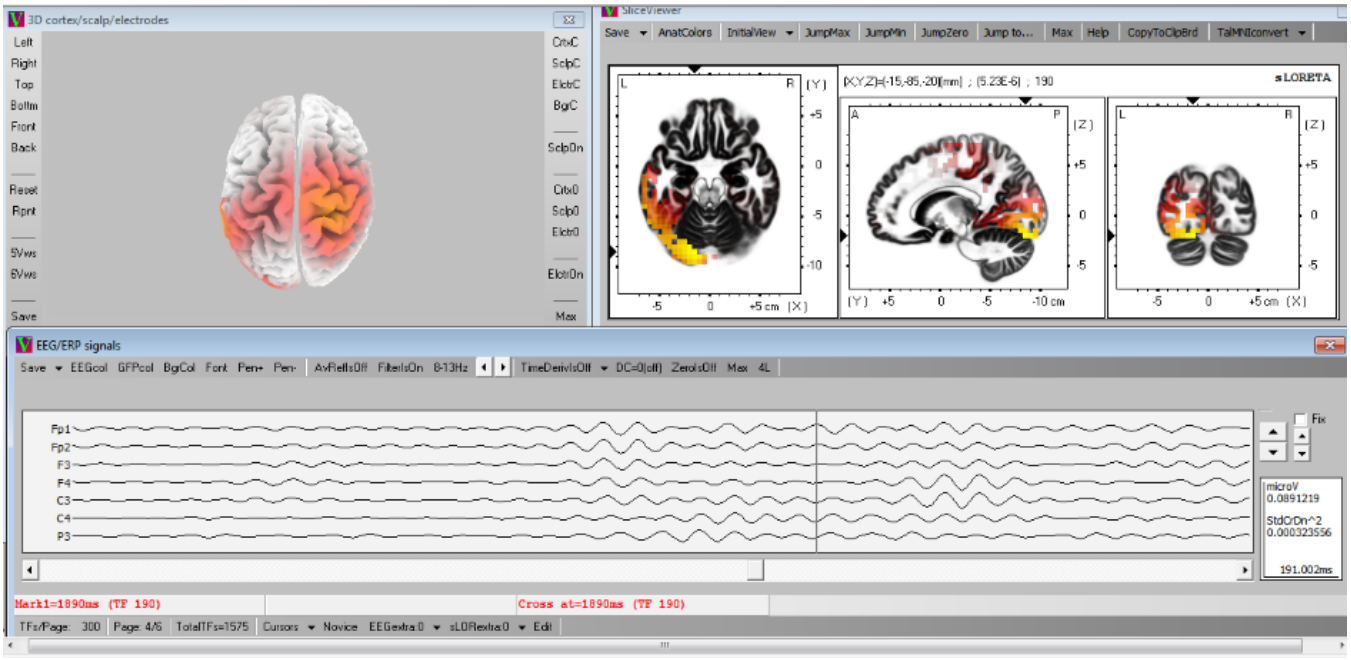




(a)



(b)

which also indicates that the Beta activity's spatial shift's speed is at least 15 to 18 times faster than that of Delta oscillations. This signifies that the activated brain regions during Beta oscillations are relatively higher in interactivity with each other than that of Delta oscillations. The spatial shift of Beta and Delta oscillations observed from these sLORETA plots show back-and-forth tracking arrows between frontal lobe and visual cortex, which can also be regarded as certain communication between these two brain regions, more frequently for beta wave than that for delta wave activity. This gets further asserted by our standard deviation analysis of functional connectivity computed via sliding window approach as the maximum and medium (median) standard deviation is the lowest for beta wave activity among all other waves (Figure 5). Hence, mostly Beta wave activity related neuron oscillations are correlated in the most consistent manner than the other waves. This strongly suggests that beta wave activity is involved with locking neurons together thereby playing a critical utility role for information query.

between its activated brain regions whereas Beta wave activity, with least deviation, represents most consistently correlated activity. Considering the fact that all subjects were asked to generate various kinds of images in their mind, we can draw a conclusion that prefrontal lobe participate in the processing of image formation with visual cortex under both low frequencies (Delta oscillations, 0-4Hz) and Beta oscillations (13-30Hz) as seen from our sLORETA plots.

Cortex maps plotted by sLORETA indicate that Theta oscillations do not show a retention at the frontal lobe within the 300ms before the subjects generate images in their mind. However, a detectable annular movement trace can be observed, as displayed in Figure 8, which is transmitting along the edge of the cortex map from its top view. Considering the sampling rate, this trace with Theta wave was continuous during the processing of image formation unlike the sudden shifts of activated regions as seen with the Delta and Beta oscillations. This circulating movement of activated Theta rhythm's regions would be either clockwise or counter clockwise. The cycle of annular movement varies for different subjects, as well as for different tasks of image formation for the same subject. For most datasets that we recorded from the six subjects, these cycles were between 60ms and 150ms long in duration.

Since all subjects were completing the tasks with their eyes closed while EEG signals were being recorded, Alpha waves dominated and presented a relatively higher intensity than other waves for most of the time, which can be finalized from the time-frequency plots of EEG signal on O1 channel (left side occipital region) in Figure 9(a). For some EEG datasets, the image formation in subjects' mind also excites Mu waves, which share the same frequency range of Alpha rhythm, but are detected from the motor cortex, rather than occipital region. Figure 9(b) is an example of Mu waves on motor cortex. We believe that this domination of alpha wave and mu wave is also the reason why we see its correlation is overall consistent and not highly erratic (Figure 5). Due to the activity of Alpha waves and Mu waves, the mirror neural system must be suppressed by the corresponding executive network. A global view of Alpha rhythm activity during the analyzed 300ms presents an anomalous movement trace. However, compared with Theta and Beta rhythm, the performance characteristics of Alpha rhythm activity regions mostly falls in between them, which means that for some cases, an obvious annular movement trace along the cortex edge from a top view is observed; for the other cases, oscillations of brain activity under Alpha rhythm between frontal lobe and visual cortex are present; or even both phenomenon are detected in the same dataset at different time period.

On an overall level, we observe from connectivity analysis (Figure 5) that channel-pairs with consistent correlation, i.e. less varied correlation or minimum standard deviation in correlation, tend to remain least varied for the entire task for Alpha followed by Beta, Delta and then Theta oscillations. Whereas, for pairs of channels that are highly erratic in phase with each other, i.e. with maximum or medium standard deviation in correlation, tend to be least varied for Beta followed by Alpha, Theta and then Delta oscillations. The precise nature behind this pattern observation remains elusive. It was not clear why Alpha oscillation's pair of nodes remain least varied for minimum standard deviation and not for maximum and median standard deviation group. Here, we quantified task-evoked correlation's variation for each wave and we see that overall, Alpha and Beta oscillations tend to be at the lower end of variation for correlated pairs. We believe this could be for the following reason. Alpha wave is dominating as subject's eyes were closed as seen from frequency plots in Figure 9(b) also and Beta wave appears to be involved with locking neurons and information query as described earlier in Figure 7.

Individual studies of Delta, Theta, Alpha and Beta oscillations during the 300ms period before subjects realized image formation in their mind demonstrate totally different performance of these rhythms. This also indicates that the rhythms provide different functions for the processing of self-contemplating image formation with its corresponding executive network. Self-contemplating image formation involves multiple brain regions' activation, and these activations of brain is dynamic during the period from the formation in the mind to the time when subjects realize this image formation. The higher frequency the rhythm has, the higher the speed of spatial shifts, i.e. movement of activated brain regions, was observed.

Finally, for each EEG dataset, we generated 30 time progressive plots representing the 300ms time to trace the highest brain wave intensity positions. Figures 10 to 12 show accumulated traces of the 30 points in sequence. In Figure 10, the activity of forming an image of someone they love, which produced heavy activity towards the front cortex of the brain and some activity in the visual cortex. This persisted in multiple subjects with the Alpha brain wave. Alpha wave displayed both characteristics of wrapping around the brain, clockwise or counter clockwise motion and persisting activity in visual cortex and frontal lobe. With Figure 11, the subject is completing a simple mathematical calculation. Note that Beta wave moves at a much faster pace, seeing as it is at 13 – 30Hz. Beta displays characteristics of rapid movement between the frontal lobe and the visual cortex. The activity of a mathematical cognition does show a higher concentration in the frontal lobe. And we see a much more even distribution between the left and right brain with Beta wave, however, Alpha becomes more likely to favor the left or right side of the brain. Figure 12 displays a subject's performance while thinking about some part of their body. The Theta wave, instead of confining towards a specific region of the brain, seems to have a wraparound pattern, either clockwise or counterclockwise. Other subjects also show a favoritism of the right side of the brain. Delta wave moved at a much slower pace, as we had anticipated since it is defined between 0 – 4Hz, concentrating a majority of its time by moving between the frontal lobe, further towards the positive Y axis, and the visual cortex, further back towards the negative Y axis. However, it travels at around 45 degree angle to the X and Y axis. The above described brainwave activity characteristics reproducibly happened to every subject under test.

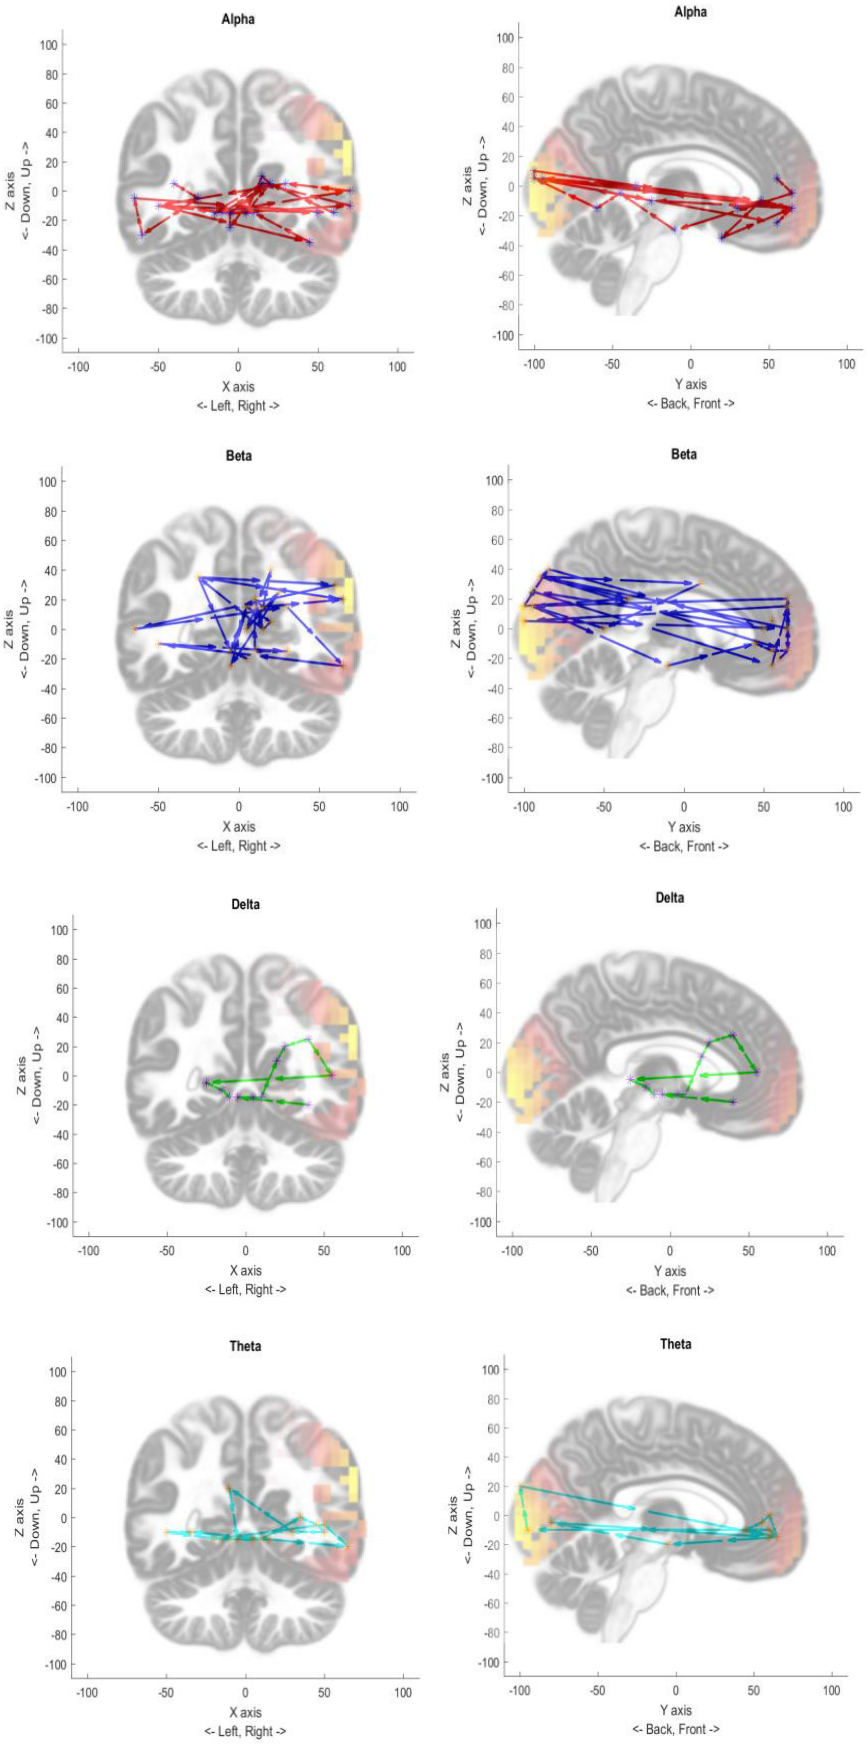


Figure 10: Performance of Alpha, Beta, Delta, and Theta wave across the brain while subject thought about the faces of the people that they loved.

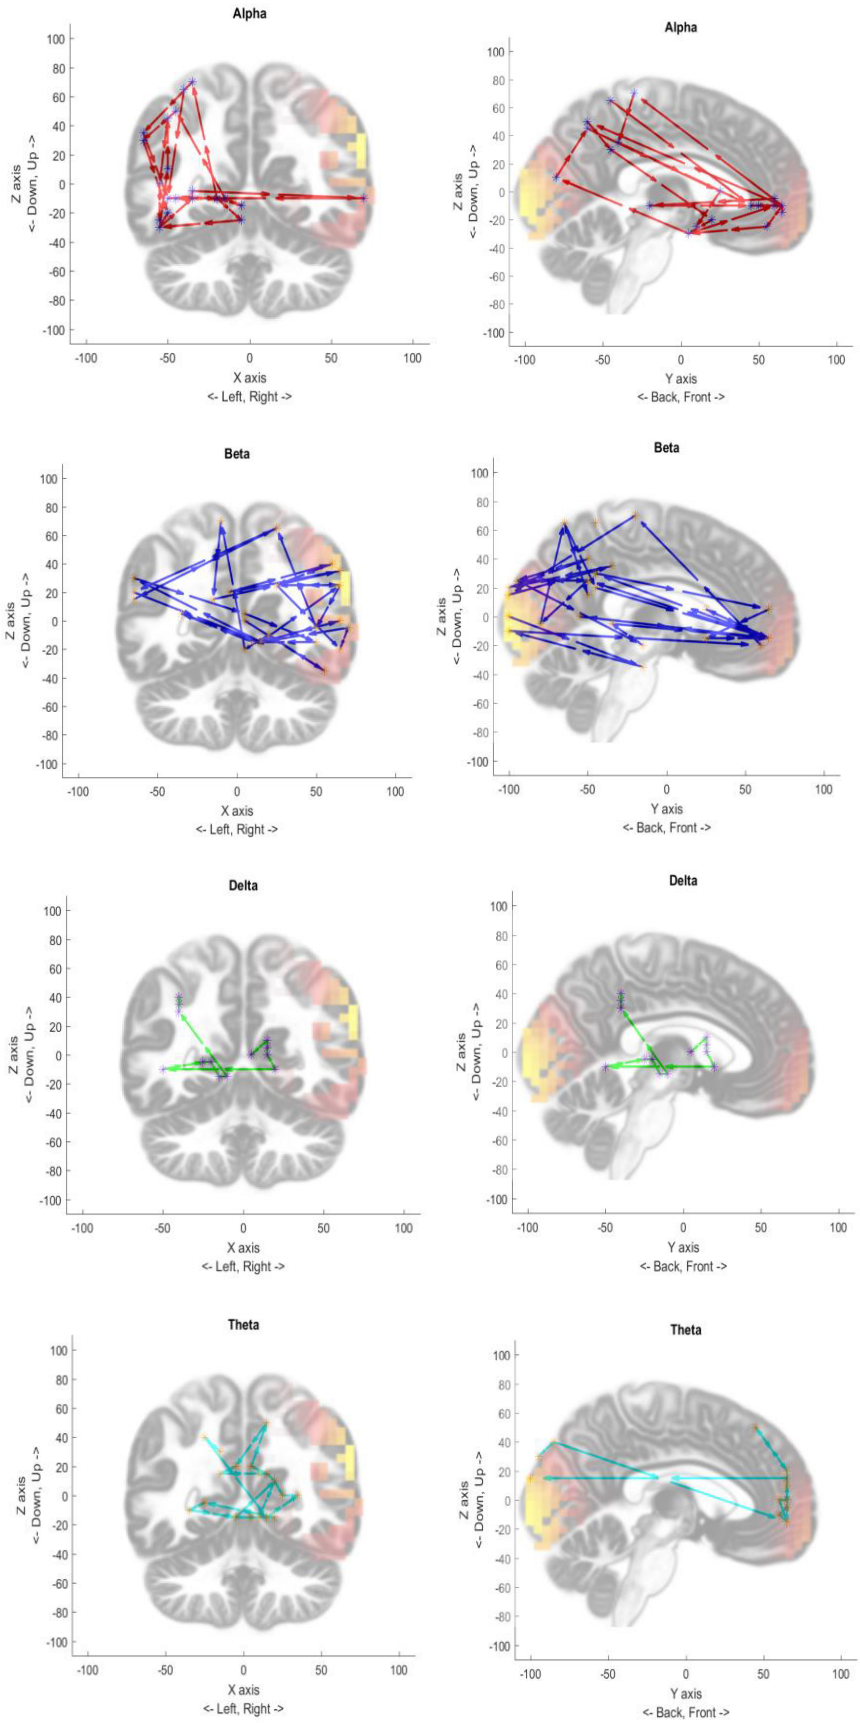

Figure 11: Performance of Alpha, Beta, Delta, and Theta wave across the brain finish some simple mathematical calculation, in this case 15*18.

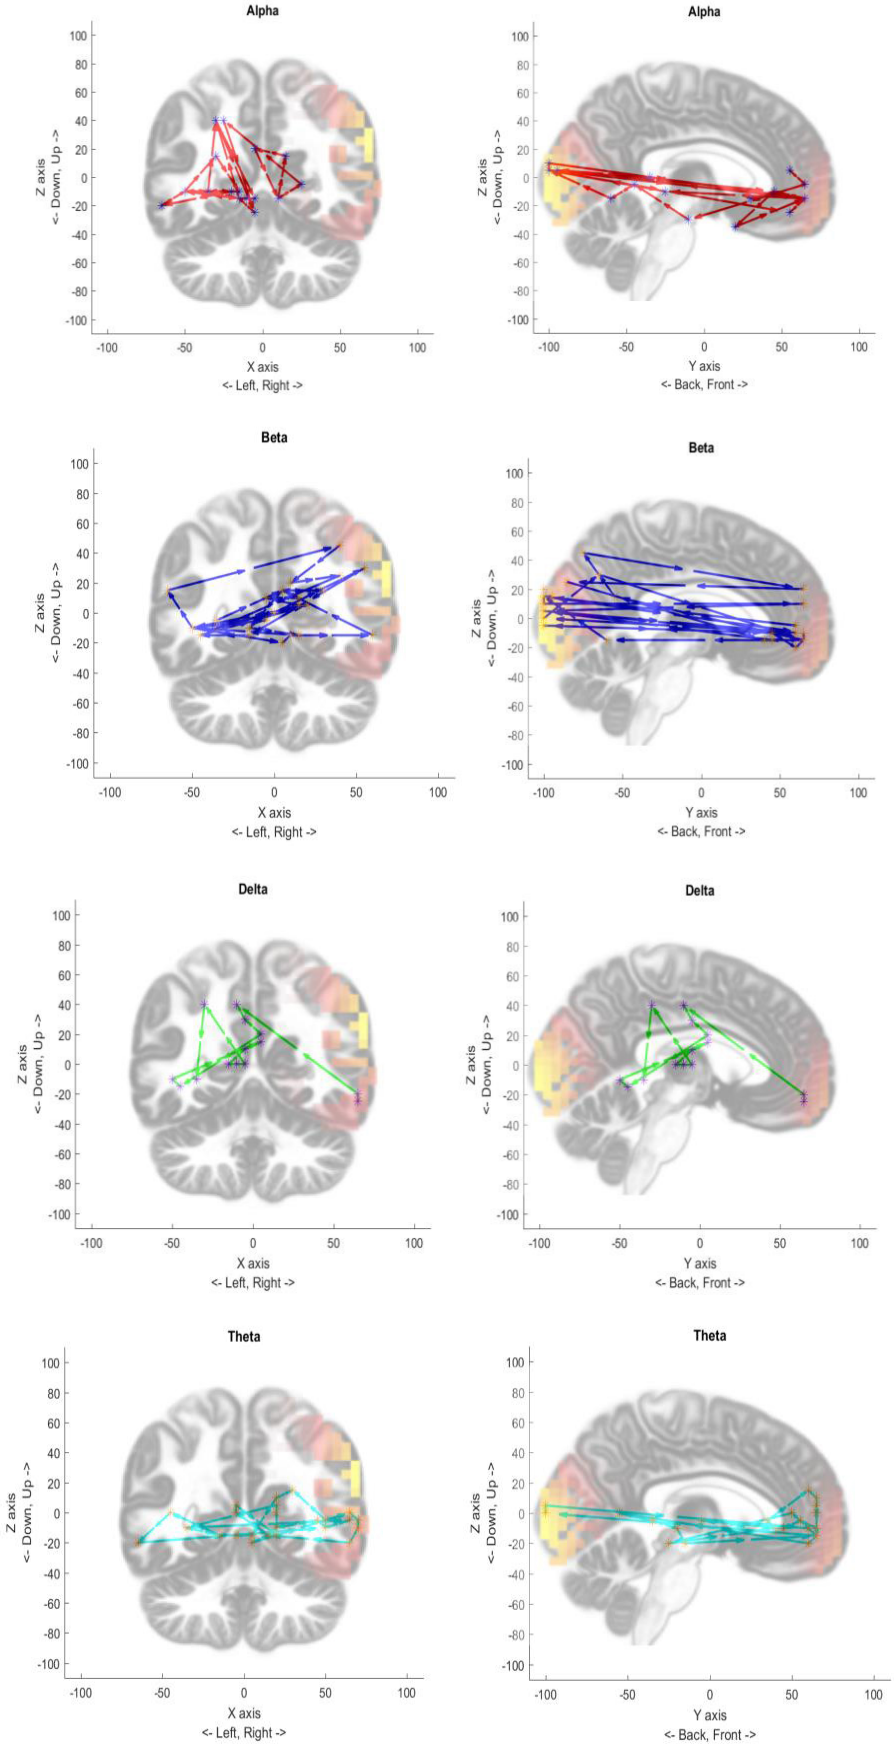

Figure 12: Performance of Alpha, Beta, Delta, and Theta wave across the brain while the subject thought about some parts of their body, in this case the left hand.

4. Conclusions

In this work we proposed a new method to monitor dynamic activities of brain functions at different frequency band without using averaging techniques like even repeats. In our example experiments, to associate subject behaviors with 3-D tracing characteristics, we found that each wave band had its own identifiable behavior that reproducibly generated notable characteristics along the 3 categories including emotion, math calculation, and motor functions. Our data analysis indicates that beta waves play key important roles in linking different brain areas together for information inquiry. Theta and low Alpha are more likely playing the role of information control, integration, and image formation. Conclusions derived from these tracing results were further confirmed with sliding window spatial correlation analysis.

ABSTRACT

In this paper the front-end power solution for automotive ADAS electronic systems is analyzed. The increased complexity of electronic systems in ADAS automotive brings new challenges for hardware design, especially with regard to improving the efficiency of the switched-mode power supply while maintaining the overall cost reasonably low and keeping the occupied area on the PCB as small as possible. Four topologies of Non-inverting step-up/step-down converter are analyzed. A real-life case is considered and 4 DC-DC converters are designed and simulated to fulfill the requirements. Finally a comparison between the circuits is undertaken. Results are analyzed from the point of view of efficiency, area and price and a decision is reached for the most optimized converter.

1. Introduction

This paper is an extension of work originally presented in 2016 at the 12th IEEE International Symposium on Electronics and Telecommunications (ISETC) [1].

Advanced driver assistance systems (ADAS) are probably the fastest-growing electronic systems in the automotive industry. Every year more and more features are added to the cars to make them safer and to help drivers. A brief list of the kind of feature available today is as follows: pedestrian detection, traffic sign recognition, blind spot monitor, lane departure warning, forward collision warning, driver monitor, adaptive cruise control and emergency braking control, and the list can continue. This extraordinary increase in available ADAS brings to reality something that once was just a dream or a nice theme for Sci-Fi movies: autonomous car. Researches and trials for self-driving cars have a long history of about 100 years. But only in the last 10 years have notable results been achieved. ADAS are basically the foundation of the self-driving vehicle. Today there are already cars on the road with self-driving features with the most advanced publicly available systems being at Level 2 of autonomy (based on SAE Society of Automotive Engineers International's J3016 document definition [2]). Level 3 cars are expected to be on the road in 2018.

To support all these features for ADAS and autonomous driving, electronic systems in cars are very complex. To be able to detect the environment many sensors of different types must be available and the information collected must be processed extremely fast. Systems for ADAS and autonomous driving utilize today the following: cameras (4-12), ultrasonic sensors (12-20), radar (short and long range) and LiDAR. Each of these sensors has its own specific capability and by combining the information from them the system is more capable of reading the world around the car.

However the next challenge is to process the huge amount of data received from all these sensors. In a sense self-driving cars will be extremely powerful computers on wheels.

Extremely powerful multi-core processors like Renesas R-Car, Nvidia Parker, EyeQ4 from Mobyleye, etc. are available. Electronic control units (ECU) that can handle and process such large amounts of data are usually multi-processor systems with 1-4 processors and 1 – 2 microcontrollers (MCUs). Such ECU contains also all the required digital interfaces and decoding blocks necessary to capture data from external sensors. Power consumption and power dissipation for these ECUs is important and becomes critical in the automotive context. High requirements for robustness and reliability combined with the need for a long life (10 years) usually demands passive cooling (i.e. with no fans) for the vehicle's electronics. This is not easy to achieve when the ambient temperature can reach 85°C. These are some of the reasons that compel hardware design engineers to focus on reducing the power consumption and power dissipation of its devices. Besides selecting modern ICs (advanced technology) one can reduce the dissipated power by increasing the efficiency of local power supplies.

The following pages cover the topic of selecting and designing the optimised front-end power supply for ADAS electronics and examine several crucial aspects for automotive use:

- Efficiency, with the overall goal of reducing power loss;

*Corresponding Author Name: Beniamin Dragoi, Valeo Vision System, Tuam Galway, Ireland | Email: beniamin.dragoi@valeo.com

- Board occupied area, considering that the PCB is one of the most expensive parts in an ECU;
- Price reduction, which is the goal when the technical and quality aspects are fulfilled.

2. Power supplies in automotive

Most of the cars in the world today use 12-volt automotive electrical systems. Typically a car battery operates with a voltage in the range of 9V to 16V. Therefore, all electronic circuits powered by the battery power line should be able to account for this input-voltage variation. For modern electronics with most ICs powered at 3.3V or below (2.5V, 1.8V, 1.2V, 1.1V and lower) and only a few ICs that still require 5V or higher (CAN, Flexray, LIN transceivers), this input voltage range (9-16V) seems to be perfect. However, if for the battery the normal voltage is 12V (engine off) and 14.4V (engine on), this also can fall to 7V (warm / hot start) or as low as 3.2V (during cold start) or increase to as high as 34V (load dump).

Figure 1 and Figure 2 show typical warm and cold start profiles, while Figure 3 presents the typical load dump [3]

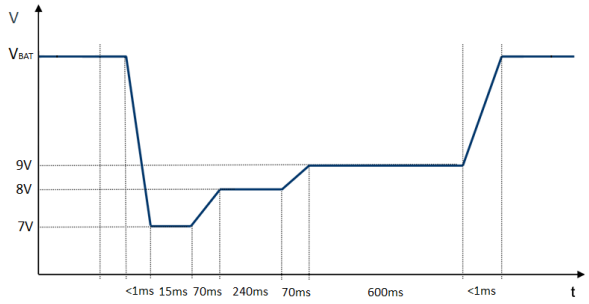

Figure 1. Example of a warm start profile

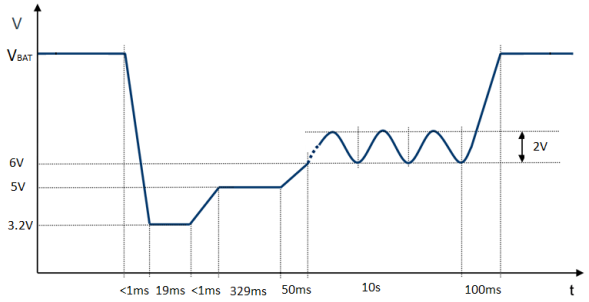

Figure 2. Example of a cold start profile

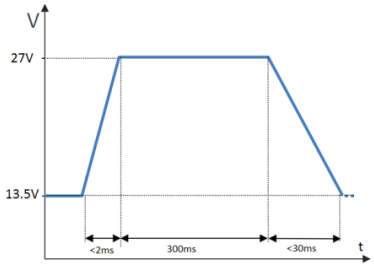

Figure 3. Example of a load dump profile

Voltage levels and timings presented in these figures are typical but they can vary from one car manufacturer to another. They are also dependent on the location of the ECU in the car. Standard profiles for these events are described by ISO 7637-2.

Some electronic systems in the car (engine ECU, safety systems, navigation, infotainment, dashboards, etc) must be live during a cold-crank event and also during a warm start with the requirement to be in Functional Status A: *the system must fulfill all functions during and after exposure to the event.*

In conclusion many electronic circuits for automotive must be designed to be powered from batteries with a voltage range of 3V – 34V. This wide voltage range is challenging from at least two aspects:

- Minimum input voltage is around 3V and is below some very common voltage rails needed for ICs like 3.3V and 5V. This leads to the need for a way to boost the input voltage to the required levels.
- Maximum input voltage is much higher than the usual rails for the processor's cores (1V, 0.8V or even lower). It is difficult to directly step down a high voltage like 34V, to a level like 0.8V because the duty cycle is very small. The minimum duty-cycle is limited by the converter's minimum ON time and its switching frequency. For such a low duty cycle it is highly likely that the step-down converter enters into "pulse-skipping" mode with the risk of increased output voltage ripple and a shift in frequency. Both effects might be unacceptable and result in a high voltage noise that is too high and the risk of failing EMC (electromagnetic) emissions.

To solve both above-mentioned aspects one can use the power supply topology presented in Figure 4. Below can be found a typical block diagram for a power supply system based on an intermediate voltage rail. This is probably the most used power supply topology for complex ECUs in automotive.

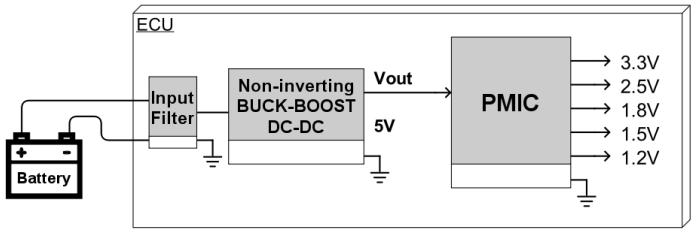

Figure 4. Typical block diagram for an automotive power supply

For this case where the intermediate regulated power rail is $V_{OUT}=5V$, if the cold start profile goes below 5V, a front-end step-up/step-down DC-DC is required. In Figure 4 this converter is mentioned as being Non-inverting BUCK-BOOST because the input voltage range can be below or above the output voltage (5V) and the output voltage has the same polarity as the input one. 5V as output of the front end power supply is not a magic number, but it is a suitable value for at least 3 reasons:

- A 5V rail is still needed in the automotive electronics for circuits like CAN, and Flexray;
- Most of the available power management ICs (PMIC) have a maximum input voltage of 5.5V;
- A lower value for the output of the front-end supply brings the converter into the zone of very low duty cycles and the associated risks and issues.

3. Non-inverting Step-up/Step-down converter topologies

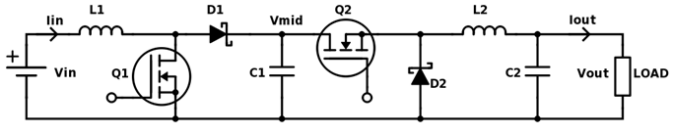
In the literature, there are few DC-DC converter topologies that can produce the *non-inverting step-up/step-down* function [4].

Some of them, such as BOOST-BUCK and SEPIC are well-known, whereas others such as 4-switch BUCK-BOOST and ZETA are not so popular. One solution is to use two-stage conversion: one BOOST is followed by one BUCK (BOOST-BUCK). Another approach is the single-stage buck-boost converters such as: 4-switch BUCK-BOOST, SEPIC or ZETA.

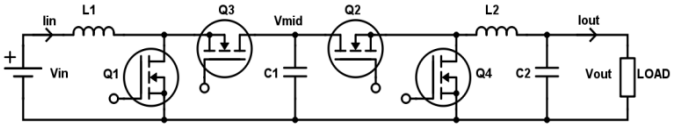
3.1. BOOST-BUCK converter

Figure 5 shows the *Boost-Buck* converter with two implementations: a) asynchronous and b) synchronous. This converter is basically a cascade of two converters, a BOOST formed by L1, Q1, Q3 (or D1) and C1 followed by a BUCK made by Q2, Q4 (or D2), L2 and C2. The purpose of the Boost converter is to provide a minimum intermediate voltage V_{mid} during cold or warm start battery voltage sags. V_{mid} is set to provide enough input voltage for the Buck converter. As long as $V_{in} > V_{mid}$ the Boost converter is disabled and the Buck converter is powered through L1 and Q3 (or D1). For this case Q3 or D1 are ON and Q1=OFF. During this phase V_{mid} is not regulated and is: $V_{mid}=V_{in}-V(L1)-V_{DS}(Q3)$ for the synchronous converter or $V_{min}=V_{in}-V(L1)-V_F(D1)$ for asynchronous one.

When $V_{in} \leq V_{mid}$ the boost converter kicks in and maintains V_{mid} as a regulated voltage.



a) Asynchronous

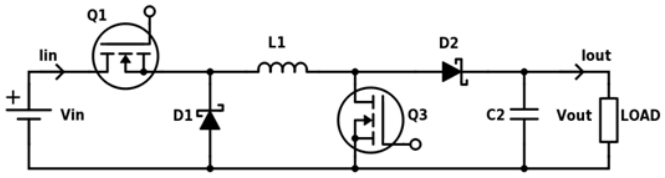


b) Synchronous

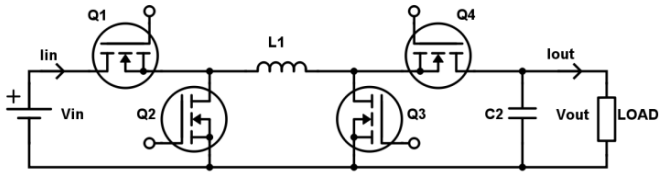
Figure 5. BOOST-BUCK converter

3.2. 4 switch BUCK-BOOST converter

Another topology capable of producing a positive regulated output voltage for V_{in} below or above V_{out} is the synchronous *4-switch Buck-Boost* – Figure 6 a) and b).



a) Asynchronous



b) Synchronous

Figure 6. 4-Switch BUCK-BOOST converter

Basically, this is a simplification of one BUCK converter followed by one BOOST converter; both converters share the same inductor L1 [6]. There are 3 modes of operation based on the relationship between V_{in} and V_{out}:

1. V_{in} much higher than V_{out} → Buck mode

Q3 is constant OFF and Q4 (or D2) is constant ON. This is the preferred mode of operation because the efficiency is good. This is basically a buck converter's efficiency reduced by the Q4 loss in constant conduction ($I_{out}*R_{ds(on)}$). However, for the asynchronous version, Q4 is replaced by a diode D2 and there could be important power loss due to the forward voltage of the diode being continuously ON ($I_{out}*V_{F(D2)}$). If the output voltage V_{out} selected is low enough (e.g. 5V), this mode of operation is the mode of operation for most of the time, normal operation, warm start and load dump. So it is important to minimize the power loss produced by the inactive Boost section.

2. V_{in} much lower than V_{out} → Boost mode

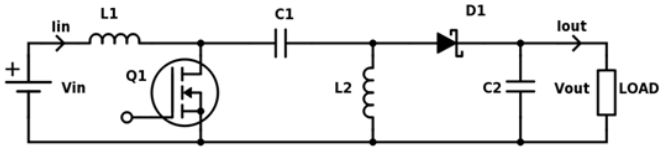
Q1 is constant ON and Q2 (or D1) is constant OFF. If V_{out}=5V, according to Figure 2, the converter will work in this mode only for about 20ms (lowest section of the cold start profile).

3. V_{in} close to V_{out} → Buck-boost mode.

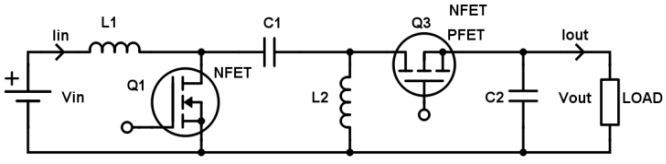
In this mode all 4 transistors are controlled by the driving controller to ensure a proper transition from Buck to Boost or vice-versa. The converter will work in this mode only for few hundreds of milliseconds, when the battery is recovering from the cold crank.

3.3. SEPIC converter

The most common single-stage converter with non-inverting buck-boost behaviour is SEPIC. Asynchronous and synchronous versions are shown in Figure 7. This topology uses only two switches (transistor of diode) [7]. The most known SEPIC configuration is the asynchronous one but here the synchronous SEPIC converter is considered as well [8]. The synchronous SEPIC convertor can be implemented with Q3 NFET (N-channel Field Effect Transistor) of PFET (P-channel Field Effect Transistor) depending on the available driving controller. Overall efficiency of the converter is reduced because two inductors are used in operation and due to high currents and voltages for the switch elements.



a) Asynchronous

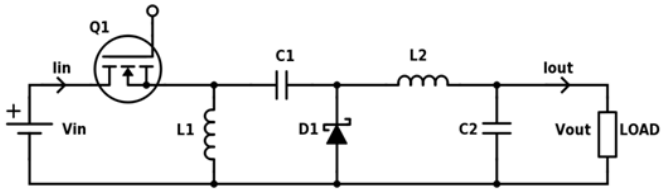


b) Synchronous

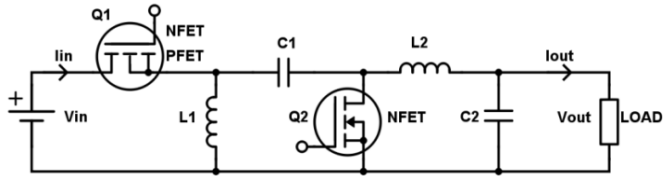
Figure 7. SEPIC converter

3.4. ZETA converter

Zeta is a very similar topology to SEPIC; it is named "inverse SEPIC" and has the topology shown in Figure 8. It has two inductors and two active switches [4]. One of the active switches can be a diode (D1) or a FET (Q2). Like SEPIC the two inductors can be coupled or independent.



a) Asynchronous



b) Synchronous

Figure 8. ZETA converter

ZETA topology is better for lower output voltage ripple due to continuous output current in L2. This reduces the required output capacitance to maintain a low output voltage ripple. However due to the input discontinuous current (through Q1) ZETA shows higher input voltage ripple. ZETA convertor can be implemented with Q1 NFET of PFET, depending on the available controller.

3.5. Topology comparison

As previously shown, all 4 types of non-inverting step-up/step-down converters considered here have their asynchronous and synchronous variants. To avail of increased efficiency this work considers only the synchronous type of converters here. This one reduces the power loss associated with diodes in conductions and proves to have higher efficiency for higher current load [5].

Some advantages and disadvantages have been already mentioned but a more detailed comparison is undertaken in Table 1. This table contains two sections, one for advantages for each converter and one for disadvantages [9, 10].

Each type of SMPS presented here has its own advantages and disadvantages, so there is no unique answer to the question: '*what non-inverting step-up/step-down is the best?'* The final decision in selecting one or another topology belongs to the design engineer based on his application's requirements. The next section contains a comparison for all these 4 types of converter for a real life case, comparisons that helps the designer to decide what the most optimized converter for an application is.

4. Case study and simulations

A real life case for a front-end power supply was selected to show the differences between these 4 converters. Design requirements are listed in Table 2.

To be able to compare the board occupied area and price for all converters it was decided to use real components, available on the market, components that are automotive qualified. For the same reasons it was decided to use controllers from a single supplier - Linear Technology, now part of Analog Devices [12]. All four designs were simulated using the same Spice simulator – Ltspice.

Table 1. Comparison of advantages and disadvantages for 4 non-inverting step-up / step-down converters

BOOST-BUCK	4 switch BUCK-BOOST	SEPIC	ZETA
Advantages			
Continuous, non-pulsating input and output currents due to input and output inductors (L1 and L2). This reduces ripple voltage (input and output) and improves the EMI noise, and can simplify the input filter design and size.	Single inductor design. Lower price and smaller board occupied area.	Only two active switching components are required	Only two active switching components are required
Easy to design and compensate. Both converters, Buck and Boost are mature circuits and well known, easy to design and easy to compensate for stability	Switch rating = V_{in} for input section, V_{out} for output section => Mosfet transistors with lower V_{DS} can be used, so with better (lower) $R_{ds(on)}$	Low input voltage ripple	Low output voltage ripple
Can be designed using two completely separated controllers / converters	High efficiency	Inherent short-circuit protection at output due to DC-block capacitor	Inherent short-circuit protection at output due to DC-block capacitor
Disadvantages			
Two inductors are required: price and area. Inductors are expensive and big components.	Input and output are both noisier due to discontinuous currents *Iin* and *Iout*	High output ripple (similar to Boost)	High input voltage ripple (similar to Buck)
4 switches are needed - price	4 switches are needed	Two inductors are required	Two inductors are required
Low efficiency – during normal Vbat range converter works in Buck mode but it has a power loss in L1 and Q3	The controller for the entire converter is more complex and contains two driver sections	Coupling capacitor C1 is needed. In automotive use two series capacitors might be need to protect against MLCC failure (failure mode is *short)*	Coupling capacitor is needed but the voltage across it is lower (V_{out}). Series capacitors might not be needed
Controller needed is complex (two driver sections or two controllers)	Special consideration for crossing point between *Buck-mode* and *Buck-mode* is needed.	Frequency compensation is more difficult to be implemented	Frequency compensation is more difficult to be implemented. Zeta is not well understood.

Table 2. Design Requirements for the front-end SMPS

V_{IN}	4-35V
f_{sw}	400KHz
V_{OUT_ripple}	<50mV
V_{OUT}	5V
I_{OUT}	5A

The switching frequency is set at 400 kHz as a trade-off between several factors: *efficiency, area, cost* and *EMC risks.*

It is known that lower switching frequency improves efficiency due to lower switching losses, but also increases the occupied area (expensive) [11]. Big and expensive inductors and big and expensive capacitors are needed to reduce the input and output voltage ripple. So, higher efficiency at low frequency comes with higher cost [12]. On the other hand, these DC-DC converters must comply with very strict requirements in terms of conducted and radiated EMC emissions. It is very important to avoid generating noise in the radio AM band (535 kHz to 1705 kHz) so the switching frequency should be below or above AM band. Switching frequencies above AM band suffer from low efficiency and might force the controller into pulse-skipping mode during load-dump. So, the switching frequency is selected just below AM band.

All four designs use as a starting point the application notes available from the supplier. The target is to design a stable power supply capable of fulfilling the requirements with the minimum of components. However, to have a fair comparison passive components from the same family/series are used and where possible even the same components are used. This approach helps to obtain a fair comparison in terms of occupied area and price. In Table 3 a BOM comparison is shown as a result of the design of these for SMPS.

Next controllers are used in these designs:

- Boost-Buck - LTC7812
- 4-switch Buck-Boost - LTC3789
- SEPIC - LT8710. Un-coupled inductors are used.
- ZETA - LT3840 Un-coupled inductors are used.

Table 3. BOM comparison

	BOOST-BUCK	**4-switch BUCK-BOOST**	**SEPIC**	**ZETA**
Controller	Dual: Boost + Buck	4 Switch Buck-Boost	BOOST	BUCK

4.1. Simulation results

Due to lack of space only the schematics for *4-switch Buck-Boost* converter (Figure 9) and *ZETA* converter (Figure 10) are provided here.

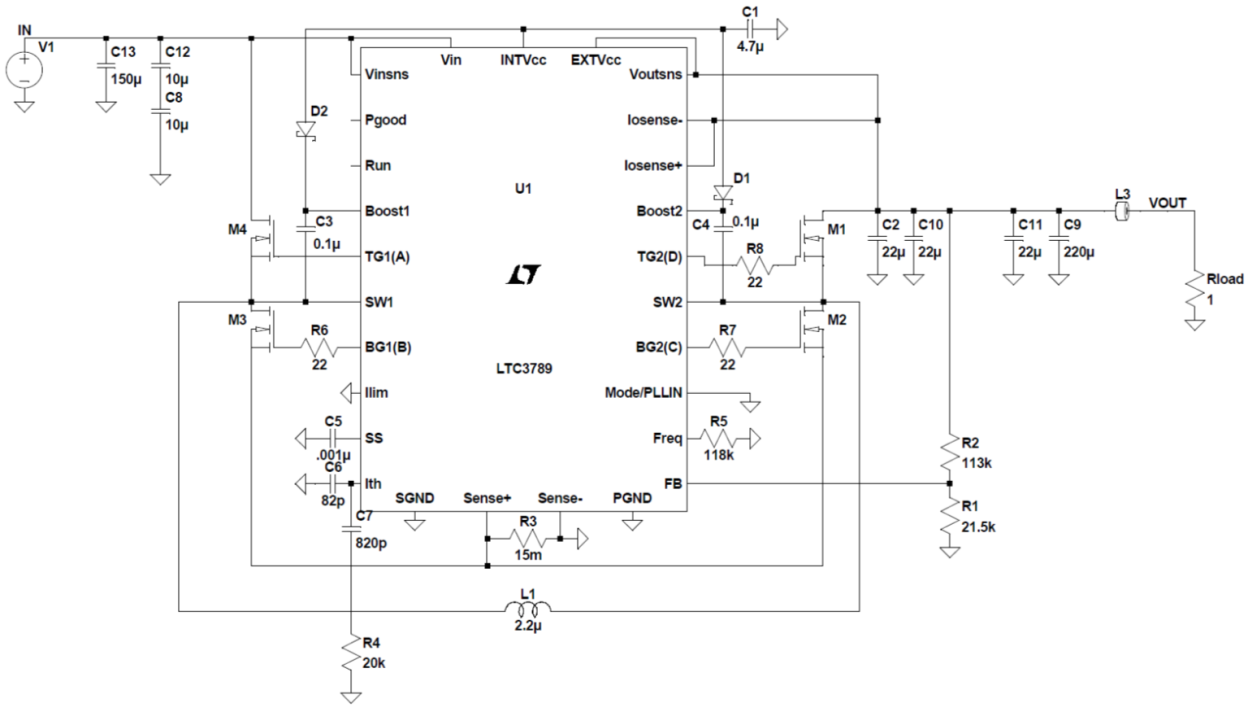

Figure 9. 4-switch Buck-Boost converter schematic

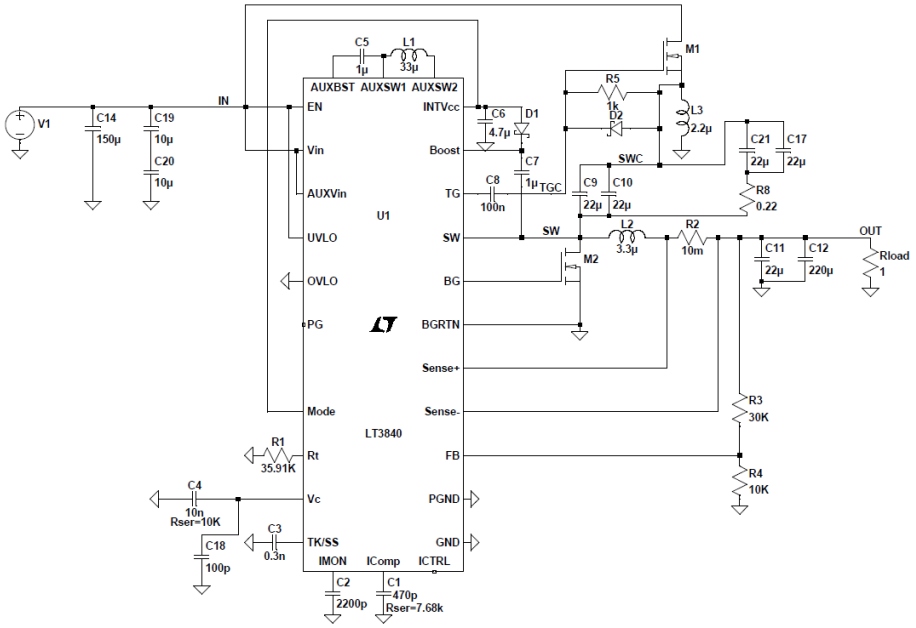

Figure 10. ZETA converter schematic

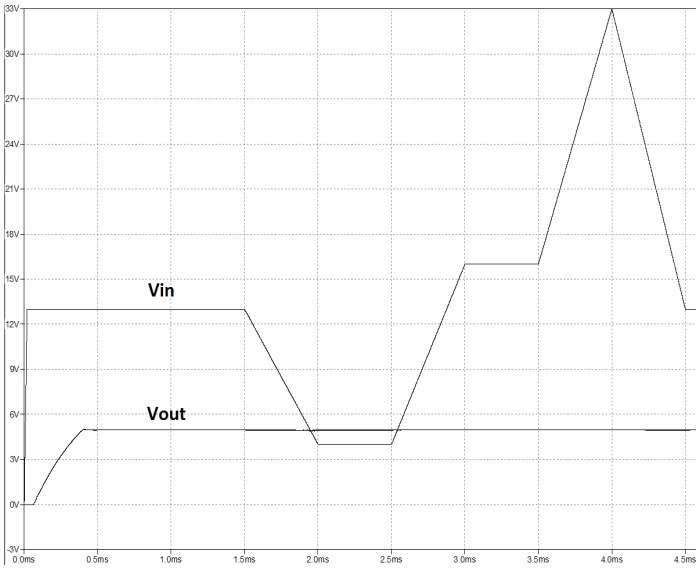

Figure 11. Simulations results for *4-switch Buck-Boost*

Figure 11 shows the transient simulation result intended to verify the behavior of the converter when the input voltage V_{in} varies from 0V to 33V. The response to Cold-crank and Load-Dump events is verified in the same simulation. To speed up the simulation, all the timings from these two profiles are compressed and reduced. However, the converter reacts very well to these faster transitions too.

All simulation results for all 4 considered converters are virtually identical with those shown in Figure 11.

Based on the simulation performed and their results it can be concluded that all 4 designed converters are suitable to be used for the case being considered. All converters can handle the automotive cold-crank, warm-start and load-dump events and provide a regulated output voltage.

4.2. Comparison for efficiency, are and cost

Because all 4 converters are suitable to be used as a front-end power supply for ADAS ECUs (from electrical point of view), one can optimize the power solution for automotive applications by using several criteria:

- *Efficiency* comparison is shown in Figure 12. Ideally, one would like to select the converter that has the best efficiency over the entire input voltage range for a given output current and system requirements; however, the converter stays a brief time in cold-crank so the efficiency in this phase might be not so important for some applications. The left side of Figure 12 shows the efficiency comparison during cold-crank profile for a weak battery while the right side shows the efficiency for each converter when the battery is healthy.

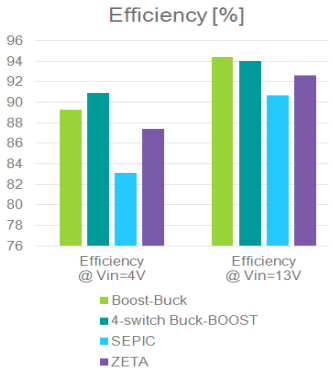

Figure 12. Efficiency comparison

- *Occupied area, with and without controller* – Figure 13. The entire PCB occupied area by a converter is important and it is shown in the left section of Figure 13. Controller size / package might vary from one supplier to another while the external components remain almost the same so a comparison of the space requirement without the controller is presented in the right side of Figure 13. For comparison of the occupied area the sum of areas of all components was considered plus an additional 0.5mm keep-out area on each side for each component;

- *Price with and without controller* - Figure 14. Prices used in the comparison are obtained from the supplier website (Linear Tech) for SMPS controller and all the other parts are from component distributor Mouser. Prices are expressed in € and are for 1k pieces.

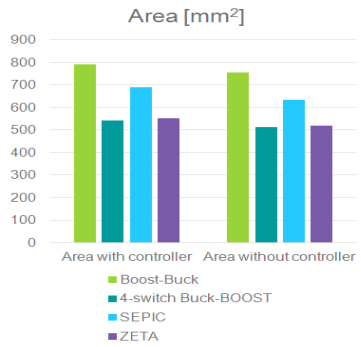

Figure 13. Occupied area comparison

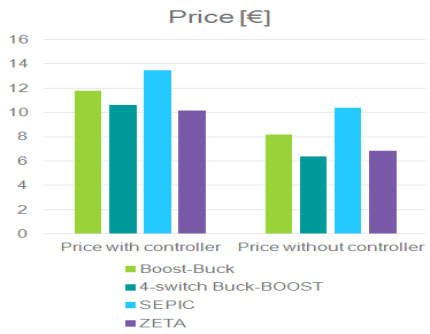

Figure 14. Price comparison

A summary of these comparisons is available in Table 4.

Table 4. Summary of comparisons

	BOOST-BUCK V_{mid} =7V	4-switch BUCK-BOOST	SEPIC	ZETA
Efficiency @ V_{in}=4V	89.3%	90.9%	83.1%	87.4%
Efficiency @ V_{in}=13V	94.4 %	94.0%	90.7%	92.6%
V_{OUT_ripple} [mV_{pkpk}]	22.4	42.6	46.6	27.6
Area [mm²] with controller	791	541	689	553
Price [€] with controller	11.8	10.6	13.5	10.17
Area [mm²] without controller	755	511	633	518
Price [€] without controller	8.2	6.36	10.4	6.83

5. Conclusions

Four synchronous converters suitable to perform the non-inverting step-up/step-down function for powering an ADAS electronic system are considered in this work. A short theoretical analysis is presented and a list of advantages and disadvantages of all topologies is undertaken and summarized, from the perspective of automotive applications. One must know all the advantages and disadvantages of all suitable DC-DC converters before being able to obtain an optimized solution. A method of optimization for automotive ADAS front-end power supply is to consider the efficiency, board occupied area and cost along with the quality parameters of an SMPS (not studied in this work) (as input and output voltage ripple, loop response, stability and transient response).

A real life case was considered and according to the simulation results obtained and the comparisons made for efficiency, occupied area and cost, it can be concluded that the *4-switch Buck-Boost* converter is the optimal one for the real-life case which was considered. This converter meets all the requirements specified in Table 2 and has the smallest occupied area (calculated with or without controller), has a low price and exhibits high efficiency. The SEPIC converter (with un-coupled inductors) proves to be the worst solution: lowest efficiency, highest cost (due to high voltage coupling capacitors) and almost the biggest PCB occupied area. An interesting solution is ZETA that is very competitive in terms of price and space. Also ZETA shows decent efficiency. However precautions must be taken to properly compensate it in frequency.

Future work is planned to analyze the suitability and performance of new/improved converter topology as multi-phase converters (buck-boost, SEPIC) and multi-switch SEPIC/ZETA [13].

Conflict of Interest

The author declares no conflict of interest.

Emotion recognition

ABSTRACT

The matters regarding speech signal processing and analyzing in terms of emotional states recognition were presented in this paper. An experiment was conducted to perform both objective and subjective emotional states recognition tests for Polish language.

1. Introduction

The aim of the experiment was to test the effectiveness of fixed seven emotional states recognition. Tests were carried out with use of Polish language speech recordings from two acoustic databases. Samples consisted of professional actor and amateur speakers voice recordings. During studies, an objective, computer method was used composed of speech signal parameters extraction, selection of parameter vectors, and classification tests. The investigations were extended by carrying out subjective emotional state recognition tests performed by group of respondents. In various cases [1] emotional states investigations are implemented, e.g. in automated systems, analysing customer satisfaction level in telecommunication companies hotline systems. The experiments described in the paper should be regarded as pilot studies. However, their subsequent development could contribute to emergence of an automatic system, designed for Polish language, capable of recognizing emotions in speech signal.

2. Acoustic Databases Acquisition

Emotions are one of the most important elements of human life. We can define them as short and usually strong mental arousal induced under the influence of a particular stimulus, often leading to physical reaction. For example, a person in a state of anger, joy or fear usually responds by speaking louder, faster and with increased energy in the higher frequency band.

A popular way of classification is the division of emotions into basic and complex. Basic emotions are up to a dozen [2], and they result from the natural human reactions, while the complex states are to be their appropriate combinations. Despite the lack of consensus on a single set of basic emotions, there is one popular theory named "The big six" by Paul Ekman [3]. Accordingly, basic emotional states are: joy, anger, disgust, surprise, fear and sadness. They can be recognized from facial expressions, gestures and voice, even by people from different cultures, speaking different languages. The studies of emotional states in the speech, in some cases, use only 3 states [4]: positive, negative and neutral. However, due to its versatility and easy recognition "big six" was chosen for conducted experiment.

Emotional state databases contain 3 types of recordings:

- Spontaneous speech recordings.
- Forced emotional states recordings.
- Simulated emotions recordings.

Spontaneous speech databases include recordings of emotions induced in a natural way. To create this type of database usually recordings from multiple sources are used. These include conversations with emergency dispatchers [5], utterances of the participants of TV game shows, journalist relations from dramatic events and the interaction with a robot. Second type of databases include collections of enforced emotions recordings. Each emotional state in speakers voice needs to be induced. It is possible, e.g. through, presentation of movies or recordings stimulating appropriate emotions. Another, slightly more controversial method relies on putting speaker in a stressful situation. The advantage of this type of database is to obtain naturally excited emotions.

The result of this work was development of two acoustic databases (MD – amateur and TS – professional speaker). The

*Corresponding Author: Krystian Kapala, Wroclaw University of Science and Technology, Department of Acoustics and Multimedia, Wybrzeze Wyspianskiego 27, 50-372 Wrocław, Poland | Email: krystian.kapala@pwr.edu.pl

structure of each was divided into training and testing sets. The first (MD) training set contained 543 recordings of women and 556 men. Test set consisted of 509 women recordings and 510 men. In total MD database was composed of 2118 recordings. TS base contained only one speaker recordings. Training and test sets consisted of adequately 219 and 243 recordings, in total - 462.

Table 1. Comparison of databases

	MD	TS
Place of recordings	WUT recording studio	Amateur recording studio
Microphone	T-Bone SCT 700 - condenser	Shure SM 58 - dynamic
Mixer	Yamaha 03D	Behringer Eurorack mx - 802a
Sound Card	SoundMax Integrated Digital Audio	Sound Blaster Audigy 2 NX
Sampling frequency	44.1 kHz	44.1 kHz
Resolution	16 bits	24 bits
Language	Polish	Polish
Speakers	Amateurs - men and women	Professional actor
Speakers number	6 male, 7 female	1 male
Utterances	10 sentences	10 nearly identical sentences
Simulated emotions	6 + neutral state	6 + neutral state
Number of recordings	At least 1	At least 6

Recording sessions for each database were carried out in different conditions as Table 1 shows. A set of 10 sentences was selected, and put in the following order (translations in brackets).

- •Jutro pójdziemy do kina.
  - (Tomorrow we are going to the cinema.)
- •Musimy się spotkać.
  - (We have to meet.)
- •Najlepsze miejsca są już zajęte.
  - (The best seats are already occupied.)
- •Powinnaś zadzwonić wieczorem.
  - (You should have called yesterday.)
- •To na pewno się uda.
  - (I am sure it will succeed.)
- •Ona koniecznie chce wygrać.
  - (She really wants to win.)
- •Nie pij tyle kawy.
  - (Do not drink that much coffee.)
- •Zasuń za sobą krzesło.
  - (Tuck in your chair.)
- •Dlaczego on jeszcze nie wrócił.
  - (Why has not he returned yet.)
- Niech się pan zastanowi.
  - (Think about it, sir.)

Table 2. Phonems appearance frequencies in databases

Phonem	Frequency [%]		Phonem	Frequency [%]

ʃ	1.67	2.16	#	0	0

Databases of simulated emotional states include recordings of either amateur or professional speakers. This type is the easiest to obtain and analyze. Recording conditions may be adjusted. The list of utterances, with suggested emotional states and number of repetitions are prepared before the recordings. Typically they contain recordings of single sentences, sometimes longer statements [5]. Usually, the content of spoken sentences is not emotionally characterized (e.g. interrogative sentences are rarely used, for possible suggestion of surprise). The biggest drawback is the difference between the natural and simulated emotions, which is impossible to determine. In addition an amateur speaker may simulate either expressively or faintly, which may also affect the results of subsequent analysis. There are many databases of simulated emotional states recorded in multiple languages e.g.. Spanish [6], German [7], Danish [8] or Polish [9].

3. Parameters and vector selection

Recognition of emotions in utterances requires parameterization of the speech signal. After parameters extraction

investigated acoustic material is represented by a vector of extracted features. Unfortunately, there is no universal set of parameters allowing to achieve optimum subsequent analysis, therefore usually a large number of parameters is extracted, which then is used for determining the most representative sets of features - selection.

The following parameters were selected and extracted for further analysis:

- Pitch frequency,
- The first four formant frequencies,
- Intensity of the speech signal,
- LPC coefficients.

Parameters extraction was conducted with Praat and jAudio software. Parameters were characterized with values such as minimum, maximum, mean, median, standard deviation, range and mean absolute slope. Extracted features were exported to a text file and each sample was assigned to a specific emotional state. Parameters selection was conducted in Weka software [10] with usage of ChiSquaredAttributeEval algorithm.

4. Classification

As first trials showed algorithms using support vector machines [11-13] were the most effective, thus both SVC were selected to carry out the final tests. Table 3 presents the effectiveness of various algorithms used for database classification.

Most often training sets contain linearly inseperable data. In these situations algorithms that allow for the existence of components beyond the margin are used e.g. C-SVC. When forming the hyperplane, requirements reduction is determined with special value. Parameter C (cost) is responsible for the number of vectors inside the margin. Its value is determined experimentally in order to obtain maximum efficiency of classification process. Increasing the parameter C causes an effect similar to the linear classification. Small values allow to adjust the hyperplane to the training set.

Tests were performed for the seven cases of various TS (professional actor) and MD (amateur speakers) training and test sets combinations (Table 4).

The algorithm using υ-SVC classification is very similar to C-SVC. An additional parameter is υ coefficient with a value between <0; 1>. This parameter specifies the number of possible violations found in the case of linear classification and the number of support vectors. With increasing υ value the amount of vectors within the margin increases. When υ coefficient has a value of 0, linear classification is performed.

LibSVM library imported to Weka software enabled conducting classification processes with usage of support vector classifiers such as C-SVC and υ-SVC. During tests υ-SVC algorithm showed better effectiveness, thus further classification results were described only for this method.

Table 3. Recognition results for selected algorithms

Used classifier	Effectiveness [%]
Fast decision tree [14]	55.82
K-star	56.04
NN [15]	56.62
KNN5[16]	59.08
KNN10	57.31
Naive Bayes [16]	38.57
Multi layer perceptron	52.60
C-SVC (polynomial kernel)	56.33
C-SVC (radial basis kernel)	63.69
υ-SVC (polynomial kernel)	56.92
υ-SVC (radial basis kernel)	64.38

5. Results presentation

Recognition efficiency results for each emotional state and all 7 test were presented in confusion matrixes, respectively Tables 6-12.

Conducted classification tests brought varied results. The lowest effectiveness was achieved for different database training and test set cases. In case of MD test and TS training set, overall effectiveness was 21.6%. Fear and surprise were recognized with the best score - above 40%. State of anger was recognized as fear 75 times out of 157 samples. The opposite situation (MD training, TS test set) improved results to 29.6%. Anger and neutral emotional states were recognized in 54.1 and 57.6% of cases.

Table 6. Confusion matrix (MD>MD)

	anger	neutral	joy	sadness	fear	disgust	surprise	Effectiveness [%]
anger	**106**	6	14	4	13	10	4	67.5
neutral	2	**103**	1	24	1	23	1	66.5

fear	11	0	34	5	**56**	5	16	44.1
disgust	5	1	17	31	43	**19**	28	13.2
surprise	4	0	37	1	31	6	**61**	43.6

Maximum efficiency results as expected, were achieved while using training and test sets from the same databases. In case of MD database overall performance was 64.4%. The best result for single state concerned surprise - 70.7%, the worst one, disgust 56.3%. In the classification conducted on sets from the database TS total effectiveness of 75.3% was obtained. Most likely this was a result of single person recordings within database - professional actor using similar expression of emotions in each repeated sentence. All the emotions were identified with efficiency higher than 60%, achieving the best results for anger - 89.2% and neutral state - 84.8%.

Important tests were also carried out for combined training sets of both databases (TS+MD). The conducted classifications highest score (62,9%) was obtained for the test set derived from the MD database. The lowest result was (49,6%) observed in case of TS database test set. Anger state recognition results in both cases were very similar, whereas in case of neutral state for TS derived test set was higher by nearly 30%. The rest of the emotional states were recognized with greater efficiency when testing MD derived set. It should be noted that the recognition results for TS test set in case of single emotional states were varied - the respective values ranged between 8.8 and 81.8%. An experiment was also conducted on combined collection of training and test sets of both databases. The overall result was 57.4%. The results for individual emotional states recognition were similar to the ones obtained when testing MD database itself, most likely due to the impact of large number of samples from the

MD database. They were not strongly diversified and the results for all emotional states exceeded 50%. Adding TS training set deteriorated 4 emotional states recognition effectiveness by approximately 10%, leaving the rest with similar results.

Table 11. Confusion matrix (MD>TS)

	anger	neutral	joy	sadness	fear	disgust	surprise	Effectiveness [%]

6. Empirical studies

Empirical studies were done in two stages. The first step involved preparing the appropriate test material from both acoustic databases. Step two involved empirical research and analysis of results.

The task of the person taking part in the experiment was to assign the proper emotional state to each sample. The selection was made from only seven states (6 basic and neutral one). Preliminary studies have shown that the test material meets the criteria of objectivity. After listening to each sound sample, the listener was supposed to determine what emotional content it was carrying. The listener answered by clicking on the appropriate emotional state button. If in doubt, the sample could be replayed. A picture representing questionnaire appearance was added below (Figure 1)

The first step was to determine the number of people to take part in the experiment so that the results could be representative. The selected group consisted of 10 people (2 female, 8 male participants). Age of group members varied between 26 and 32.

Survey was composed of two parts. The first one referred to recordings from the amateur speakers database. Table 13 presents the recognition effectiveness for each individual participant. It turns out that the accuracy of their emotional states recognition in given experiment ranged between 55 and 70 percent. These results could be the beginning of an interesting discussion connected with their interpretation. Psychological reasons were omitted in this article. They will be addressed during subsequent studies.

Figure 1. Questionnaire used in subjective tests

Table 13. Test participants results

Number of samples	Participant ID	Right answers	Effectiveness [%]
266	1	146	54,9
267	2	151	56,6
266	3	154	57,9
267	4	157	58,8
266	5	162	60,9
267	6	166	62,2
267	7	172	64,4
267	8	180	67,4
267	9	180	67,4
267	10	188	70,4
In total		**In total:**	**Average:**
2667		1656	62,1

A confusion matrix was presented (Table 14), which also show the effectiveness of recognizing individual emotional states. The best recognized emotion for ameteur speakers among the participants was „surprise", which reached almost 75 percent of the correct interpretations. The worst state to determine was "disgust". This state was correctly identified in 40 percent of cases.

Table 14. Confusion matrix (amateurs)

Amateur speakers database	anger	neutral	joy	sadness	fear	disgust	surprise	Effectiveness [%]
anger	**236**	39	14	8	14	38	10	65.7
neutral	5	**257**	3	62	7	32	1	70.0
joy	14	62	**210**	1	25	16	20	60.3
sadness	2	45	3	**231**	20	46	4	65.8
fear	18	33	13	27	**176**	28	26	54.8
disgust	22	77	2	71	11	**149**	40	40.0
surprise	8	5	10	5	30	28	**253**	74.6

In the second part of the survey, the respondents were presented with sound samples of professional actor voice (confusion matrix in Table 15). The best interpreted state was "anger" recognized correctly in all cases. The least effectiveness was achieved for fear, where efficiency was only 20%. In fact fear was even more times interpreted as anger which could indicate on quite specific, different actor expression.

Table 15. Confusion matrix (professional)

Professional speakers database	anger	neutral	joy	sadness	fear	disgust	surprise	effectiveness [%]
anger	**29**	0	0	0	0	0	0	100
neutral	1	**28**	0	0	0	1	0	93,3
joy	1	1	**29**	0	0	0	0	93,5
sadness	2	8	0	**12**	2	6	0	40
fear	9	5	0	4	**6**	4	2	20
disgust	7	5	0	0	2	**15**	1	50
surprise	0	0	4	0	0	1	**25**	83,3

The differences in test results obtained from both parts of empirical studies seem to be quite obvious, given the various way of expression. Actor utterances could have been significantly different from the amateur's in pace or dynamics of the voice. Another important fact is the use of only one speaker in comparison with 13 people (both genders) in amateur database. Table 16 shows the results of emotion recognition for each recorded speaker. Attention was drawn to the fact that some non-professional speakers have gained better interpretation results of their emotions.

Table 16. Speakers individual results

Amateurs:			
Speaker ID (M- Male, F-Female):	**Number of samples**	**Right answers**	**Effectiveness [%]**
M4	198	96	48,5
M7	171	89	52

K2	209	145	69,4
M3	211	169	80,1
Professional:			
M1	144	210	68,6

7. Empirical studies

The results obtained during the investigations both for empirical and computer methods are comparable, which could suggest that there is a possibility to create and further develop an effective automatic tool capable of recognizing emotions from speech signal. In experiment both amateur and professional speakers were used. The results show that unlikely to initial assumptions including professional speaker in investigations did not improve the recognition effectiveness – using his recordings in training sets in objective method gave good result in case of test set composed only of his own recordings. Additionally during empirical studies some amateur speakers were recognized with better effectiveness.

Tyre Activated Carbon (TAC)

A B S T R A C T

Economic gains are generally the outcome of industrialization and consequently urbanization. However, positive fiscal index generates a negative impact on natural environment sources heaving pollutant burden on soil, air and water. Industries throw tones of contaminated water into soil and water bodies without proper treatment and create a potential threat for both living and non-living species. Chromium in trivalent state (Cr^{3+}) is added in water bodies and soil through waste water from tanneries, cooling water systems, chemical and pulp and paper industries. The present research work aims at the preparation of an inexpensive activated carbon prepared from non- degradable waste scrap rubber tyres. The carbon produced from scrap rubber tyres was activated by 5% solution of $BaCl_2$ and 0.4 N solution of HCl and verified by ethylene blue solution. The adsorption capacity of the Tyre activated carbon (TAC) was investigated for different parameters i.e., initial chromium (III) ion concentration, activated carbon dosage, contact/ stirring time and pH. The adsorption capacity of TAC depends on the initial metal ion concentration and the TAC dose. pH of the chromium solution effects the adsorption capacity of TAC due to the formation of tetra hydroxochromate(III) complexes,. The results show that TAC offers a cost effective reclamation process for the removal of Cr^{3+} from effluent waters.

1. Introduction

Industrialization and urbanization at a fast rate, especially in the developed countries, is todays leading need due to rapid population growth and thus directly linked with advancements in economics. High economic gains has its beneficial as well as adverse effects. Industrial progress has intensified pollution problems worldwide. Land, air and water pollution is building up due to inefficient execution of environmental laws. One of the major concerns is water pollution caused by effluents from various industries. The present paper is an extension of the original work that presented the removal of Copper ions (Cu^{2+}) from industrial waste waters by TAC [1].

Economic booms have lifted up many people from agonizing poverty through industrialization. However, this has resulted in serious environmental degradation (China Water Quality Management Policy and Institutional Considerations, World Bank, 2006). Industries use tones of water for various processes and also release large quantities of waste water (loaded with spent chemicals and metallic residues) in the nearby lakes, rivers and canals without suitable treatment. Many areas of the world have now lost access to safe drinking water. It is estimated that 2000 children under the age of five die daily. 90 % of such deaths are linked with diarrheal diseases due to intake of contaminated water and improper sanitation and hygiene conditions. A press release by UNICEF (New York, 22 March 2013) states that 783 million people do not have access to safe drinking water (comprising of China on the top with 119 million, then India, Nigeria and lastly Pakistan at the bottom with 15 million).

Release of chemicals in aquatic environment brings changes in the structure and functional properties of water species [2] and sometimes results in their total extinction. A major concern of today are the heavy metals which are toxic above certain concentration [3-4] and henceforth, a potential threat for the consumers. Severe ecological problems are arising due to the contamination of surface and ground water. Some plant species

are able to withstand low concentrations of certain metals but generally face eradication at high levels [5]. Mostly heavy metals are carcinogenic and get incorporated in the food chain. Biomagnification and bioaccumulation [6] of heavy metals in the living beings has further aggravated the situation.

Chromium metal possesses three stable valence states i.e., 0, +3 and +6. Dietary Cr^{3+} is an essential trace mineral requirement of human body for the control of glucose metabolism by insulin [7]. is proved to be a potential carcinogen [8-9]. In [10]-[11], the authors have reported that even Cr^{3+}, when taken as supplement, can accumulate in tissues and can bring about structural changes in DNA. A major release of Cr^{3+} is through tanneries and cooling water systems, and from refractory, chemical and metallurgical industrial operations. Cr^{3+} incorporation into the ecosystem and delivery to humans via e.g., vegetables [12] and seepage to the ground water has adversely affected human lives. It is therefore, immensely important to address this pertinent issue which needs strict implementation of Cr^{3+} removal systems from waste waters.

Several methods for the removal harmful ions in water are effective e.g., chemical precipitation, electrolysis, membrane technology, ion exchange etc. and are in common practice by the industries. Adsorption of ions onto a suitable adsorbent is a low cost, effective and easy method for the separation of undesired chemicals. Adsorption [13-14] i.e., physiosoprtion or chemisorption can adequately remove matter in solid, gas or liquid form. Several waste materials are reported to be good adsorbents [15-16]. Activated carbon is especially favored due to its inert nature [17-18]. In this study, activated carbon derived from scrap rubber tyres is used as an adsorbent for the removal of Cr^{3+} from aqueous solutions. The major aim was to test the performance of TAC as the function of adsorbent dose, Cr^{3+} concentration in solution, pH and the contact time. This will be a cost-effective utilization of non-degradable scrap rubber tyres for water purification.

2. Materials and Methods

2.1. Preparation of Activated Carbon from Scrap Rubber Tyre

Scrap rubber tyres were collected from disposal sites. These were cut into small pieces, washed several times with distilled water and dried. Pieces were then crushed and grinded in mortar and pestle. 600gms of the ground rubber tyres was taken in a round bottomed flask fitted with a water condenser. Dry distillated of tyres was done at 450 °C. Three main fractions were obtained i.e., chars, oils plus water mixture and obnoxious gases. The residue chars were heated in a muffle furnace at 800-900 °C for 30 seconds and cooled to room temperature in desiccators. It was then soaked in 5% $BaCl_2$ solution for 12 hours for chemical activation and then filtered. The carbon was firstly washed with HCl (0.4 N) and then several times with distilled water to remove the oxides and soluble impurities. The final residue sample was dried in an oven overnight at 105°C. The dried TAC was sieved and 200 mesh size was selected for Cr^{3+} removal studies.

2.2. Confirmatory Test for the adsorption capacity of TAC.

The efficiency of TAC was tested by Methylene Blue test. 0.2gm of TAC was immersed in 10ml of 1% Methylene blue solution in a 50ml beaker. Same test was performed with commercially available Merck activated carbon for comparison. The absorbance was measured at λ_{max} of 660nm.

The adsorption capacity. AC (%) of TAC was calculated using following relationship:

$$AC\ (\%) = \frac{Ci - Ct}{Ci} x\ 100$$

Where

$Cí$ = initial concentration of the simulated solution

Ct = The concentration of solution after treatment.

The adsorption capacity (or the removal of Cr^{3+} - %) of TAC was checked on Varian spectrophotometer using an acetylene-air flame and lamp current of 7 mA for Cr^{3+} determination.

2.3. Preparation of Chromium(III) solutions

Chromium sulphate ($Cr_2(SO_4)_3.12H_2O$) salt was dried in an oven overnight at 50 °C. Stock solution of 1000 ppm was prepared by dissolving 7.70 gms of salt in de-ionized in a measuring flask of 1L. Further dilutions of 50 ppm, 100 ppm & 200 ppm solutions were made from stock solution.

The following tests were performed to check the adsorption capacity of the prepared TAC.

2.4. Effect of TAC dosage on adsorption of chromium (III) ions

Five volumetric flasks of 50 ml capacity were taken. 25 ml of 200 ppm solution of Cr^{+3} ions was poured in each flask. 0.1 gm, 0.2 gm, 0.3 gm, 0.4 gm and 0.5 gm of TAC was added. The solutions were stirred for 3 hours on magnetic stirrer at 600 rpm and then filtered. The concentration of Cr^{3+} left in solution after adsorption tests was checked by Atomic absorption spectrophotometry (AAS).

2.5. Effect of chromium (III) ions concentration on adsorption by the TAC

25 ml of 10 ppm, 50 ppm, 100 ppm, 150 ppm and 200 ppm Cr^{3+} solutions were taken in five measuring flasks. 0.1 gm of TAC was added. The solutions were stirred for 3 hrs on magnetic stirrer at 600 rpm and then filtered. The amount of Cr^{3+} remaining in solution in each flask was measured by AAS.

2.6. Effect of contact time on the adsorption capacity of TAC

25 ml of Cr^{3+} solution (200 ppm) was taken in five separate 50 ml volumetric flasks (x5). TAC (0.1 gm) was added to each flask and the solutions were stirred for different time intervals i.e., 1, 2, 3, 4 and 5 hours on magnetic stirrer at 600 rpm. Cr^{3+} remaining in solution after each time interval was checked by AAS.

2.7. Effect of solution pH on the adsorption capacity of TAC.

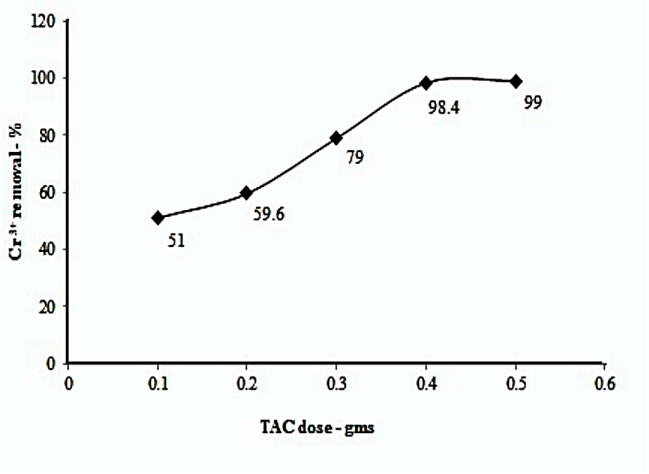
Cr^{3+} solutions (25 ml) were taken in four separate 50 ml volumetric flasks. The pH of solutions was maintained at pH 4, pH 5, pH 7 and pH 10. TAC (0.1gm) was added to each flask and the solutions were stirred for 3 hours at 600 rpm. After the adsorption test each solution was filtered and the Cr^{3+} concentration was checked by AAS.

3. Results & Discussion

Water pollution by the industries have risen to colossal disasters in many parts of the world. The developing countries are facing tremendous ill health effects due to water contamination especially by heavy metals [19-20]. Many living species are eradicated leaving environmental issues that need remediation. This has led the scientists to find new methods and materials for survival of living beings. Adsorption of harmful chemicals and heavy metals is a cheap method for the removal of contaminants. In recent years, several adsorbents and particularly bio adsorbents [21-23] have been investigated to combat pollution arising as a consequence of anthropogenic activities. Rubber tyres are non-biodegradable. These have no use except illegally burned to produce obnoxious fumes or dumped in tones at waste sites. We have made use of waste rubber tyres and converted it to activated carbon for the reclamation of waste water.

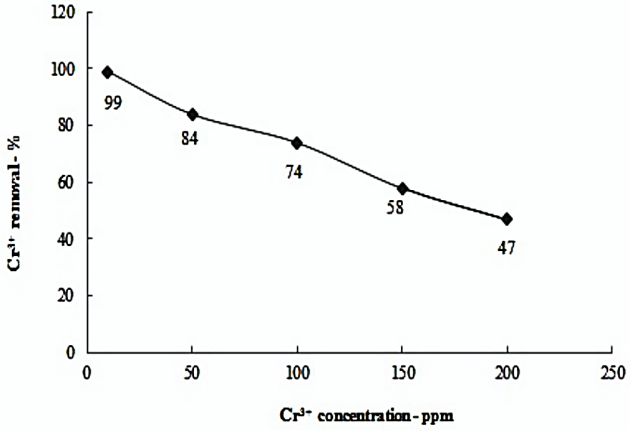
The efficiency or the adsorption capacity of the prepared TAC was checked by the Methylene blue test and compared with commercial Merck Activated Carbon (powdered) at λ_{max} of 660 nm. The blank solution showed an absorbance of 2.707. The dye absorbance test showed that TAC had absorbance of 0.053 and the commercial Merck Activated Carbon had absorbance of 0.035. Thus, our prepared TAC showed good absorbance capacity for the dye.

It is envisaged that as the amount of adsorbent is increased, the removal of metal ions should also increase systematically. TAC required to effectively adsorb Cr^{3+} was checked by varying TAC dose for 200 ppm concentration. The results are presented in Figure 1.



The adsorption percentage of Cr^{3+} (200 ppm) increases with the amount of adsorbent dose. Maximum adsorption of 99 % was observed with 0.5 gm TAC of 200 mesh size at pH 6.5 (nearly neutral) after a contact period of 3 hours held at a stirring speed of 600 rpm. This important parameter has been studied by several researchers before [24-25]. In our earlier work [1], TAC proved to be an effective adsorbent for the removal of Copper (II) ions from industrial waste water. Sharma and Goyal [26] have found strong effect of adsorbent dose on removal of Cr^{3+} from tannery effluents at pH-4 by Aspergillus sp biomass. Recently, Jamil et al [27] have reported similar dose effect of Pakistani coal derived activated carbon on removal of Cr^{3+} from simulated solutions. The exchangeable sites for the metal ion adsorption increase with the increase in TAC dose and hence, the water is cleaned from the contaminant ions. The distribution coefficient for the TAC dose tests varies in the range of 10.4 to 198. The Gibbs free energy (ΔG)changes from -5.8 KJ/mole through -13.4 KJ/mole telling that Cr^{3+} removal by adsorption is a favorable process. We selected TAC (mesh-200) dose of 0.1gms and Cr^{3+} concentration of 200 ppm for further experimentation so that variations can be studied more thoroughly.

The effect of initial metal ion concentration is shown in Figure 2.



The removal of metal ions from aqueous solutions by adsorption is highly dependent on the initial metal ion concentration in solution [28-29]. The adsorption efficiency of adsorbents is applicable in a specific range of concentrations as the active site may be filled above certain concentrations. Figure 2 shows that the adsorption decreased when the concentration of the metal ions increased. Maximum adsorption of 99% was observed at low concentration of Cr^{3+} ions i.e., 10 ppm and linearly declined as the initial Cr^{3+} concentration increased. Adsorption reduced to 47% with 0.1gms of TAC at 6.2 pH at contact time of 3 hours. TAC amount is the limiting factor. The exchangeable sites with a low dose amount of 0.1gms became saturated with Cr^{3+} ions at 10 ppm concentration. The site coverage is reached and equilibrium is established. At higher initial concentrations of Cr^{3+} ions, the adsorption percentage decreases due to low availability of active sites. We observed the surface charge interaction phenomenon in absence of diffusion.

The contact time of adsorbent with the metal ion solution is an important factor that effects the adsorption capacity [30, 31]. Cr^{3+} absorption by 0.1 gm TAC dose as the function contact time is shown in Figure 3.

The results show that as the contact time of TAC with Cr^{3+} solution is increased, the removal of Cr^{3+} also increases. Under constant stirring conditions, maximum adsorption of Cr^{3+} (50%) was observed in 3 hours. After 3 hours, no significant change in Cr^{3+} removal is observed. Thus, 3 hours was found sufficient for achieving equilibrium.

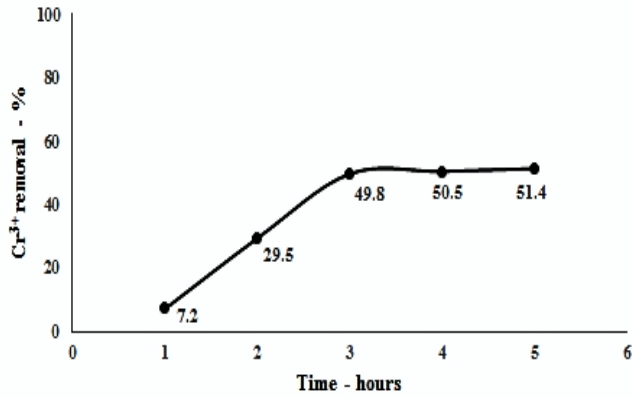


Figure.3. Effect of contact time on Cr (III) adsorption (initial Cr^{3+} concentration: 200 ppm, TAC dose: 0.1g, pH - 6, stirring speed: 600rpm)

The effect of pH on adsorption process is presented in Figure 4.

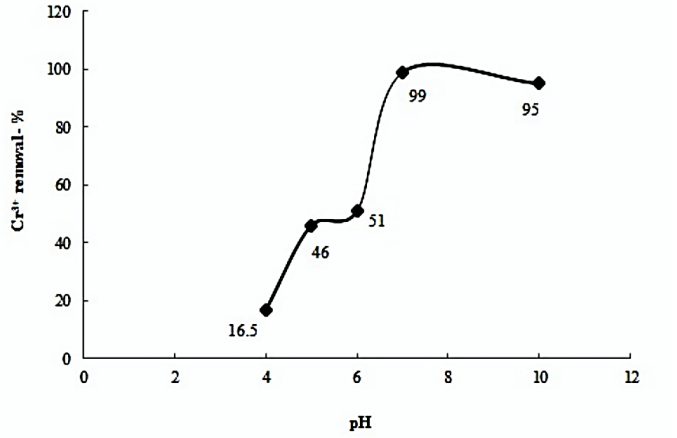

Figure.4. Effect of solution pH on Cr (III) adsorption (initial Cr^{3+} concentration 200ppm, contact time: 3 hours, activated carbon dose: 0.1g, stirring speed: 600rpm)

The removal of metal ions i.e., the absorptive capacity of adsorbents is dependent upon optimal pH level of the metal ions solution (32-33). In acidic medium (pH-4), Cr^{3+} is present as mononuclear hydrated ion. Figure 3 shows that the adsorption efficiency of TAC for Cr^{3+} is very low i.e., only 16.5%. At acidic pH, the hydronium (H^+) ions affiliation to the adsorbents surface is responsible for TACs' poor adsorption efficiency. The adsorption efficiency of TAC for Cr^{3+} increases with an increase in pH till pH-5 to 46 %. Deprotonation of metal binding sites on TAC also occurs when the solution pH increases. The Cr^{3+} ions are attracted to the vacant sites and hence, higher adsorption is observed. Decrease in positive charge at TAC removes repulsion and hence, improves the attraction of Cr^{3+} ions for active adsorption. Lyubchik et al. [34] have identified carboxylic groups on surface of activated carbons for enhancement in removal of Cr^{3+} at initial solution pH between 2 till 4. Weak change in adsorption occurs between pH 5 through pH 6. At this pH, Cr^{3+} precipitates as hydrated $Cr(OH)_3$. As the pH rises, solubility of chromium (III) increases. Apparently, adsorption of the Cr^{3+} ions is maximum at pH 7 i.e., 99% which is close to 95% adsorption at pH -10. At alkaline pH, adsorption efficiency is disturbed due to the precipitation of Cr^{3+} as tetra hydroxochromate(III) complexes, $Cr(OH)_4^-$ [35]. Cu^{2+} [1] go into hydroxide formation at high pH. Precipitation is not as effective as adsorption as the separation of precipitates from water is cumbersome. The adsorption efficiency may increase at acidic pH with that activated carbon which has negatively charged surface. Dai, Ren and Tao [36] used solution pH for distinction between Cr (VI) and Cr^{3+} adsorption on chemically modified Chitosan. The adsorption efficiency of Cr(VI) was maximum i.e., 97% at pH 4.0, whereas the adsorption efficiency of Cr(III) was 5%. We have also observed very weak adsorption of Cr^{3+} ions i.e., 16.5 % at pH-4.

4. Conclusions

TAC is an effective low cost adsorbent for the removal of Cr^{3+} and Cu^{2+}ions. It offers treatment of impaired water at reduced energy and time consumption. The inert nature of TAC secures its reliability versus biomaterials which degrade over long time exposures. TAC almost completely removes Cr^{3+} ions from solutions when the metal ions are present in low concentration at pH 5.5. In higher alkaline medium, tetra hydroxo-Cr(III) complexes formation increases.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors are indebted to thank Prof. Dr. P.H. Armacost, Rector, Forman Christian College – A chartered University, Lahore, Pakistan for providing the necessary laboratory facilities and Mr. Rashid Masih, Laboratory Supervisor, Department of Chemistry, Forman Christian College – A chartered University, Lahore, Pakistan, for his constant help in doing the atomic absorption work.

ABSTRACT

Aging is a natural process that progressively introduces limitations in a person's life, which can have dramatic effects on the person's lifestyle and wellbeing and in most cases is related to the strength of the person's social bonds with the family and friends group. Therefore, it is important to maintain these bonds in the various stages of life, especially in the later life, when the individual has health limitations and may be living in a care centre. In this work, we developed an exploratory approach to the usage of ICT systems in order to autonomy assist the elderly in maintaining their social connections and relationships with family and friends. It doesn't substitutes the human care, but it should assist and encourage the elderly to preserve and develop their social activities and the relationships with their family and friends social group. We propose the design of a software system, capable of running in autonomous devices, such as, robots and other consumer appliances, enabling them to recognize and interact with the users, according to their state of mind and the specific current moment context. The interactions should be simple and focused on keeping the users engaged and informed about the current life events of their family and friends, and create the opportunities for the users to interact with the participants of those events by creating interaction proposals. On a technical level, the system should have knowledge about the user and be able to acquire and update context information from social media, video cameras, email, etc, regarding the user and the persons from his family and friends groups, in order to develop meaningful interactions with the user. An adaptive user interface would present and manage the interactions, acting as a mediator between the user and his family and friends group.

1. Introduction

This paper is an extension of a work originally presented in the 2017 International Conference on Technology and Innovation on Sports, Health and Wellbeing [1].

In Portugal, it was estimated that by 2016 there should be a ratio of three elderly people per youth and an average longevity of 81 years. In the last 2011 Census, this trend was confirmed, with a percentage of 19% of the population at or over 65 years old [2]. This increase longevity is a trend of the modern societies, from the second half of the twentieth century, which are facing a substantial growth of the aging population, conducting to new and relevant economic, social and political challenges

One of these challenges regards the sustainability of the health and social security systems, which have to deal with old and dependent people, living alone. In fact, about 60% of the elderlies is living alone or in the exclusive company of other, also elderly people. The elderly dependency ratio has been increasing gradually and, in 2012, it was at 28.8%, which corresponds to more than a quarter of the active population, and positions the elderly people in a category of individuals associated with isolation, loneliness, disease, poverty and even social exclusion [3][4].

In this context, the older people group is a social and economic vulnerable group, suffering from losses at the psychic and physical levels, which inevitably introduces modifications on their social relations and increases the risk of isolation and loneliness. On this regard, the World Assembly on Ageing under the theme "Society for all ages" refers to the importance of the full realization of the right of all people to enjoy the maximum physical and mental health [5].

To address these modifications and changes that occur in the family and in the individual's social interaction patterns, it is necessary to research alternative solutions for new models of

[*]Corresponding Author: Arsénio Reis, INESC TEC and Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal | Email: ars@utad.pt

aging, in which the individual retains emotional, physical, mental and social stability. This approach requires a new strategy for healthy aging, promoting intergenerational cooperation, community cohesion and social inclusion. During the aging process, the elderly individuals should maintain healthy social relationships in order to minimize psychological decline, which is particularly serious in age related institutionalized persons [6]. Becoming elder shouldn't introduce major changes in the individual's social role, otherwise, there will be great difficulties and the person, will struggle to adapt to the changes. Instead, the person should be active and engaged in stimulating activities [7].

Aging and the evolutions of the elderly's social roles is setting the tone for the development of specific devices and services that will support the user in the later phases of the aging process, particularly in regard to quality of life, maintaining social and family interactions, reducing the risk of loneliness and loss of social status in institutionalized elderly. Without detracting from the importance of the care, as provided by professionals and the value of humanized personal relationships, there is the need for additional aid, and the solutions based on social robotics are becoming a specialized technological branch, which can support the interactive dimension of the care process [8] [9]..

2. Assisting social activity

The process of an individual becoming older or aging encompassed physical, psychological and social changes. It is one of the highest risk factors known for most human diseases and it will introduce limitations to the individual life style [10]. The reduction in physical and social activity will rise these risk factors and degrades the aging process, causing or increasing suffering to the individual and to his family and friends [11]. Most times, the individual well-being is related to the strength of the social bonds with the family and friends group, so it is important to keep this bonds in the various stages of life, especially in the later life, when the individual has health limitations and is living in a community centre [12].

In a study regarding the older people active aging perception, the authors found that the most common perception were related to: maintaining physical health and functioning (43%), leisure and social activities (34%), mental functioning and activity (18%) and social relationships and contacts (15%) [13]. This study reveals that the maintenance of the social and mental activity accounts for the 57% of the perceive aging and is an important issue regarding successful aging and the Later Life or eight stage of life [14].

On another recent study, conducted on several Portuguese care centers, the users (elderlies) were interviewed regarding their motivation to use information and communication technologies (ICT), including artificial intelligent personal assistants as companions and assistive mediators. It was concluded that in this group, elderly people living in a care center, there is a strong will and open mind to try to use new technologies and new forms of interaction. In fact, this population is composed mostly by old people (more than 70 years old), suffering from some type of chronic disease and loneliness related problems (95%). The health issues also manifest as disabilities (75%), mostly causing mobility problems (53%) and sight problems (40%). The adoption of social robots or assistants would be welcome as well as other assistive technologies [15]. These conclusions were surprising, in the sense that the literature suggests that the usage of ICT by older adults is complex and extends beyond the dichotomy between 'successful users' and 'unsuccessful non-users' [16]. On closer look, the successful adoption of ICT solutions by older people is related to attitudes, experience of use, and perceived benefits [17], with many studies emphasizing the potential benefits of the use of ICT for elderly people, particularly by allowing them to stay connected to what is happening around them and to interact with others [18][19][20]. This interaction possibility is particularly important, if not dramatic, for people living in a care centre, which might explain the motivation to use ICT solutions.

The Ambient Assisted Living embraces the concept of helping senior citizens to improve their quality of life and expand their participation in the community by using systems to overcome their special needs, based on ubiquitous sensing, individual-environment interaction, context awareness, and learning information systems [15]. The European overview report of Ambient Assisted Living (AAL) researches this concept and aims to find out an efficient solution to help these elderly people independently living [21]. The usage of ICT has been researched as a tool to support the therapeutic process, in which the main actors are the physicians [22]. The usage by the patients themselves is a new approach and requires the patient ability to properly use a system [23].

3. Autonomous assistance in social activities

This prospective proposal has the objective of design and implement a system to monitor and support users with age related limitations, in order to promote their daily well-being. Most times, these users are living in an institution and have health limitations affecting their social activity. They also have limitations on using modern information and communication based equipment. This systems aims to overcome those limitations by promoting and reinforcing the bonds between the user and the elements of his family and friends group, with the usage of information and communication technologies.

The software system should enable autonomous equipment to recognize and interact with the users, according to their state of mind and the specific momentary context. The main features should provide the ability to identify the users and have a set of interactions to inform the users about the everyday life of their family and friends group. It should promote interactions with them in order to mitigate the tendency for social isolation and its negative consequences.

Due to the user's limitations, the system's user interface should be designed by following the adaptive interfaces paradigm [24], in accordance with the user profile and the context. It should use simple interactions, based on natural language [25], in order to be user friendly to the expected age group.

The system is meant to be installed in autonomous equipment, such as autonomous robots or consumer appliances, and should be tested in elderly care institutions, such as social support centres, where users are admitted as residents. Specific testing plans should be designed as intervention plans suited to test the equipment and the software in order to evaluate their suitability and feedback the system development project [26].

This assistive system should forge a new type of relationship with the users by maximizing their social activity and maintenance of the relationship with their family and friends social group, which is often degraded due to the user's limitations and institutionalization.

4. Methods

The teams working on the system development should have two distinct backgrounds: software engineering; and health care. The work should be done in short, interactive, cycles, in which the healthcare team should validate the requirements; verify the usability of the developed features; and test the features with real users. The software engineering team should develop the system using the state of the art technologies, following a user centric development method in order to meet all the usage requirements, related to the user's limitations [27][28][29][30].

The development and implementation of this system should have two main phases. A first phase, focused on software development and a second phase, focused on the field tests

In the first phase it should be designed and developed the system software, with the necessary features in order to accomplish the main objectives. The main areas of software development will be related to:

- Image acquisition and analysis, for the users identification and state of mind recognition;
- Application design with databases and social media APIs, for the development of the user activities;
- Natural langue and adaptive user interfaces, for the development of the system's user interface;
- Remote equipment management, for the planning and execution of the equipment deployment during the field tests.

The software development should be executed using agile methods in an incremental process. In this phase, the healthcare professionals should be part of the team in order to create the requirements and specifications as well as to monitor the development results.

On a second phase, the focus should be on the field tests and the monitoring of the system usage by the real users. Some development will still be necessary in order to adjust and develop some features, according to the users monitoring feedback. In this phase, a strong effort should be done to monitor the users in different usage contexts.

The autonomous equipment should be adapted for usage in the testing institutions, including the necessary adjustments for the remote management of the equipment.

5. Requirements and features

The system should provide a set of basic functionalities, features or requirements, related to the interaction with the users, namely: user identification; state of mind assessment; current context; personal information retrieval; a set of activity proposals.

The user identification and state of mind evaluation will be based on image acquisition and analysis, after which the system should retrieve the user profile and decide on an activity proposal. The activity proposal could be as simple as a personalized greeting or a more complex interaction, according to the current context and the user state of mind.

The context, personal information and state of mind, should include information about: gender, age, special needs, personal preferences, time of day, time of year, physical location, state of mind (sadness, joy, etc.), etc.

The interactions with the user should be developed as a set of activities that can be proposed and executed with the user. Figure 1 and Figure 2 have sequence diagrams illustrating two interactions. Some activities to be developed are: (1) Basic greeting; (2) Email management; (3) Social Network management; (4) Social and family events management; and (5) Social games.

- The basic greeting activity is a simple greeting interaction, in which the system greets the user according to the state of mind and context of the moment.
- The email management activity should provide a personal email box to each user and inform the user about the current messages status. In particular dates, such as family anniversaries, the system should offer the user a chance to send a congratulations message.
- The social media management is a more sophisticated activity in which the system monitors the user group of family and friends, regarding their activity in the social networks, e.g., facebook, twitter, Instagram, etc., and informs the user about relevant updates.
- The social games activity has the objective of adapt and create a set of social games, e.g., cards, trivia, etc., that the user can play in the system.

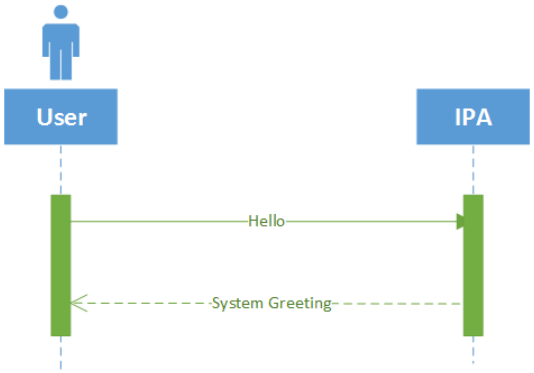

Figure 1 - Sequence diagram of basic greeting activity

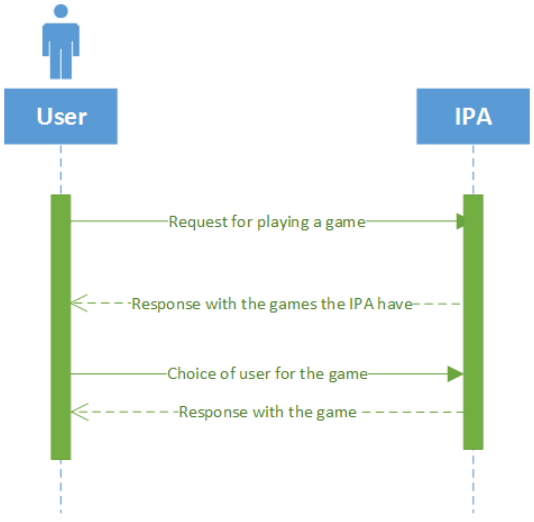

Figure 2 - Sequence diagram for social game activity.

The email and social media management are specially targeted to strengthen the user bonds with the elements of his family and friends. The user should be kept up to date with the course of lives of his friends and family and the systems should provide

opportunities for the user to interact with those person on the social media networks. In Figure 3, it is described the basic workflow of an interaction with a user. As previously described, the system engages with the user and based on the available data about the user and the current context, it proposes an activity in order to forward an interaction.

The set of features should be extensively tested with real users in order to evaluate their tangible contribution to the main objective and their usability, considering the user interface and the user's limitations. So, a series of interventions plans should be created in order to test the system and the equipment in several real scenarios, together with partner institutions. For each intervention, a specific plan should be created, considering the specific conditions such as: the user's characteristics; the context of the hosting institution; the technical resources available.

6. The current consumer electronic assistants

Currently there are on the market several electronic assistants, e.g., Amazon Alexa, Google Assistant, Apple Siri, Microsoft Cortana, that are able to assist the user in some daily tasks. Some of this companies also provide hardware appliances uniquely designed to house their assistant software. In TABLE I are summarized the main features of this assistants.

Table I – Electronic assistants main features

Interactions	Google Assistant	Amazon Alexa	Apple Siri	Microsoft Cortana
Create a shopping list	yes	yes	no	no
Check Calendar	yes	yes	yes	yes
Manage Calendar	no	yes	yes	yes
Check date and time	yes	yes	yes	yes
Set an Alarm	yes	yes	yes	yes
Check Weather	yes	yes	yes	yes
Check Traffic	yes	yes	yes	yes
Play news	yes	yes	no	no
Play music	yes	yes	yes	yes
Search Online	yes	yes	yes	yes
Perform Calculations	yes	yes	yes	yes
Call a Uber	no	yes	yes	no
Control home temperature and lights	yes	yes	yes	no
Lock/Unlock Doors	no	no	yes	no
Play games	yes	yes	yes	yes
Make a call	yes	yes	yes	yes
Read books	no	yes	no	no
Shopping on amazon	no	yes	no	no
Order pizza	no	yes	yes	yes
Manage SMS	yes	yes	yes	yes
Read emails	no	no	yes	yes
Send emails	no	no	yes	no
Send posts in Facebook	yes	yes	yes	no
Send posts in Twitter	yes	yes	yes	
Receive Facebook notifications	no	no	no	no
Receive Twitter notifications	no	no	no	no

It is a very promising set of interactions, but on some preliminary tests we concluded that there is a gap between what the assistants can do and what they effectively do when confronted with a user expecting to execute an interaction. We cannot categorically state that the assistants can't execute the actions, but effectively it would be very difficult for an elderly to use them in order to maintain some sort of social interaction with their friends and families. The preliminary testing suggest that these assistants lack the empathy and common sense engagement necessary to interact with an elderly. In future work we expect to measure the quality of the interaction and assess the effectiveness of the interaction.

7. Conclusion

In Figure 3 it is presented the general system workflow, regarding an autonomous user interaction. Although it is a simple workflow, the strict software implementation depends of a diverse set of concepts and technologies. The field tests and implementation, with real users in real institutions, are a main care endeavour and its constant feedback is determinant to the success of the system development.

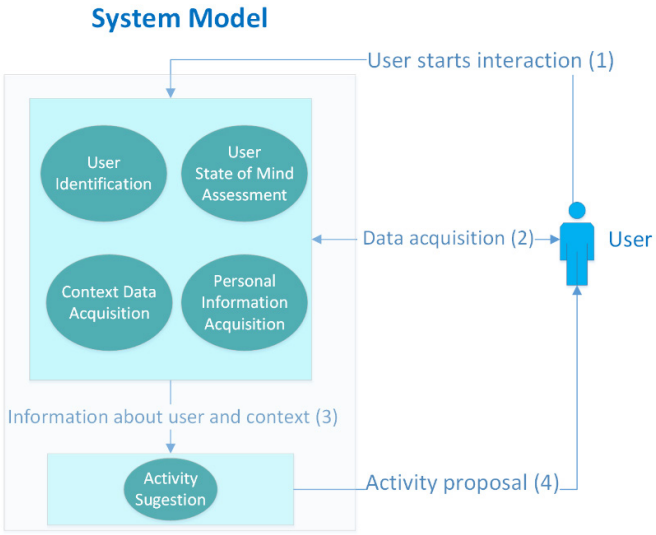

Figure 3 – System workflow

The success of this proposal is dependent of two main fiends of study: software engineering and elderly care. In such a sensible context, of elderly users with age related limitations, the subtle details of the system, in particular the user interface usability, are paramount and an excellent multidisciplinary team management is necessary. In TABLE I is summarized the features and the related research areas that the software system combines.

Table II - Features and research areas

Features	Research areas
User identification	Image processing (face recognition)
State of mind assessment	Image processing (emotion detection)
Context acquisition	On-line services APIs Localization services Image proecessing (Object detection and recognition)
Data retrieval	Databases
Social media related activities	Social media APIs
Social games	Gaming and Serious games
Natural language user interface	Adaptive interfaces Natural language

The success of the features implementation must be assured by a user centric development with the continuous participation of the health care team elements. They should also act on behalf of the users in order to assure a user participated development.

This system proposal is intended for usage with autonomous systems such as robot devices, but it can be adapted and incorporated in other user appliances, such as settop tv boxes or even mobile phones. We didn't refer to a system architecture, but in a real system, with an extensive catalogue of user interactions and activities proposals, it should be considered the usage of a cloud backend implementation and a user device front end.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

To perform an exploration process over complex structured data within unsupervised settings, the so-called kernel spectral clustering (KSC) is one of the most recommended and appealing approaches, given its versatility and elegant formulation. In this work, we explore the relationship between (KSC) and other well-known approaches, namely normalized cut clustering and kernel k-means. To do so, we first deduce a generic KSC model from a primal-dual formulation based on least-squares support-vector machines (LS-SVM). For experiments, KSC as well as other consider methods are assessed on image segmentation tasks to prove their usability.

1 Introduction

In general, for classifying or grouping a set of objects (represented as data points) into subsets holding similar objects, the field of machine learning - specifically, the pattern recognition- provides two great alternatives being essentially different from each other: Supervised- and Unsupervised-learning-based approaches. The former ones normally establish a model from beforehand known information on data normally provided by an expert, while the latter ones form the groups by following a natural clustering criterion based on a (traditionally heuristic) procedure of data exploration [1]. Therefore, unsupervised clustering techniques are preferred when object labelling is either unavailable or unfeasible. In literature, we can find tens of clustering techniques, which are based on different principles and criteria (such as: distances, densities, data topology, and divergences, among others) [2]. Some remarkable, emerging applications are inbalanced data analysis [3] and time-varying data analysis [4]. Particularly, spectral clustering (SC) is a suitable technique to deal with grouping problems involving hardly separable clusters. Many SC approaches have been proposed, among them: Normalized-cut-based clustering (NCC), which, applied as explained in [5], heuristically and iteratively estimates binary cluster indicators [5] or approximates the solution in a one-iteration fashion by solving a quadratic programming problem [6]. Kernel k-means (KKM) that can be formulated using eigenvectors [7]. Kernel spectral clustering (KSC), which uses a latent variable model and a least-squares-support-vector-machine (LS-SVM) formulation [8]. This work has a particular focus on KSC, being one of the most modern approaches. It has been widely used in numerous applications such as time-varying data [9,10], electricity load forecasting [11], prediction of industrial machine maintenance [12], and among others. Also, some improvements and extensions have been proposed [12–14].

The aim of this work is to demonstrate the relationship between KSC and other approaches, namely NCC and KKM. To do so, elegant mathematical developments are performed. Starting from either the primal or dual formulation of KSC, we show clearly the links with the other considered methods. Experimentally, in order to assess the clustering performance, we explore the benefit of each considered method on image segmentation. In this connection, images extracted from the free access Berkeley Segmentation Data Set [15] are used. As a meaningful result of this work, Also, we provide mathematical and experimental evidence of the usability of combining together a LS-SVM formulation and a generic latent variable model for clustering purposes.

The rest of this paper is organized as follows: Section 2 outlines the primal-dual formulation for KSC starting with a LS-SVM formulation regarding a variable model, which naturally yields an eigenvector-

https://dx.doi.org/10.25046/aj0203208

based solution. Sections 3 and 4 explore and discusses on the links of KSC with NCC and KKM, respectively. Some experimental results are shown in Section 5. Section 6 presents some additional remarks on improved versions of KSC and its relationship with spectral dimensionality reduction. Finally, section 7 draws some final and concluding remarks.

2 Kernel Spectral clustering

Accounting for notation and future statements, let us consider the following definitions: Define a set of N objects or samples represented by d-dimensional feature vectors. Likewise, consider a data matrix holding all the feature vectors, so that $\mathbf{X} \in \mathbb{R}^{N\times d}$: $\mathbf{X} = [\mathbf{x}_1^\top, \ldots, \mathbf{x}_N^\top]^\top$, where $\mathbf{x}_i \in \mathbb{R}^d$ is the i-th d dimensional feature vector or data point. KSC is aiming to split $\mathbf{X}$ into K disjoint subsets, being K the number of desired groups.

2.1 Latent variable model and problem formulation

In the following, the clustering model is described. Let $\mathbf{e}^{(l)} \in \mathbb{R}^N$ be the l-th projection vector, which is assumed in the following latent variable form:

$$\mathbf{e}^{(l)} = \boldsymbol{\Phi}\mathbf{w}^{(l)} + b_l \mathbf{1}_N, \tag{1}$$

where $\mathbf{w}^{(l)} \in \mathbb{R}^{d_h}$ is the l-th weighting vector, b_l is a bias term, n_e is the number of considered latent variables, notation $\mathbf{1}_N$ stands for a N dimensional all-ones vector, and the matrix $\boldsymbol{\Phi} = [\phi(\mathbf{x}_1)^\top, \ldots, \phi(\mathbf{x}_N)^\top]^\top$, $\boldsymbol{\Phi} \in \mathbb{R}^{N\times d_h}$, is a high dimensional representation of data. The function $\phi(\cdot)$ maps data from the original dimension to a higher one d_h, i.e., $\phi(\cdot) : \mathbb{R}^d \to \mathbb{R}^{d_h}$. Therefore, $\mathbf{e}^{(l)}$ represents the latent variables from a set of n_e binary cluster indicators obtained with $\text{sign}(\mathbf{e}^{(l)})$, which are to be further encoded to obtain the K resultant groups.

From the least-squares SVM formulation of equation (1), the following optimization problem can be stated:

$$\max_{\mathbf{e}^{(l)},\mathbf{w}^{(l)},\mathbf{b}^{(l)}} \frac{1}{2N}\sum_{l=1}^{n_e} \gamma_l \mathbf{e}^{(l)\top}\mathbf{V}\mathbf{e}^{(l)} - \frac{1}{2}\sum_{l=1}^{n_e} \mathbf{w}^{(l)\top}\mathbf{w}^{(l)} \tag{2a}$$

$$\text{s.t. } \mathbf{e}^{(l)} = \boldsymbol{\Phi}^\top \mathbf{w}^{(l)} + b_l \mathbf{1}_N, \tag{2b}$$

where $\gamma_l \in \mathbb{R}^+$ is the l-th regularization parameter and $\mathbf{V} \in \mathbb{R}^{N\times N}$ is a diagonal matrix representing the weight of projections.

2.2 Matrix problem formulation

For the sake of simplicity, we can express the primal formulation (2) in matrix terms, as follows:

$$\max_{\mathbf{E},\mathbf{W},\mathbf{b}} \quad \frac{1}{2N}\text{tr}(\mathbf{E}^\top\mathbf{V}\mathbf{E}\Gamma) - \frac{1}{2}\text{tr}(\mathbf{W}^\top\mathbf{W}) \tag{3a}$$

$$\text{s.t. } \mathbf{E} = \boldsymbol{\Phi}\mathbf{W} + \mathbf{1}_N \otimes \mathbf{b}^\top, \tag{3b}$$

where $\mathbf{b} = [b_1, \ldots, b_{n_e}]$, $\mathbf{b} \in \mathbb{R}^{n_e}$, $\Gamma = \text{Diag}([\gamma_1, \ldots, \gamma_{n_e}])$, $\mathbf{W} = [\mathbf{w}^{(1)}, \cdots, \mathbf{w}^{(n_e)}]$, $\mathbf{W} \in \mathbb{R}^{d_h\times n_e}$, and $\mathbf{E} = [\mathbf{e}^{(1)}, \cdots, \mathbf{e}^{(n_e)}]$, $\mathbf{E} \in \mathbb{R}^{N\times n_e}$. Notations $\text{tr}(\cdot)$ and $\otimes$ denote the trace and the Kronecker product, respectively. By minimizing the previous cost function, the goals of minimizing the weighting variance of $\mathbf{E}$ and maximizing the variance of $\mathbf{W}$ are reached simultaneously. Let $\Sigma_\mathbf{E}$ be the weighting covariance matrix of $\mathbf{E}$ and $\Sigma_\mathbf{W}$ be the covariance matrix of $\mathbf{W}$. Since matrix $\mathbf{V}$ is diagonal, we have that $\text{tr}((\mathbf{V}^{1/2}\mathbf{E})^\top\mathbf{V}^{1/2}\mathbf{E}) = \text{tr}(\Sigma_\mathbf{E})$. In other words, $\Sigma_\mathbf{E}$ is the covariance matrix of weighted projections, i.e., the projections scaled by square root of matrix $\mathbf{V}$. As well, $\text{tr}(\mathbf{W}^\top\mathbf{W}) = \text{tr}(\Sigma_\mathbf{W})$. Then, KSC can be seen as a kernel, weighted principal component analysis (KWPCA) approach [8].

2.3 Solving KSC by using a dual formulation

To solve the KSC problem, we form the corresponding Lagrangian of the problem from equation (2) as follows:

$$\begin{aligned}\mathcal{L}(\mathbf{E},\mathbf{W},\Gamma,\mathbf{A}) = &\frac{1}{2N}\text{tr}(\Gamma\mathbf{E}^\top\mathbf{V}\mathbf{E}) - \frac{1}{2}\text{tr}(\mathbf{W}^\top\mathbf{W}) \\ &- \text{tr}(\mathbf{A}^\top(\mathbf{E} - \boldsymbol{\Phi}\mathbf{W} - \mathbf{1}_N \otimes \mathbf{b}^\top)),\end{aligned} \tag{4}$$

where matrix $\mathbf{A} \in \mathbb{R}^{N\times n_e}$ holds the Lagrange multiplier vectors $\mathbf{A} = [\alpha^{(1)}, \cdots, \alpha^{(n_e)}]$, and $\alpha^{(l)} \in \mathbb{R}^N$ is the l-th vector of Lagrange multipliers.

Solving the partial derivatives on $\mathcal{L}(\mathbf{E},\mathbf{W},\Gamma,\mathbf{A})$ to determine the Karush-Kuhn-Tucker conditions, we obtain:

$$\begin{aligned}\frac{\partial\mathcal{L}}{\partial\mathbf{E}} = 0 \quad &\Rightarrow \mathbf{E} = N\mathbf{V}^{-1}\mathbf{A}\Gamma^{-1}, \\ \frac{\partial\mathcal{L}}{\partial\mathbf{W}} = 0 \quad &\Rightarrow \mathbf{W} = \boldsymbol{\Phi}^\top\mathbf{A}, \\ \frac{\partial\mathcal{L}}{\partial\mathbf{A}} = 0 \quad &\Rightarrow \mathbf{E} = \boldsymbol{\Phi}\mathbf{W}, \\ \frac{\partial\mathcal{L}}{\partial\mathbf{b}} = 0 \quad &\Rightarrow \mathbf{b}^\top\mathbf{1}_N = 0.\end{aligned}$$

Therefore, by eliminating the primal variables from initial problem (2) and assuming a kernel trick such that $\boldsymbol{\Phi}\boldsymbol{\Phi}^\top = \boldsymbol{\Omega}$, being $\boldsymbol{\Omega} \in \mathbb{R}^{N\times N}$ a given kernel matrix, the following eigenvector-based dual solution is obtained:

$$\mathbf{A}\Lambda = \mathbf{V}(\mathbf{I}_N + (\mathbf{1}_N \otimes \mathbf{b}^\top)(\boldsymbol{\Omega}\Lambda)^{-1})\boldsymbol{\Omega}\mathbf{A}, \tag{5}$$

where $\Lambda = \text{Diag}(\lambda)$, $\Lambda \in \mathbb{R}^{N\times N}$, $\lambda \in \mathbb{R}^N$ is the vector of eigenvalues with $\lambda_l = N/\gamma_l$, $\lambda_l \in \mathbb{R}^+$.

Also, taking into account that the kernel matrix represents the similarity matrix of a graph with K connected components as well as $\mathbf{V} = \mathbf{D}^{-1}$ where $\mathbf{D} \in \mathbb{R}^{N\times N}$ is the degree matrix defined as $\mathbf{D} = \text{Diag}(\boldsymbol{\Omega}\mathbf{1}_N)$; then the $K-1$ eigenvectors contained in $\mathbf{A}$, associated to the largest eigenvalues, are piecewise constant and become indicators of the corresponding connected parts of the graph. Therefore, value n_e is fixed

to be $K-1$ [8]. With the aim of achieving a dual formulation, but satisfying the condition $\mathbf{b}^\top \mathbf{1}_N = 0$ by centering vector $\mathbf{b}$ (i.e. with zero mean), the bias term should be chosen in the form

$$b_l = -1/(\mathbf{1}_N^\top \mathbf{V}\mathbf{1}_N)\mathbf{1}_N^\top \mathbf{V}\boldsymbol{\Omega}\alpha^{(l)}. \quad (6)$$

Thus, the solution of problem of equation (3) is reduced to the following eigenvector-related problem:

$$\mathbf{A}\boldsymbol{\Lambda} = \mathbf{V}\mathbf{H}\boldsymbol{\Omega}\mathbf{A}, \quad (7)$$

where matrix $\mathbf{H} \in \mathbb{R}^{N\times N}$ is the centering matrix that is defined as

$$\mathbf{H} = \mathbf{I}_N - \frac{1}{\mathbf{1}_N^\top \mathbf{V}\mathbf{1}_N}\mathbf{1}_N\mathbf{1}_N^\top, \mathbf{V},$$

where $\mathbf{I}_N$ denotes a N-dimensional identity matrix and, $\boldsymbol{\Omega} = [\Omega_{ij}]$, $\boldsymbol{\Omega} \in \mathbb{R}^{N\times N}$, being $\Omega_{ij} = \mathcal{K}(\mathbf{x}_i, \mathbf{x}_j), i, j \in [N]$. Notation $\mathcal{K}(\cdot,\cdot) : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$ stands for the kernel function. As a result, the set of projections can be calculated as follows:

$$\mathbf{E} = \boldsymbol{\Omega}\mathbf{A} + \mathbf{1}_N \otimes \mathbf{b}^\top. \quad (8)$$

Once projections are calculated, we proceed to carry out the cluster assignment by following an encoding procedure applied on projections. Because each cluster is represented by a single point in the $K-1$-dimensional eigenspace, such that those single points are always in different orthants due also to the KKT conditions, we can encode the eigenvectors considering that two points are in the same cluster if they are in the same orthant in the corresponding eigenspace [8]. Then, a code book can be obtained from the rows of the matrix containing the $K-1$ binarized leading eigenvectors in the columns, by using $\text{sign}(\mathbf{e}^{(l)})$. Then, matrix $\widetilde{\mathbf{E}} = \text{sgn}(\mathbf{E})$ is the code book being each row a codeword.

2.4 Out-of-sample extension

KSC can be extended to out-of-samples analysis without re-clustering the whole data to determine the assignment cluster membership for new testing data [8]. In particular, defining $\mathbf{z} \in \mathbb{R}^{n_e}$ as the projection vector of a testing data point $\mathbf{x}_{\text{test}}$, and by taking into consideration the training clustering model, the testing projections can be computed as:

$$\mathbf{z} = \mathbf{A}^\top \boldsymbol{\Omega}_{\text{test}} + \mathbf{b}, \quad (9)$$

where $\boldsymbol{\Omega}_{\text{test}} \in \mathbb{R}^{n_e}$ is the kernel vector such that

$$\boldsymbol{\Omega}_{\text{test}} = [\Omega_{\text{test}_1}, \ldots, \Omega_{\text{test}_N}]^\top,$$

and $\Omega_{\text{test}_i} = \mathcal{K}(\mathbf{x}_i, \mathbf{x}_{\text{test}})$. Once, the test projection vector $\mathbf{z}$ is computed, a decoding stage is carried out that consists of comparing the binarized projections with respect to the codewords in the code book $\widetilde{\mathbf{E}}$ and assigning cluster membership based on the minimal Hamming distance [8].

2.5 KSC algorithm

Following the pseudo-code (Algorithm 1) to perform KSC is shown.

Algorithm 1 Kernel spectral clustering: $[q_{\text{train}}, q_{\text{test}}] = \text{KSC}(\mathbf{X}, \mathcal{K}(\cdot,\cdot), K)$

1: Input: K, $\mathbf{X}$, $\mathcal{K}(\cdot,\cdot)$
2: Form the kernel matrix $\boldsymbol{\Omega}$ such that $\Omega_{ij} = \mathcal{K}(\mathbf{y}_i, \mathbf{x}_j)$
3: Determine $\mathbf{E}$ through (8)
4: Form the training codebook by binarizing $\widetilde{\mathbf{E}} = \text{sgn}(\mathbf{E})$
5: Assign the output training labels q_{train} according to similar codewords
6: Compute the training codewords for testing
7: Assign the output testing labels q_{test} according to the minimal Hamming distance when comparing with training codewords
8: Output: $q_{\text{train}}, q_{\text{test}}$

3 Links between KSC and NCC

This section deals with the relationship between KSC and NCC, starting from the formulation of the NC problem until reaching a weighting principal component analysis (WPCA) formulation in a finite domain.

3.1 Multi-cluster spectral clustering (MCSC) from two point of view

In [5], the so-called Multi-cluster spectral clustering (MCSC) is introduced, which is based on the well-known k-way normalized cut-based formulation given by:

$$\max \frac{1}{K}\frac{\text{tr}(\mathbf{M}^\top \boldsymbol{\Omega}\mathbf{M})}{\text{tr}(\mathbf{M}^\top \mathbf{D}\mathbf{M})} = \max_{\mathbf{m}^{(k)}} \frac{1}{K}\frac{\sum_{k=1}^K \mathbf{m}^{(k)\top}\widehat{\boldsymbol{\Omega}}\mathbf{m}^{(k)}}{\sum_{k=1}^K \mathbf{m}^\top \mathbf{m}} \quad (10a)$$

$$\text{s.t. } \mathbf{M} \in \{0,1\}^{N\times K}, \quad \mathbf{M}\mathbf{1}_K = \mathbf{1}_N. \quad (10b)$$

Expressions (10a) and (10b) are the formulation of the NC optimization problem, named (*NCPM*). Previous formulation can also be expressed as follows. Let $\widehat{\boldsymbol{\Omega}} = \mathbf{D}^{-1/2}\boldsymbol{\Omega}\mathbf{D}^{-1/2}$ be a normalized kernel matrix and $\mathbf{L} = \mathbf{D}^{1/2}\mathbf{M}$ be a binary matrix normalized by the square root of the kernel degree. Then, a new *NCPM* version can be expressed as:

$$\max_{\mathbf{L}} \frac{1}{K}\frac{\text{tr}(\mathbf{L}^\top \widehat{\boldsymbol{\Omega}}\mathbf{L})}{\text{tr}(\mathbf{L}^\top \mathbf{L})} = \max_{\ell^{(k)}} \frac{1}{K}\frac{\sum_{k=1}^K \ell^{(k)\top}\widehat{\boldsymbol{\Omega}}\ell^{(k)}}{\sum_{k=1}^K \ell^{(k)\top}\ell^{(k)}} \quad (11a)$$

$$\text{s.t. } \mathbf{D}^{-1/2}\mathbf{L} \in \{0,1\}^{N\times K}, \quad \mathbf{D}^{-1/2}\mathbf{L}\mathbf{1}_K = \mathbf{1}_N, \quad (11b)$$

where $\ell^{(k)}$ is the column k of $\mathbf{L}$.

Solution of former problem has been addressed in [5, 16] by introducing a relaxed version, in which numerator is maximized subject to denominator is constant, so

$$\max_{\mathbf{L}} \frac{1}{K}\text{tr}(\mathbf{L}^\top \widehat{\boldsymbol{\Omega}}\mathbf{L}) \qquad \text{s.t. tr}(\mathbf{L}^\top \mathbf{L}) = \text{const.} \quad (12)$$

Indeed, authors assume the particular case $\mathbf{L}^\top\mathbf{L} = \mathbf{I}_K$, i.e. letting $\mathbf{L}$ be an orthonormal matrix. Then, solution correspond to any K-dimensional basis of normalized matrix eigenvectors. Despite that in [16] it is presented an one-iteration solution for *NCPM* with suboptimal results avoiding the calculation of SVD per iteration, the omitting of the effect of denominator $\text{tr}(\mathbf{L}^\top\mathbf{L})$ by assuming orthogonality causes that the solution cannot be guaranteed to be a global optimum. In addition, this kind of formulation provide non-stable solutions due to the heuristic search carried out to determine an optimal rotation matrix [16].

3.2 Solving the problem by a difference: Empirical feature map

Recalling original problem 3.1, we introduce another way to solve the *NCPM* formulation via a minimization problem where the aims for maximizing $\text{tr}(\mathbf{L}^\top\widehat{\mathbf{\Omega}}\mathbf{L})$ and minimizing $\text{tr}(\mathbf{L}^\top\mathbf{L})$ can be accomplished simultaneously, so:

$$\max_{\mathbf{L}} \text{tr}(\mathbf{L}^\top\widehat{\mathbf{\Omega}}\mathbf{L}\,\text{Diag}(\gamma)) - \text{tr}(\mathbf{L}^\top\mathbf{L}) \tag{13}$$

where $\gamma = (\gamma_1,\ldots,\gamma_N)^\top$ is a vector containing the regularization parameters.

Let us assume $\mathbf{\Omega} = \mathbf{\Psi}\mathbf{\Psi}^\top$ where $\mathbf{\Psi}$ is a $N \times N$ dimensional auxiliary matrix, and consider the following equality:

$$\begin{aligned}\text{tr}(\widehat{\mathbf{\Omega}}) &= \text{tr}(\mathbf{D}^{-1/2}\mathbf{\Omega}\mathbf{D}^{-1/2}) = \text{tr}(\mathbf{D}^{-1}\mathbf{\Omega}) \\ &= \text{tr}(\mathbf{D}^{-1}\mathbf{\Psi}\mathbf{\Psi}^\top) = \text{tr}(\mathbf{\Psi}^\top\mathbf{D}^{-1}\mathbf{\Psi}),\end{aligned}$$

then

$$\mathbf{D}^{-1/2}\mathbf{\Omega}\mathbf{D}^{-1/2} = \mathbf{\Psi}^\top\mathbf{D}^{-1}\mathbf{\Psi}.$$

Previous formulation is possible since kernel matrix Ω is symmetric. Now, let us define $\mathbf{h}^{(k)} \in \mathbb{R}^N = \mathbf{\Psi}^\top\ell^{(k)}$ as the k-th projection and $\mathbf{H} = (\mathbf{h}^{(1)},\cdots,\mathbf{h}^{(K)})$ as the projections matrix. Then, formulation given by (13) can be expressed as follows:

$$\max_{\mathbf{h}^{(k)},\ell^{(k)},\gamma_k} \frac{1}{2K}\sum_{k=1}^{K}\gamma_k\mathbf{h}^{(k)\top}\mathbf{V}\mathbf{h}^{(k)} - \frac{1}{2}\sum_{k=1}^{K}\ell^{(k)\top}\ell^{(k)} \tag{14a}$$

$$\text{such that } \mathbf{h}^{(k)} = \mathbf{\Psi}\ell^{(k)}, \tag{14b}$$

where matrix $\mathbf{V} \in \mathbb{R}^{N\times N}$ can be chosen as:

- $\mathbf{I}_N$: We can normalize matrix $\mathbf{\Omega}$ in such way for all i condition $\sum_j^N \omega_{ij} = 1$ is satisfied and therefore we would obtain a degree matrix equaling the identity matrix. Then, $\sum\mathbf{h}^{(l)\top}\mathbf{h}^{(l)} = \text{tr}(\mathbf{H}^\top\mathbf{H})$, which corresponds to a PCA-based formulation.
- Diag($\mathbf{v}$): With $\mathbf{v} \in \mathbb{R}^N$ such that $\mathbf{v}^\top\mathbf{v} = 1$, we have a WPCA approach.
- $\mathbf{D}^{-1}$: Given the equality $\mathbf{V} = \mathbf{D}^{-1}$, optimization problem can be solved by means of a procedure based on random walks; being the case of interest in this study.

3.2.1 Gaussian processes

In terms of Gaussian processes, variable $\mathbf{\Psi}$ represents a mapping matrix such that $\mathbf{\Psi} = (\psi(\mathbf{x}_1),\ldots,\psi(\mathbf{x}_N))$ and where $\psi(\cdot) : \mathbb{R}^d \to \mathbb{R}^N)$ is mapping function, which provides a new N-dimensional data representation where resultant clusters are assumed to be more separable. Also, matrix $\mathbf{\Omega}$ is to be chosen as a Gaussian kernel [17]. Therefore, according to optimization problem given by (14), term $\mathbf{h}^{(k)}$ is to be the k-th projection of normalized binary indicators as $\mathbf{h}^{(k)} = \mathbf{\Psi}\ell^{(k)}$.

3.2.2 Eigen-solution

We present a solution for 14, which after solving the KKT conditions on its corresponding Lagrangian, an eigenvectors problem is yielded. Then, we first solve the Lagrangian of problem (14) so:

$$\mathcal{L}(\mathbf{h},\ell,\gamma,\alpha) = \frac{1}{2K}\mathbf{h}^\top\mathbf{V}\mathbf{h} - \frac{1}{2}\ell^\top\ell - \alpha^\top(\mathbf{h} - \mathbf{\Psi}\mathbf{w}), \tag{15}$$

where α is a N-dimensional vector containing the Lagrange multipliers.

Solving the partial derivatives to determine the KKT conditions, we have:

$$\begin{aligned}\frac{\partial\mathcal{L}}{\partial\mathbf{h}} = 0 \quad &\Rightarrow \mathbf{h} = \frac{K}{\gamma}\mathbf{D}\alpha, \\ \frac{\partial\mathcal{L}}{\partial\ell} = 0 \quad &\Rightarrow \ell = \mathbf{\Psi}^\top\alpha, \\ \frac{\partial\mathcal{L}}{\partial\alpha} = 0 \quad &\Rightarrow \mathbf{h} = \mathbf{\Psi}\ell.\end{aligned}$$

Eliminating the primal variables, we obtain the following eigenvector problem:

$$\lambda\alpha = \mathbf{D}^{-1}\mathbf{\Omega}\alpha, \tag{16}$$

where $\lambda = N/\gamma$. Then, matrix $\mathbf{\Delta}_K = (\alpha^{(1)},\cdots,\alpha^{(K)})$ can be computed as the eigenvectors associated with the first K longest eigenvalues of $\mathbf{D}^{-1}\mathbf{\Omega}$.

Finally, projections matrix $\mathbf{H}$ is in the form

$$\mathbf{H} = \mathbf{\Psi}\mathbf{L} = \mathbf{\Psi}\mathbf{D}^{1/2}\mathbf{M} = \mathbf{\Omega}\mathbf{\Delta}_K, \tag{17}$$

and therefore $\mathbf{M} = \mathbf{\Psi}^{-1}\mathbf{D}^{-1/2}\mathbf{\Omega}\mathbf{\Delta}_K$, where $\mathbf{\Psi}$ can be obtained from a Cholesky decomposition.

Then, within a finite domain, both solution and formulation of NCC can be expressed similarly as done in KSC. So it is demonstrated the relationship between a kernel-based model and Gaussian processes.

4 Links between KSC and KKM

Kernel K-means method (KKM) is a generalization of standard K-means that can be seen as a spectral relaxation when introducing a mapping function in the objective function formulation [18]. As mentioned throughout this paper, spectral clustering approaches usually are performed on a lower-dimensional space, keeping the pairwise relationships among nodes. Then, it often leads to a relaxed NP-problems where continuous solutions are obtained by a eigen-decomposition. Such an eigen-decomposition is regarding the normalized similarity matrix (Laplacian, as well). In a Kernel K-means framework, eigenvectors are considered as geometric coordinates and then K-means methods is applied over the eigen-space to get the resultant clusters [19, 20].

Previous instance is as follows: Suppose that we have a gray scale matrix $m \times n$ pixels in size. Characterizing each image pixel with d features -e. g., color spaces, morphological descriptors- it is yielded as a result a data matrix in the form $\mathbf{X} \in \mathbb{R}^{N \times d}$, where $N = mn$. Afterwards, the eigenvectors $\mathbf{V}\mathbb{R}^{N \times N}$ of a normalized kernel matrix $\mathbf{P} \in \mathbb{R}^{N \times N}$ such that $\mathbf{P} = \mathbf{D}^{-1}\mathbf{\Omega}$, being $\mathbf{\Omega}$ the kernel matrix and $\mathbf{D} \in \mathbb{R}^{N \times N}$ the corresponding degree matrix. Then, we proceed to cluster $\mathbf{V}$ into K groups using K-means algorithm: $\mathbf{q} = \text{kmeans}(\mathbf{V}, K)$, being $\mathbf{q} \in \mathbb{R}^N$ the output cluster indicator such that $q_i \in [K]$. The segmented image is then a $m \times n$ sized matrix holding regions in accordance with $\mathbf{q}$.

Briefly put, one simple way to perform a KKM procedure is applying k-means over the eigen-space. In Equation (7), the dual formulation is regarding the matrix $\mathbf{S} = \mathbf{VH\Omega}$ where weighting matrix can be chosen as $\mathbf{V} = \mathbf{D}^{-1}$ and $\mathbf{D}$ is the degree of the data-related graph. Since $\mathbf{H}$ causes a centering effect, matrix $\mathbf{S}$ is the same as $\mathbf{P}$ when kernel matrix $\mathbf{\Omega}$ is centered. In other words, KKM can be seen as a KSC formulation with an incomplete latent variable model being a non-centered one (with no bias term).

5 Results and discussion

In order to show how considered methods work, we conduct some experiments to test their clustering ability on segmenting images. To do so, the segmentation performance is quantified by a supervised index noted as Probabilistic Rand Index (PR), explained in [21], such that $PR \in [0, 1]$, being 1 when regions are properly segmented. Images are drawn from the free access Berkeley Segmentation Data Set [15]. To represent each image as a data matrix, we characterize the images by color spaces (RGB, YCbCr, LAbB, LUV) and the xy position of each pixel. At the end, data matrix $\mathbf{X}$ gathers N pixels represented by d characteristics (variables). To run the experiment, we resize the images at 20% of the original size due to memory usage restrictions. All the methods are performed with a given number of clusters K manually set as shown in shown in Fig. 5 and using the scaled exponential similarity matrix as described in [19], setting the number of neighbors to be 9.

To test all the methods in a fair scenario, kernel-based methods (KSC and KKM) use $\mathbf{\Omega}$ as kernel matrix, whereas such a matrix is the affinity matrix for NCC. As well, to perform the clustering procedure, the number of clusters is the same for all the considered methods. As can be readily appreciated, KSC overcome the rest of studied clustering methods. This fact can be attributed to the KSC formulation, which involves a whole latent variable model being in turn incorporated within a LS-SVM framework. Indeed, just like principal component analysis (PCA), KSC optimizes an energy term. Differently, such an energy term is regarding a latent variable instead of directly the input data matrix. Concretely, a latent variable model is used, which is linear and formulated in terms of projections of the input data. The versatility of KSC relies on the kernel matrix required during the optimization procedure of its cost function. Such a matrix holds pairwise similarities, then KSC can be seen as data-driven approach that not only consider the nature of data but yields a true clustering model. It is important to quote that -depending on the difficulty of the segmentation task- data matrices representing images yield features spaces, which may present hardly separable classes. Then, we have demonstrated the benefit of the KSC approach that uses a model along with a LS-SVM formulation -everything within a primal-dual scheme. Other studies have also proven the usability and versatility of this kind of approaches [8, 22].

6 Additional remarks

As explained in [23], KSC performance can be enhanced in terms of cluster separability by optimally projecting original input data and performing the clustering procedure over the projected space. Given the unsupervised nature, spectral clustering becomes very often a parametric approach, involving then a stage of selection/tunning of collection of initial parameters to avoid any local-optimum solution. Typically, the initial parameters are the kernel or similarity matrix and the number of groups. Nonetheless, in some problems when data are represented in a high-dimensional space and/or data-sets are non-linearly separable, a proper feature extraction may be an advisable alternative. In particular, a projection generated by a proper feature extraction procedure may provide a new feature space wherein the clustering procedure can reach more accurate cluster indicators. In other words, data projection accomplishes a new representation space, where the clustering can be improved, in terms of a given mapping criterion, rather than performing the clustering procedure directly over the original input data.

The work developed in [23] introduces a matrix projection focusing on a better analysis of the structure of data that is devised for a KSC. Since data projection can be seen as a feature extraction process,

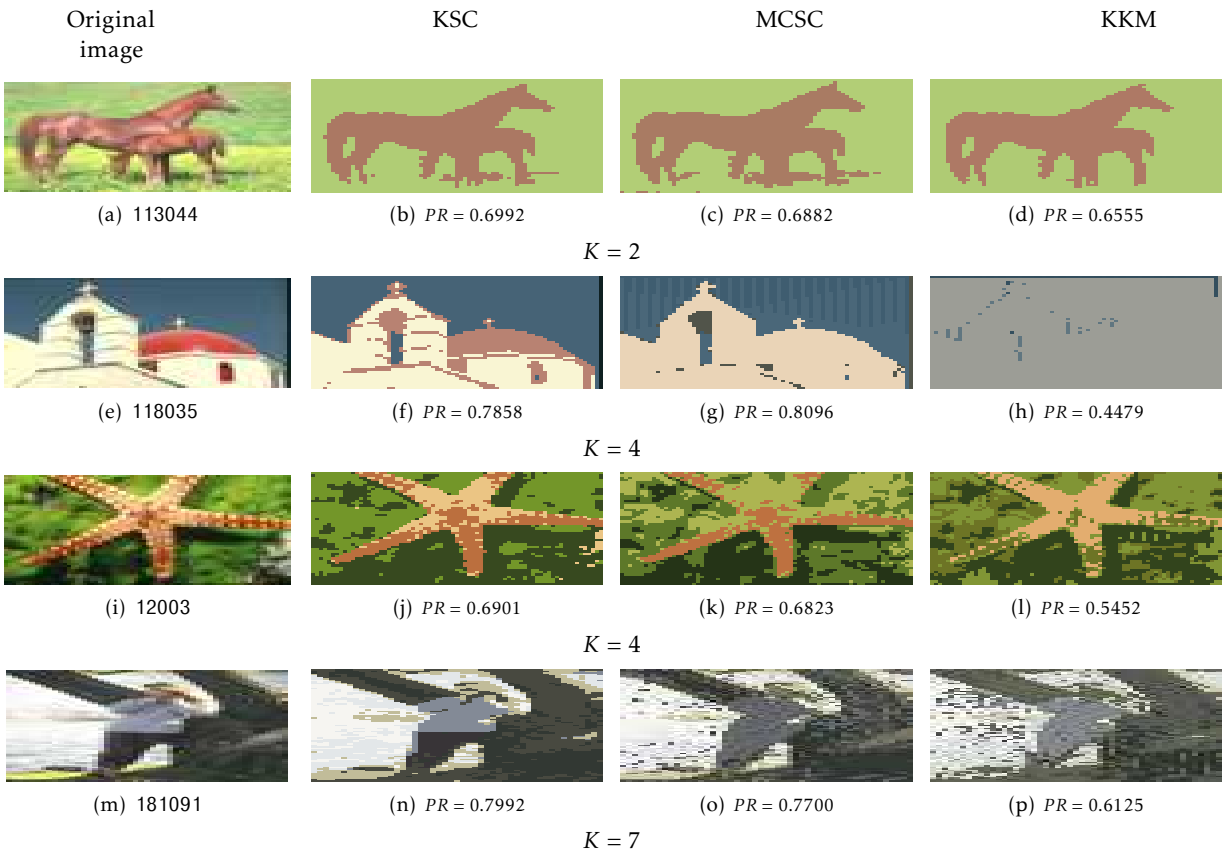

Figure 1: Clustering performance on image segmentation reached by all the considered methods. It is noticeable that KSC overcome the remaining methods. Images are data that traditionally involve highly non-separable clusters. Therefore, the benefit of using a whole latent variable model within a LS-SVM formulation is verified.

we propose the M-inner product-based data projection, in which the similarity matrix is also considered within the projection framework, similarly as discussed in [24]. There are two main reasons for using data projection to improve the performance of kernel spectral clustering: firstly, the data global structure is taken into account during the projection process and, secondly, the kernel method exploits the information of local structures.

Another study [25] explores the links of KSC with spectral dimensionality reduction from a kernel viewpoint. Particularly, the proposed formulation is LS-SVM in terms of a generic latent variable model involving the projected input data matrix. In order to state a kernel-based formulation, such a projection maps data onto a unknown high-dimensional space. Again, the solution of the optimization problem is addressed through a primal-dual scheme. Finally, once latent variables and parameters are determined, the resultant model outputs a versatile projected matrix able to represent data in a low-dimensional space. To do so, since the optimization is posed under a maximization criterion and dual version has a quadratic from, the eigenvectors associated with the largest eigenvalues can be chosen as a solution. Therefore, the generalized kernel model may represente a weighted version of kernel principal component analysis.

7 Conclusions

This works explores a widely-recommended method for unsupervised data classification, namely kernel spectral clustering (KSC). From elegant developments, the relationship between KSC and two other well-known spectral clustering approaches (normalized cut clustering and kernel k-means) is demonstrated. As well, the benefit of KSC-like approaches is mathematically and experimentally proved. The goodness of KSC relies on the nature of its formulation, which is based on a latent variable model incorporated into a least-square-support-vector-machine framework. Additionally, some key aspects and hints to improve KSC performance as well as its ability to represent dimensionality reduction approaches are briefly outlined and discussed.

As a future work, a generalized clustering framework is to be designed so that a wide range of spectral approaches can be represented. Doing so, the task of selecting and/or testing a spectral clustering method would become easier and fairer.

ABSTRACT

The Internet is the premier platform that enable the emergence of new technologies. Online news is unstructured narrative text that embeds facts, frames, and amplification that can influence society attitudes about technology adoption. Online news sources are carriers of voluminous amounts of news for reaching significantly large audience and have no geographical or time boundaries. The interplay of complex and dynamical forces among authors and readers allow for progressive emergent and latent properties to exhibit. Our concept of "Double subjectivity" provides a new paradigm for exploring complementary programmable insights of deeply buried meanings in a system. The ability to understand internal embeddedness in a large collection of related articles are beyond the reach of existing computational tools, and are hence left to human readers with unscalable results. This paper uncovers the potential to utilize advanced machine learning in a new way to automate the understanding of implicit structures and their associated latent meanings to give an early human-level insight into emergent technologies, with a concrete example of "Uber". This paper establishes the new concept of double subjectivity as an instrument for large-scale machining of unstructured text and introduces a social influence model for the discovery of distinct pathways into emerging technology, and hence an insight. The programmable insight reveals early spatial and temporal opinion shift monitoring in complex networks in a structured way for computational treatment and visualization.

1. Introduction

This paper is an extension of work originally presented in 2017 IEEE 11th International Conference on Semantic Computing (ICSC) [1]. The Internet is the premier platform for the proliferation of voluminous online news and has been compared to a huge social and psychological laboratory [2]. It has enabled a globally and connected world which is greatly transforming computational approaches for exploring online social interactions for gaining early insight into emergent technology. News sources propagate online news that function within a complex and dynamic system via the Internet. This system comprises informational flows, interactions, dynamical forces, and emerging properties, which lead to asymmetries and have a tendency to influence society. Online news is a form of narrative text that embeds facts and strategic communication frames for shaping and transforming group standards, values, attitudes, and beliefs about technology adoption. The embedded facts represent absolute, relevant truths characterized by their rigid (or fixed) nature. These absolute truths are shared among news sources. However, purely factual articles would be hard to write and read. Adding tone, writing style, attitude, opinions, related context, and non-factual comments and arguments often make text more subjective but easier to read. The exercise of news framing—and the amplification of subjectivity that it communicates—is where multidimensional aspects of the content emerge and where expressivity happens for transformational and maximal influence. Framing is the use of strategic devices for presenting prominent aspects and perspectives about an issue using certain words as well as stereotyped images and sentences for the purpose of conveying hidden meanings about an issue [3].

1.1. What is Insight?

News sources play a critical role in the activation of frames about technology society adopt, and the amplification of subjectivity in online news drives a wedge between evidence and beliefs [4]. In addition, the combination of facts, frames, and amplified subjectivity represents instruments that offer a space of possibilities for deeper exploration of the cognitive aspects of narrative text. Natural Language Processing (NLP) made significant progress using Artificial Intelligence (AI) to parse narrative text by applying analytical techniques. However, less success has been made with computational treatment when it comes to semantic levels. Semantic parsers work well only at a phrase level, but it becomes challenging to semantically parse several sentences together. Some approaches can look for keywords to determine the sentiment of a text, provide a summary, or a basic language-to-language translation, but they remain by far limited in understanding the deep latent meanings which contribute to the richness and depth of ideas within a complete text or of a related set of articles at the same level humans do. We define this as an "Insight" which is "the ability to understand the latent meanings within an article". The definition of Insight can be generalized to a group of related articles, and refers to "the ability to synthesize the relationship between a group of articles as well as how the contents of latter articles were affected or influenced by those in earlier articles of the same group." The need to understand this insight becomes particularly important with online news, as the number of related articles tend to be generally larger than printed media due to the far reach and hence the significantly larger and more diverse readership of the Internet. This "understanding" process is typically highly cognitive, and is best done by humans. However, with the large number of online news, the need for software tools becomes essential for gaining programmable insight at a very large scale. We define programmable insight as "the ability to apply computational models and methods and hence software tools to leverage human cognitive ability to gain insight into very large narrative text".

1.2. Challenges of Processing Subjective Text

When attempting to identify potential pathways to address the complexities and dynamics that exist in online news text, frames are instruments for experimenting and learning about the production of language and forces at work for gaining programmable insight that may lead to new instruments for exploring cognitive computation. Here, pathways mean the potential routes that one may take to explore patterns about a subject. The authors recognize the need for an integration of multiple models and perspectives that advance what is known about hidden meanings and latent structures in text. Modeling narrative text allows software tools to provide help in automating human efforts using computational leverage. However, providing a deep model that represents hidden meaning in text is relatively hard. Several NLP methods in artificial intelligence use word matching and probability functions to determine the correctness and possible meaning of words with the help of language corpus containing trillions of words. This "brute force" and highly analytical top-down approach could be computationally heavy, and does not provide an insight beyond the phrase level. An acknowledgment of the multidimensional aspects—degrees of freedom—of the narrative text in news calls for computational research to fill knowledge gaps and to transform the current understanding of alternative pathways to learning that leverage cognitive science research.

Leveraging the scholarly work of mathematicians, the fathers of the digital computer developed the initial logical machine using a rather formal grammar structure. The first level of grammatical expressivity the computer machine could understand is propositional logic—that is, knowledge of facts or truths. Considering the "form" of the English language (i.e., subject, verb, object), the logical machine could make valid arguments using as few as two premises and simple symbols, thereby drawing a logical conclusion. Propositional logic became the basic component of symbolic logic. It became the enabler for the logical machine to reason using simple English grammatical structure. This breakthrough led to machines being able to reason as either true (1) or false (0), using simple binary symbols and boolean algebra to express "and," "or," "not," "implies/then," and "if and only if."

By switching out fixed sentence structure for symbols, as was done in mathematics for centuries, the logical machine could express a primitive level of truth. The computer could express with "0" or "1" with this simple syntactical machine code. Although this advanced in the logical machine was very impressive in its day, this level of formalism with its strict grammatical structure falls short of reaching the goal of AI, as it gave no insight into the topic proposed in the sentence structure.

Propositional logic usage in the logical machine had no properties nor a sense of relationships, all of which were embedded in the internal structure of the text. Rather, its sole focus was on pure factual, blocks of sentence structures as isolated objects for expressing what logicians for centuries thought to be real. Real objects were point masses and forces; as such, properties leading to an understanding about the relationships and internal structures of text were dismissed as subjective. Discounting relational properties as the inferior status of "secondary" properties resulted in excessive adherence to the theoretical approach of attaining machine intelligence. However, researchers soon came to realize that if there is any future for theory, it must be applied. This meant that the internal structure in text must delve into deeper levels of expressivity where hidden meanings and relationships could be explored for advancing machine intelligence. Since this time, as shown in Fig. 1, numerous levels of machine logic have been established to allow for the variety of properties to reason about relationships, individuals, identities, and quantifiers—thereby, giving way to make more elaborate assertions, inferences, and semantic expressions of phrases. Fig. 1 shows the progressive climb up the stack from the formal space where computer machines focused on propositional logic, formal grammar, and, thereafter, phrases.

With the pendulum swinging from machine-to-human logical expression—where the programmer of the computer machine had to learn the psychology of the machine—to human-to-machine logic for expressing rational human thoughts, higher-level programming languages were developed, such as Fortran, Prolog, and Lisp. With the foundations for reasoning and with higher levels of expressivity at the researcher's grasp, attention turned to another field of research, AI.

Here, at the phrases layer (NLP using AI) is where much of the computer science research today continues to focus. This has led to great breakthroughs for learning AI, NLP, and fuzzy logic; however, this approach shed very little insight into cognitive computation.

This research advances beyond the phrases layer and bridges the computational and cognitive worlds using the instrument of

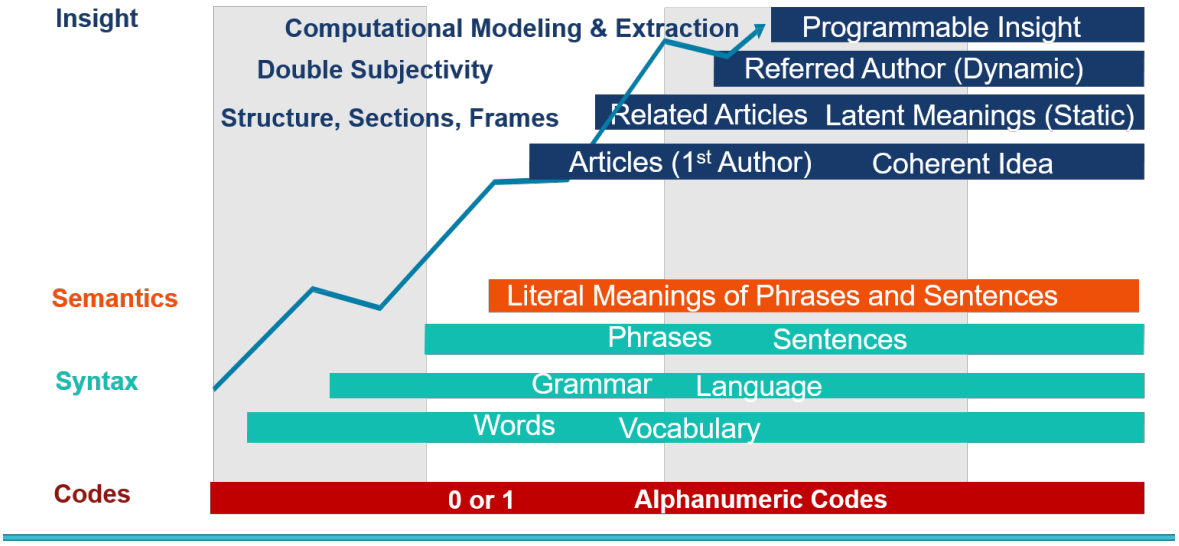

Fig. 1. A view of the end-to-end bridge to cognitive computation model. Here, the stack, from bottom to top, represents the evolution of computational processing from grammar to insight, as shown on the right, and the value or outcome that results as shown on the left. For instance, computer processing of 0 and 1 bits were the catalyst for primitive storage, transmission, and processing logic.

frames that exist in narrative text for exploring programmable insight that may lead to deeper learning for machine intelligence.

In exposing the discovery of new knowledge about text, transformations (or shifts) in which dynamic forces reach a critical point make clear the new structures, pathways, and influence patterns to be accepted or new questions or alternatives in the scope of an issue to be revised. The ability to seek out novel, uncharted relationships that are implicit from a body of unstructured narrative text—yet not explicitly stated within that text—has obvious scientific value. This process is called "novel knowledge discovery." It enables the use of the current state of knowledge for an emergence of possible new relationships and pathways that have yet to be studied.

1.3. Structured Expert Support (SES) Models

Fully structured data render itself easily to computation. A sales receipts generated by point-of-sale (POS) software in most retail stores includes a fully-structured list of items code, text, sale price as well as subtotal, total, date and time of each receipt. Terabytes of such data follow a well-known model and would be easy to process with software tools and provides solid foundation of business intelligence (BI) and other advanced insight, data science, and consumer-behavior pattern discovery. Narrative text, on the other hand, is highly unstructured and hence represent a nightmare to computational algorithms trying to extract deep knowledge buried within. One of the main reasons is the lack of a representative model that this data follow. While humans can understand and even enjoy the contents of such text, the lack of concrete models prohibits the computational treatment of such text. In the proposed approach, the authors use the framing theory—as will be shown later—to build representative models of narrative text. While these models need to be built by hand using human experts (thus the name expert support), they are done in a structured way to normalize human cognitive ability into nominal structure (hence the qualifier Structured Expert Support) as shown in Fig 2. Fig. 2 also is a graphical depiction of the process for discovering news frames. The formal problem definition of framing is presented as follows:

Let U_t be a universe of online news documents at time t. Let $\{d_i\}, 1 \leq i \leq n$, denote a finite subset of documents from the universe of documents U_t, where n is the total number of documents being considered. Let $S_i = \{P_i, C_i\}$ be the set of document properties, where P_i is the source that produced the article and that propagates a central organizing idea (i.e., framing) and C_i is the set of terms (i.e., features or content descriptors) from the news article where common words have been removed—all of which supply a context and suggest what the issue is through the use of selection, emphasis, exclusion, cues, and elaboration [5, 6]. For issues of interest, the process leads to the discovery of standard frames dominantly used in U.S. news coverage [7]: human interest, conflict, economic, managerial, and science. Let f_1, f_2, f_3, f_4, and f_5 correspond to each of these frames, where each f_i is associated with a pair $\{x_i, y_i\}$; $\boldsymbol{x_i}$ is the feature vector, and $\boldsymbol{y_i}$ is the vector with the corresponding weights. Discover five dominate news frame signatures.

Humans would manually extract certain keywords present in a text, and build representative data structures (vectors) representing hidden meanings within the text. On the one hand, these vectors will be a strong representation of the hidden frames in a text, and -on the other hand- they will be highly structured and hence readily computational. As will be discussed later, the proposed SES relies heavily on the theory of framing as the modeling concept and the bridging mechanism between cognitive contents and computational capability of narrative text.

This manuscript includes a model for expressing the multidimensional aspects of news framing—and the amplification that it conveys—for transformational and maximal influence. The model is a pathway to explore programmable insight to expose a deep level of expressivity into the hidden structures in text—what is referred to in this paper as "double subjectivity," a term introduced here [8]. Double subjectivity is the term to describe the secondary subjectivity that results after receiving indirect informal cognitive data in online news. The double subjectivity method expands Axelrod's [9] and Klienberg's [10-12] research on cultural dynamics and social influence for constructing an issues

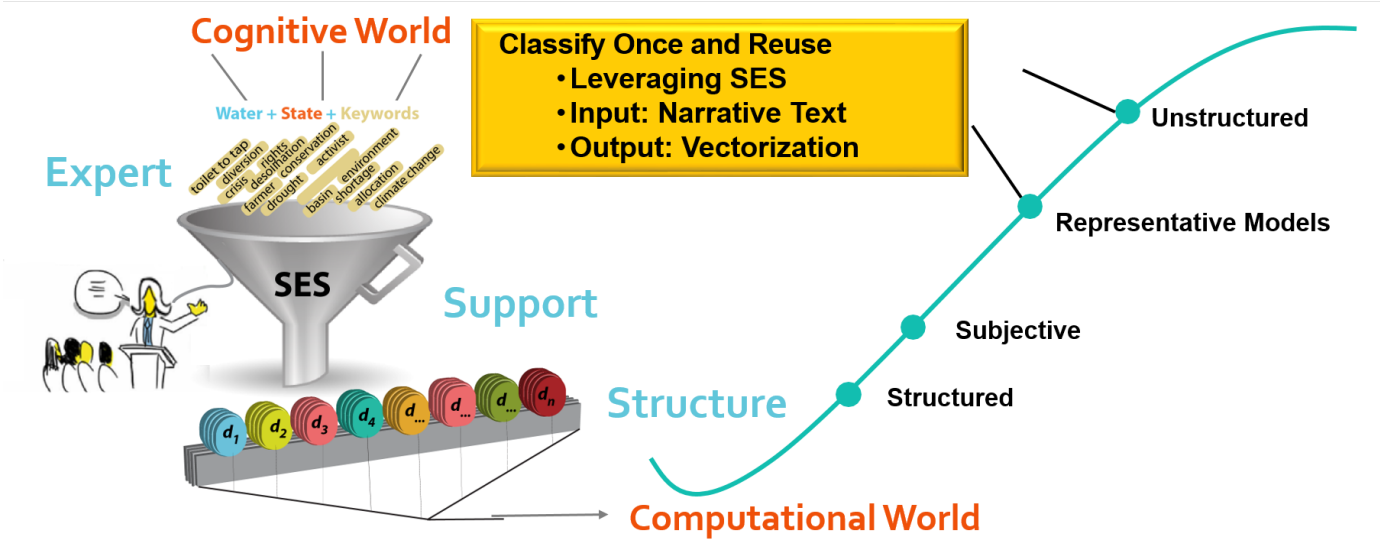

Fig. 2. Depiction of SES significance in the development of a representative model in support of the discovery of frames that exist in unstructured narrative text.

network representation and designing a visual language for exploring spatio-temporal dynamics. The issues network is exemplar of a complex dynamical system whereby migration paths may be visualized. The migration path is defined as the movement of frame choices in articles across a network to establish a new bridge for information exchange. The way the issues network grow (gain node connections) and shrink (loss node connections) is discussed in a subsequent section in this manuscript. The aim of the authors is to demonstrate news framing as a step toward deep learning about the production of language that may inform scholars about pathways that offer new approaches that advance cognitive computation for improved intelligent behavior in machines.

To the best of the authors knowledge, in computer science scholarly research, examining double subjectivity using online news and framing effects for gaining programmable insight has not been addressed previously for the class of problems discussed in this paper. This research inquiry will give insight into the following questions: What is the migration path of online news frames as it evolves over time? What is the effect of double subjectivity? What are the conditions observed that allow for the evaluation of shifts in influence or amplification intensity?

The following sections will describe the conceptual framework, related works, background on the issues of application, methods, possibility space transitions, observations of the models in action, and the conclusion.

2. Conceptual Framework

In the last decade, advances in fields such as AI, text summarization, and NLP have enabled gains in understanding text syntactic structure and limited gains in text semantics by offering algorithmic and theory-based methodologies. However, these fields have struggled in efforts to unlock hidden meanings and abstractions found in unstructured text such as jokes, poems, or art that are readily expressed through cognitive structures. This is due in large part to barriers that exist when using machine learning algorithms that are still limited in their understanding of complex unstructured text where factors such as semantic context, culture, and complex relationships must be considered for making sense of the narrative text.

Humans have the unique and superior ability to get beyond the syntax of data in order to make meaning. However, a great deal of cognitive science research has focused on cognitive structures called “frames” (sometimes “schemas”) that exist in the recesses of the brain [13]. The framing of online news articles by news sources consequently has the effect of evoking a word and phrase in the unconscious cognitive structure in the mind of the reader. These structures are built over time through repetition. The repetitive framing of critical issues will strengthen the circuits about the issue in a reader’s brain. When online news sources repeat frames often, they become “normalized” unconscious activation points in the brains of readers. This behavior by online news sources is equivalent to placing ideas in a container, referred here as an article. These ideas are sent through communication channels that have tremendous influence on the perception and real value of knowledge. When neighboring news sources take the ideas out of the container by way of adoption or copying, the cumulative effect is double subjectivity. A property of double subjectivity is spatio-temporal dynamics, which has the capacity to display a larger context of influence. As a number of related articles grows, the cumulative effect of subjectivity could grow and take on certain direction or shape, influenced by the article-to-article changes or the amplification or suppression of frames. This dynamic behavior may be best shown through a network visualization. A network visualization is a mechanism that has been used to leverage people’s ability to acquire knowledge for revealing hidden meanings, social influence, and migration paths of information and interactions.

The automation of unstructured text can be generally categorized under two main areas: computational data and cognitive data.

2.1. Computational Data

Computational data—represented by mathematical formulas, propositional logic, and formal (computer) languages—have little room for subjective interpretation and are typically concise, context-free, and fully predictable. For instance, a correctly developed source code can compile and run on a computing

machine and will always produce the same output for a specific input. The combination of a formal set of instructions resulting from the successful compilation and run of source code can transition a computer through a set of well-defined states, depending exclusively on the compiled code and input data. This leaves no room for interpretation or subjectivity. In other words, the meaning and interpretations must be fully represented in the source code. A good programming language must, therefore, have sufficient expressiveness to fully represent a feasible solution in a specific problem space. If a source code arrives at an undefined state, it will simply freeze or crash; it is unable to make an independent decision. Some areas of computer science such as fuzzy logic and AI attempt to address these inherent limitations by providing a default or recovery system. Some languages also provide exception handling constructs and error recovery mechanisms. However, these approaches remain rigid mechanical methods, and are not the focus of the work conveyed here. This expresses the "formal space" as depicted in Fig. 4.

Although the computational language of source code is a good medium for communicating with computers, natural languages that embed cognitive structures are the mediums of communication among humans, and natural languages are informal and ambiguous in comparison to the computational language of computer code. In Fig. 4, the "informal space" is shown to describe the embeddedness of informal cognitive data structures that humans are superior over machines in conveying which are contained in narrative text. Cognitive data can be further divided into two subcategories, depending on the source of origination: direct and indirect.

2.2. Direct Cognitive Data

Direct cognitive data are the result of a person's encounter with an event and the perception, in part, of its details firsthand. Human perceptions of events lead to personal interpretations of events. Interpretation depends greatly on the viewer's perception, as different people can arrive at different interpretations of the same event. Perception is often associated with the viewer's state of mind, prejudice, background, and beliefs. Two persons witnessing the same event or being involved in the same situation could assign different interpretations and end with separate conclusions. Although the external situation is the same (the perception of which is uniquely defined in this paper as the absolute baseline), it could be internalized differently by different people. Such a case is a first-level subjectivity. Even when different people are asked to report an incident or a situation (the same absolute baseline), different accounts are often the result, indicating first-level subjectivity. Many factors further affect this subjectivity:

- Subjectivity: Humans have different expressive abilities and styles in reporting events using natural languages, leading to increased subjectivity.
- Ambiguity: The ambiguity of natural languages allows for different interpretations of spoken or written sentences.
- Complexity: Complex, extended situations, such as movie showings, are harder to perceive and interpret compared to simple or atomic events like the occurrence of a rocket launch.
- Expressiveness: Unlike a computational language, a natural language does not fully express the contents in its syntax. Natural languages report about something, rather than fully describe an action, artifact, or event in a specific way.
- Context: Natural languages are highly context dependent. The same sentence could have different meanings in different contexts.
- Modality: Natural languages are often combined with other modalities like para-verbal communication, body language, and face impressions, which can influence the meanings or interpretation of spoken words.

The aforementioned factors explain why—even for different people directly witnessing the same situation—substantial subjectivity can be present in reporting or discussing an event that was mutually witnessed.

People often try to reduce first-level subjectivity. Television reporters try to abide by certain rules to maximize neutrality and leave it up to the viewers to build their own opinions freely. The scientific community tries to show the stated facts through rigorous research and scientific experiments in attempts to eliminate or reduce subjectivity. However, subjectivity is not so simple to discard. Consider newspaper and television reporters who are known for their opinions.

2.3. Indirect Cognitive Data

The Internet and World Wide Web have led to an explosion of indirect cognitive data although events can still be directly perceived and subjectively interpreted. Because of technology advancements, it is possible to receive a much larger number of events indirectly. Because these events are not directly witnessed, an absolute baseline is not available. Because knowledge of an event is often based on the written or spoken reports of others, the baseline will be relative to the reporter's subjectivity or simply "float."

With the acceptance of indirect reports and their interpretation, the receiver adds his or her own subjectivity. Again, no longer is the absolute baseline available. It is replaced with a reporter-relative baseline or a floating baseline. If the reporter's subjectivity is strongly framed and influenced towards certain beliefs, the receiver of the account already starts with a baseline that is completely different from the absolute baseline. This new baseline could strongly affect the receiver's beliefs. Double subjectivity is the term introduced in this paper to describe the secondary subjectivity that results after receiving indirect informal data. Fig. 3 illustrates the cumulative influence effects of double subjectivity.

The illustrated formula depicts a generic function for double subjectivity in online news. Here, the assumption is that there is an observer-dependent function $f(x)$, such that the level of subjectivity L_i is the relative baseline of the situation or event dependent on firsthand account or cumulative effect. First-level subjectivity it is expressed as,

$$L_1 = f_1(L_0), \text{ and} \quad L_2 = f_2(L_0) \tag{1}$$

whereas, double subjectivity is expressed as,

$$L_1 = f_1(L_0), \text{ and} \quad L_2 = f_2(L_1) \tag{2}$$

f is an amplification intensity function with cumulative influence effects B_i that depends on the person observing, then reporting a situation or event.

An analogy drawn from photocopying illustrates double subjectivity in that, ideally, a photograph copy should be a close replica of the copied photograph. Yet, in actuality, the resulting photograph is the copied photo with its amplification plus the distortion amplification gained from the copying process or machine.

Online news is exemplary of double subjectivity in that its assemblage consists of subjective properties such as context, interpretation, multimodal interaction, background, compensation, and assumptions. These properties are critical building blocks that characterize narrative text for its a) signification (i.e., the semantic content signifying an association or concept given a word, sentence, or phrase) and b) significance (i.e., the relevance, rank, importance, or capacity to make a difference). Unfortunately, there remain substantial gaps in advancing what is known about the production of language in narrative text where double subjectivity exists. Therefore, exploring deeper levels of expressivity with an emphasis on double subjectivity may inform a new direction in research.

Discovering double subjectivity in narrative text poses a difficult problem, as it seeks to give insight and meaning to open-ended statements and indirect data. More complex structures within the narrative text provide an expansive landscape for advancing effective tools and crafting applications to automate many language-related tasks—for example, document

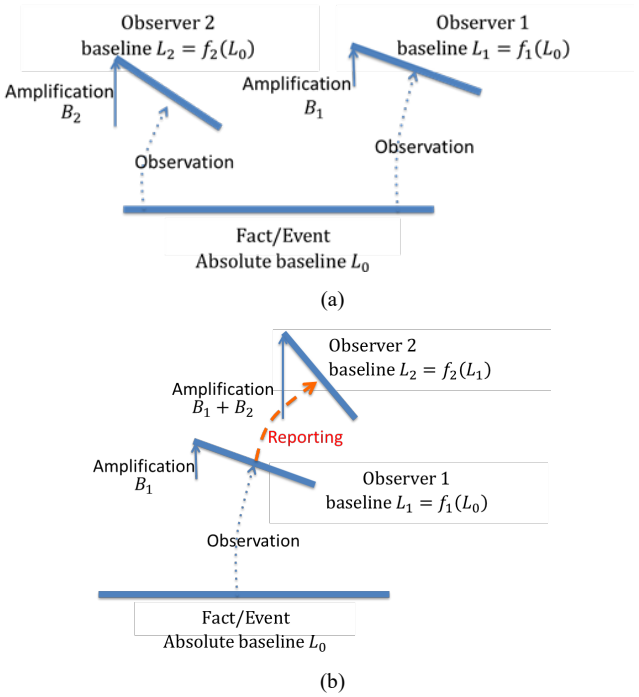

Fig. 3. Two representative illustrations of the double subjectivity framework. (a) There is an event (Observation) about an issue that two observers see: Observer 1 and Observer 2. Although it is the same event, their perceptions are different. Their amplification may be different, but independent. (b) This graph illustrates the introduction of an indirect account of an event, whereby the reporter does not receive the information firsthand. Rather, Observer 2 adopts the report of Observer 1, which sets into motion the cumulative effect of double subjectivity.

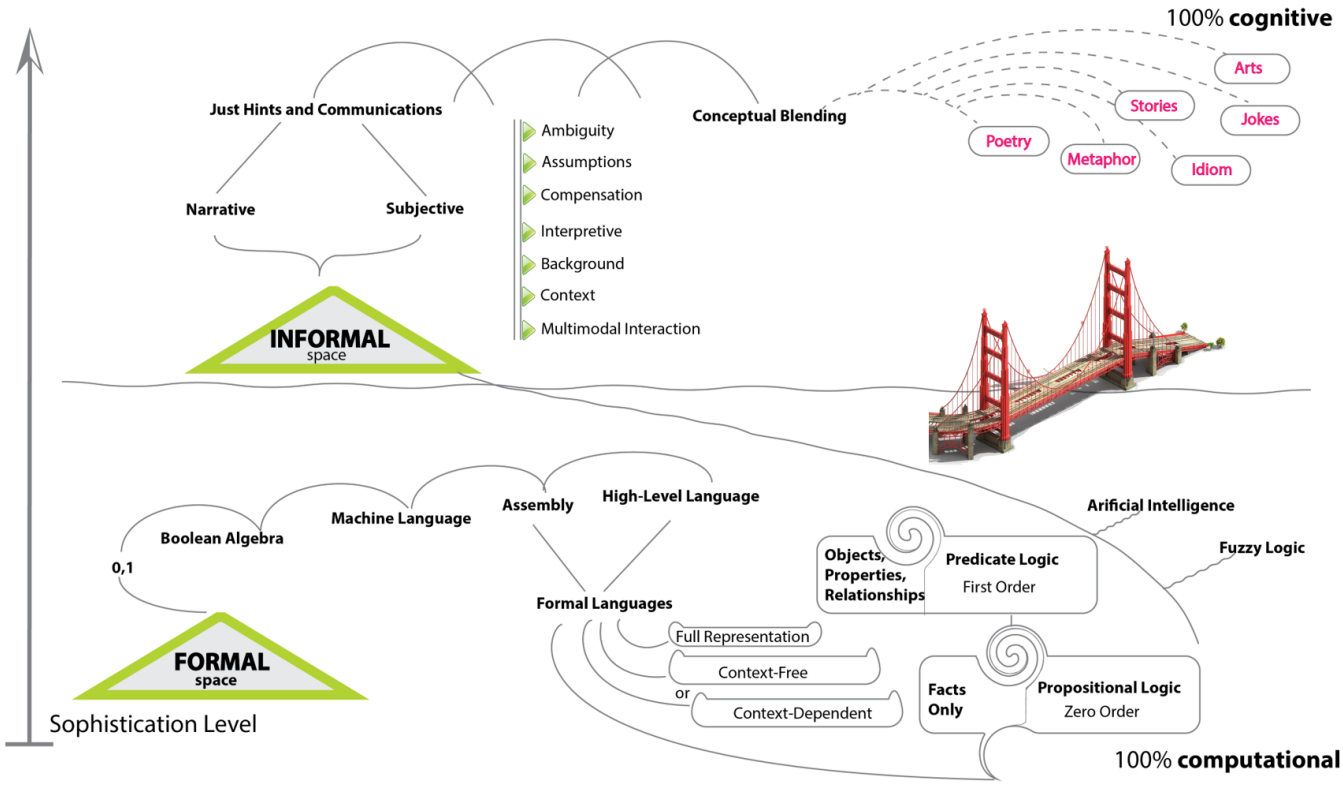

Fig. 4. A depiction of the evolution of first-level subjectivity and double subjective potentials.

summarization, automated text generation, and many others. To show the gains in logic and reasoning, Fig. 4 depicts advances made using current tools and new frontiers that double subjectivity may act as a bridge, such as poems, metaphors, idioms, jokes, art, and storytelling. This is to be achieved by exploring levels of narrative text.

3. Broader Impact of This Work

Media attention and framing can influence society concern about a specific topic. To observe the potential pathway of cognitive, informal, natural language, the authors focus on Uber as a case study. Uber intersects the economic and technology domain with characteristics of emergence, complex and dynamical forces, and the amplification of frames. Uber uses data as foundation for transforming the transportation ecosystem. It has played a key role in shaping the shared economy that heavily rely on social influence and online news frames. The framing of an issue has an impact on the ultimate course of the issue. The ways that Uber use framing has a direct impact on dynamical forces, such as, accessibility, mobility, shared value, or policy outcomes. Uber is a good case because it is context specific, complex, and characterized by multiple interacting forces. Newspapers in the U.S. regularly produce in-depth articles about automation of machines, emergence of platforms, and the influence of the crowd that are published online. However, the general public often has little experience with understanding the underpinning dynamical forces at work. As an example, amplified framing is more likely to influence uninformed respondents [14] or respondents with reduced exposure to or interest in an issue [15].

Therefore, consumers attitudes and beliefs about emergence and behavior shifts are likely influenced by the way reporters frame this issue.

This research can generally apply to any large, unstructured dataset that is affected (or amplified) by framing. Therefore, it can be extended to other applications such as health, economics or political discourse. It may lend multiple benefits to analyses of other domains, such as politics or presidential elections: 1) a tool for measuring amplification intensity over time and in real time, 2) a framework for exploring the social influence attributed to the double subjectivity with its primary property being the unique cumulative effect afforded in an online news network, 3) a model for exploring the dynamic forces at work when shifts occur in attitudes and beliefs, and 4) a real-time visualization of these dynamic forces.

4. Related Works

In the literature reviewed, no computational treatments were identified to address a) the concept of double subjectivity for automatic emergence of knowledge of narrative text or b) a model for exploring the interactions and implications of news frame choices. However, several works were identified that have some relevance for the research topic.

4.1. Text Summarization, Text Data Mining, and Information Retrieval

In computer science, scholarly research on latent meanings in the association between terms and documents to reveal relationships is found in literature related to text summarization, text data mining, and information retrieval. The earliest paper on text summarization identified for the current report is a description of work at IBM in the 1950s [16]. In his work, the authors proposed that the frequency of a particular word provides a useful measure of its significance, and he identified the concept "term frequency" (TF), which states that it is possible to identify the significant terms based solely on the term's calculated frequency within that document [16]. Term frequency relates to average information, or entropy, of a term or group of terms in the ranking of their relationship to each other.

Outstanding contributions to text data mining in the 1990s and beyond, with the advent of machine learning, include text representation and models construction [17-20]; data dimensions reduction re-search in feature extraction [21, 22]; and deep semantic mining [23].

The research on online news frames reported in this paper is motivated by framing theory, which focuses on understanding the latent meanings of observable messages in their contexts [15] and can provide important insight into how the presentation or framing of an issue affects the choices people make. Other disciplines have focused on framing. In linguistics research, similar approaches are also described as "latent semantic analysis" (LSA) [24]. Furthermore, social network analysis (SNA) focuses on the importance of relationships among interacting units [25].

4.2. Opinions and Social Influence

Whereas text data mining techniques and methods have given insight into first-level subjectivity, dynamic systems modeling provides insight into the double subjectivity that exists in narrative text. Models of social influence, cultural dynamics, and information diffusion (i.e., topic modeling, sentiment analysis, and opinion mining) are active areas of research [9, 1, 12, 13].

It has been posited that social impact theory explains the impact of a social group on an agent as being dependent on the prominence of the social sources, their proximity, and source group mass (i.e., the number in the group) [26]. Political opinions and Axelrod's cultural dynamics model behave similarly to these models that capture the interplay between selection and influence [27-30].

4.3. Networks

The ability to visualize vast amounts of data clearly creates a capacity for gaining insights about critical issues affecting society. At the most basic level, a network is a collection of points joined together in pairs [31]. Using Graph Theory, the data points are called nodes (or vertices) and the pairs connections are called edges (on links). Graph theory provides a strong mathematical foundation that helps us in visualizing the information geometric (special) aspects like the relationships be-tween different news sources, as well as it's progress and evolution over time (temporal aspects). Here, in this manuscript the terms nodes and edges are used. Networks is a powerful way to represent patterns of connections or interactions between the parts of a system [31]. The issues network is best expressed using a net-work to understand the underlying global and local structure of the network, the connections and interactions between nodes, the clusters of highly connected nodes, influence patterns, and migration paths.

5. Contextual Case

Founded in San Francisco, California in 2009, Uber Technologies describes itself as a transportation network company which develops, markets and operates the Uber car transportation and food delivery mobile apps [32]. In Ubers' short history, the

company that connects riders with drivers using the Uber mobile app has become one of the fastest growing companies in the United States and worldwide. With approximately $200K in seed capital from founders Travis Kalanick and Garrett Camp, UBER entered the market with an improved automated car service that offers better pricing over traditional taxi providers. This improved car service could be easily accessed on demand by consumers using a smartphone. It is on the basis of consumers shifts in values, attitudes, and behaviors from ownership to the shared economy—ride sharing—and the advances in technology that make access to product and services a realization that afforded Uber to become the prominent company it is today. In contrast to traditional taxi providers who own assets (e.g., cars, shuttles, or limousine), Uber use drivers cars for delivering convenience and efficiency. This change have inspired the shared economy to reframe the way in which businesses operate for reaching large numbers of people across cities in the United States and worldwide. As a result, the company has met many legal complications, court injunctions, complaints from taxi providers of unfair competition, and complaints from public utilities commissions about Uber's lack of compliance to safety rules that are adhered to by traditional taxi providers. These challenges did not impede Uber's influence and growth with its $68 billion paper valuation. In just 6 years, it surpass the valuation of 100 year-old companies like General Motors and Ford, as well as "traditional" short-term transportation companies like Hertz and Avis [33].

With Uber's recognition of consumer behavior shifts and advances in technology as emergent properties within complex and dynamical systems, the company set out to chart an alternative way for delivering cars and convenience to consumers, particularly through the use of social influence and opinions formation in online media and narrative text. Harnessing, the power of social influence, Uber evinces their reliance on consumers, lobbyist, and elites as influencers in online media as they a) created a team for community management, social-media outreach, and the creation of articles about Uber in online media and b) enlist celebrities, VIPs, and elite investors (i.e., Morgan Stanley, Saudi Arabia's Public Investment Fund, Goldman Sachs, and Fidelity Investments are among Uber's billion dollar investors). The emergence of consumers shifts, technology advances, and the interplay of complex and dynamical forces provides a useful context in which to explore Uber's approach to transform the transportation ecosystem through the use of social influence for gaining deeper understanding of the cumulative effects of double subjectivity and the expressive function that programmable insight offers.

Uber's mission to "bring safe reliable transportation to everyone everywhere" [34] is accomplished using its unique software platform and infrastructure that enable the company to meet consumers transportation needs with data rather than traditional methods, such as steel, glass, rubber, and salespeople. Uber's reliance on data to drive social influence and opinions formation, places a demand for the company to hire an enormous number of data scientist and data engineers to gain command of the vast amounts of data that derives from interactions between consumers, drivers, network traffic, pricing algorithms, and online media. These interactions leave traces of patterns about behaviors that indicate the interworking of forces that may go unnoticed due to the limitations of existing tools available in machine learning and NLP.

While text data mining techniques and methods have proven to give insight to first-order subjectivity (i.e., words, grammar, phrases, and sentences—syntax and semantics), complex and dynamical systems modeling offers insight into the cumulative effects of double subjectivity that exist in narrative text [8]. Uber's data scientist use tools that allows for treatment of disassembled factors and/or forces, however Uber data analytics could benefit from an account for the composite of data over space and time as a whole, not just its parts. An assemblage treatment of data will give Uber the needed insight for understanding its effective use of social influence and data-driven techniques and technology that enables them to reframe transportation and logistics globally.

Uber's data management and analytics can be improved on using the double subjectivity model for gaining programmable insights where spatio-temporal dynamics is the expected outcome as described in this manuscript. The double subjectivity model could benefit Uber by a) offering a visualization tool for managing data more efficiently, b) delivering accurate results of the various interacting factors and forces in a shorter time period that considers the spatio-temporal dynamics of incoming data, and c) a human level visualization tool. This could benefit Uber's data scientists from doing data analytics individually on dissembled data factors and forces. According to [8], the cumulative effects of the double subjectivity model has the ability to apply computational models and methods and hence software tools to leverage human cognitive ability to gain insight into very large narrative text. As a result, the double subjectivity model graphs will improve the accuracy of solving abstract engineering and data problems and will give Uber a tool for getting a handle on their effective use of social influence for shifting values, attitudes, and behaviors.

5.1 Forces of Emergence, Change, and Conversion

Elucidating the underpinning forces at work in complex interactions and social influence—the capacity to affect or be affected—is essential for an adequate explanation of emergence, change, and conversion. There were a number of forces that converge to make Uber an attractor and help situate Uber as market leaders. The timing of Uber's innovative mobile app coincides with shifts in consumers values and attitudes about ownership versus the shared economy. These shifts stem from forces of emergence, such as ubiquitous computing and mobility, economic pressures and recessions, the desire for improved conveniences, access to transportation in cities and communities where consumers were underserved or poorly served, a new awakening of limited resources, and Uber's use of online media for propagating a message about their elite consumers. "Coverage of elites in articles is a property of particular interest in this study, as this factor has an effect on the bias intensity that news sources adopt over time [8]." According to Druckman [35, 36], the way elites frame an issue is a driving force for shaping public opinion. An example should help to clarify the implications the interplay of forces within the complex interactions and social influence that gave rise to Uber's emergence. Elites are individuals in power relationships or positions of authority.

Imagine Uber decides to enter a city, it follows a number of aggressive steps to quickly penetrate the market. Uber enters a city secretly and uses the local media to influence consumers by letting others know that it has entered the market (i.e., free advertising). Likewise, a promotion offering first-time consumers free rides while marketing to recruit new drivers aggressively in the new city starts immediately. Uber ignores regulators or fights them with an army of lawyers. The causal effects of Uber's entrance into a city

is felt immediately as evidence by price reduction in transportation fares, an initial increase to drivers commissions, and large sign-up bonuses for on boarding drivers. Uber braces itself for the challenges that it must overcome when entering a city, particularly regulatory constraints and competitors complaints, therefore the company invest a great amount of their cash base (in billions) in lobbyist who act as carriers of influence in the online media and within policy makers circles. Leveraging consumers sentiment about the shared economy—ride sharing and a less expensive alternative to car ownership, Uber enlist consumers as influencers and carriers of their messaging in online narrative text as they report their support of more efficient and less expensive transportation services. According to [37], "Uber employees whose sole job in the 'playbook' is to gain political influence start pushing for regulations that legalize Uber's operations. In almost all cases, this has worked and Uber is given the chance to gain a firm foothold in the city." Economic forces caused by the recession of 2007 put into motion the need for individuals to seek alternative income sources as many Americans were experiencing unemployment and had much less disposable income. Uber drivers may work part-time and full-time with the freedom to set their own schedule. This income on demand is a perk for individuals needing to supplement their income or those who desire non-traditional work flexibility. What all this means is that Uber's consumers, drivers, lobbyist, competitors, and other stakeholders adopt and copy Uber's narrative of sharing, efficiency, and convenience which reporters use in online news. The double subjectivity model captures cumulative effects of copying and gives insight to complex and dynamical forces whereby gradual shifts in amplification-intensity in online news is made visible.

5.2 Uber's Future — Double Subjectivity as a Key to Programmable Insight

Uber's decision to rely on data for social influence affords the company to expand to new lines of business. For example, Uber recently expands to on-demand trucking, b) car-pooling, c) mass transit, and d) meal delivery services. A consequence of Uber's expansion is the need to manage a vast amount of generated data on a daily basis—primarily narrative text—,this the human cannot scale through the hiring of more data scientist. Unfortunately, the existing tools machine learning and NLP has available to analyze these large quantities of data are designed for structured text which are inadequate for handling the Uber's data. Furthermore, existing tools must go beyond identifiable variables involved in the spatio-temporal production of human-generated data to an understanding of the entire assemblage. This involves factoring in the interworking of complex and dynamical forces coupled with cultural dynamics and social influence such that effective adjustments may be made that will transform Uber's generated data into information advantages.

Modeling double subjectivity provides a human readable tool in real-time whereby gradual cumulative effects are visible that considers identifiable variables and interactions between diverse forces. This tool may give Uber programmable insight into social influence effects and shifts in values, attitudes, and behaviors. A tool for gaining programming insight into how the myriad human and non-human variables and forces affect one another in associations for shifting values, attitudes, and behaviors should reveal more about Uber's long-term capacity to grow using data as its driving force for market penetration.

6. Methods

6.1. Dataset Description

The news data for the study were collected from Google News,[1] a newsfeed aggregator. Each article was selected based on four characteristics: a) its publication by an online news source, b) the prominence of the news source that generated the articles, c) the frequency of news publications by sources over time, and d) the salient terms contained in the article. All articles were published on the Internet between January 2015 and March 2017.

Articles were gathered by limiting the search for keywords associated with Uber and transportation consequences. After the collection of the articles, the articles were stored in a database for undergoing data preprocessing that included removing errors and inconsistencies to improve data quality.

6.2. Issues Networks for Online News

The first step in the construction of an issues network for news frames is to define the nodes. The issues network is a collection of news sources and article nodes of interest joined together in pairs by edge connections. In this research, the news articles being published by online news sources and the news sources that generate the articles served as the nodes. Though the proposed model and network extends to most bodies of unstructured narrative text, where frame amplification may exist, this manuscript focus on the case of Uber for illustrating the way complex and dynamical forces effect shifts in attitudes, values, and behaviors. It is the reasoning of the authors that news sources play a critical role in the propagation of amplification about issues, and amplification in online news drives a wedge between evidence and beliefs [4].

Uber is transforming the way data is used for shaping on-demand transportation service. As such, one can expect that the number of articles being produced on the issue is an indicator of its prominence and the framing choices of the news sources. The framing of Uber case is key to shaping attitudes and values. Such framing also indicates areas of amplification. Connections are made between news sources through the capture of framing adoption over time as it happens during migration. Migration pathways can be understood as assemblages and adopters of online articles frames. This adoption is a result of the framing effects that happens when online news sources repeat a narrative and its neighboring nodes copy what is reported, thereby this news narrative increases prominence in the network and causes growth and clustering of the mass. Undoubtedly, reciprocal relationships (i.e., news sources using the same frame choice) can be valuable, but such relationships are a challenge to capture using the article content. This is largely due to news sources not crediting other news sources in reports. The resulting network aim is to capture structures that were created and maintained through repeated patterns of framing and to capture the migration path of those structures over time.

6.3. Graphs and Problem Formalization

Framing of critical socio-environmental issues in online news is a complex and dynamic social network, which can be studied as

[1] http://news.google.com/

a graph, as it is here. Graph analysis has become important in understanding the dynamic process in the production of news frames. Graphs allow for the visualization of the social network, showing interdependency of actors (or nodes) in terms of the social relationships such as friendship, kinship, or financial exchange [38, 39]. Graphs represent objects where order and disorder coexist. Graphs serve well for showing social interactions, influence, migration paths, and framing effects. For instance, a graph may expose which news sources hold central positions that function as points of prominence, control, and stability and may show edges that act as highways for lead relationships and exchanges of news frames. These intertwined dynamics, coupled with the vast amounts of online news being produced daily, make graphs an important tool for visualization and analysis of information flows pertaining to critical issues.

The overarching research problem is expressed through the construction of an issues network, and the model of a news frame issues network is presented in this paper as a graph $G = ({S_g}^t, {A_h}^t, {E_r}^t)$ consisting of a) S_g that denotes a set of source nodes containing $g = \{s_1, s_2, \cdots, s_g\}$ elements and b) A_h as a set of article nodes containing $h = \{a_1, a_2, \cdots, a_h\}$ elements that operate within the time window t. In general, t indicates one discrete time step of a reporting period. Let $S_g = \{C_i, F_i\}$ be the set of source properties, where a) C_i is the set of terms (i.e., sub-issue keywords or content descriptors) and b) F_i is the dominant frame choice (identity) that the news source uses. Each relation R_r has a corresponding set of edge connections, ${E_r}^t$, directed/undirected as edge elements. The issues network subscript $r = 3$, corresponds to the total number of relations. The edge set represents the communication channels between node pairs. A_h are children of S_g; therefore, they may inherit the properties of the parent news source, as shown in Fig. 5.

The relations (or rules denoted as R_1, R_2, R_3) for E_r edge connections are as follows:

$\boldsymbol{R_1}$. A & A (articles to articles). A non-directional edge connection is constructed for E_1 when $A_h(a) = \{a: (a_1, a_2, \cdots, a_h) \in E_1\}$ is the set of neighbors of $\boldsymbol{a_h}$ such that $\boldsymbol{a_h}$ represents articles with a similar sub-issue.

$\boldsymbol{R_2}$. A & S (articles produced by the same source). A directional edge connection is constructed for E_2 when $S_g \in E_2 \rightarrow A_h(a) = \{a: (a_1, a_2, \cdots, a_h) \in E_2\}$ is the source (or producer) of the set of neighbors of $\boldsymbol{a_h}$ articles, where $\boldsymbol{a_h}$ represents articles with similar sub-issues.

$\boldsymbol{R_3}$. S & F (sources with sub-issue to sub-issue with the same frame choice). A non-directional edge connection is constructed for E_3 when $S_g(s) = \{s: (s_1, s_2, \cdots, s_g) \in E_3\}$ is the set of neighbors of $\boldsymbol{s_g}$ such that $\boldsymbol{s_g}$ shares the same dominant frame choice.

Problem: Given $G = ({S_g}^t, {A_h}^t, {E_r}^t)$ about I issue, construct a graph for determining how frames are produced in online news media over time.

6.4. Model Setup

To model the news frame issues network, the authors of this paper propose formulating a new model for information feedback based on a social system. The new framework is within the tradition of previous frameworks. These are the previous models [27, 9, 11, 40, 41] for studying the evolution of personal position, social influence multi-dimensions, and forces that cause cultural shifts. Axelrod's model [9] is built on two simple assumptions: a) selection, a phenomenon in which people are more likely to interact with those who are more similar to them, and/or to be more receptive to influence from those who are similar and b) influence, a term that describes the case in which interactions tend to cause similarity among interacting actors. The model proposed in the present study promotes the additional emphasis of amplification that emerges as double subjectivity in narrative text. Although the behavior of the proposed model is similar to that in Axelrod's [9], when deciding how to interact in the network, the proposed model differs in that insight is given into the endogenous and exogenous forces that may be at play in dynamic systems. Therefore, the double subjectivity in the proposed social influence model integrates cultural dynamics extensions [9, 10-12, 42, 43] with the cusp catastrophe model [41]. The cusp catastrophe model is useful for describing nonlinear relationships such as those found in narrative text. In the proposed model, the particular focus is on the different forces at work in the amplified slant employed in news frames as it allows for the degrees of freedom whereby alternative pathways may be realized. The cusp catastrophe model allows for understanding the different forces at work when quantifying framing amplification and the migration path.

Conceptually, the switch from linear to nonlinear relationships involves taking into account not only a news source's capacity to select (or affect), but also another news source's capacity to be influenced (or affected). Thus, an important aspect of selection and influence is the characterization of dynamical systems not just by their properties, but also by their capacities.

Consider this contextual example. When a news event occurs that impacts society, it thereby becomes an issue. It is partly defined by its properties, such as the absolute baseline facts, as well as being in a certain state, like the event having taken place on a certain day. This same news framing, however, has the capacity to intensify its amplification that may have the causal effect of a revolt or eruption by the people, an exacerbation of

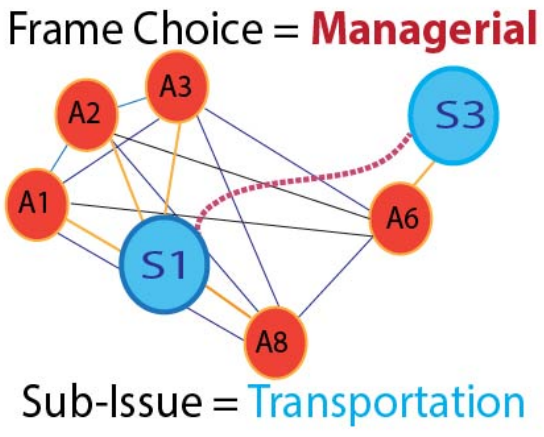

Fig. 5. A subset of the news frame issues network with two news source nodes with connecting articles using the same sub-issue and the same frame choice. The blue circles around notation S_g show online news sources node that produced the article and propagates a central organizing idea (i.e., framing), orange circles around A_h show an online news articles node, black lines show edge connections among neighboring articles on the similar issue, golden lines show edge connections of news sources who produce articles covering similar issue, and the red line shows a managerial news frame.

sentiment about a group of people, or the viral sensation of the news frame. This can happen through interactions with news sources that have the capacity to exercise strong amplification and to simultaneously weaken the agency of the people, group, or opposing view.

Properties are always reality based, since at any given point in time the facts—absolute baseline—are either true or false. Hence, facts are logical, formal, and rigid, but the causal capacity of news when exercising double subjectivity has a cumulative effect, which acts as a fabrication of what is real without being actual (or absolute). Unlike the limitations that facts in online news offer, amplification intensity within the construct of double subjectivity allows for the freedom to change dimensions through the parameterization of different forces—frame identity, justice, and amplification intensity—and distributions of sudden changes. The end effect is the perception of reality about an issue in online news that may offer new structure formations (or pathways) that lead to alternative views for shaping attitudes and beliefs. Stated differently, that which was only potential becomes a reality when changes in the different forces reach a certain critical threshold and a sudden jump happens. At this point, changes in beliefs can be tracked with the proposed model, even if the news framing amplification mechanism morphs the facts into something far from the truth.

The cusp catastrophe model calls this possibility space "the response surface space and control space," which represents all possible states in the system. In this research, the relationship among frame identity, justice (or a sense of fairness), and amplification intensity are acknowledged through the cusp catastrophe differential calculus formula, which allows the measurement of the rapidity or slowness with which forces can change. In the geometric approach to the calculus, each degree of freedom becomes one dimension of a possibility space. The space of possible states in the system allows for the differential relations between them to determine a certain distribution of stable states around points or loops of attractions. They have a fractal dimension (intermediate between one and two) and are referred to as "chaotic attractors" [40]. Thom's cusp catastrophe model [41] shows specific transitions of the forces, which have the tendency to cycle through the same set of states over and over [44].

The integration of cultural dynamics and the cusp catastrophe model for defining the new double subjectivity social influence model may shed insight into deep levels of expressivity in narrative text where amplification offers alternative pathways and possibilities. This remains an emerging research topic for understanding the production of language that may help in synthesizing vast amounts of unstructured text and learning online social behaviors.

The authors of this study explore the process that news sources use when producing online news articles. The main factors considered in this production are the facts, amplification intensity, and signals that derive from neighboring news sources. The signals that derive from news sources are likened to the reporter-relative or a floating baseline as mentioned previously. In the process of time, the news sources' absolute baselines will undergo adjustments as the amplification intensity changes.

6.5. Double Subjectivity Social Influence Model

The proposed double subjectivity social influence model integrates cultural dynamics extensions [9, 10-12] with the cusp catastrophe models [41, 44] for modeling double subjectivity in narrative text. The cusp catastrophe model is useful for describing nonlinear relationships such as those found in narrative text. The cusp catastrophe model allows for understanding the forces at work when quantifying amplification and the migration path.

Online news sources tend to produce articles about an issue I of interest to society, such as Uber emergence, changes, and sentiment that fosters shared value and cost savings. Additionally, news sources may receive signals β from other news sources on the importance of the issue, based on observed increase to the number of articles other neighboring news sources produce. They receive facts f about an issue. Each news source, then, selects a amplification strategy α using as the basis of its calculation the amplification intensity. More specifically, each news source S_g with interest in I issue at time t generates news articles

$$I(\mathrm{g}) = \alpha_g + \beta_g(f) \quad (1)$$

where α_g and β_g are the coefficients of the news source while f are the facts received. Furthermore, it is supposed that α_g corresponds to the endogenous propensity of the news source nodes to express its own amplification (or double subjectivity), while β_g represents the exogenous force in the network. In the first interaction, set $\alpha_g = 0$, denotes amplification intensity; this value will be calculated upon interacting with neighboring nodes and should change to give shape to the news source's absolute baseline. Time evolves in discrete steps t = 0, 1, 2, . . ., and $S_g(t)$ denotes the mass count on S_g at time t. The maximization of $\{S_g\}$ gives the sub-issue most important, M_i—a count of the largest cluster (the mass) of nodes reporting on an issue (case). This initialization of α_g and β_g provides access to new nodes to enter the overall conversation about Uber by linking to the most prominent mass, thereby, leveraging facts and the neighboring nodes of the relative baseline. This is similar to the operation observed in the hidden Markov model (HMM), whereby the news sources' absolute baseline is hidden with adjustments made over time. In contrast, the relative baseline is likened to the observations one can make in the HMM for getting a sense of the state [45].

Problem: Given $\{S_g\}$ interactions within graph G_t over time, determine the migration path and the nonlinear, causal linkages about $I(\mathrm{g})$.

At the start of the process, each news source $g \in S$ has a nonnegative node mass associated with it, corresponding to the fraction of the news sources that initially reports (i.e., through signaling) on similar sub-issues about Uber or transportation sub-issue. The dynamical system allows for each news source to switch frame choice, $F(e)$, and sub-issue interest, thereby enabling random selection of news source interaction. Also, news sources are susceptible to being influenced when they interact with neighboring news sources that share similar amplification intensity. The full state space may be calculated by counting the news sources as expressed as the mass vector $S_g(t)$.

6.6. Defining Amplification Intensity

The quantification of amplification intensity is situated in terms of the mathematical catastrophe theory [41]. Catastrophe theory is a branch of nonlinear dynamic systems theory that originated with the work of the mathematician Rene´ Thom [41] to help explain biological morphogenesis as one of the great

mysteries confronting mathematical biology. A key property in catastrophe theory is that the system under study is driven toward an equilibrium through its use of gradient descent or potential function for seemingly automatic guidance (i.e., through the law of attraction) occurring in the system, which is important in research on social influence, particularly when considering the property of convergence and stable states. The cusp model is the most well-known and the simplest model of catastrophe theory, positing that nonlinear transition within a system from one state to another is guided by two controlling variables: asymmetry and the bifurcation factor.

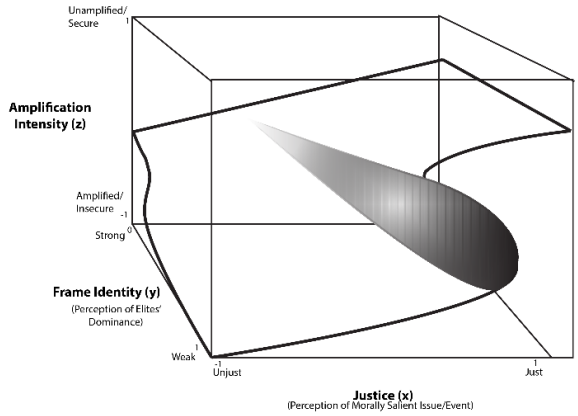

Fig. 6. The image depicts the cusp catastrophe model for measuring the shift in news sources amplification intensity.

Consider, for example, the social and economic inequality movement Occupy Wall Street. What began as small grassroots pressure points to address pay inequality among fast food workers and Walmart employees has transitioned to giving voice to 99% of the U.S. population and moving the political conversation in the U.S. election. This transition, from a grassroots protest in Manhattan's Zuccotti Park to making inequality and the wealth gap the core of the political race, is a catastrophe in accordance with catastrophe theory.

6.7. Model Variables Defined

Frames are a characteristic of human cognition structures, that operate simultaneously in human minds and texts. These latent structures of subjective interpretation are often produced and transmitted through the lens of power relations, hence elites [35].

The strategic use of managerial, economic, or conflict frames as expressivity in language embedded within online news, particularly when reporting on critical issues that impact society, have grave cost and consequences, which are far reaching. In the end, perceptions, beliefs, and attitudes by society become polarized or conflicted about critical issues even in the same domain, rather than society coming to a common consensus.

According to Lakoff [13], deep frame structures—where moral foundations exist—must be in operation in the mind during the production of language for justice about critical issues to prevail.

These emerging insights is justification for using justice in relation to frame identify as forces for understanding shifts in amplification intensity that lead to programmable insights about online news sources reporting on critical issues.

Fig. 6 graphically displays the possibility space of cusp model, an extension of the cusp catastrophe base model.

Let $M = \{Managerial, Economic, Human\ Interest\}$ and $S = \{Human\ Interest, Science\}$ be the aggregate count of the sets of frame choices obtained from the edge connection. S_g is assigned the frame identity corresponding to its F_i property at time t.

Definition: Amplification is represented by , a projection on the behavior surface for predicting the migration path that shows the gradual shift in amplification intensity of the online news source when shaping the frame narrative about the issue under study. This factor is a measure of the strength of amplification—that is, "weak amplification" is considered safe and is represented by *S(ecure)*, and "strong amplification" is considered insecure or harmful and is represented by *I(nsecure)*.

Definition: Asymmetry control (or normal) factor is represented by $\boldsymbol{x}$. This factor receives the label *Justice*, denoted on a scale that ranges from $J(ust)\ to\ U(njust)$. Justice is a measure of the news source's perception of forces about fairness where a multi-dimensional formulation is a desirable consideration. A utility-like function, we call the "aggregate" variables comprising of accessibility, mobility, disposable funds, low cost for ride share, and ubiquitous wireless technology are used to summarize forces that give one a sense of Justice.

Definition: Splitting factor or bifurcation factor is represented by $\mathbf{y}$. This factor receives the label *Frame Identity*, denoted as $S(trong)$ or $W(eak)$. This is the perceived dominance by elites when reporting the news.

The authors, here, argue that Frame Identity and the perception of Justice are key forces for predicting the amplification intensity of news sources when producing articles about emergent technology.

Frame Identity is one form of amplification; it is shaped by strategic devices for presenting prominent aspects and perspectives about an issue using a strong slant for the purpose of conveying latent meanings about an issue [3, 35, 46]. The position of the authors is that *Justice* is of equal importance, as it captures the perceived sense of fairness about an issue. A discretized approach to opinion research has been conducted in scholarly research [44] and applications of cusp catastrophe [47, 48].

7. Visual Language

Traces of visualization for communicating ideas predates to thousands of years. Recently, attention has turned to the usage of visualizations for audience influence and persuasion. Most importantly, with the influx of big data on the Internet, visualizations have become the premier tool for exploratory data analysis that enables the formation of hypothesis about a network.

Visualization is a powerful human-oriented perception and comprehension tool. It provides special usability benefits, particularly when the goal is to monitor and analyze vast amounts of multi-dimensional data over time. Visualizations can provide insights into the spatial and temporal informational flows and dynamics, they allow for inference and discovery.

The properties of visual, spatial, and time are essential to building human intelligence. As this research introduces the double subjectivity social influence model for exploring the interplay of the dynamical system about critical issues. In this case, Uber.

In this research, a visual language that comprises alphabets for expressing nodes and grammar for expressing relational edge

connections is presented. It is used for communicating double subjectivity cumulative effects for understanding the spatial-temporal dynamics underlying the network of collective influence of framing in online news and as a factor in the production of language in text narratives.

Table 1. Visual language notations, symbols, and definitions

NOTATION	SYMBOL
S_g	
Thick blue circles around the notation S_g denote online news sources node.	
A_h	
Thin orange circles around the notation A_h denote an online news articles node.	
E_1	
Solid black lines correspond to edge connections among neighboring articles covering the similar issue.	
E_2	
Solid lines with colors {red, green, purple} correspond to edge connections of news sources who produce articles covering similar issue within domains.	
E_3	
Dotted lines with colors {red, blue, green, purple, orange} correspond to news frame choice (or strategy).	

Fig. 7 is an illustration given to show scenarios where news sources belief converges to a state of consensus, as shown in Fig. 7(a)., and conflict, as shown in Fig. 7(b). For this illustration, one may use a Euclidean distance measure for showing the degree of change among news sources.

The overarching research inquiry may be explored and is expressed through the construction of an online news frame issues network. Table 1 is the visual language for expressing and exploring the double subjectivity social influence model using the issues network for understanding the network structure and underpinning dynamical forces.

Given behavior of news sources when reporting on issues that impact society, like Uber, are complex, the interactions are not static, even when measured for very short intervals. The double subjectivity social influence model, make visible dynamics that may be easily missed in big data platforms, such as the Internet. The instruments identified in Table 2 may be used as probes for gaining programmable insights into the network and the forces at work.

This research offers a method for time stepwise transitions when navigating the dynamic online news issues network. The double subjectivity social influence model provides a mechanism for control over belief learning using the values of α_g, while β_g offers news sources inside signaling mechanism by leveraging historical knowledge about neighboring nodes.

Table 2. Instruments for measuring

NOTATION	DESCRIPTION
G_t	Graph composed of nodes and edges with respect to time t
S	Total number of online news source nodes in a graph
A	Total number of online news articles nodes in a graph
E_a	Total number of article to article edges in a graph
E_s	Total number of article to source edges in a graph
E_f	Total number edges of sources employing the same frame in a graph
$S_g(t)$	Number of online news source nodes in a graph at time t
$A_h\ (t)$	Number of online news articles nodes in a graph at time t
$A\ (e)$	Number of article edges in a graph at time t
$S\ (e)$	Number of source edges in a graph at time t
$F\ (e)$	Number of frame edges in a graph at time t
b	Amplification Intensity Constant
$f(b)$	Amplification Intensity Function

8. Possibility Space for Transitions and Steady States

Nonlinear relationships represent a variety of possibilities and pathways of which the linear case is a limiting one. The authors propose to express the possibility space for the study using three variables as shown in Table 3. The possibility space represent simultaneous actuality and potential structures formed by differential interacting forces and distributions of singularities. The term singularities means an non-ordinary event that triggers a shift, such as, the repetitive framing of the need for car ownership in a way that bring into question its utility given its economic cost and utilization. The possibility space described here, at a minimum, is three-dimensions as we consider frame identity and an aggregate of justice as forces affecting the amplification intensity, which may cause shifts in attitudes. The

state of online news framing on the issue at a particular time is actual, while all the other available states are potential, waiting to be triggered into actuality by a force.

Table 3. Possibility space index

FRAME IDENTITY (SPLITTING FACTOR)		
INDEX-1	**DESCRIPTION**	**VALUES**
S	S(trong)	0
W	W(eak)	1

JUSTICE (NORMAL FACTOR)		
INDEX-2	**DESCRIPTION**	**VALUE**
J	J(ust)	1
U	U(njust)	-1
0	N(eutral)	0

AMPLIFICTION INTENSITY		
INDEX-3	**DESCRIPTION**	**VALUE**
S	S(ecure)	1
I	I(nsecure)	-1
0	N(eutral)	0

Note. Explanation of Index meanings. Index 1 represents the control variable frame identity, which is the perceived dominance by elites when reporting the news. Index 2 represents the sense of justice in the handling of the issue. Index 3 represents the dependent variable amplification intensity, which has the effect of signaling a secure (or safe) or insecure (or harmful) issue.

Index-1, Index-2, and Index-3 are combined to denote state transitions for updating shrinkages and growth. For instance, SJS denotes strong frame identity (S), a sense of justness (J), and a sense of security or being safe (S). SJS represents an actual state.

News sources' selection and influence occur through signaling news message amplification intensity. Table 4 indicates where news sources change amplification intensity based on interactions and it is an illustration of the gains and losses that may occur over time. Each column shows location of growth in the number of recipients switching from one news source to another, as a result of observed amplification intensity. The shrinkage and growth at a single site are proportional to the number of recipients and the number of senders signaling.

9. Discussion on Influence Dynamics and Migration Path

In this manuscript, models of cultural dynamics are integrated with the cusp catastrophe model to explore double subjectivity through quantifying the amplification intensity. The analysis shows that this measure (i.e., amplification intensity) has potential to change the network structure, as prominent mass count is not the only law of attraction at work. Figure 6 is a representation of the outcome of the model socio-temporal dynamics.

Although the proposed model is capable of scaling to full dataset capacity, a small subset of the network is used for this preliminary evaluation. Given online news sources receive signals that provide a relative baseline—leveraging other news sources' opinions, interpretations, and perceptions—it is most likely that a news source will choose interactions with similar sources. A chance exists for a news source to interact with another news source based on an increase in its amplification intensity although no connection exists. However, the chance is higher that news sources will interact only with connected sources; thus, breaking out of the cluster is caused by catastrophic shifts in amplification.

Table 4. Migration possibility space.

	Signaling content (state of news sender)						
Recipient	**SUI**	**S00**	**SJS**	**WUI**	**W0I**	**W0S**	**WJS**
SUI			S00			WUI	W0I
S00	SUI		SJS				
SJS	S00			WOS	WJS		
WUI	SUI		W0I				W0I
W0I	S00						
W0S			S00				
WJS	W0S		W0S	WOS			

With the amplification intensity function, a variant of the cusp catastrophe model shows possibility space in behavior when making decisions about trust and distrust. Any space on the surface response represents the state of the observed news source. As the news source perceives that the issue will not lead to fair consequences, the cusp triggers them to start attributing blame toward the population causing harm. For instance, the most recent report of Uber previous CEO distracting behavior. The contextualization of this case with Uber shows that a news source with ties to nodes that employ the frame choice of perceived unfairness (unjust) will notice that the sources more aligned with elites are becoming increasingly bullish on the value of the emergent technology issue that promises to deliver improved efficiencies and conveniences. These news sources who initially framed the issue as unjust attract other news sources (i.e., homophily) because their narrative is spreading. When feelings of unfairness intersect with the dominance of the elites, the news sources start scanning for those to whom to attribute blame, thereby entering a space of distrust and strong amplification. This kind of model is associated with hysteresis, making it hard to shift between surface response planes, as the migration path will be different.

10. Result of Research

Uber is a major international company with millions of customers. While the company uses advanced technology to offer its services, its main reliance is on influencing public opinions to improve its acceptance, reputation, and hence maintain a sustainable growth. Uber identified the need to keep a close eye on what is being said about the company in online news and different media. The current technology largely depends on humans—and traditional analytical tools—to follow-up and analyze Uber-related media, which can be expensive and limited in scale.

This manuscript presents the programmable insight approach that allows the new software to manage and analyze very large number of digital data. Thereby, providing immediate insight into different Uber social influence as characterized through opinions formation, network growth or shrinkage, amplification shifts, and news influence on consumer behaviors. This approach has the

potential to give Uber a large scale, real-time overview of digital data social influence and causal effects of complex dynamics, such as their sources, growth rate, or effects of frame choice.

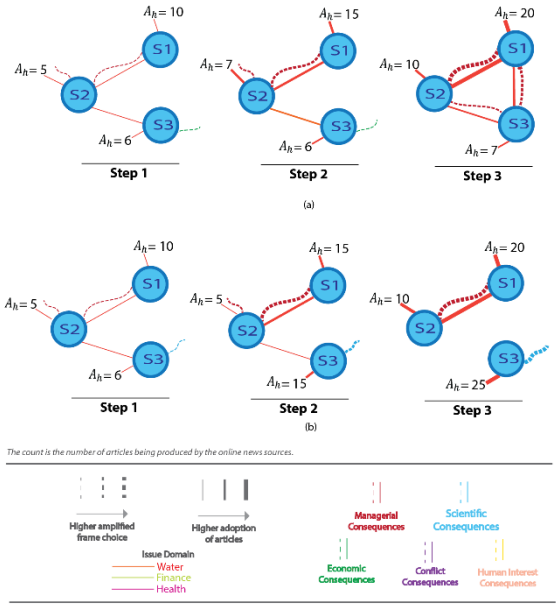

Fig. 7. A visual representation of the model. This is an illustrative scenario of news source interactions where Double Subjectivity has spatial-temporal dynamics and social influence with causal effect. Diagram (a) shows interactions that results in consensus. Whereas, (b) shows the formation of an alternative path that may be expressed as conflict in beliefs or attitudes about Uber. This depiction shows the five standard communications frames used in this research and three domains where vast amounts of narrative unstructured text exist online.

Over time, the programmable insight software will track the progress and trend of online data, providing Uber executives with a true map of ongoing opinions. Uber will be able to enhance positive trends as well as observe negative opinions early on, track their influence, and manage any related problems early on.

Results will be displayed visually using a graph with nodes representing news sources and articles produced, and edge relationships representing the frame type and strength of the associated influence. A human executive will be able to read the graph and observe any new node appearing on it, as well as influence level measures; represented by the number of links going out of the node and their thickness. This node or edge metric will immediately inform executives the emergence of new social influence and opinion sources (the node), as well as their significance (the number and thickness of edges).

While these metrics can be displayed in an excel sheet, it renders itself much easier to the graph theory, and a very large amount of information can be comprehended by a human person much faster.

The performance gain is threefold:

1. *Spatial*: The ability to observe, analyze, and provide "Insight" on a very large number of digital data emanating from many sources in real-time. Traditionally, this would require an army of human analysts using simple tools to work on each document, which could be very time consuming.
2. *Temporal*: The software will be able to continuously observe a large number of online news and other digital data over an extended period of time, and displaying the temporal progress of opinions, showing not only all existing ones, but the history of each news source, and how much it has been influencing others. This will emphasize the dynamics of opinion, and will help focus on significant ones while ignoring others with less or diminishing influence.
3. *Cost*: Running the programmable insight software will cost less than the efforts of human analysts.

11. Conclusion

In this manuscript, a new concept was presented that allows for an adjustment of the absolute baseline of a news source (or agent) that takes into account one's amplification for expressing double subjectivity through news frames. Further, offered in this research is a) the first known formal news frame issues network in computer science, b) a model for learning the migration paths and patterns about issues, and c) the first known formulation of a amplification intensity function using the cusp catastrophe model for showing the possibility space and gradual shifts in views that are sensitive to news framing amplification. Preliminary experiments suggest that the integration of cultural dynamic models with a cusp catastrophe model is promising for exploring double subjectivity for revealing latent relationships found in online news articles. Future work will involve testing other hypotheses and unfolding the potential function to explore conditions of convergence. Also, future work will give treatment to other hypotheses associated with amplification that leads to trust or distrust, as a result of perceived positive consequences.

Conflict of Interest

The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

ABSTRACT

The objective of this paper is to investigate the use of the 1-D wavelet analysis to extract several patterns from signals data sets collected from healthy and faulty input-output signals of control systems as a preliminary step in real-time implementation of fault detection diagnosis and isolation strategies. The 1-D wavelet analysis proved that is a useful tool for signals processing, design and analysis based on wavelet transforms found in a wide range of control systems industrial applications. Based on the fact that in the real life there is a great similitude between the phenomena, we are motivated to extend the applicability of these techniques to solve similar applications from control systems field, such is done in our research work. Their efficiency will be demonstrated on a case study mainly chosen to evaluate the impact of the uncertainties and the nonlinearities of the sensors and actuators on the overall performance of the control systems. The proposed techniques are able to extract in frequency domain some pattern features (signatures) of interest directly from the signals data set collected by data acquisition equipment from the control system.

1. Introduction

This paper attention is focused now on the most likely actuators prone to failures during operation for a particular case study such as for example, an electro-pneumatic control valves integrated in the forward path of a neutralization wastewater plant control structure. These control valves dose the input flows of the acid and base reactants and are controlled by a proportional-integral (PI) controller in order to keep the pH-level of the neutralized solution at its target value. A pH-probe measures pH-actual value of the neutralized solution inside the reactor during the transient and steady state neutralization process, transmitting its feedback to the controller with time delay. Typically, the cause roots of the majority faults in neutralization control processes are the result of unexpected control valves failures during the frequent opening and closing operations, due to the backlash, dead-band, leakage, and blocking. In the literature several works are dedicated to identify some of the control valve critical failures, as a fuzzy classification solution for fault diagnosis of valve actuators in 2003 well documented in [1]. Also, in 2005 are proposed methods to detect and to diagnose faults in HVAC control systems, including backlash, based on frequency and spectral analysis such as in [2]. Furthermore, in 2006 a graph method that describes each fault by three levels of knowledge is suggested in [3] by using a structural analysis as a powerful tool for early determination of the possibility to detect and isolate the faults. The results evaluated on the DAMADICS control valve benchmark model reveal "how to determine which faults in the benchmark need further modeling to get desired isolation properties of the diagnosis system". In 2007 was proposed a nonparametric statistical method in order to diagnose at least four valve failure issues, among them the backlash, dead-band, leakage, and blocking, as is mentioned in [4]. Moreover, in 2007 was proposed a new method for detection and estimation of

Email: ntudoroiu@gmail.com

backlash in control loops such in [5]. The detection procedure is automated and based on normal operating data, without measuring the backlash output. In addition, the proposed detection procedure provides an estimate of the dead-band caused by the backlash, in order to offer all information needed to compensate for the backlash. The authors from [4] revealed also in 2012 an interesting statistic record that confirms again that "among the most frequents "loop illnesses", the valve has one major disorder: around of 30% of all valves has any degree of damage, being responsible for increase significantly loop variability. Two of the most frequent valve injuries are stiction and backlash". The stiction causes limit-cycles in the loop that increases its variability, while the backlash increases the loop variability, reducing the control performance and inserting limit-cycles only for integrator plants, similar to stiction failure [4].

The distinction between stiction and backlash that generate limit cycles in the case of integrator plants is done based on a data-based method developed in [4]. Well, it sounds that the closed-loop patterns features provide enough information to verify when either stiction or backlash is available [4]. Also in 2012 a new nonlinear control valve model was developed in [6] and its effectiveness in simulating valve stiction using MATLAB/SIMULINK software package was demonstrated. In this research defective measurement and control loops equipment, in particular a pH and acid concentration loops with a control valve as actuator are under investigation. More precisely, we assume that the neutralization control process is subjected to known deterministic disturbances, and its pH level and acid concentration are controlled separately by two negative feedback closed-loops by using a state feedback control law strategy with two PI separate controllers integrated in the closed-loop control structures. As a most suitable real time implementation and analysis tools are the Wavelet and Signal Processing Toolboxes provided by the one of the most powerful and well spread tools from the market such as the MATLAB/SIMULINK software package. This paper is organized as follows: in section 2 a brief control valve nonlinearities –terminology is introduced. In section 3 is made a brief description of the wavelet. In section 4 is introduced the neutralization process as a case study proposed in this paper. In section 5 are presented the main results obtained in MATLAB SIMULINK in time domain related to process modeling and closed-loop control. In sections 6 and 7 are presented a multi signal 1-D wavelet analysis used finally as a basics detection tool of the actuators faults in control systems. The paper ends with the concluding remarks.

2. The Control Valve Nonlinearities -Terminology

To understand better the nonlinearity control valve effects during its operation in order to control the input acid reactant flow on the overall performance of the neutralization control process in open-loop, as well as in closed loop, the key concepts that inspire the following discussion of static and dynamic friction in control valves need first to be defined. Furthermore, the reader gets a better insight of the stiction (static friction) and backlash mechanisms and a more formal definition of all possible valve actuator nonlinearities well documented in [7]. This section reviews the American National Standard Institution's (ANSI) formal definition of terms related to the control valve nonlinearity effects, in a similar way as is presented in [7]:

1. **Backlash:** ''In process instrumentation, it is a relative movement between interacting mechanical parts, resulting from looseness, when the motion is reversed''.
2. **Hysteresis:** ''Hysteresis is that property of the element evidenced by the dependence of the value of the output, for a given excursion of the input, upon the history of prior excursions and the direction of the current traverse. It is usually determined by subtracting the value of dead-band from the maximum measured separation between upscale-going and downscale-going indications of the measured variable (during a full-range traverse, unless otherwise specified) after transient have decayed".

This concept is illustrated in Figure 1 (a) and (c)[7] for a pneumatic control valve with the layout shown in Figure 2 [8].

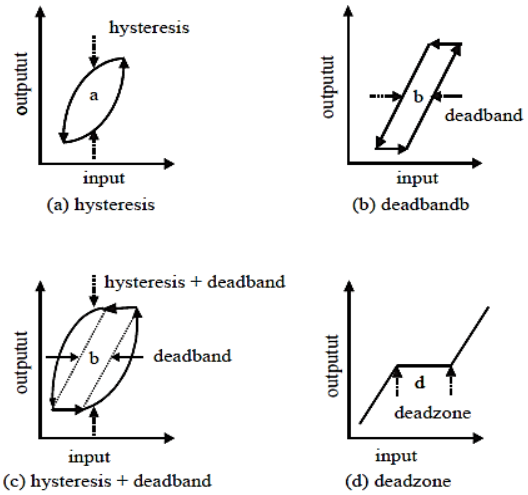

Figure 1: The hysteresis, dead-band, and dead-zone valve nonlinearities (screenshot view [7], according to ANSI/ISA-S51.1-1979).

3. **Dead-band:** ''In process instrumentation, it is the range through which an input signal may be varied, upon reversal of direction, without initiating an observable change in output signal'', as is shown in Figure 1(b).

The dead-band is not a bijection relationship; it is characterized by an input-output phase lag, expressed in percent of its span [7]. Moreover, a combination of the effects of dead-band and the hysteresis may be met as a new nonlinearity in a control valve actuator, as is shown in Figure 1(c). "Some reversal of output may be expected for any small reversal of input. This distinguishes hysteresis from dead-band'' [7].

4. **Dead-zone:** ''It is a predetermined range of input through which the output remains unchanged, irrespective of the direction of change of the input signal'', as is shown in Figure 1(d).

Unlike dead-band, the dead-zone doesn't produce an input - output phase leg, so it is expressed by a bijective input-output relationship.

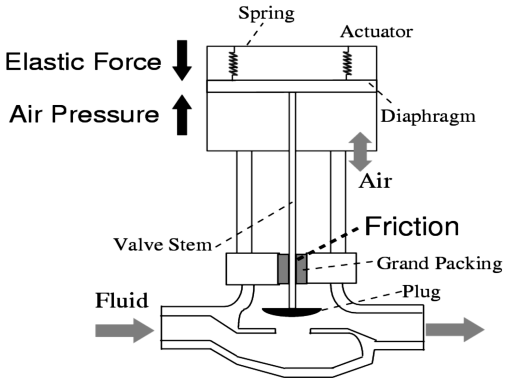

Figure 2: The structure of the pressure control valve (snapshot view [8])

These definitions reveal that the term ‘‘backlash’’ specifically applies to the slack or looseness of the mechanical part when the motion changes its direction [7]. In addition, the above ANSI (ISA-S51.1-1979) definitions illustrated clearly in Figure 1 prove without doubt that hysteresis and dead-band nonlinearities have distinct effects on a control valve. More precisely, the dead-band can be quantified in terms of x-axis input signal span, while hysteresis refers to a separation in the y-axis measured (output) response [7]. The combined effects of the static and dynamic effects of the previous nonlinearities generate one of the most complex control valve nonlinearity known under the name of control valve stiction (static friction). Its input–output characteristics consist of four components: dead-band, stick-band, slip jump and the moving phase of a stiction faulty valve as is shown in Figure 3 [7].

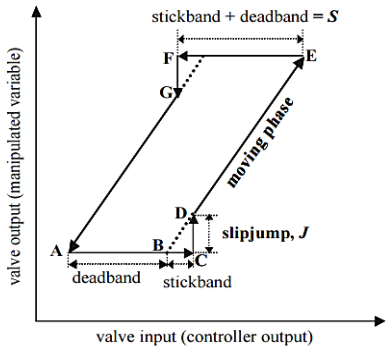

Figure 3: The characteristics of a sticky faulty control valve (Screenshot view [7])

The behavior of a sticky faulty valve is completely described in [7] as ‘‘a property of an element such that its smooth movement in response to a varying input is preceded by a sudden abrupt jump called the slip-jump. Slip-jump is expressed as a percentage of the output span. Its origin in a mechanical system is static friction which exceeds the friction during smooth movement’’. In this description the dead-band and stick-band represent the behavior of the non-moving control valve, while its input keeps changing. The slip jump releases suddenly the potential energy stored in the control valve chambers due to its stem high static friction in order to balance the kinetic energy as the valve starts to move. More precisely, the magnitude of the slip jump is one of the main causes in generating the limit cyclic behavior by the control valve stiction [7]. Once the valve slips, it continues to move until it sticks again (e.g., in the point E from Figure 3), and during all this moving-phase was proved that the dynamic friction may be much lower than the static friction [7]. The definition of the stiction well illustrated in Figure 3 can be considered as a rigorous description of the effects of friction in a control valve. Closing, these definitions will be very useful in the following sections to characterize the pattern features of the impact of several actuators nonlinearities in industrial control systems practice; under consideration will be the both continuous and discrete time state-space models of healthy and faulty open or feedback closed-loop control systems configurations. The healthy and faulty control systems responses from time domain will be converted in frequency domain by using different types of wavelet transforms that will be defined in the next section. Based on wavelet analysis in frequency domain will be extracted the matching pattern features that characterize each control valve nonlinearity under investigation.

3. Wavelet Signals Processing Technique Approach

The signal processing approach is one of the most used techniques used in practice for signal analysis. It is focused on particular signal characteristics, dealing also with the effects of the “white” or “colored” noises that contaminate the useful signals, by using statistical methods, such as the signals correlation and autocorrelation functions, covariance and cross-covariance, power spectral density, likelihood, or the autoregressive-moving-average (ARMA) models [9]. Frequency analysis is suitable for detecting the signals that contain particular meaningful frequency information, very useful to be used for example to detect, diagnose and isolate the healthy or faulty behavior of the control systems as response to the effects of a particular actuator nonlinearity or sensor faults, known in the control system literature as fault detection and isolation (FDI) techniques [10]. In this paper work are extracted only some of the pattern features of the healthy or faulty responses corresponding to control valve (actuator) nonlinearities under investigation. The wavelet transform is useful to detect the abrupt changes (signals pattern features) in the faulty actuators or sensors. It provides a useful set of time-scale or time-frequency domain tools and techniques to operate on a large range of signals [9]. The wavelet transform carries out a special form of analysis by shifting the original signal from the time domain into the time–frequency [11]. According to [11] “the idea behind the wavelet transform is to define a set of basic functions that allow an efficient, informative and useful representation of signals”, and first preliminary attempts to demonstrate the new theory based on the wavelet analysis started with the modeling of “a certain signal by a combination of translations and dilations of a simple, oscillatory function of finite duration, named wavelet “, and this technique is referred to as a continuous wavelet transform (CWT) [9]. In [11] also is mention that “Having emerged from advancement in time–frequency localization from the short–time Fourier analysis, the wavelet theory provides facilities for a flexible analysis as wavelets figuratively “zoom” into a frequency range. Moreover, the “wavelet methods constitute the underpinning of a new comprehension of time–frequency analysis”. Based on CWT many other wavelet analysis techniques have been developed in the literature [9], among them, due to paper space limitation, only one of these it will be considered. Depending on the intended purpose, if low-frequency information is required then the wavelet analysis deals with long time intervals, otherwise it will deal with short time intervals when high-frequency information is preferred. In the following we will give some

definitions that can be of real interest for the readers in order to have a good insight on all these concepts related to wavelet transforms as well as their manipulation in signals analysis and processing.

CWT Definition 1: The continuous-time wavelet transform of one-dimensional real-valued function, $f(t) \in L^2(R)$-Hilbert space, measurable and square-integrable, i.e. $\int_{-\infty}^{+\infty} |f(t)|^2 dt < \infty$, with respect to a wavelet function $\psi(t)$ is defined as the sum over all time of the signal multiplied by scaled, shifted versions of function $\psi(t)$ [9]:

$$Wf(s,u) = \frac{1}{\sqrt{s}} \int_{-\infty}^{+\infty} f(t) \psi^*(\frac{t-u}{s}) dt \quad (1)$$

where $\psi^*(t)$ represents the complex-conjugate of the "*mother wavelet*" $\psi(t)$, a real or complex-valued continuous time function that must satisfy the following two conditions:

$\psi(t)$ is a function with zero-average:

$$\int_{-\infty}^{+\infty} \psi(t) dt = 0 \quad (2)$$

$\psi(t) \in L^2(R)$, i.e. is a squared-integrable function, i.e. $\int_{-\infty}^{+\infty} |\psi(t)|^2 dt < \infty$.

A "mother wavelet" is a waveform for which the most energy is restricted to a finite duration [9], with the mention that there are an infinite number of the functions that candidate to be considered as a "mother wavelet".

In Eq. (2) the variable s is a "scale" or "dilation" variable that performs a stretching or compressing action on the "mother wavelet" while the variable u is referred as a "time shifting" or "translation" that delays or hastens the signal start.

More precisely, the function $\psi^*(\frac{t-u}{s})$ means that the mother wavelet $\psi(t)$ is shifted over time with u units of time and s times dilated. Therefore the wavelet analysis is a powerful tool that provides a time-scale view of the signal under investigation.

Denoting by

$$\overline{\psi}_s(t) = \frac{1}{\sqrt{s}} \psi(-\frac{1}{s}) \quad (3)$$

then the CWT of the continuous function $f(t) \in L^2(R)$ can be expressed by a the following convolution product (*):

$$Wf(s,u) = f * \overline{\psi}_s(u) \quad (4)$$

Also, it is worth to emphasize that the result of applying CWT to a signal under investigation is a wavelet coefficient vector that is a function of scale and translation g(s, u). An interesting interpretation related to a wavelet coefficient vector is done in [9], stating that "each coefficient represents how closely correlated a scaled wavelet is with the portion of the signal which is determined by translation". The CWT coefficients are nothing else than time-scale view of the analyzed signal, and so the CWT is an important analysis tool capable to "offers insight into both time and frequency domain signal properties" [9]. The results of this interpretation lead to the following useful observations [9] that will be considered for developing the proposed wavelet signals processing and analysis strategy:

The higher scales correspond to the "most" stretched wavelets, furthermore "the more stretched the wavelet, the longer the portion of the signal with which is compared, and thus the coarser the signal patterns features measured by the wavelet coefficients".

The "…coarser features called "approximations" providing basic shapes and properties of the original signal under investigation correspond to low frequency components, whereas the low scale components capture the high frequency information, called "details"…".

The main drawback of CWT is its computationally inefficiency due to the calculation of the CWT coefficients at every single scale with an impressive amount of work generating a huge bunch of data that must be stored in a considerable computer memory space. An alternative to the CWT is the discrete wavelet transform DWT, much more efficient and of high accuracy. The DWT is based on the wavelet analysis at particular scales and translations that are power of two, such as 2, 4, 6, 16, and so on [9], [10]. In [9] is stated that "the approximations" of the signals under investigation "provide basic trends and characteristics of the original signals, whereas the details provide the flavor of the signal", and the result of the applying DWT on the analyzed original signal is the so called wavelet decomposition around two key coefficient vectors, one of them is an "approximation" coefficient vector Ca, and other one is a "detail" coefficient vector Cd, representing "approximations" and "details" of the original signals under consideration. If the decomposition is repeated on the approximations in each stage, then the multiple stage DWT will break down the original analyzed signal into many successively lower resolution components, as is shown in [9], section 5.1.2, pp.79. According to [9] "at each stage, the approximation coefficient Ca represents the signal trend, and the detailed coefficient Cd includes the information on noise or nuance". The inverse process opposite to decomposition is the signal reconstruction by using an inverse discrete wavelet transform (IDWT). More details about sample wavelet definitions known as Haar, Mexican Hat, Morlet and Daubechies wavelets are well documented in [10]. Using the MATLAB/SIMULINK Wavelet and Processing Toolboxes will be implemented in real time the proposed multifractal and multisignal 1-D wavelet analysis strategy following the guidelines from [13], [14].

4. Case Study: pH Neutralization Plant

For simulation purpose the experimental setup for the pH neutralization process and the dynamic model coefficients are the same as in [15]. The tank layout is shown in Figure 3.

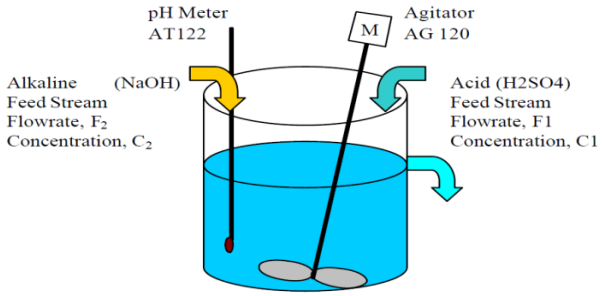

Figure 4: The reactor tank layout (screen shot view [11], pp. 41, Section 4)

Of technical viewpoint as the piping and instrumentation diagram layout, the tank and the overall architecture we preferred the simplified representation shown in Figure 4 to Figure 7 reproduced from [11] for their simplicity and better insight. They are related to the same pH neutralization process, only the coefficients of the models make the difference due to the changes in reactors geometry, flow rates and concentrations of acid and alkaline reactants.

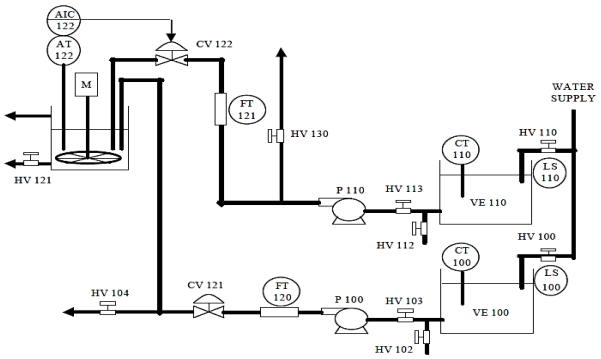

Figure 5: Piping and Instrumentation Diagram of pH neutralization plant (screen shot view [11], pp. 37, Section 3)

Figure 6: The picture of the neutralization pilot plant (snapshot view [11], pp. 38, Section 3)

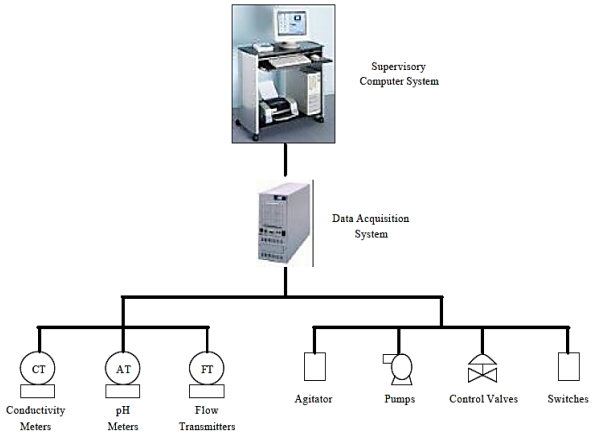

Figure 7: Overall architecture of the pH neutralization pilot plant (screen shot view [11], pp. 39, Section 3)

In Figure 8 is shown the block scheme of the both control loops, i.e. pH concentration value, and level of the solution inside the neutralization reactor.

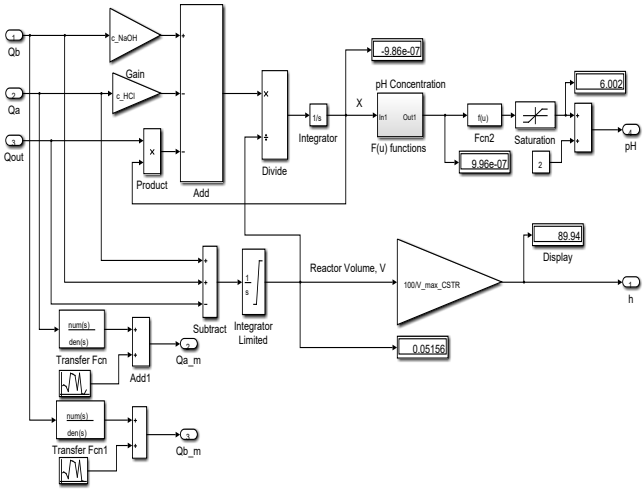

Figure 8: The SIMULINK model of the solution level control inside of the neutralized reactor and pH control closed-loops [15]

In Figure 9 is shown the SIMULINK model of the pH-controller with a back-propagation windup reset to avoid the saturation of the integrator due to the saturation nonlinearity of the control valve actuator. In Figure 10 and Figure11 is shown in detail the PI level controller with a windup reset from the same raison as for PI pH-controller.

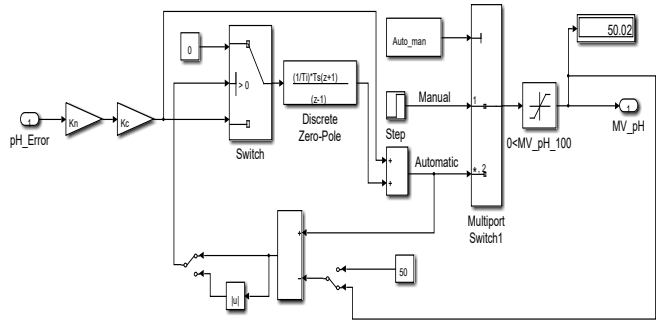

Figure 9: The SIMULINK model of pH controller with windup integrator [15]

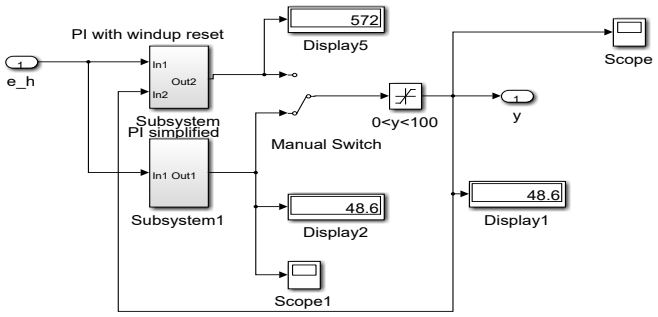

Figure 10: The simplified SIMULINK model of the Level PI Controller Block [15]

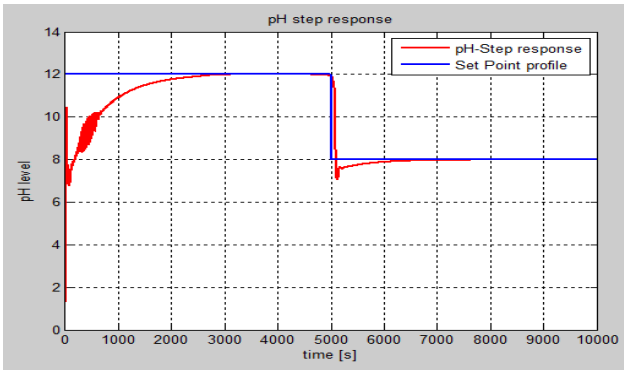
5. MATLAB and SIMULINK Simulations Results in Time Domain

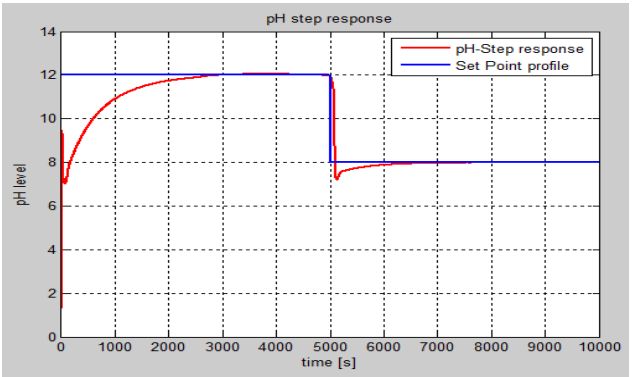
In this section we will present the simulation results of the control system performance in closed-loop, in time domain.

A. Healthy Control System with Pump and Control Valve Actuator Enabled

The pH step response is shown in Figure 11, for which the input profile changes the initial step input from pH12 after 5000 seconds (1h23min) to standardized pH8, the total simulation time taking 10000 seconds (2h46min).



(a)



(b)

Figure 11: The step response of the pH concentration of the neutralized solution inside the reactor.

Legend: a. Control valve enabled

b. Pump enabled

From performance analysis prospective the simulation results reveal a very accurate performance for the both PI controllers with windup reset. All these simulation results are carried out in a MATLAB SIMULINK simulation environment based on the SIMULINK model of the overall control system structure with the both feedback closed-loops, shown in Figure 12, similar as is developed in [16]. The step response of the level of neutralized solution inside the reactor controlled by a PI controller with windup reset is shown in Figure 12. In Figure 13 is presented the step response of the neutralized solution level inside the reactor. The controller efforts for pH and level are shown in Figure 14 and Figure 15.

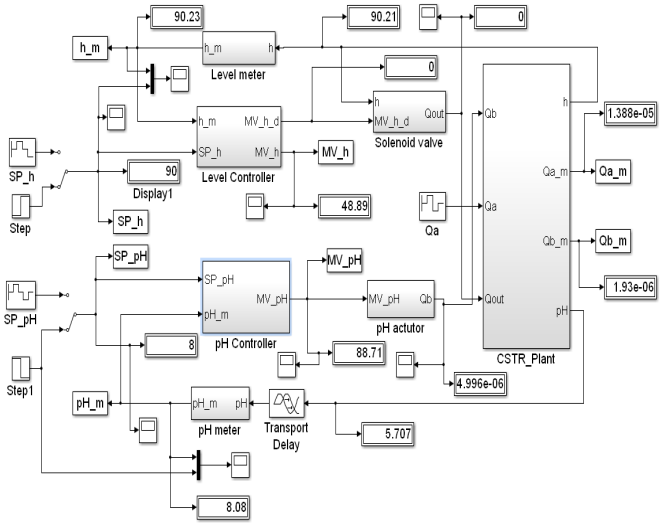


Figure 12: The SIMULINK model of the overall closed-loop control system [15]

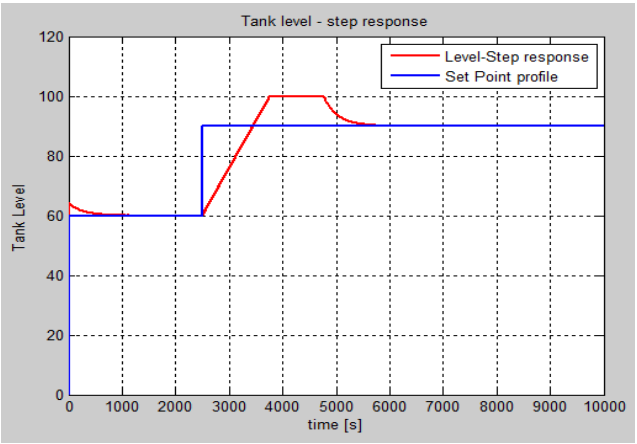

Figure 13: The step response of the neutralized solution level inside the reactor.

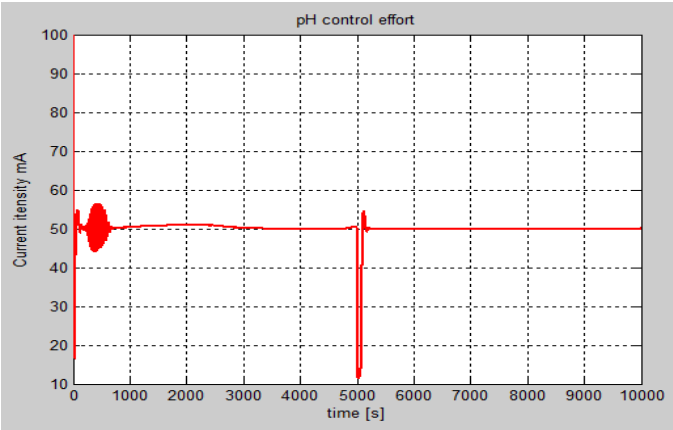
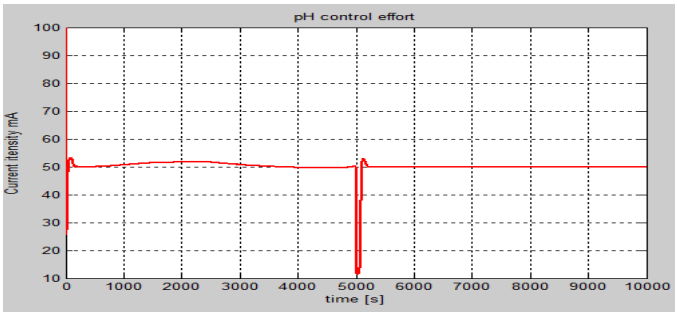
Let us now to consider the presence of a time delay in the pH control loop, i.e. pH sensor transmits the pH measured value to the input of the pH controller with certain amount of transport delay, let say for example 10 seconds, same value as is the time constant of the pH controller, you can see in Figure 16 that the pH control loop starts to oscillate at beginning of the simulations reaching the target steady-state for a while (2000 seconds) since after the first switching moment in setting point the closed-loop reaches the limit of stability around the second target setting

point, thus the controller becomes now inadequately. In this case is required a simple adaptive Smith-Predictor control structure for controlling time-delay systems, such is developed in [16].



(a)



(b)

Figure 14: The SIMULINK simulations of the pH controller effort in closed-loop

Legend: a. Control valve enabled

b. Pump enabled

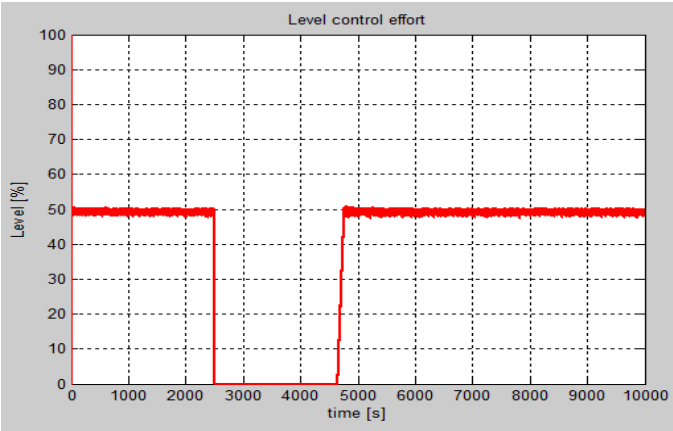


Figure 15: The SIMULINK simulations of the controller level effort in closed-loop

A considerable control effort of pH controller can be seen in this case in Figure 17. During these simulations no interferences between the two controls loops were noticed, thus the level control loop still remains very accurate.

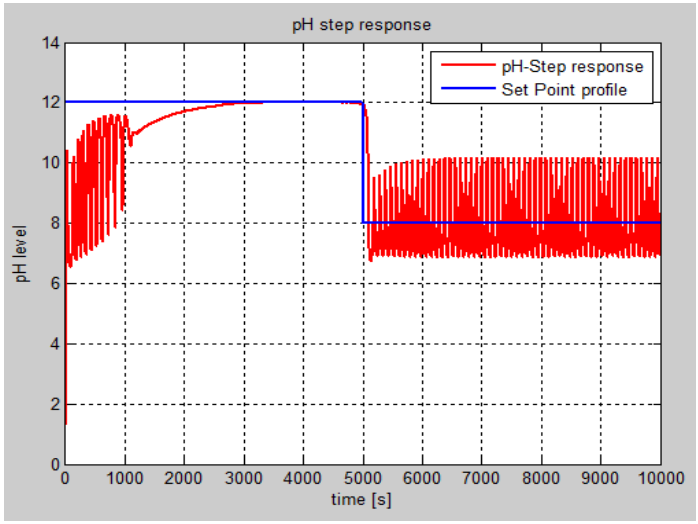

Figure16: The SIMULINK simulations of the pH concentration in closed-loop with 10 seconds time delay in signal transmission

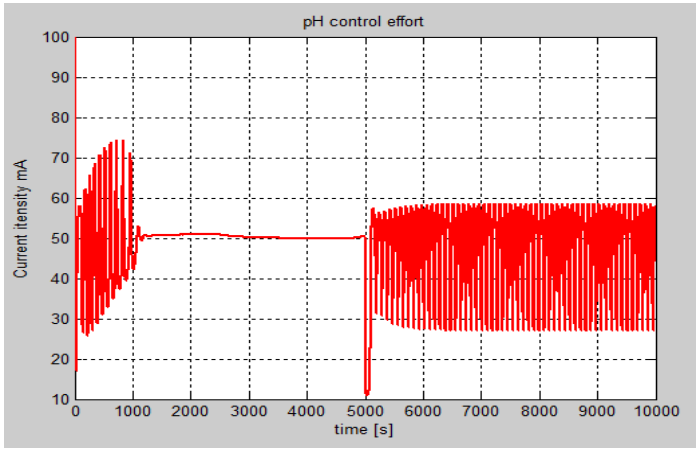

Figure 17: The SIMULINK simulations of pH controller effort in the presence of 10 seconds time delay in signal transmission

B. Faulty Control System with Control Valve Actuator Enabled

In this subsection we analyze the impact of control valve actuator nonlinearities on the overall control system performance.

1. Backlash control valve actuator nonlinearity shown in Figure 18 with dead-band width = 0.7, SIMULINK model.

In Figure 19 is shown the impact of the control valve backlash nonlinearity on the pH closed-loop control for the same set point input profile setup and the same tuning values for the pH controller parameters as for healthy control system structure. In this case the overall performance of pH control closed-loop degrades significantly. This is the first pattern feature extracted from measured pH output signal in time domain that will be analyzed in frequency domain by using a fractal analysis based on the wavelet transforms. The control effort is considerable also in this case, as is shown in Figure 20.

2. Coulomb and Viscous friction nonlinearity in control valve actuator shown in Figure 21 with the coefficient of viscous friction (gain) = 0.1, the Coulomb friction value (offset) = 1, SIMULINK model.

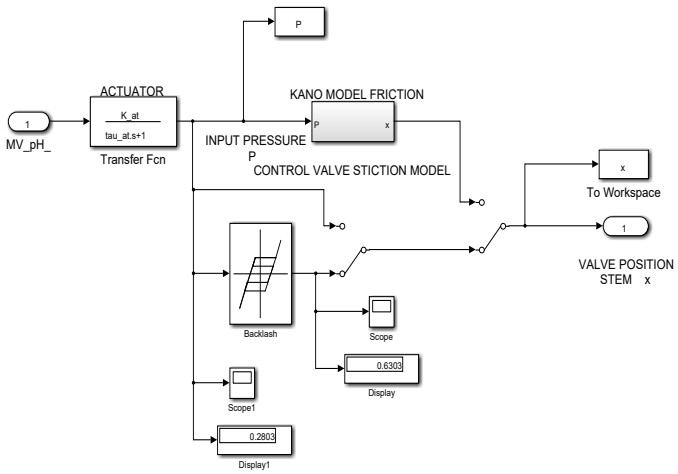

Figure 18: SIMULINK model of the control valve actuator with backlash nonlinearity (dead-band width = 0.7)

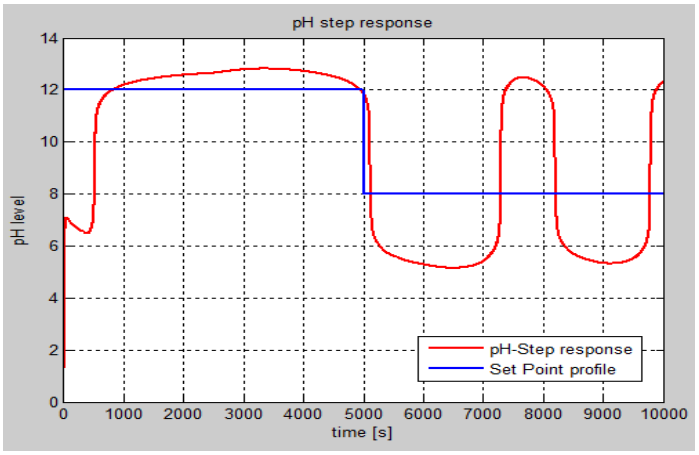

Figure 19: The impact of backlash control valve actuator nonlinearity on the pH evolution in closed-loop (dead-band width = 0.7, SIMULINK model).

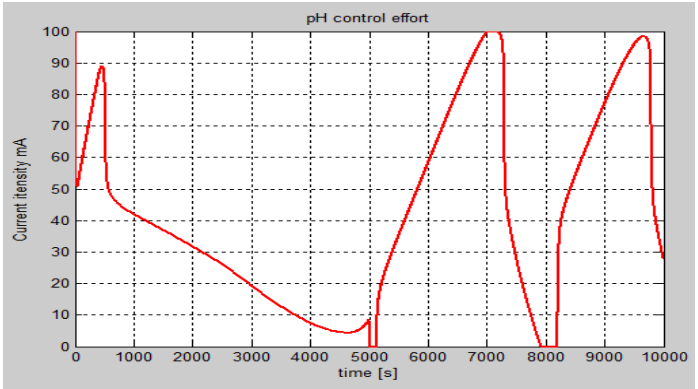

Figure 20: The pH control effort in the presence of backlash nonlinearity in the control valve actuator integrated in the pH control closed-loop (dead-band width = 0.7).

3. Dead-zone nonlinearity in control valve actuator shown in Figure 23 with a symmetric dead-zone width = 1, SIMULINK model.

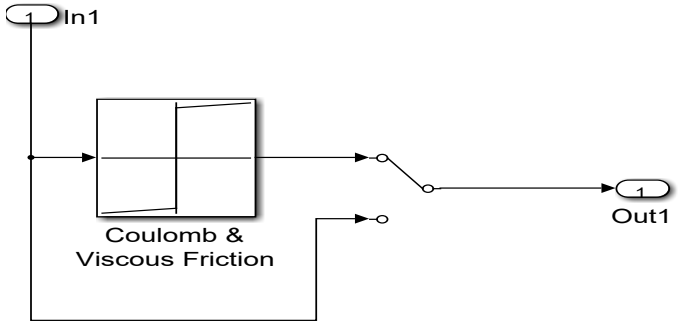

Figure 21: SIMULINK model of the control valve actuator with Coulomb and Viscous friction nonlinearity, SIMULINK model

Similar, compared to backlash nonlinearity case the overall performance of pH control closed-loop degrades drastically, as is shown in Figure 22. This is the second pattern feature extracted from measured pH output signal in time domain that will be analyzed in frequency domain by using a fractal analysis based on the wavelet transforms.

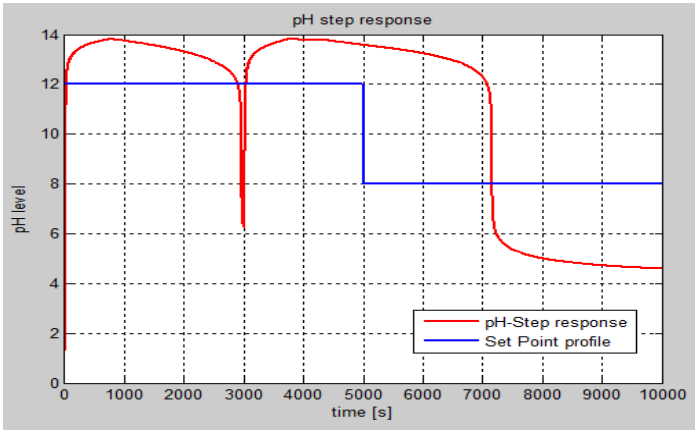

Figure 22: The impact of Coulomb and viscous friction nonlinearity of control valve actuator on the pH evolution in closed-loop (Coefficient of viscous friction (gain) = 0.1, the Coulomb friction value (offset) = 1, SIMULINK model).

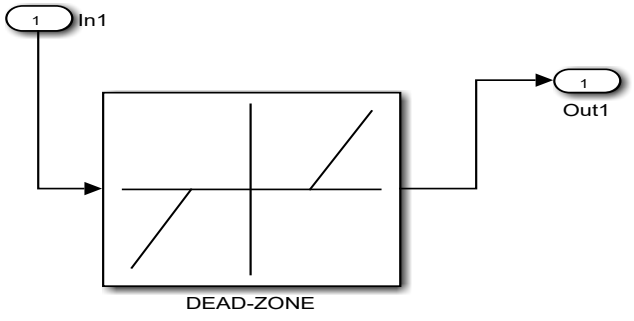

Figure 23 SIMULINK model of the control valve actuator with Dead-zone nonlinearity, SIMULINK model (dead-zone width =1)

The impact of dead-zone nonlinearity on the overall performance is shown in Figure 24. This is the third pattern feature extracted from measured pH output signal in time domain that will be analyzed in frequency domain by using a fractal analysis based on the wavelet transforms.

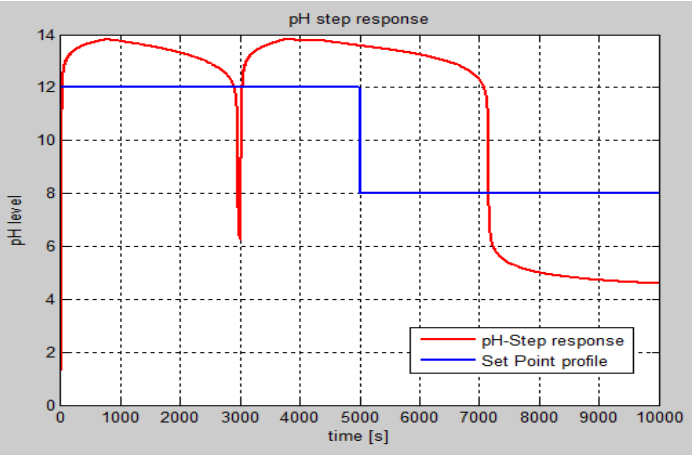

Figure 24: The impact of Dead-zone nonlinearity of control valve actuator on the pH evolution in closed-loop (dead-zone width = 1, SIMULINK model).

4. ***Saturation nonlinearity*** in control valve actuator shown in Figure 25 with superior limit = 0.5 [Pa], and the inferior limit = 0[Pa], SIMULINK model.

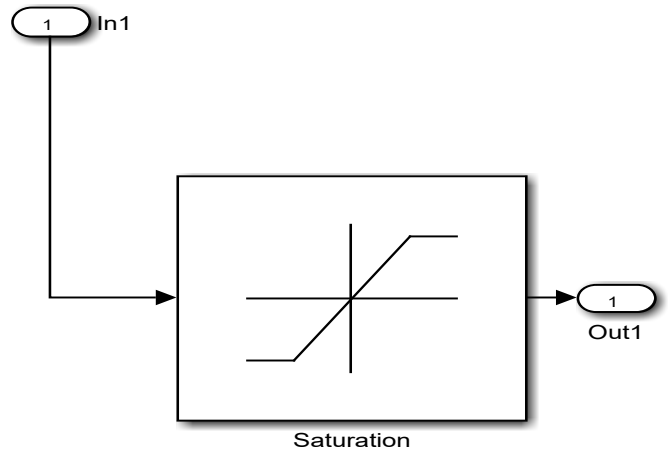

Figure 25: SIMULINK model of the control valve actuator with saturation nonlinearity, SIMULINK model

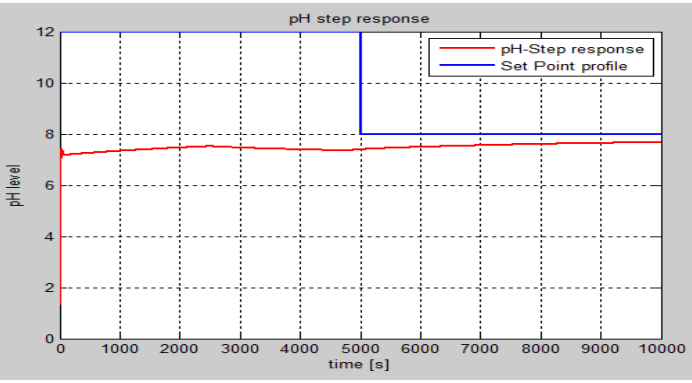

Figure 26: The impact of saturation nonlinearity of control valve actuator on the pH evolution in closed-loop (dead-zone width = 1, SIMULINK model).

6. Multisignal 1-D Wavelet Analysis - MATLAB Simulations Results

1-D Multisignal Definition 2: A 1-D multisignal is a set of 1-D signals of same length stored as a matrix organized rowwise (or columnwise) [14]. In the proposed case study all the signals are stored in a matrix with two rowwises, in a first row is stored the healthy signal and in second one is stored the corresponding faulty signal representing the impact of each actuator nonlinearity on the overall performance of healthy control system. The purpose of this section is to make a wavelet analysis of the 1-D multisignal set containing all the nonlinearities described in the previous section. How you will see the wavelet analysis is a precious analysis tool to denoise, compress and cluster different representations or their simplified versions. In first step a deeply analyze is made for all the signals collected in the previous section from the closed-loop control system, and then we will find some representations and also simplified versions for these signals by reconstructing their approximations at given levels, denoising and compressing them.

Denoising and compressing are two of the main applications of wavelets, often used as a preprocessing step before clustering [14]. The last step performs several clustering strategies and compares them. It allows summarizing a large set of signals using sparse wavelet representations. In Figure 27 you get an overall image about the impact of all control valve actuator nonlinearities on the closed-loop performance of the neutralization control system discussed in previous section.

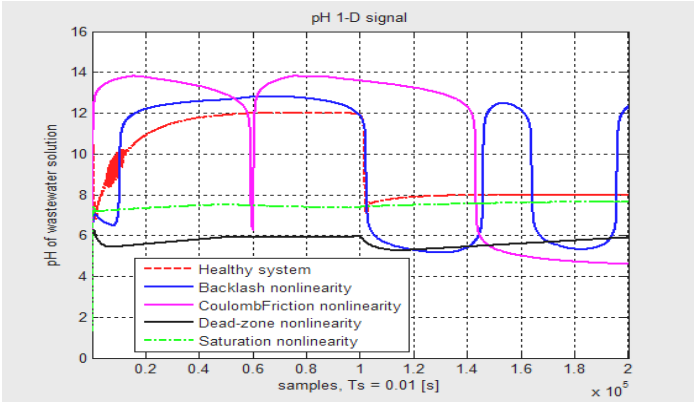

Figure 27: The impact of the control valve nonlinearities on the closed-loop performance of pH control system

The same overall image you can get as more attractive in a 3-D representation of all these nonlinearities including also the healthy control system, as a reference for the severity of each impact, is offered in Figure 28, The 3-D representation is preferred in addition to highlight the periodicity of the multisignal.

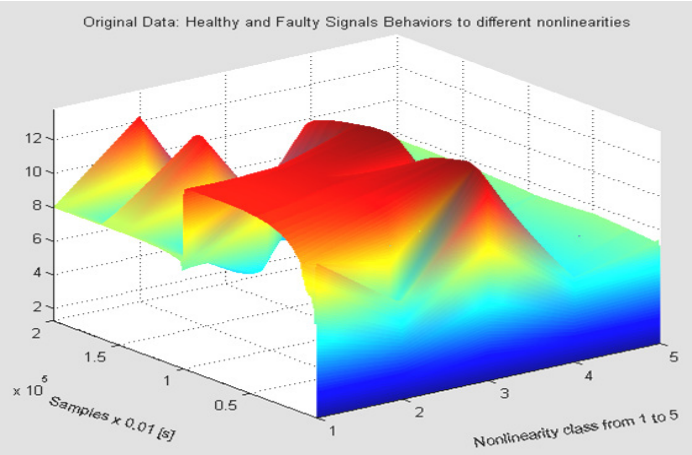

Figure 28: The 3-D representation of the impact of several control valve nonlinearities, on the closed-loop control system performance.

In 3-D representation each nonlinearity impact can be seen more clearly. In Figure 29 is shown the row decomposition of the multisignal related to the following fields of the generated structure in MATLAB R2013a:

```
dirDec: 'r' (row decomposition)
         Level of decomposition: 7
         wname: 'sym4'(near symmetric wavelet, as is shown
                       in Figure 29)
         dwtFilters: [1×1 struct]
         dwtEXTM: 'sym'
         dwtShift: 0
         dataSize: [35 1440]
            ca: [35×18 double]
            cd: {1×7 cell}
```

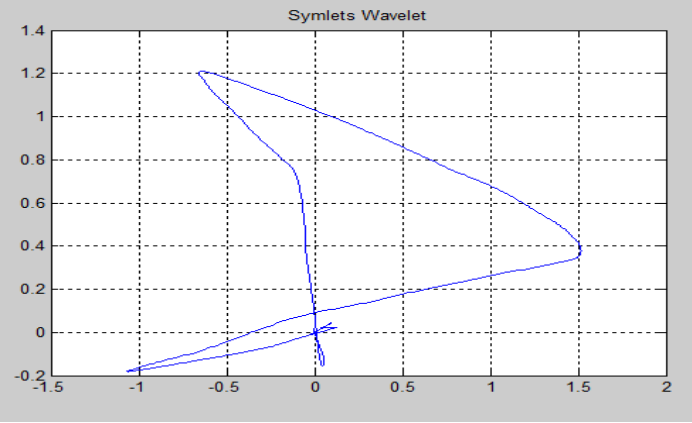

Figure 29: The symlet wavelet ("sym4') representation

MATLAB Wavelets Toolbox offers you more facilities to get information about all these wavelets functions using the MATLAB command waveinfo('name'), where 'name' is the assigned short name for the wavelets families such as 'sym', 'morl', 'haar', 'db', and so on. The reconstruction of the approximations at level 7 for each row signal is shown in Figure 30. The signals reconstructed are also compared in the same graph to the original signals. Furthermore, to get a better insight about the control valve nonlinearities under investigation in Figure 31 the signals are split in two groups, in the first group the healthy signal, the backlash and Coulomb viscous friction, and in second group the last two nonlinearities, control valve dead-zone and saturation.

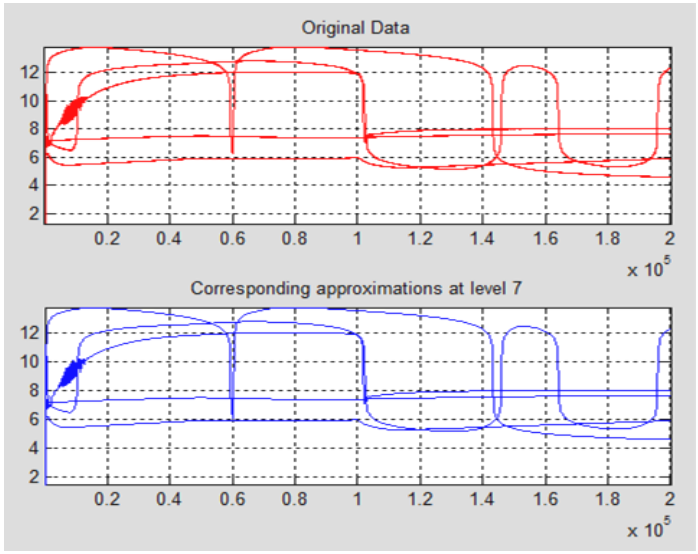

Figure 30: The original signals and the reconstruction of the approximations at level 7 for each row.

The top plot shows all the original signals and the bottom one shows all the corresponding approximations at level 7. As it can be seen, the general shape is captured by the approximations at level 7, but sometimes some interesting features are lost, as for example, the bumps at the beginning and at the end of the signals could disappear.

In order to perform a more subtle simplification of the multisignal preserving these bumps a denoise operation of the multisignal is useful. The denoising procedure is performed in MATLAB R2013a following three steps, namely [15]:

- **Decomposition**: First is required to select a wavelet function and to set up the level of its decomposition N, and then compute the wavelet decompositions of the signals at level N.
- **Thresholding**: For each level from 1 to N and for each signal, a threshold is selected and thresholding is applied to the detail coefficients.
- **Reconstruction**: Compute wavelet reconstructions using the original approximation coefficients of level N and the modified detail coefficients of levels from 1 to N.

If a slightly change will be made at the level of decomposition by changing N from 7 to N = 5 in Figure 32 can be seen similar results as in Figure 30, but now the quality of the results is better since the bumps at the beginning and at the end of the signals are well recovered. Conversely, in the same figure the residuals look like a noise except for some remaining bumps due to the signals. Furthermore, the magnitude of these remaining bumps is of a small order.

In Figure 33 are shown the results of the signals compression operation that follows the same three steps as in denoising case, a slightly difference in terms of the procedure is found only in step 2 that where two compression approaches are available [15]:

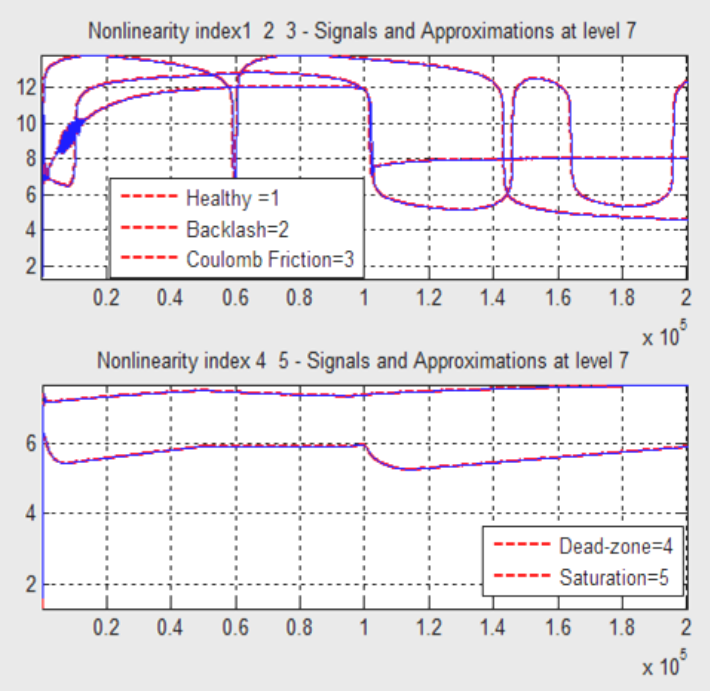

Figure 31: The signals and approximations at level 7 of row decomposition split in two groups

In the first approach the wavelet signals are expanded and keep the largest absolute value coefficients; in this case, a global threshold, a compression performance, or a relative square norm recovery performance can be set [15]. Therefore, for this approach only a single signal-dependent parameter needs to be selected. In the second approach a determined level-dependent threshold is chosen visually. The compression performance can be evaluated by calculating the corresponding densities of nonzero elements, as is shown in Figure 34.

For all the control valve nonlinearities under investigation that causes faulty signals, as well as for healthy signal, the percentage of required coefficients to recover 99% of the energy is the same, approximately 0.75%. This is one of the stronger wavelets features to prove a high capacity to concentrate all signal energy in few coefficients [15].

The last step is the clustering of the wavelets signals that offers a convenient procedure to summarize a large set of signals using sparse wavelet representations (with small number of elements). In Figure 35 the wavelets signals are clustered by 3. The first one is related to the Coulomb viscous friction nonlinearity of the control valve, the second cluster is related to the healthy and baclash nonlinearity, and the third cluster is related to dead-zone and saturation nonlinearities.

7. 1-D Wavelet Analysis as a Detection Tool of the Actuators Faults in Control Systems

In this section we investigate how to use the 1-D wavelet analysis to detect changes in the variance of a process control.

Changes in signal variance provide precious information anytime when something fundamental has changed about the data-generating mechanism that is basically the main idea of implementation for Fault Detection Diagnosis and Isolation (FDDI) strategies capable for detection, diagnosis and isolation of the faults that occur in actuators and sensors in a lot of control systems applications. In this section we investigate the effectiveness of using the 1-D wavelet analysis to detect some anomalies caused by malfunctioning of the equipment or different control system parts, especially actuators and sensors more likely prone to the errors. Encouraged by the experience and the preliminary results obtained in the control systems field, such as modeling and process identification, state estimation and FDI control strategies, a new FDI approach based on signal processing analysis to improve the accuracy, robustness and implementation design of these techniques is a big challenge. For simulation purpose we analyze only the impact on the overall closed-loop control performance of two control valve actuator nonlinearities, namely the backlash and Coulomb viscous friction, met frequently in the control industrial applications, as is shown in the Figures 37 and 38. In the Figure 37 is shown the SIMULINK model of the backlash nonlinearity that occurs often in control valve actuator, with the injection mechanism of the related fault at the instant $t_{fault_injection}$ = 7000 seconds. The set point input profile changes also at the instant t_{SP1}=5000 seconds, from pH12 to pH8. Similar, in the Figure 38 is shown the SIMULINK model of the Coulomb viscous friction control valve nonlinearity and the injection mechanism of the related fault. Similar, in Figure 39 is presented the mechanism of generating the values for the backlash width using the *clock* block and *if-then* with separate triggered action block.

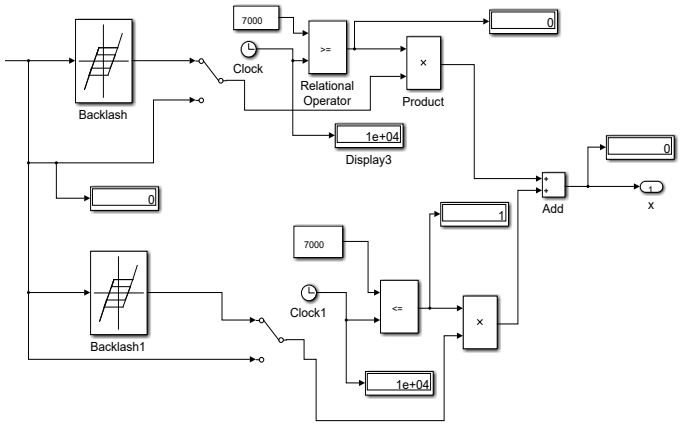

Figure 37: The SIMULINK model of backlash nonlinearity in the faulty control valve and the injection mechanism

In the Figures 40 and 41 are shown the injection instant of the both faults (backlash and Coulomb viscous friction), and also the faulty behavior of the control system after this instant.

Precious information about the time detection and the severity of the faults in each case is provided by the residuals defined as a difference between the healthy signal output (free fault) of the control system and faulty signal output, as is shown in Figure 42 and 43.

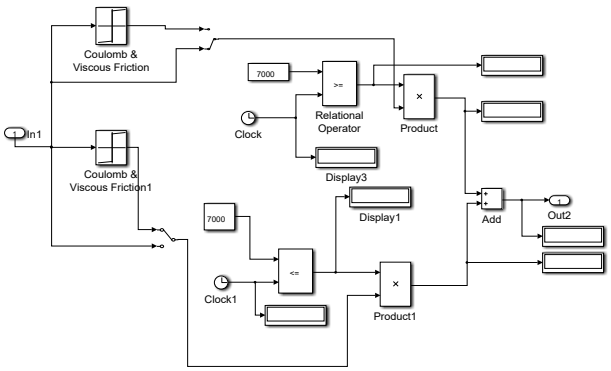

Figure 38: The SIMULINK model of Coulomb viscous friction nonlinearity in the faulty control valve and the injection mechanism.

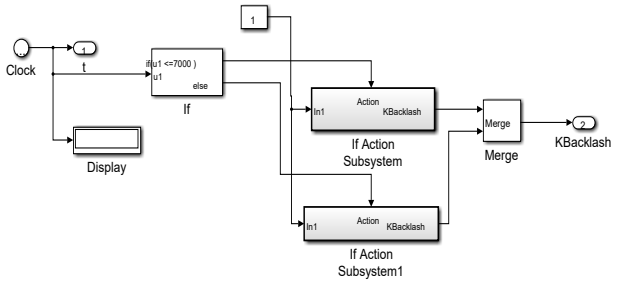

Figure 39: The SIMULINK model of generating the width values for backlash nonlinearity in the faulty control valve required in the injection mechanism.

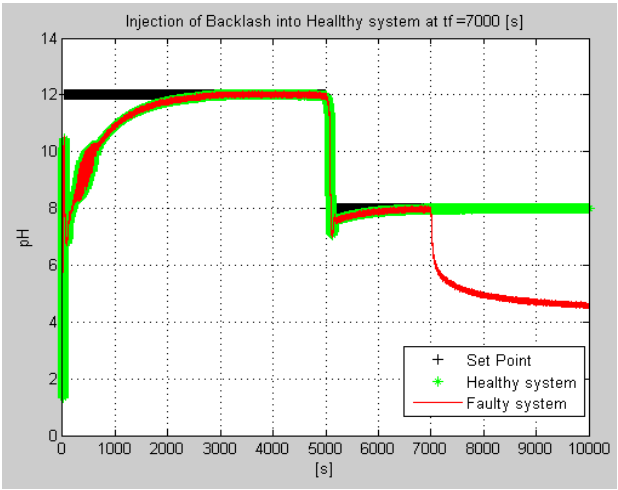

Figure 40: The MATLAB simulation results for healthy and faulty behavior caused by the backlash nonlinearity in the control valve actuator

Amongst the wavelets families functions the Morlet wavelet function shown in Figure 44 is suitable for continuous analysis using a continuous wavelet transform (CWT) [10], [17]. There is no scaling function associated with the Morlet wavelet. In many signal processing applications the Daubechies wavelet family functions are most used, especially for discrete wavelet transforms (DWT) [19]. To display detailed information about the Daubechies' least asymmetric orthogonal wavelets is used the MATLAB command *waveinfo*('sym'). To compute the wavelet and scaling function (if available), use *wavefun*( ):

```
[psi,xval] = wavefun('morl',10);
plot(xval,psi); title('Morlet Wavelet');
```

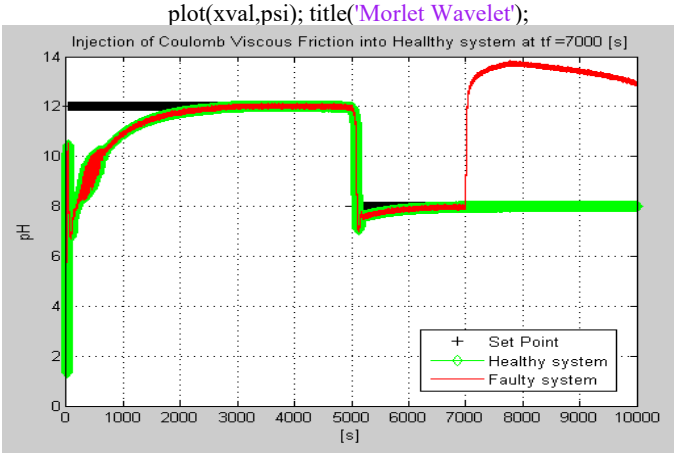

Figure 41: The MATLAB simulation results for healthy and faulty behavior caused by the Coulomb viscous friction in the control valve actuator

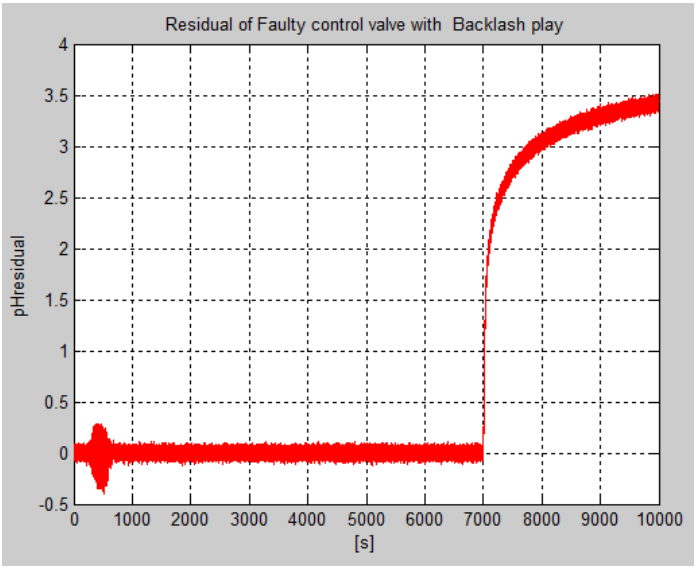

Figure 42: The MATLAB simulation results for output control system residual caused by the backlash nonlinearity in the control valve actuator

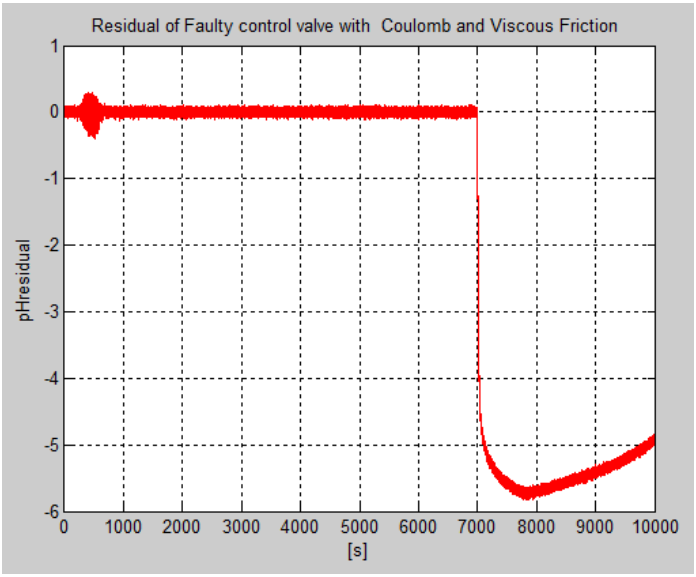

Figure 43: The MATLAB simulation results for output control system residual caused by the Coulomb viscous friction in the control valve actuator

For wavelets associated with a multiresolution analysis can be computed both the scaling function and wavelet. The following MATLAB code returns the scaling function and wavelet for the Daubechies' extremal phase wavelet with 4 vanishing moments [17], as is shown in Figure 45:

```
[phi,psi,xval] = wavefun('db4',10);
subplot(211);
plot(xval,phi);
title('db4 Scaling Function');
subplot(212);
plot(xval,psi);
title('db4 Wavelet');
```

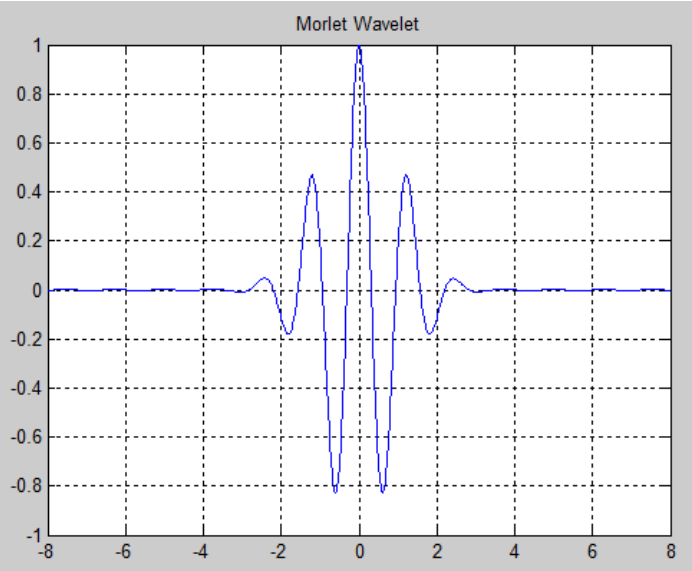

Figure 44: The Morlet wavelet function representation with 10 vanishing moments

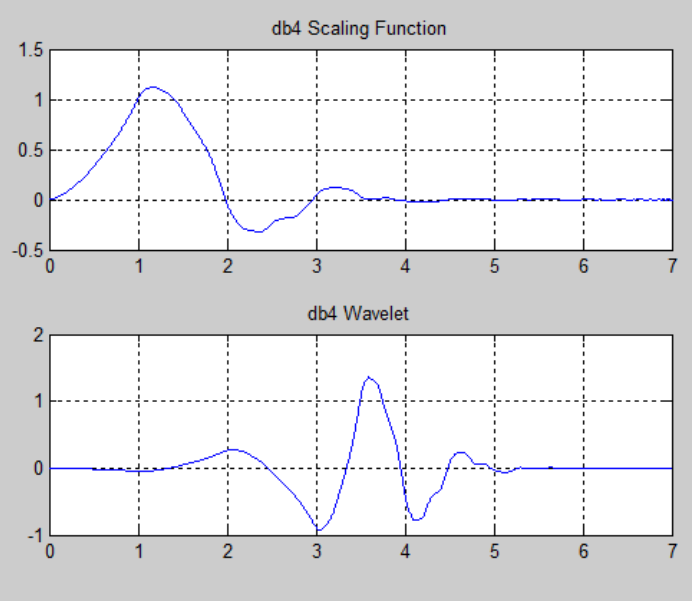

Figure 45: The Daubechies' extremal phase wavelet with 4 vanishing moments

In discrete wavelet analysis, the analysis and synthesis filters are of more interest than the associated scaling function and wavelet. For filter design and implementation you can use *wfilters*( ) to obtain the analysis and synthesis filters. For example, in order to obtain the decomposition (analysis) and reconstruction (synthesis) filters for the Bspline biorthogonal wavelet is required to specify 3 vanishing moments in the synthesis wavelet and 5 vanishing moments in the analysis wavelet with the following MATLAB cod lines to generate and to plot the filters' impulse responses, very useful in this section for fault detection based on the wavelets filters analysis and synthesis (Low Pass Filters and High Pass Filters, used for low frequencies and high frequencies signals filtration respectively) [17]:

```
[LoD, HiD, LoR, HiR] = wfilters('bior3.5');
subplot(221);
stem(LoD);
title('Lowpass Analysis Filter');
subplot(222);
stem(HiD);
title('Highpass Analysis Filter');
subplot(223);
stem(LoR);
title('Lowpass Synthesis Filter');
subplot(224);
stem(HiR);
 title('Highpass Synthesis Filter');
```

The simulation results are shown in Figure 46.

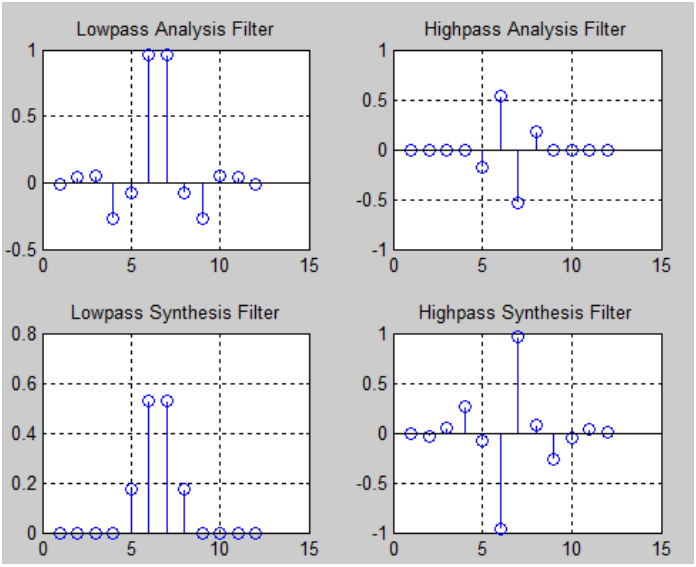

Figure 46: The Daubechies' extremal phase wavelet with 4 vanishing moments

The Daubechies wavelets (dbN) are the Daubechies' extremal phase wavelets, for which N refers to the number of vanishing moments. These filters are also referred to in the literature by the number of filter taps, which is 2N [17], [21].
The Symlet wavelets (symN) are also known as Daubechies' least-asymmetric wavelets. The symlets are more symmetric than the extremal phase wavelets. In symN, N is the number of vanishing moments. These filters are also referred to in the literature by the number of filter taps, which is 2N [17], [21].To obtain a survey of the main properties of this family, you must enter waveinfo('bior') at the MATLAB command line. More precisely, the orthogonal and biorthogonal filter banks are arrangements of lowpass, highpass, and bandpass filters that divide the signals data sets into subbands [17], [21]. If the subbands are not modified, these filters enable perfect reconstruction of the original data. In most applications, the data are processed differently in the different subbands and then reconstruct a modified version of the original data. Orthogonal filter banks do not have linear phase. Biorthogonal filter banks do have linear phase [17], [21]. The wavelet and scaling filters are specified by the number of the vanishing moments, which allows removing or retaining polynomial behavior in the signals data sets. Furthermore, lifting allows designing perfect reconstruction filter banks with specific properties. In order to obtain and use the most common orthogonal and biorthogonal wavelet filters can be used Wavelet Toolbox™ functions [17]. The design of custom perfect reconstruction filter bank can be performed through elementary lifting steps. In addition, can also be added your own custom wavelet filters. However, by using

the wavelet filter bank architecture depicted in Figure 47 it is possible to obtain residues that change in a noticeable manner in order to offer precious information about the time detection of the faults and its severity [19, 20]. The subband model is suggested in [19] of the form:

$$M(z) = (1 - z^{-1})^{-s}(a + bz^{-1}) \quad (5)$$

where s is an integer number and a, b are real numbers. In [19] is used the '**db8**' wavelet for wavelet filter bank design of level 3 decomposition [19] for a Single-Input Single-Output (SISO) plant extended in [20] for a Multivariable (MIMO) plant. A wavelet based-frequency subband analytical redundancy scheme to calculate the residuals for different faults is shown in Figure 48, and used for wavelet filter bank synthesis and analysis of level 3 decomposition in [19, 20] , and also in our case study. In this scheme G(z) and H(z) represent the z-transforms of the low pass filter (LPF) and high pass filter (HPF) respectively. A two-channel critically sampled filter bank filters the input signal using a lowpass and highpass filter [21]. The subband outputs of the filters are downsampled by two to preserve the overall number of samples. To reconstruct the input, upsample by two and then interpolate the results using the lowpass and highpass synthesis filters. If the filters satisfy certain properties, a perfect reconstruction of the input is achieved [21]. In Figure 49 is proved this perfect reconstruction by representing in the same graph the original faulty pH output signal (in the top) and the reconstruction faulty ph waveform response.

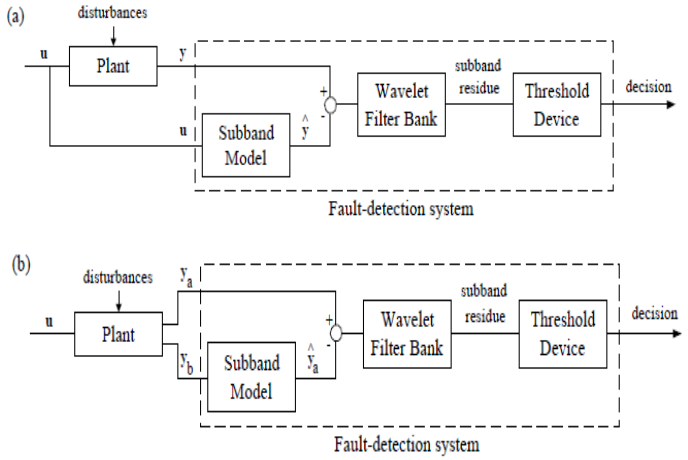

Figure 47: Original wavelet analytical redundancy architecture for (a) input-output and (b) output-output consistency (snapshot view from [19], [20])

At each successive level, the number of scaling and wavelet coefficients is downsampled by two so the total number of coefficients is preserved. In order to obtain the level three DWT of the pH faulty signal is using the 'sym4' orthogonal filter bank, using the MATLAB code line [21]:

[C,L] = wavedec(wecg,3,'sym4');

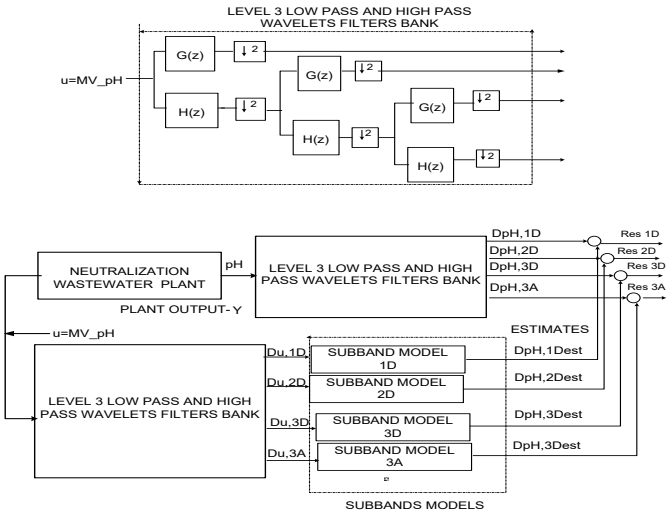

Figure 48: A wavelet based-frequency subband analytical redundancy scheme (suggested in [19, 20])

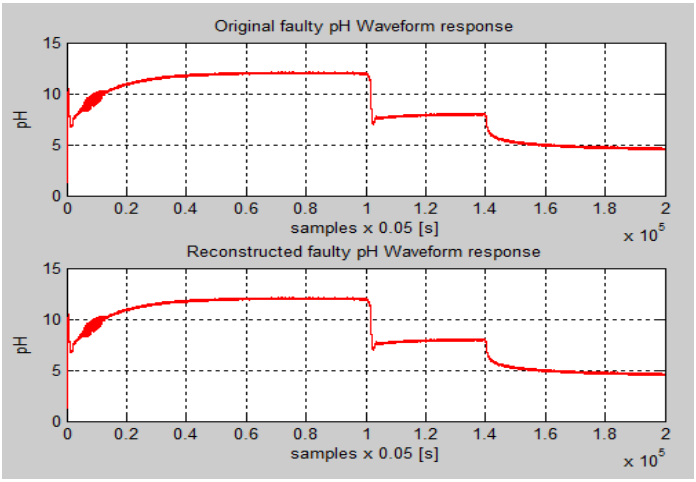

Figure 49: The original and reconstruct pH faulty signals

The number of coefficients by level is contained in the vector L. The first element of L is equal to 256, which represents the number of scaling coefficients at level 3 (the final level). The second element of L is the number of wavelet coefficients at level 3. Subsequent elements give the number of wavelet coefficients at higher levels until the final element of L is reached. The final element of L is equal to the number of samples in the original signal. The scaling and wavelet coefficients are stored in the vector C in the same order. In order to extract the scaling or wavelet coefficients, the MATLAB commands *appcoef* ( ) or *detcoef*.( ) can be used. All the wavelet coefficients are extracted in a cell array and final-level scaling coefficients [21]. In the Figures 50 and 51 are shown all these coefficients for faulty pH signal caused by backlash nonlinearity and for healthy pH signal (free faults) respectively.

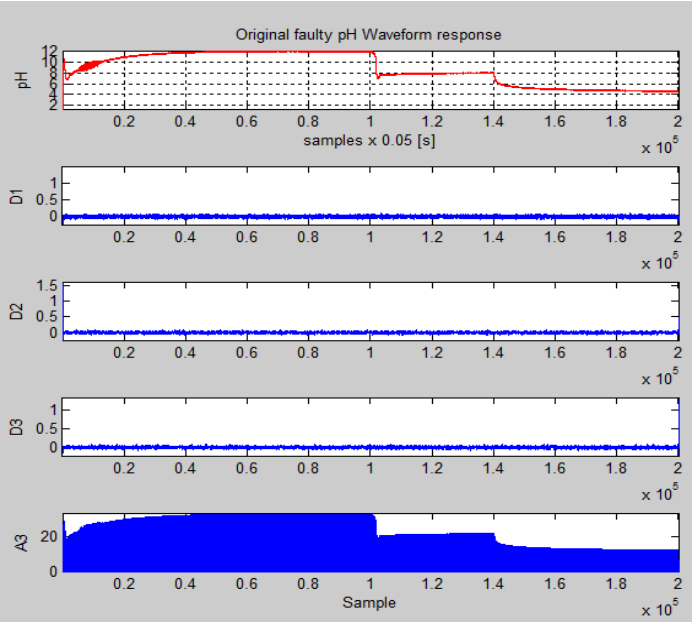

Figure 50: The detailed vectors coefficients D1, D2, D3 and approximation vector coefficients A3 for faulty pH signal caused by the backlash in control valve actuator.

The residuals of the detailed coefficients Res1D, Res2D, Res3D and also of the approximation coefficients Res3A are shown in the Figures 52 until 55. All these figures reveal a good detection of the fault injection instant, and also provide useful information about the fault severity, as is shown in Figure 55. The residuals for detailed vectors coefficients are almost zero if the noise will be filtrated. Similar, for the second nonlinearity in the control valve actuator the detection procedure of the faults is the same. The simulation results are shown in Figures 56 until 61.

8. Conclusions

In this research paper we open a new research direction in control systems applications field by performing a lot of investigations on the use of multisignal 1-D wavelet analysis to improve the accuracy, robustness, the design and the implementation in real-time of FDI techniques. These investigations are performed on the particular case study, mainly chosen to evaluate the impact of the uncertainties and the nonlinearities of the sensors and actuators on the overall performance of the control systems, namely a neutralization of

wastewater plant, in an attractive MATLAB SIMULINK simulation environment. The preliminary simulation results are encouraged and extensive investigations will be done in future work to extend the applications area. The 1-D wavelet analysis proved its effectiveness as a useful tool for signals processing, design and analysis based on wavelet transforms found in a wide range of control systems industrial applications. Based on the fact that in the real life there is a great similitude between the phenomena, we are motivated to extend the applicability of these techniques to solve similar applications from control systems field, such is done in our research work.

Nano-Patterns

ABSTRACT

Pluggable controllers are a different way to design control constructors such as `if`, `while`, `do`, *switch, and operators such as short circuit conjunction (*`&&`*) and the "*`?.`*" operator of the Swift programming language. Adoption of pluggable controllers enables the final user to modify and extend the control flow constructs (*`if`, `while`*, etc.) of an underlying programming language, the same way they can do if they implement functions such as* `printf` *and class* `String` *in a standard library.*

In modular, pluggable controller based language design, beside core control constructors, there are others, defined in standard libraries, with the purpose of augmenting and enriching the language. These pluggable controllers are extensible and replaceable. Being less intertwined in the main language, control constructor libraries can evolve independently from it, and their releases do not mandate new language releases.

We illustrate the implementation of pluggable controllers using Lola*, a powerful language-independent preprocessor and macro language. We demonstrate the introduction of new pluggable controllers with two case studies. The implementation of a Java stenography based on prevalent Java idioms, called "nano-patterns" or nanos, and the introduction in Java of new code constructs inspired by the Mathematica language's commands.*

1 Introduction

A recent publication [1] described a preliminary new perspective of viewing keywords such as `if` and `while` as library functions such as `printf`: standardized, but user extendable and replaceable. In this work, we expand on this vision, demonstrating the extension of Java with control keywords for two applications: a stenography for a concrete nano-patterns language whose prevalence in Java was previously demonstrated [2] and the implementation of Mathematica-like control structure in Java.

1.1 Control Constructors

Control Constructors are defined as those elements of a programming language that make it possible to assemble *commands*. In textbooks [3–5] as well as in classic works on programming languages [6–9], is reported that there are essentially three kinds of control constructors:

| ***Sequential*** | ***Iterative*** | ***Conditional*** |

A further distinction can be made between *atomic* and *compound* commands, where the latter are formed by primitive and other smaller compound commands. In Pascal, for example, atomic commands are the empty command, the assignment, and the procedure call. On the other hand, `Begin`...`end` is the sequential constructor, whereas `While`...`do`... is an iterative constructor, and, `If`...`then`... is a conditional constructor.

In real languages, there is no sharp separation between *expressions* and *commands*. Many *operators* that form expressions can act as control constructors. This is the case of standard short circuits operators such as "`&&`" and "`||`", and standard conditional operators such as "`· ? · : ·`", Other examples worth mentioning are represented by:

1. The "`,`" (comma) operator of C (the sequential comma operator of C).
2. The "`||`" operator, which "provides a default value", the Python variant of a short circuit.
3. The "`??`" operator (`null` coalescing) of C#.
4. The "`?.`" operator (*fluency on* `null`) of Swift.
5. The "`noexcept`" operator of C++, recently introduced, which guards against exceptions.

[*]Computer Science Dept. The Technion—IIT, Taub Building, Haifa 3200003, matteo.orru@cs.technion.ac.il

These operators can be expressed in terms of sequential, iterative, and conditional control constructors (henceforth, "*SIC*"). *Structured programming* [7] is defined by the notion of SIC, meaning that SIC are sufficient to impose structure on the unstructured. In fact, any program that has **goto** instructions in it can automatically be converted into an equivalent one that uses only SIC [10].

Concrete languages sometimes deviate from the traditional concept of SIC. A typical example is the **while** command of Python that has its peculiar **else**. Another example is represented by the different ways **switch** statements deal with fall-through cases, which is different in some languages. Variations and diversifications also appear in the semantics of

try...**catch**...**finally**

blocks. Language engineers, developers and practitioners are generally interested in using new language features that are likely to enhance their productivity, efficiency and reduce their errors. In general, the creativity of language engineers slows down after a languages' first release. Even small changes to a (successful) language definition might have unpredictable, potentially negative effects in the least expected places [11, p.497–508].

For the above reason, the long time taken before introducing the **switch**ing on strings feature in Java (see Fig. 1) is understandable. It took around twenty years from proposal[1] to implementation[2]—probably because of worries about its implications for engineers.

```
public static void main(String[] args) {
  for (String arg: args)
  if (arg.equals("-c") || arg.equals("--bytes"))
  . . .
  else if (arg.equals("-m") || arg.equals("--chars"))
  . . .
  else if (arg.equals("-w") || arg.equals("--words"))
  . . .
  else if (arg.equals("-l") || arg.equals("--lines"))
  . . .
  else if (arg.equals("--help"))
  . . .
  else if (arg.equals("--version"))
  . . .
  . . .
}
```

Figure 1: Java code with multiple comparisons of the same string variable with a sequence of string literals.

The drawback of the prudence characteristic of language architects, when it comes to introducing new features, is that it might negatively affect software systems. For example, consider that the late introduction of generics in Java forced developers to use the unsafe **Vector** as a substitute.

1.2 A Modular, Plugin-Oriented Approach

This paper raises the idea that the design of programming languages, specifically in respect to their control constructors' design, may follow a different, modular *plug-in* oriented approach. This proposal suggests that a programming language should have a number of core control constructors, whereas additional and more sophisticated control constructors, which we called *pluggable controllers*, can be defined in standard libraries of controllers, similar to what happens with functions such as **printf** in C or classes such as **String** in Java.

This approach promotes the decoupling between the controllers and the language architecture, leaving to both sides the freedom to evolve independently. This solution has advantages in different scenarios. The final user would be able to modify and extend the control flow constructs such as **if**, **while**, etc. of an underlying programming language. Language designers would be able to experiment new features before changing the language architecture. The proposed approach could also foster more sound discussions on the introduction of new features inside the users community.

The problem of the modularization of languages components is he main problem of *Modular Language Development*, a research branch that investigates how to componentize language design. Several solutions to the problem of componetization are available—see, for example, Cazzola and Vacchi [12] which adopt a solution based on *Traits* [13].

Another approach exploits the concept of *extensible language*, which presents some challenges such as that of adapting the parser according to language evolution [14] .

1.3 Lola

The imposition of a new code constructors on an underlying language can be done using Lola [15], the ***L**anguage **O**f **L**anguage **A**mendment*, which is a modern, language-independent, preprocessor and macro language, orientated to *language extension*. Lola makes it possible to augment and amend syntactical constructs of any host language.

Lola works like a filter [16] (see also [17, Sect. 3.1]) that converts an input stream comprising tokens of different kinds into an output stream. Lola allows designers to extend and enrich existing languages with new constructors without affecting languages architecture, since plugged controllers can be defined in Lola configuration files. In addition, with Lola, experiments on new language features can be conducted in controlled environments by scholars, designers and practitioners.

1.4 Nano-Patterns

A *nano-pattern* is a recurring solution adopted by developers, for a common task that involves control constructors. The fact that they are recurring solutions means that they are used often by developers. Another possible interpretation is that they are workarounds that developers found to overcome languages restrictions. In a previous study, it has been shown that there exist a number of prevalent nano-patterns. With the term "prevalent" we mean that they recur often in software systems. These solutions are potential candidates for inclusion as new language features—which can be done painlessly with a pluggable controllers approach.

1.5 Contribution

The present paper makes several contributions:

- We propose a novel, modular approach to the design of control constructors, the use of *pluggable controllers*. This approach makes it easier to add new (experimental) features to an existing programming language.
- We introduce Lola, a new preprocessor and macro language, oriented to language augmentation. We illustrate its syntax, work flow and present some meaningful examples.
- We further discuss the concept of *nano-patterns* (from now on *nanos*), introduced in previous works [1] as recurring solutions adopted by developers, to common tasks that involve control constructors.
- We demonstrate how to impose pluggable controllers on top of Java using Lola. Specifically, we present two case studies that show a specific usage of control constructors: a new *stenograpy* for Java nano-patterns and the Java implementation of common Mathematica commands.

Outline: The paper is organized as follows. Sect. 2 illustrates some basic concepts to establish a common vocabulary. Sect. 3 presents Lola, the Language Of Language Amendment. Sect. 4 describes the two case studies above mentioned. Sect. 5 discusses some practical applications and outlines some promising avenues for researchers and practitioners. Sect. 6 reports on related work. Sect. 7 concludes and suggests future directions for this research.

2 Background

2.1 Pluggable Controllers

The following is an intuitive definition of pluggable controllers:

> **Pluggable Controllers**
>
> Controllers should be just like functions and classes found in a library: *standardized*, yet *extendable* and *replaceable*.

The term *controller* in this definition encompasses both classical control constructs such as `while` and `if` ⋯ `else`, *and* operators such as "`??`" that control the order of evaluation of their arguments. According to the pluggable controllers approach, a language has only essential, *built-in* SIC. A standard library of varieties of controllers complements the basic SIC: For example, built-in might be the following:

$$\{c_1; \cdots c_n\} \tag{2.1}$$

or

$$\texttt{while (}e\texttt{)}\ c \tag{2.2}$$

and

$$\texttt{if (}e\texttt{)}\ c_1\ \texttt{else}\ c_2, \tag{2.3}$$

while a standard library contains `for`, `do` and `switch`. In any case, the library is not sealed. On the contrary, developers may add their own control constructors, e.g., adding

$$\texttt{while (}e\texttt{)}\ c_1\ \texttt{else}\ c_2 \tag{2.4}$$

to Java. With pluggable controllers, extending `switch` to strings becomes possible using by library evolution rather than a new language version. Further, no disturbance to the language's core should occur by adding a "`?.`" operator to it. Pluggable controllers join the trend of parameterization of programming languages' elements.

Historically, standard procedures such as `Write` were hardwired in many programming languages, and the same happens today, even in contemporary languages such as AWK. Pascal was the first language to introduce pre-defined procedures such as `Writeln`, functions such as `Sin`, literals such as `true`, and types such as `Integer`. These predefined types, functions, literals or procedures can be overridden by developers when necessary. Likewise, in C, anyone can produce their own version of `printf` from the standard `<stdio.h>` library. In Java, the atomic types, e.g., `int`, `double` and `boolean`, are built-in, whereas their Go equivalent are *pre-defined*.

2.2 Nano-Patterns

The definition of nano-patterns (or simply nanos) was introduced at the end of the seminal work on Micro-Patterns [18] and lately used by authors such as Singer et al. [19] and Batarseh [20], who provided their definitions. In this paper we use the following definition:

> **Nano-Patterns** (*intuitive definition*)
>
> A *nano-pattern* (or *nano*) is a pattern of (typically less than a dozen) control constructs, which recurs frequently, serving common or similar purpose, yet cannot be abstracted easily by a function.

Our working hypothesis was that ordinary control constructors are designed with a prudent view of their usability. At the same time, nanos leverage a unique way of using control constructors that emerges from their function, heretofore not necessarily discerned by language designers. Moreover, the different ways in which control constructors may be used are not static but evolve over time. They are continually being developed and perfected in many specific domains.

A case in point regards the nanos of iterations that were not included in the design of traditional languages. Consider the design of a pluggable controller that captures the following nano[3] in Java code:

$$\texttt{while (}e\texttt{)}\ c_1\ \texttt{else}\ c_2 \tag{2.5}$$

[3] This is actually a control constructor in Python.

Introducing this pluggable controller in Java might be worth the effort depending on the frequency of the patterns using `if` and the auxiliary variables required to capture its behavior. The same applies to other constructs that capture recurring tasks such as "apply an and/or/sum" and other associative operations on `Iterable`s" or "iterate, zipper style, on two lists" A high frequency of reuse may suggest that developers would gain some benefits by the introduction of a pluggable controller. In order to avoid dangerous side effects on the language architecture, the proposed solution is to place controllers in a library rather than in the language core.

In a previous work, a catalog of 38 nanos was identified through a process that includes an initial *subjective* scrutiny and successive further evaluations using the *objective* prevalence threshold test against a *baseline* corpus [2]. All the found nanos are:

- *Traceable*, using an appropriate parser (our nano tracer).
- *Purposeful*, because they are aimed at performing a specific programming task.
- *Prevalent*, according to the definition that follows.

The *Prevalence* of a nano in a given project of a corpus is equivalent to the number of times that it recurs in that specific project. A nano is "prevalent" if its *prevalence* value is higher than a given *prevalence threshold*. The *prevalence threshold* ρ is defined as the fraction of projects of a corpus, for which nano prevalence is higher than a given *reuse threshold*. Here we are considering $\rho = 0.5$, as in reference [2]. The *reuse threshold* r_{th} of a project p is computed similarly to the way done for the popular h-index [21] of a researcher: A project p has a method reuse index r if it has r-methods that are reused r times or more. Thus a nano meets the prevalence threshold criterion if its prevalence is higher than the *reuse threshold* in, at least, 50% of the projects in a corpus C.

The prevalence threshold criterion is robust, objective and filters out irrelevant or domain specific candidate nanos. The reuse index is more robust than other statistics such as *mean* and *median* [22]. In fact, reuse is characterized by a long tail distribution as it happens in many software engineering contexts [23–26]. Being based on the h-index, also the r-index presents the same advantages, apart from the mentioned robustness, such as the fact that it captures the "core" of projects' methods, namely those that are more reused. The insensitiveness towards small values (low reuse of methods) allows to filter out those values that are related to project idiosyncratic features [27]. At the same time, the r-index "inherits" from the h-index some of its drawbacks. When it is used to compare different projects, it is needed to take into account that there are intrinsic differences between projects, such as their age. The *reuse threshold* tends to mitigate some of these drawbacks. Moreover, when comparing the r-indexes of two projects, the only thing that matters is that it refers to the "core" methods. Two projects with the same r-index are treated as equivalent, even if there are marked differences in terms of total number of reuse or maximum number of reuse. From a different perspective, this can be considered an advantage because it means that the r-index implicitly ignores outliers.

Table 1 lists 19 out of the 38 nanos in the original catalog [2]. These nanos are those that involve **SIC**s. This new catalog has two categories: *"Expressions and Command Elaborators"* and *"Operation and Operators on Multitudes"*. Nanos included in the first category are used to manage small errors and exceptional values, substituting missing values with default ones, guarding against null parameters or missing pre-conditions in method execution and handling unusual control flow. The second category covers simple operations on multitudes (i.e., arrays, lists, sets, etc.) including but not limited to: retrieving subsets of values, applying commands, computing cardinality of a multitude, etc. The second column provides the names of the nanos, whereas the third column presents their *Intent*, which is a description of their purpose, written in pseudo code. It is worth noting that often a nanos' name is obtained by juxtaposing the corresponding pseudo code keywords. For example, the following code describes the intent of the nano evaluateUnlessDefaultsTo:

$$[\ \textbf{Evaluate}\ ]\ e\ \textbf{unless}\ b\ [\ \textbf{default}\ e'\ ], \tag{2.6}$$

which captures the following Java snippet of code like:

```
pos > 0 ? pos - 1 : 0
```
(2.7)

The pseudo code adopts the following conventions: C–**c**ommand, e–**e**xpression, p–**p**redicate, M–**M**ultitude (i.e., an array, stream, list, set, collection, etc.), b–**B**oolean expression, i–**i**dentifier, T–**T**ype, and, X–e**X**ception type. The fourth column reports the prevalence. Its values are related to the first, *baseline*, corpus, called Gil-Lalouche Corpus (from now on GL Corpus). It is composed of 26 popular projects selected from the *GitHub's TrendingWikiBookJavaIdiom repositories* [4] augmented by the *GitHub Java Corpus* [5] list due to Allamanis and Sutton [28]. See Table 2 for a list of the projects. This corpus was previously used in other independent research [29].

		Total:	*26 projects*	38,250	1,932

The complete study regarded a total of 78 Java projects, split into three parts: 26 belong GL Corpus, 26 are the most starred GitHub Java projects and the remaining 26 are the most starred Android GitHub projects at the time we collected the projects[6]. The GL corpus was used as a training corpus. At first the initial catalog of candidates was collected, through a process of *pattern harvesting*, by analyzing a set of six Java projects (partially overlapping with the GL corpus). Next, the prevalence of each nanos belonging the initial catalog of candidates, was computed on the GL corpus. Following this, the nanos whose prevalence is lower than the prevalence threshold, were discarded. Finally, the prevalence was computed for the projects of the remaining corpora (testing corpus). Information regarding the reproducibility appears in Table 2.

[6] February 2017

3 Lola

Lola combines computational expressiveness with minimal syntax. This is made possible through the adoption of Python as an underlying computation model. Lola also includes high level pattern matching, independence from the host language and a declarative nature (achieved with directives from C). Lola input is composed of *host tokens*–those of the host language, Python *snippets* of code, Lola *keywords* and *user defined* keywords. In order to distinguish the host-tokens from the Lola keyword (such as **`##Find`** and **`##replace`**), the former are defined in an XML configuration file.

The output stream is the result of the application of "directives" found in the input stream to subsequent input. The directives correspond to macros whose invocation is triggered by a pattern matching engine that relies on regular expressions over tokens. This makes it possible to augment the host language syntax without having to meddle with the language semantics. Macros are expanded to equivalent constructs written in the host language syntax. They can also be expanded in the augmented syntax, with the purpose of being further expanded by other Lola macros to code in the host language such as Java or C.

There are two kinds of directives: *Generator*s and *Lexie*s. Generators are constructs that use *Generating Expression*s (*GE*s) to return sequences of host-tokens inside the output stream. We can distinguish between two kinds of generators: *atomic* or *constructor*. Examples of atomic generators are **`##`**, **`##Include`** and **`##Import`**. Constructors are, for example, **`##If`**, **`##Unless`** and **`##Case`**. When the

preprocessor encounters generators, it pauses the process of copying host tokens from the input to the output stream and inserts into the stream the result of the generating expression.

Lexies are Lola's basic elements of computation and contain the instructions that determine the outcome of the Lola execution. In practice, they describe the augmentation to the host language. The augmentation is expressed in terms of *extended Regular Expressions* (*RE*s). When the preprocessor finds a lexi in the source code, it tries to match the *RE* reported in **##Find** directives against the subsequent tokens. Lexies are structured in sections, with a *Declarative Header*, an *Action Section*, and a *Declarative Footer*. Sections may occur in any order. Directives such as **##Find** and **##description** belong to the Declarative Header, which contains the *RE* that can be matched by the subsequent host language tokens. Section such as **##replace** and **##run** belong to the Action Section, which contains the elaborators for the code matching *RE*s in previous sections. The Declarative Footer usually contains directives such as **##example** and **##log**, used for documentation purposes.

*GE*s and *RE*s are both *Compound Object*s of Lola. GEs are used as conditional commands (i.e., **##If**, **##Unless**, etc.) or to iterate over the elements of a collection (usually a list) such as in the case of **##ForEach**. REs appears in a lexi after the **##Find** directive. When the input stream *RE* matches, Lola creates a Python object that contains information about the location in the input. This information is accessible by the other directive such as **##run** and **##replace** in other sections of the lexi. For example, it is possible to access the **self** and **__str__** attributes (and many others).

In sum, the Lola workflow is the following: Lola tries to match the pattern reported in the **##Find** directive. When it succeeds, this triggers, for example, the **##replace** directive reported in Fig. 4, which replaces the found pattern with code written in the host language. *Patterns* are extended regular expressions (REs). Whenever a snippet of code matches with a *RE* , Lola creates a Python *reifying* object, which can be manipulated. The computations performed by a lexi include code replacement, but a lexi can also invoke Python code.

Lola's syntax strives to adhere to English sentence structure. Furthermore, it uses capitalization conventions to make code easier to read: `@CamelCase` convention is used for constructors and `@camelCase` is for elaborators. The use of abbreviations or acronyms, including those of familiar terms such as EOF it is strongly discouraged. Lola can be used also for computing code metrics, enforcing code standards, and adding a C preprocessor functionality to any programming language. Nevertheless, its main purpose is to allow developers to introduce new keywords and operators, and in general, new syntax to the host language.

4 Case Studies

In the present Section we demonstrate the use of Lola to implement custom pluggable controllers with two specific goals:

1. To implement a Java Stenography.
2. To define new commands taken from a different programming language, Mathematica.

4.1 Stenography for Java Nano-Patterns

Stenography[7] is defined as *"an abbreviated symbolic writing method that increases speed and brevity of writing as compared to longhand, a more common method of writing a language"* [8]. The idea behind a stenography for Java nano-patterns, comes from the experience common to any developer. Everyone has written a lot of code is familiar with the feeling of repetitively writing small fragments of code. Although frequent fragments may take only few seconds to be written, if their frequency is high it may lead to a non-trivial effort for the developers, on the long run. With this mind, it is easy to understand that a stenography for nano-patterns is likely to increase programmers' productivity, by shortening the syntactic structure of several code constructs.

Nano-patterns are common Java idioms that have been proven to be recurring, namely prevalent, in a meaningful dataset of Java software systems. Since they refers to working code, their Lola implementation preserve the semantics in the host language. Table 1 provides the proposed stenography in the *Intent* column. Due to space constraints, we are going to illustrate two significant examples, one for each group. Specifically, for the first group we are illustrating notNullRequired nano whereas for the second group we are describing forEach.

Each snippet of code has a similar structure. The top part present a lexi, which reports the directives written in Lola language. These directives determine the substitutions of the tokens in the input stream. In the bottom part is reported the code governed by Lola. We can distinguish three kinds of keywords: *host specific* (Java keywords in this case), Lola's *built-in* (beginning with a double hash character **##**). These are *reserved* keywords. Finally we have *user defined* keywords, defined in Lola directives that, by convention, begin with a single hash character **#**. For example in Fig. 4 we have:

- **#safe** that is a new defined keyword.
- **##Find**, **##NoneOrMore**, **##Either**, **##or**, **##separator**, **##Any**, are Lola's keywords.
- **##ArgumentDeclaration**, **##Identifier**, **##SafeArgumentDeclarationList**, **##Type** are not primitive Lola's keywords, but are defined in a separate **##Find** directives contained in the **std.lola** library.
- **int** and **return** are Java keywords.

The first is an **##Import** directive:

##Import "std.lola" (4.1)

which is used to access to predefined directives. In fact, **##ArgumentDeclaration**, **##Identifier**,

[7] Also known as *shorthand writing*.

[8] https://en.wikipedia.org/wiki/Shorthand

##SafeArgumentDeclarationList, **##Type** are defined in the **std.lola** library.

The fundamental directive is **##Find**: It allows Lola to find sequences of tokens (patterns) in the input stream that match a specific extended regular expression (*RE*). For example in Fig. 5 the *RE* is the following:

$$for\ (\#\#Any(loop)\ |\ \#\#Expression(filter))\ \ \#\#Any(statements) \tag{4.2}$$

When a match is found Lola may trigger a number of actions, such as the substitution or deletion of elements, the recording of elements for later use, etc. The most common directive is the substitution according to the instruction found in the **##replace** directive (after the homonym reserved keyword). On occasion, it is possible to run Python script of code inside the **##run** directive. The mentioned Python code must be surrounded by curly braces.

Whenever a pattern matches, Lola creates a Python reifying object which can be manipulated in the **##run** section. The results of the matches are stored in variables whose identifiers correspond to the parameters of the directives. In case of multiple values, they are stored in lists.

For example, eq. (4.2) shows the use of an atomic *RE* , **##Any**. **##Any** is used twice one with **loop** parameter and the second with the **statements** parameter. **loop** and **statement** are the names of the variables in the reifying object. **##Expression** is a not a build keyword but is defined in the **std.lola** library.

4.1.1 The notNullRequired Nano

The notNullRequired is used to guard against **null** expressions. In case the expression is **null** the method returns. The lexi appears at the beginning of the code reported in Fig. 4. It introduces a user defined keyword called **safe**. The **#safe** modifier is applied to the parameters **x** and **s** of the method declaration at the bottom. It is used to check if the **##safe** parameters are **null**. In this case the method returns.

The first **##Find** directive defines the first pattern, which consists in a **#safe** modifier followed by the classic Java syntax for methods parameters. This is defined in the **##ArgumentDeclaration** directive in the imported **std.lola** library. Each match is stored in **SafeArgumentDeclaration**.

In the second **##Find**, *RE* matches if it finds:

1. one or more standard (unsafe) parameters declaration;
2. one or more **#safe** parameters declaration;
3. both the first and the second case interleaved (**##Either**);
4. none of them (**##NoneOrMore**).

In the third **##Find**, the *RE* matches the method declaration. Finally the **##replace** directive perform the substitution. It is worth to note the use of Python code, and specifically of the method **join** of the **String** class, inside a *list comprehension* expression, to generate the output. This script have access to **##SafeArgumentDeclaration** variable, to the element **l** of the **##SafeArgumentDeclarationList** **ls**. Each **l** has two fields (**name** and **type**, each of them has a **name** field).

```
int f(Integer x, String s) {
  Objects.requireNonNull(x);
  Objects.requireNonNull(s);
  return x + Integer.parse(s);
}
```

Figure 2: Java output of the notNullRequired nano

The Java implementation is reported in Fig. 2. It exploits the **java.util.Objects** class which includes 9 static methods to work on objects. For each method argument **x** with **#safe** modifier, adds a call to the static method **Objects.requireNonNull(x)** at the start of the method's body. This specific implementation throws **NullPointerException** when one of **#safe** arguments is **null**. However, we can think of other actions that can be done (i.e., printing a warning, returning null, etc.).

4.1.2 The forEach Nano

forEach implements a *filtered* **ForEach** loop. It is used to apply a command by iterating over a multitude or a subset of a multitude (as it happens in SQL). The lexi reported in Fig. 5 have a single **##Find** directive, that matches a pattern that includes an enhanced **for** loop and an expression separated by a *pipe* character **"|"**. The loop contains statements that are applied just if the expression after **"|"** is **true**.

```
for (final Integer i : nums()) {
  if (!(i%2==0))
  continue;
  f(i);
}
```

Figure 3: Java output of the forEach nano

Fig. 3 shows the Java code in output. The loop iterates over an Iterable returned by the nums() method, skipping the elements that do not satisfy the predicate *p* - in this case, if they are not even numbers. *p* can be a lambda expression.

4.2 Mathematica's Commands in Java

In the present section we present, as case study, the introduction of new commands in Java using Lola. We are particularly interested is on some commands of Mathematica, a popular language for technical computing. Mathematica presents several control structures that differs from those available in Java.

Table 3 reports the selection of the Mathematica's commands that we implemented. The second column reports the command in the Mathematica syntax, that is also the stenographic convention we adopted in the implementation. Descriptions are taken from the Mathematica documentation. Due to space constraints we are illustrating only one of the most meaningful commands, represented by the **Do** command.

```
##Import "std.lola"
##Find(SafeArgumentDeclaration) #safe ##ArgumentDeclaration
##Find(SafeArgumentDeclarationList) ##NoneOrMore ##Either ##ArgumentDeclaration(dec)
##or ##SafeArgumentDeclaration(dec) ##separator,
##Find ##Type(type) ##Identifier(name) (##SafeArgumentDeclarationList(ls)) {##Any(statements)}
##replace ##(type) ##(name) (##(",".join([l.type.name + "␣" + l.name.name for l in ls.decs]))) {
  ##("".join(["Objects.requireNonNull(" + l.name.name + ");" for l in ls.decs]))##(statements)}

int f(#safe Integer x, #safe String s) {
  return x + Integer.parse(s);
}
```

Figure 4: Java code governed by Lola for the notNullRequired nano

```
##Import "std.lola"
##Find for (##Any(loop) | ##Expression(filter)) { ##Any(statements) }
##replace for (##(loop)) {if (!(##(filter))) continue; ##(statements)}

for (final Integer i : nums() | i % 2 == 0) {
f(i);
}
```

Figure 5: Java code governed by Lola for the forEach nano

4.3 Loops: the Do Command

The **Do**[9] has multiple options and can be used in different ways. An example is reported in eq. (4.3): It iterates *n* times *expr*.

Do[expr, n] (4.3)

Fig. 6 reports the lexi and the Java code governed by Lola. It is possible to see the use of the **##run** directive: the **doName** variable is elaborated in the successive **##replace** directive as well as the **times** parameter of **##Literal** and the **ee** parameter of **##Any** in the **##Find** directive.

```
##Find do[##Any(e),{##Literal(times)}];
##run {
  if 'x' not in locals():
   x=0
  else:
   x=x+1
  doName='_i'+str(x)
}
##replace for(int ##(doName)=0;##(doName)<##(times);++##(doName)) {
  ##(e);
}

public void foo(){
  do[f(),{5}];
  do[g(),{15}];
}
```

Figure 6: Lexi for Do

Fig. 7 reports the output of the Lola engine. **f()** and **g()** are iterated *n* times (having *n* different values for each **for** loop).

```
public void foo(){
  for(int _i0=0; _i0<5; ++_i0) {f();}
  for(int _i1=0; _i1<15;++_i1) {g();}
}
```

Figure 7: Java output for Do

5 Discussion

Several opportunities may derive from the adoption of a pluggable, modular approach for programming language design. With every likelihood, some innovations in languages design might have been introduced faster and earlier. Also discussions around the new features would have been more sound, because supported by more realistic evidence of their feasibility and impact on languages architecture. In this work we are specifically interested in the design of control constructors. Lola is certainly helpful in this regards. Its preprocessing and macro language capabilities allow the final user to augment a language with new controllers (in a pluggable way) without affecting the language architecture.

With every likelihood using Lola we could have had **switch** on strings by augmenting the language with a library without changing the language version. It would have been the same for the C#'s **?.** operator[10]. Other improvements made possible by Lola is it multi-way, non-fall through branching conditional operator. And this would have been made using standard libraries of varieties, without changing language's core.

Some language extensions, such as the **?.** operator, are expected to be widely adopted by any kind of user, meaning that everyone is expected to eventually use them. Other application may be related to specific tasks. Programmers writing tests for an experts system may wish to define their own control constructors to support declarative tests such as

```
#Tweaking "int␣i=3;i+=2;" #gives "int␣i=5;";
```

Developers trained in the functional programming school, may find useful to use also in Java list expressions such as:

```
#sum #apply (_) -> 1./(_*_) #to primes();
```

Another possible application is represented by the development of libraries to deal with common tasks such as logging or interacting with SQL . As an example, consider Mockito, a popular "mocking framework for unit tests

Table 3: Mathematica commands in Java

	Name	Command[a]	Description[b]
1	If	**If**[*condition*,*t*,*f*]	Gives *t* if *condition* evaluates to True, and *f* if it evaluates to False
		If[*condition*,*t*,*f*,*u*]	Gives *u* if *condition* evaluates to neither True nor False
2	Do	**Do**[*expr*,*n*]	Evaluates *expr* *n* times
		Do[*expr*,{*i*,i_{max}}]	Evaluates *expr* with the variable *i* successively taking on the values 1 Through i_{max} (in steps of 1)
		Do[*expr*,{*i*,i_{min},i_{max}}]	Starts with $i = i_{min}$
		Do[*expr*,{*i*,i_{min},i_{max},*di*}]	Uses steps di
		Do[*expr*,{*i*,{i_1,i_2,...}}]	Uses the successive values i_1, i_2, ...
		Do[*expr*,{*i*,i_{min},i_{max}},{*j*,j_{min},j_{max}},..]	Evaluates *expr* looping over different values of *j* etc., for each *i*
3	Nest	**Nest**[*f*,*expr*,*n*]	Gives an expression with *f* applied *n* times to *expr*
4	NestWhile	**NestWhile**[*f*,*expr*,*test*]	Starts with *expr*, then repeatedly applies *f* until applying test to the result no longer yields True
5	Which	**Which**[$test_1$,$value_1$,$test_2$,$value_2$,...]	Evaluates each of the $test_i$ in turn, returning the value of the $value_i$ corresponding to the first one that yields True

[a] Mathematica instruction.
[b] As reported in Mathematica's documentation.

in Java". Using a future (not the current) release of Lola, Mockito's developers would be able to rewrite the following snippet of code[11]:

```
Iterator i=mock(Iterator.class);
when(i.next()).thenReturn("Hello").thenReturn("World");
String result=i.next()+"␣"+i.next();
assertEquals("Hello␣World", result);
```

in the following way:

```
Iterator i=mock(Iterator.class);
#mock Iterator
#upon next() #return "Hello," #then "World!"
#affirm next() + "␣" + next() #is "Hello,␣World\n";
```

which is arguably more explanatory. With the present version of Lola it is not possible to implement the latest code, but it will be possible in the next release, currently under development.

In the Lola version, the following

```
#inlining...#to...
```

is a user defined control constructor, which can be seen as a syntactic sugar of the following instruction:

```
inliningInto("int␣i=3;i+=2;", "int␣i=5;");
```

In another form, using an appropriate fluent API library we have:

```
inlining("int␣i=3;i+=2;").to("int␣i=5;");
```

Lola can be seen as a special case of syntactic sugaring, task that is well performed by tools such as SugarJ [30], Racket [31] or Occam through Camlp4 [32]. Since Lola's focus is specifically on language extension it is possible to envision a rather coherent ensemble of applications of the idea of language extension, such as a definition of a DSL like fluent API. Lola can certainly be used during the DSLs development. At the same time, Lola itself can be seen as a DSL which uses *Macro Processing* as implementation approach [33].

Many other applications of Lola are possible in the field of testing, logging, design-by-contract, etc. (see, as an example, the recent work on *Seamless Requirement* from Naumchev and Meyer [34]) . Our current empirical study of nano-patterns in Java [2] indicates that nano-patterns occur in two thirds of methods, about half of the statements, third of conditional statements and 90% of all iterative statements, in the Gil-Lalouche corpus [29].

The basic scenario for Lola is that of language extension, amendment or augmentation. Users involved are developers, language engineers or advanced users interested in extending a General Purpose (GPL) or Domain Specific (DSL) host language. Apart from learning Lola's syntax (which, in the authors' opinion, should not have a steep learning curve for an average developer) the users need to know Python. This can be seen as a drawback of Lola. However, this issue is common to other similar solutions such as SugarJ [30], which presumes the knowledge of SDF [35] and Stratego [36]. On the other end, the use of Python might represent an opportunity, since its popularity [37,38], exposes Lola to a wider developers' community.

If language specification changes, this might in principle alter the behavior of the stenographic form of a nano-pattern imposed by Lola. In general, it is developers' responsibility to adjust Lola libraries according to the specification changes, so to guarantee *upward compatibility*. Nano-patterns have been proven to be popular solutions to small programming tasks, as results from their prevalence values. If we look at the baseline corpus described in Table 2, which represents a subset of the entire analyzed corpus, we find that the average *work volume* is, on average, 327.46 days (median 199 days), with a time range that spans from 2011 to 2014. During this time the Java Language Specification changed from version 3 (JLS3, 2004) [39] to 4 (JLS4, 2011) [40]. The JSL4 specification introduced important features, such as binary literals, diamond operators for generic type inference, etc.

Dyer et al., in their large scale investigation of Java projects hosted on SourceForge [12], found that new features are used by developers *before* the *official* release of the specification, taking advantage of the beta/pre-releases [41]. More likely than not, also the developers who worked on the projects included in the baseline corpus, adopted new language features during the development process. This means that the analysis is already, *implicitly*, taking into account the upward compatibility. In fact, the most prevalent nano-patterns emerged from source code that is likely to include both old and new features. This might suggest that either

[11] https://gojko.net/2009/10/23/mockito-in-six-easy-examples/
[12] https://sourceforge.net/

nano-patterns capture language constructs that were not interested by changes in the specification, or those that were affected by the mentioned changes, if present, did not pass our prevalence test.

Moreover, Dyer et al. found also that the majority of newly introduced language features are rarely used by developers [41], with few meaningful exception. According to Qiu et al. [42], who conducted a large-scale study on the use of Java constructs, the distribution of syntactic rules usage is *Zipfian*, with 20% of the most-used rules accounting for 85% of all rule usage, whereas the 65% of the least-used rules is used less than 5%. The same authors show that the adoption of new rules varies over time and it is contextual [42]. These findings might suggest that the problem of upward compatibility is not so significant in practice, being in fact mitigated by the tendency of developers to be, to a certain extent, recalcitrant to employ newly introduced features. Moreover, the decision to adopt an *h*-index variation as a reuse measure, is aimed at balancing the effect of such kind of statistical distribution, as discussed in Sect. 2.2.

6 Related Work

6.1 Lola

6.1.1 Embedded languages

Lola can be seen as an *embedded language*. The embedded text is distinguished by the host text because it is preceded by a hash character and ends with an un-escaped end-of-line character. The most trivial example involves comments. To a certain extent, also comments and string literals can be seen as embedded language. In Java, for example, comments begin and end with specific character sequences, `/*` and `*/`, respectively for the beginning and end of the comment. The same applies to JavaDoc comments. Inside a comment, text is treated differently than in regular code.

The most relevant example is represented by PHP, where commands are embedded in HTML [43] pages. Other meaningful examples are ASP [44] and JSP [45], which adopted the same idea. More recently we have a number examples of DSL languages which extend or enhance a host GPL language. They usually target specific problem, like interaction with databases as in the case of J% [46].

Lola is not an embedded language on its own. It actually embeds both the host language and Python. The host language is seen as a stream that can be manipulated, whereas Python snippets are used to compute the code processing.

6.1.2 Preprocessors

There are several preprocessors available. The C preprocessor [47], introduced in the early stages of its host language, C, is arguably the most famous text preprocessor, often identified by its acronym, CPP [48, 49]. It is almost entirely independent from the host programming language [50], to the point that it can be viewed as an independent programming language. As a programming language, the C preprocessor is limited. For example, it cannot perform iterations (loops) and it does not have conditionals on macro parameters and it does not allow recursive structure. It also has a minimal "library".

Other popular preprocessors are PL/1 and M4 [51]. The PL/1 preprocessor is similar to the C preprocessor in some respects (i.e., built-in types, directives, etc.) whereas M4 is a general language-independent preprocessor, which facilitates more complete processing (it allows recursive calls and has conditional constructs) if compared to the other above mentioned [52] preprocessors. M5 [53] is an improved version of M4.

Many preprocessors use a general purpose programming language, such as Python (e.g., Cog[13], jinja[14], django[15], PYM [54], pyexpander[16], pypreprocessor[17], Preprocessor in Python[18] and Cheetah[19]). Others use Perl (e.g., PerlPP[20]).

6.1.3 Macro Languages

There are several problems with macro systems. They might capture names that are already used (Hygenic Macros solve this problem [55]). Macro systems do not usually differentiate between lexical elements of the hosting language such as expressions, identifiers, constants, etc. One preprocessor that differs in this aspect is the Marco preprocessor [56], which has a way to reduce the coupling between the host language to the macro system.

6.2 Nano-Patterns

The first appearance of the term nano-patterns was in the conclusion of a work by Gil and Maman micro-patterns [57]. Singer et al. [19], starting from a work by Høst and Østvold [58], collected a language of 17 nano-patterns, which the authors demonstrated to be *prevalent* (at an 80% level), *traceable*, and, *purposeful*. The names of their found nano-patterns underscore their purposefulness. Singer et al.'s catalog is at the base of studies on the relationship between nano-patterns and defectiveness [59] or vulnerabilities [60].

Differently from our catalog, Singer et al.'s catalog regards properties of methods, whereas the nanos in our catalog are found at the method, command, expression and field

levels [2]. Singer et al.'s nanos are orthogonal. Each nano-pattern represents a binary property, meaning that it can be present or not. This property lead to the definition of composite nano-patterns, which are those that are a combination of *fundamental* nano-patterns.

Other works on nano-patterns are those of Batarseh [20], who presents a language formed by 16 method properties and Lee et al. [61], who report 67 attributes of different kind of nanos: method signature, body and ties of body and behavior.

6.2.1 Other Kinds of Patterns

In the software engineering literature (scientific and not), there has been a surge of interest regarding the theory and application of "design patterns". Such patterns are a specific arrangement of object oriented components (classes, methods, inheritance) and represent recurring solutions to common design problems [62, 63]. Research interest revolves, for example, around design patterns automatic detection.

At a lower level of granularity stands the "micro patterns" (or μ-patterns), which are predicated on OO types (classes). Micro patterns reflect a specific use of OO features, such as the absence of methods, inheritance, etc. [57]. Differently from design patterns, the 27 micro patterns in Gil and Maman's catalog are *prevalent*, which means that they are present in around 75% of all classes, as empirical studies have shown [57]. Micro patterns are *traceable*, in the sense that they can be automatically recognized. In opposition, design patterns are not traceable [64] and many attempts have been made to formalize [65–69] and to automatically detect them [70–75].

Design patterns are also purposeful, which means that they deal with a specific problem. This is not the case of μ-patterns (they just track the presence of a coding technique), albeit the prevalence might suggest that a μ-pattern is used on purpose. The lack of purpose is also a characteristic of nano-patterns, although for a different reason. Their purpose is related to the small programming task that they carry out, and can often be learned from their name, but it is usually unrelated to the system where they occur.

6.2.2 Other Pattern-Like Constructs

A concept similar to nano-patterns is that of *idiom*s, which are, quoting Allamanis and Sutton, "a syntactic fragment that recurs frequently across software projects and has a single semantic purpose" [76]. The main difference between idioms and nano-patterns is that the latter are not single fragments but predicates.

Notably we can find idiom catalogs for different languages, e.g., [77–80]. Also, IDEs provide support for the definition and customization of idioms [81, 82]. Some instructional/educational material on idioms is found in work whose aim is to teach idioms as programming tips [83–85].

Sutton et al. investigated the presence of idioms in generic C++ libraries, finding a high coverage (circa 85% of classes showing idioms) [86]. In a recent work, Allamanis and Sutton applied machine learning techniques to *automatically* detect idioms in source code. The discovered idioms included "cross-projects idioms that represent important program concepts like object creation, exception handling, etc." with a prevalence ranging between 3% to 31%, depending on some factors (i.e., the training and testing dataset, the used parameters, etc.) From their work, we can see that the prevalence of idioms tends be lower than that of nanos [76].

Another difference between the two constructs is that nanos are *sought*, whereas idioms are discovered. Some of the found idioms show semantic purposes, in the sense that they are used for object creation, exception handling, and resource management. In the literature on idioms, other relevant studies are those of Koening [87], Langer [88] and Willis [89].

6.2.3 Vocabulary *vs.* Structure

Vocabulary: Some related work deals with code nomenclature or the study of the vocabulary that developers use to describe program elements. Linstead et al. studied source code vocabulary and discovered the existence of naming trends related to specific syntactic elements such as classes and interfaces [90]. Enslen et al. worked on an optimized algorithm to split identifiers into words' sequences [91]. Abebe et al. studied the evolution of vocabulary used by developers along a time line [92]. Newman et al. studied how to determine and assign lexical categories starting from source code [93].

Høst and Østvold investigated the implementation of methods from a corpus of Java applications, to determine which word is the best for a method naming [94]. In a subsequent work, they dealt with generation of *"a semantics which captures our common interpretation of method names"* [58]. They worked on *traceable pattern*s and proposed a set of *traceable attributes* that they claim can be useful building blocks of nano-patterns.

It is worth noting that the authors *explicitly* claim they were not proposing nano-patterns. The way vocabulary matches the structure or not can also lead to "naming bugs", a problem that can be mitigated by an automatic procedure. Høst and Østvold proposed automatic tool [95] to suggest proper names. Kashiwabara et al., in different works, presented techniques to identify candidate verbs for methods [96, 97]. There were some attempts to use recurring *structure* for software engineering purposes. Examples are works on *beacons* [98, 99]—stereotypical, recurring segments of code that are quickly recognized by experienced developers.

Structure: Some researchers in the area focus their efforts on investigating the recurring elements of the syntactical *structure* of programs. A concept similar to nano-patterns is that of *stereotype*. A stereotype is a syntactical structure that capture the intent of methods and classes and can be considered an extension of the micro-nano-pattern concept [100].

Andras et al. and Moreno et al. compared the outcome of the run-time with their stereotype [101], to investigate the consistency between method design and implementation [101, 102]. Qiu et al. showed that the use of syntacti-

cal rules in actual programs follows a Zipf-like distribution (just as happens with words in natural language). In other words, small sets of syntactic structures tend to govern entire projects [103]. Abd-El-Hafiz et al. classified loops by complexity levels [104]. Wang et al. introduced an automatic approach to determine high level action through the analysis of a given loop [105]. Mens et al. proposed to describe patterns with a declarative meta-programming language similar to Prolog.

7 Conclusion

We introduced the concept of pluggable controllers as a way to facilitate the introduction of new constructors, and explained how they can be implemented using Lola, the Language of Language Amendment, a powerful preprocessor and macro-language. Lola lets developers augment or even amend language constructors without affecting the language architecture.

This argument was illustrated by two cases study: A stenography for Java nanos and the introduction of Mathematica's commands in Java. Nanos are recurring idioms devised by developers to perform simple tasks. In a recent study they revealed to be prevalent in Java, under a given definition of prevalence. We presented 19 nanos that belong to a wider catalog [2] and illustrated the implementation of Java stenography based on them.

Their prevalence make them good candidates to become pluggable controllers. A stenography for nanos, such that illustrated in this work for Java—and its subsequent definition in standard libraries of pluggable controllers, is likely to improve developers efficiency by reducing coding effort.

In the present paper we reported a peculiar application of Lola. However, Lola's applications are not limited to the extension of SIC as pluggable controllers. For example, with Lola it is possible to compute the Halstead metrics [106], simulate Aspect Oriented Programming, add syntactic sugar, and many other kinds of language augmentation [15].

Relying on a powerful preprocessing engine, Lola makes it easy to introduce augmentation. Formal and precise proofs of semantics are however difficult: Since the semantics of the underlying language is not available to preprocessors, even the formulation of precise statements on semantics seems impossible. More so, with Lola which is language independent, and draws much of its power from the loose coupling with the underlying semantics and changes made to it.

7.1 Future Work on Lola

Future works will involve both further improvement of Lola and research on the application of Lola to help developers' work.

- Currently, Lola supports *trivia* (elements such as space, tabs, etc.), though it is limited to just a few of them such as `##NewLine` and `##EndOfFile`, and must be improved. This type of support may be needed to process comments, JavaDoc (for Java) and the like.
- Pattern matching features should be improved in order to treat string literals. The introduction of features that allow the host language to be changed on the fly would enable application of Lola's preprocessing to mixed code (i.e., Java code with an SQL queries as happens using JDBC, etc.)
- Another promising research avenue emerges if we ponder the possibility of applying Lola to itself.
- We would like to allow users to define new Lola keywords from within Lola itself (now only possible with simple Python classes).
- Some enhancement are required to improve usability. For example, using single and double # to distinguish Lola keywords from host language identifiers might lead to some confusion. We are working on a different solution, such as using another character (e.g., @) instead of #.

7.2 Future Work on Nanos

Further research it is needed to improve the prevalence values of nano-patterns by specifically looking for new candidates in other corpora. In this work, we used a lightweight nano tracer to track the nanos in source code. Additional work it is needed to improve search possibilities in several aspects (i.e., improving the namespace analysis, etc.). The subjective and sample bias in the harvest may have led us to miss some patterns. Further efforts are needed to verify this suspicion and to extend the basic catalog.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment The authors thank the anonymous reviewers for their valuable suggestions. Inspiring discussions with Tomer Levy are gratefully and intentionally acknowledged. This research was supported by THE ISRAEL SCIENCE FOUNDATION (grant No. 1803/13 *).

ABSTRACT

The discovery of semantic information from complex signals is a task concerned with connecting humans' perceptions and/or intentions with the signals content. In the case of audio signals, complex perceptions are appraised in a listener's mind, that trigger affective responses that may be relevant for well-being and survival. In this paper we are interested in the broader question of relations between uncertainty in data as measured using various information criteria and emotions, and we propose a novel method that combines nonlinear dynamics analysis with a method of adaptive time series symbolization that finds the meaningful audio structure in terms of symbolized recurrence properties. In a first phase we obtain symbolic recurrence quantification measures from symbolic recurrence plots, without the need to reconstruct the phase space with embedding. Then we estimate symbolic dynamical invariants from symbolized time series, after embedding. The invariants are: correlation dimension, correlation entropy and Lyapunov exponent. Through their application for the logistic map, we show that our measures are in agreement with known methods from literature. We further show that one symbolic recurrence measure, namely the symbolic Shannon entropy, correlates positively with the positive Lyapunov exponents. Finally we evaluate the performance of our measures in emotion recognition through the implementation of classification tasks for different types of audio signals, and show that in some cases, they perform better than state-of-the-art methods that rely on low-level acoustic features.

1 Introduction

This paper is an extension of work originally presented in IEEE 11th ICSC [1].

The task of capturing emotional meaning from audio structure while disregarding trivial or irrelevant information is a complex process that cannot be inferred using low-level acoustics. Recent advances in research on sound dynamics have shown that nonlinear phenomena exist in complex audio signals [2, 3, 4, 5, 6]. Such complex information is shaped in the nonlinear dynamical structure of audio content that is brought together by repeating patterns evolving in a temporal order. Nonlinear dynamics analysis consists of a set of methods that unravel these fine-grained patterns, and study their role in conveying meaningful information[7]. Particularly, it was shown that the strange attractors of the sounds' dynamical systems carry perceptual meaning [8]. As a consequence recent studies were successful at applying methods of nonlinear dynamics to capture voice pathologies in speech signals [9, 3, 4, 10], recognize environmental sounds [11, 12] and discriminate between different singing styles [2]. Despite these advances, very few researches have applied nonlinear dynamics for modeling emotion in audio signals. In [6], measures of the geometrical properties of the phase space reconstruction are employed to recognize affect in speech; in [13], recurrence properties of the vowel accurately describe the dynamic behaviour of six basic emotions.

In our former work [1], we proposed a novel learning framework of affective auditory scene analysis us-

[*]Pauline Mouawad, 36 Rue Marc Sangnier, 33400 Talence, France, pauline.mouawad@u-bordeaux.fr

https://dx.doi.org/10.25046/aj0203212

ing a recently developed method of non-linear dynamic signal analysis, the Variable Markov Oracle (VMO), that finds the best audio structure representation in terms of the symbolized recurring patterns, while preserving their temporal order. We obtained symbolic recurrence quantification analysis (RQA) measures without reconstructing the phase space with embedding. Our contribution over previous recurrence analysis methods is that our model explored the dynamics of the most informative recurrent patterns in the signal, by means of symbolic RQA features. We showed that measures of periodicity and complexity derived from our model are relevant for the characterization of affect in auditory scenes, and that they perform better than state-of-the-art methods relying on low-level acoustic features.

In this paper we contribute to the ongoing research on affective semantics from sound by proposing a new set of symbolic dynamical invariants computed from the VMO. After the symbolization step, we propose a novel method of computing symbolic dynamical invariants from the symbolized sequences of the time series, after performing an embedding step. The invariants are: the correlation dimension (D2), correlation entropy (K2) and the Lyapunov Exponent (LE). In literature, the correlation dimension and Lyapunov Exponent have been successful in discriminating voice quality as well as in characterizing pathologies in voice [14, 9]. Furthermore, D2 and K2 are effective in the detection of emotion in speech [3, 4]. In the music domain, LE and D2 were used to characterize the clarinet tone [15], however rare are the literatures that investigate the potential of dynamical invariants in characterizing emotion in music.

The contribution of this paper is a novel method of nonlinear dynamics that derives symbolic dynamical measures from an adaptive time series symbolization method (VMO), with and without phase space reconstruction. First, it derives symbolic RQA measures from a symbolization of the signal's feature frames without embedding [1]. Second, it estimates symbolic dynamical invariants from the symbolized time series after embedding. Then we estimate our symbolic dynamical measures for the logistic map and show that they are in agreement with known methods from literature. Finally we test the performance of our symbolic complexity measures in predicting emotion by performing classification tasks on four types of sound stimuli. The advantage of our symbolic complexity measures is that first they quantify the dynamics of the most meaningful recurring patterns in the signal; second, their number is determined and hence we don't have to address the problem of the dimensionality of the dataset, therefore no feature selection methods are employed; third we show that they are efficient in recognizing emotions across three types of stimuli, which suggests that their performance does not depend on the type of sound under study.

2 Theoretical Background

2.1 Nonlinear Time Series Analysis

Nonlinear time series analysis (NLTSA) consists of a set of methods that characterize dynamical information from time-ordered values in a dataset. It is based on the fact that the real underlying dynamical state of a complex system is often unknown, and that all the information needed to determine the future behaviour of the system's state is independent of its past, and can be predicted based on knowledge of the present state, which is the observable measured by the time series.

In order to learn about the underlying dynamics of time-ordered data such as audio signals, it is necessary to reconstruct the phase space.

Phase Space Reconstruction The states of dynamical systems change in time, and their time evolution is defined geometrically in the shape of trajectories that belong to a *phase space* known as *strange attractor*.

In practice, we do not have a full knowledge of the dynamical system in order to reconstruct its phase space. But we do have a time-discrete measurement of one observable, which results in a scalar and discrete time series, that is used to reconstruct the original system's dynamics, through the reconstruction of its phase space via embedding. The embedding theorems guarantee that for noise-free data, there is a dimension m such that the embedded vectors are equivalent to the original phase space vectors [16].

To reconstruct the phase space of a system from a time series, the Takens' embedding theorem is used [17] and the framework is the following [18]:

Let $x(t)$ be a trajectory of a dynamical system and $s(t) = s(x(t))$ the result of a scalar measurement on it. Then a delay reconstruction with time delay τ and embedding dimension m is given by:

$$s(t) = (s(t-(m-1)\tau), s(t-(m-2)\tau), ..., s(t)) \quad (1)$$

Embedding parameters One of the main challenges of the delay-coordinate embedding theorem, is choosing appropriate values of dimension m and time lag τ [16].

Several methods exist that derive m and τ but we are naming the most widely used ones in literature. First τ is estimated: if τ is very small, consecutive elements of the delay vectors will highly correspond, and all the vectors will be clustered around the main diagonal, unless m is very large. If τ is very large, consecutive elements are independent, and the points will fill a large space in the phase space [16]. Two functions can be used to determine τ: the first zero of the autocorrelation function of the time series and the first minimum of the mutual information function (FMMI). In this work we use the FMMI.

Once τ is chosen, the next step is to estimate the embedding dimension m. If m is too large, the embedded data will be redundant, which will confuse the performance of prediction algorithms. Two widely known methods can be used: the false-nearest neighbour algorithm (FNN) [19] and the 'asymptotic invariant approach'. The FNN method is used in this work since it is the most widely used one, and m is chosen where the number of false neighbours drops to zero.

The resulting is equivalent to the attractor in the original phase space if $m \leq 2d+1$, were d is the dimension of the original phase space. In general we don't know what the value of d is, but using the FNN method, m is guaranteed to fulfil that requirement.

2.2 Recurrence Plots

Recurrence is a fundamental property of most dynamical systems. In fact it is due to the systems' recurrence to former states that we know how to predict the future state of the system. Recurrence takes place in the system's phase space, and the tool that measures it is called a recurrence plot (RP) [20].

Given a trajectory $\vec{x_i} \in \mathbb{R}^d$ in a d-dimensional phase space of a dynamical system, the RP is a two-dimensional visualization of the square recurrence matrix of the embedded time series defined by:

$$R_{i,j}^{m,\varepsilon} = \Theta(\varepsilon - \left\|\vec{x_i} - \vec{x_j}\right\|), \quad i,j = 1,...,N \tag{2}$$

where $\vec{x_i}$ and $\vec{x_j}$ are phase space trajectories in an m-dimensional phase space, N is the number of measured points in a trajectory, ε is a threshold distance, $\Theta(.)$ the Heaviside function such that: $\Theta(x) = 0$ if $x < 0$ and $\Theta(x) = 1$ otherwise, and $\|.\|$ is some appropriate choice of a norm, such as the L_2-norm, otherwise known as the Euclidean distance. Both axes of the RP are time axes. The dots or pixels located at (i,j) and (j,i) on the RP are black if the distance between points x_i and x_j in the phase space fall inside a *ball* or *threshold corridor* of radius ε, the threshold distance [21, 22]. In this case, the black points refer to *recurring* states also termed ε-recurrent states since they occur in an ε-neighbourhood. The ε-recurrent states are represented by the relation[20]:

$$\vec{x_i} \approx \vec{x_j} \iff R_{i,j} \equiv 1. \tag{3}$$

The dots are white if $R_{i,j} \equiv 0$. The RP always displays a main black diagonal line called the line of identity (LOI), since $R_{i,i} \equiv 1$ by definition. For more in-depth description of the RP properties, the reader is referred to [20].

2.3 Recurrence Quantification Analysis

In order to derive meaning from the structures of the RP, various complexity measures are computed that quantify those structures. Such quantification is important since it will be employed to characterize the dynamical information and to perform predictions. These statistical measures are known as Recurrence Quantification Analysis (RQA) and are based on the density of recurrence points, the diagonal and vertical line structures in the RP [21, 23, 24]. RQA can be applied to non-stationary processes in continuous or discrete time series. For example, the metric *determinism* can discriminate signals from noise, and is valuable in pattern mining and classification tasks.

2.3.1 Measures based on the density of recurrence points

Given an RP thresholded at ε (Eq. 2), the Recurrence Rate (RR) measures the density of recurrence points in the RP:

$$RR = \frac{1}{N^2} \sum_{i,j=1}^{N} R_{i,j} \tag{4}$$

The RR measure corresponds to the correlation sum (D2) measure, but D2 excludes the main diagonal line (LOI):

$$D2 = \frac{1}{N(N-1)} \sum_{\substack{i,j=1 \\ j \neq i}}^{N} R_{i,j} \tag{5}$$

2.3.2 Diagonal lines based measures

Given the histogram $P(l)$ of diagonal lines of length l, the following measures are computed:

Determinism (DET) is the percentage of points in diagonal line of at least length $l = l_{min}$, i.e. the ratio of recurrence points in the diagonals to all recurrence points, and is a measure of the predictability of the system. Processes with chaotic behaviour cause none or very short diagonals. Deterministic processes cause longer diagonals and less isolated recurrence points.

$$DET = \frac{\sum_{l=l_{min}}^{N} lP(l)}{\sum_{l=1}^{N} lP(l)} \tag{6}$$

The average length of diagonal line length L is the average time during which two segments of a trajectory are close to each other, and it refers to the mean prediction time. The length l of diagonal lines refer to the number l of time steps during which a segment of the trajectory is close to another segment of the trajectory at a different time. Therefore the diagonal lines are related to the divergence of the trajectory segments.

$$L = \frac{\sum_{l=l_{min}}^{N} lP(l)}{\sum_{l=l_{min}}^{N} P(l)} \tag{7}$$

Then the length L_{max} of the longest diagonal line in the RP excluding LOI is derived:

$$L_{max} = max(\{l_i\}_{i=1}^{N_l}) \tag{8}$$

And the inverse of L_{max} indicates the divergence (DIV) of the phase space trajectory. The faster the

trajectory segments diverge, the diagonal lines will be shorter, and the value of DIV will be higher:

$$DIV = \frac{1}{L_{max}} \tag{9}$$

The next measure is the Shannon entropy of diagonal line length distribution in the RP (S_{RP}), which is the probability $p(l) = P(l)/N_l$ to find a diagonal line of exactly length l in the RP. It is a measure of complexity in the RP in terms of the diagonal lines, such that, for uncorrelated noise the value of S_{RP} will be small, which indicates a low complexity.

It is defined as:

$$S_{RP} = -\sum_{l=l_{min}}^{N} p(l)\ ln\ p(l) \tag{10}$$

The $RATIO$ is a measure that uncovers transitions in the system's dynamics:

$$RATIO = \frac{DET}{RR} \tag{11}$$

2.3.3 Vertical lines based measures

Measures based on vertical structures in the RP uncover chaos-chaos transitions [20] in a dynamical system that are not found using diagonal line based measures. These are *laminarity* and *trapping time*.

The laminarity (LAM) refers to the occurrence of laminar states in the system independently of their lengths. If the RP contains less vertical lines and more single recurrence points, then the value of LAM will be low. Its definition is analogous to the definition of DET for vertical lines of minimal length $v = v_{min}$.

$$LAM = \frac{\sum_{v=v_{min}}^{N} vP(v)}{\sum_{v=1}^{N} vP(v)} \tag{12}$$

The trapping time measure (TT) is the average length of vertical lines, and estimates the mean time that the system's state will be trapeed:

$$TT = \frac{\sum_{v=v_{min}}^{N} vP(v)}{\sum_{v=v_{min}}^{N} P(v)} \tag{13}$$

3 Our Approach

One key concern when using RPs is finding the threshold to make sure that the RP exhibits enough recurrence points. Another difficulty to address is the length of the sequence used to generate the RP. This is considered as a second embedding step that is different from the phase space embedding, however in traditional RP construction methods these two steps are indistinguishable, as the RP is constructed first and then the recurring patterns are found by looking for diagonal lines.

In this work we propose a novel method that does not require a phase space reconstruction with embedding. This is done using the Variable Markov Oracle (VMO) [25], a suffix automaton that reduces a multivariate time series down to a symbolic sequence while retaining the recurring sub-sequences. Accordingly, we consider recurrences of symbolic sequences without a need to estimate a threshold, since this step is implicitly done during the symbolization, based on a mutual information criterion that estimates the optimal threshold in terms of maximizing Information Rate (IR) [26]. IR considers the mutual information between past and present in a signal. In the next section we describe this approach.

In a first phase, we estimate symbolic RQA from the symbolic RPs generated from the VMO without embedding. In a second phase, we estimate symbolic dynamical invariants from the VMO generated symbolic recurrences, after applying an embedding.

3.1 The Variable Markov Model

The Variable Markov Oracle (VMO) [25] is a suffix tree data structure that is derived from Factor Oracle (FO) [27, 28] as well as Audio Oracle (AO) [29].

FO is a suffix automaton that finds factors (*repeated substrings*) in a word (or sequence of symbols), as well as patterns (*repeated suffixes*) [27]. It has been employed mainly for optimal string matching algorithms, such as biosequence pattern matching. Assayag et al. 2004 showed how the FO can be adapted to learn symbolic musical sequences and generate symbolic musical improvisations in real-time [28].

AO is an extension of FO for audio signals, that is independent of the audio feature representation. AO extends the applications of FO to multivariate time series such as an audio signal sampled at discrete times. Based on a distance measure, the AO structure finds and links all the possible combinations of audio subclips that are similar. AO has been successfully applied to audio generation.

3.1.1 VMO Construction

VMO inherits the strengths of both FO and AO. The important improvement over its predecessors, is that VMO assigns symbols to the signal frames connected by suffix links during AO construction: it accepts a signal O as input, outputs the oracle structure, and keeps track of the sequence of assigned labels $Q = q_1,...,q_N$ as well as a list of pointers to their corresponding observations $O = O[1],...,O[N]$. As such VMO performs a symbolization of a signal's time series by storing the information regarding the repeated substrings via the suffix links created during AO construction and upgrades AO by assigning labels to the frames connected by suffix links.

The notations of the forward and suffix links remain the same as in FO construction. The detailed algorithm is found in [30, 25].

As mentioned earlier, a similarity threshold θ is introduced to determine if a signal sample $O[i]$ is similar to another sample $O[j]$.

In order to find the best symbolization of the signal, different VMO models can be created with different θ values. There is a tradeoff to consider when choosing θ values. If θ is very low, every frame will be different than every other frame, and VMO assigns a different symbol to each frame in O. If θ is very high, frames that are different are considered similar, and the same symbol is assigned to every frame in O. In both cases no structure in the time series can be captured by VMO.

Hence θ should be determined before VMO construction. Dubnov et al. have shown that the value of θ can be resolved by computing the Information Rate (IR) over candidate θ values [31]. The optimal θ value is the one that yields a highest IR value.

Information Rate IR is an information theoretic metric that measures the information content of a time series.

Let $x_1^N = x_1, x_2, ..., x_N$ be a time series x with N observations, where $H(x) = -\sum P(x) log_2 P(x)$ is the entropy of x, then the definition of IR is [32]:

$$IR(x_1^{n-1}, x_n) = H(x_n) - H(x_n|x_1^{n-1}) \tag{14}$$

And it is approximated by replacing the entropy terms in equation 14 by a complexity measure C associated with a compression algorithm [32]. The complexity measure is the number of bits used to compress x_n independently using the past observations x_1^{n-1}:

$$IR(x_1^{n-1}, x_n) \approx C(x_n) - C(x_n|x_1^{n-1}) \tag{15}$$

Compror is a lossless compression algorithm based on FO and the length of the longest repeated suffix link (**lrs**). Details on *Compror* as well as on the method of combining Compror with AO and IR are found in [33]

IR is the mutual information between past and present observation in a signal $O[t]$ and is maximized when there is balance between variation and repetition in the symbolized signal. This means that a VMO with a higher IR value captures more of the repeating patterns than a VMO with a lower IR value [32]. Figure 1 shows two oracle structures obtained with two extreme θ values. Figure 2 visualizes the sum of IR values versus different values of θ.

3.2 Symbolic Recurrence Plots from VMO

From the generated VMO-symbolized time series, we obtain the symbolic RP (RP_S hereafter), plotted from the binary self-similarity matrix. The index of a suffix link is a point on the RP_S and a repeated sequence is detected as a line since it includes repetitions of length 1, 2, up to the longest repeated length. This makes VMO effectively find a repetition for variable length non-uniform embedding.

We redefine the symbolic RP_S obtained from the optimal VMO model of the signal's time series:

$$R_{i,j}^{\sigma_M,\theta} = \Theta(\theta - d(\sigma_{q_i}, \sigma_{q_j})) \quad i,j = 1,...,N \tag{16}$$

Such that:

$$R_{i,j}^{\sigma_M,\theta} = \begin{cases} 1 & if\ d(\sigma_{q_i}, \sigma_{q_j}) is \leq \theta \\ 0 & otherwise \end{cases} \tag{17}$$

Where N is the number of states considered, σ_M refers to the M^{th} symbolized substring, Θ is the Heaviside step function (i.e. $\Theta(x) = 0$ if $x < 0$, and $\Theta(x) = 1$ otherwise). θ is a threshold distance, and $d(\sigma_{q_i}, \sigma_{q_j})$ is a distance metric between pairs of symbolized substrings q_i at $t = i$ and q_j at $t = j$.

3.3 Feature Extraction

In our experiments, we derive two sets of complexity features.

Symbolic RQA measures In the first phase we estimate symbolic RQA measures (RQA_S hereafter). Standard ways to consider similarity in audio signals is through time-frequency representation. In a preprocessing stage, the time series is transformed into a constant-Q transform (CQT) feature vector. CQT is a logarithmic spacing of filter center frequencies versus bandwidths, that represents the audio signal in a form that approximates human auditory analysis. Then the CQT feature vector is passed as input to the VMO constuction algorithm, that generates several symbolizations of the features in terms of their recurrence properties. by means of IR, the optimal threshold θ is evaluated to obtain the optimal VMO symbolization model $\mathcal{M}_S$. Then the symbolic RP_S is generated from the self-similarity matrix obtained from the longest repeated substrings (LRS) of $\mathcal{M}_S$. Then RQA_S estimates are obtained. Although standard RQA metrics are not invariants, in our case, since their estimation is independent of embedding, our RQA_S can be considered as invariants.

Symbolic Dynamical Invariants In the second phase we estimate symbolic dynamical invariants: the correlation dimension (D2), correlation entropy (K2) and the Lyapunov Exponent (LE).

Given a one-dimensional time series obtained from an audio signal, first we embed it using Takens' time-delay embedding method. The dimension m is determined by the false-nearest neighbour algorithm, and the value is chosen where the false nearest neighbours are zero. The value of the time delay τ is defined by the first minimum of the mutual information function. Next, we symbolize it with VMO, and select $\mathcal{M}_S$ by means of IR. Then from the selected VMO model we obtain a representation of the LRS found in the series. From this representation we proceed to extract D2, K2 and LE. The framework is depicted in figure 3.

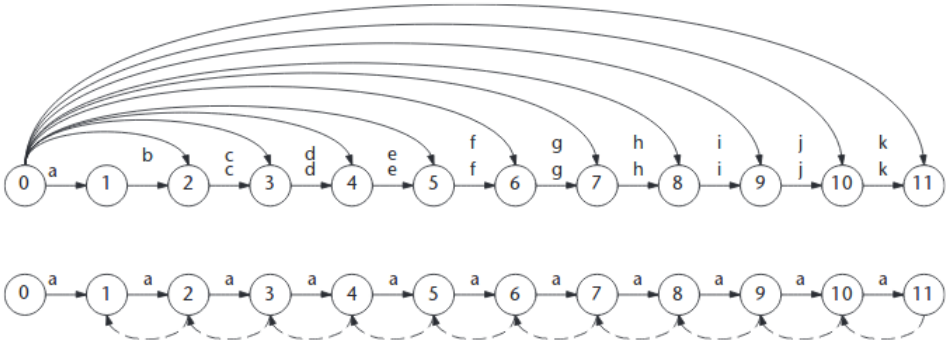

Figure 1: Two oracle structures. The top oracle has a very low θ value. The bottom oracle has a very high θ value [30]

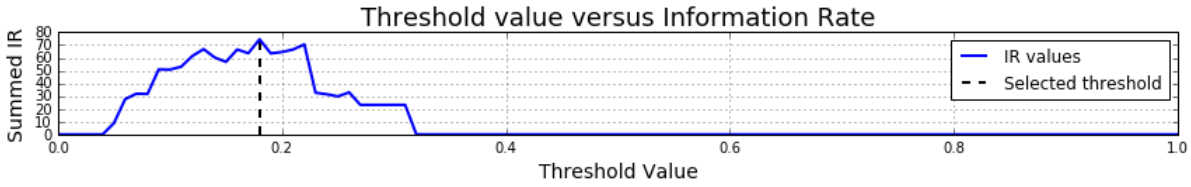

Figure 2: IR values on vertical axis and on horizontal axis. The solid curve in blue shows the relations between the two measures and the dashed black line indicates the selected θ by locating the maximal IR value. [32]

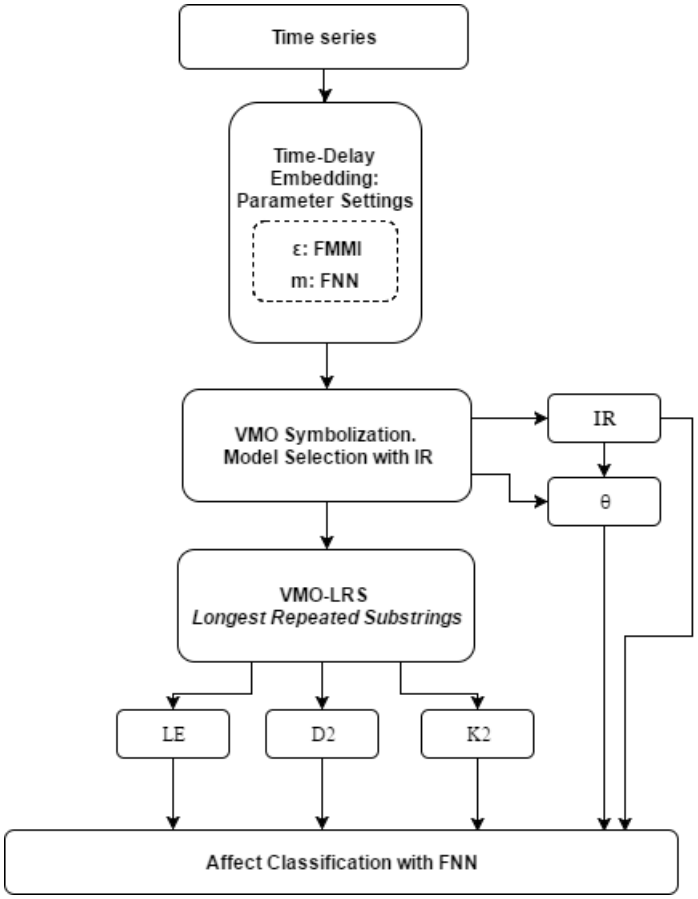

Figure 3: Dynamical Invariants extraction framework

Normally, in order to derive the LE using Rosenstein's algorithm or Eckmann's algorithm, either algorithm operates directly on the time series after embedding, and then computes the LE. In our approach we obtain our symbolic invariants from the LRS of the optimal VMO model $\mathcal{M}_S$. This is a novel aspect where we obtain symbolic dynamical invariants that describe the dynamical behaviour of only the most meaningful recurrences found in the series.

Before employing the dynamical invariants in emotion prediction tasks, we first probe to what extent our estimates are in agreement with known methods by illustrating their application to the logistic map. Then we question their role in discriminating emotion in voice, auditory scenes, instrumental music as well as in film music.

Correlation Dimension The correlation dimension (D2) is a geometric measure that tells how complex are the dynamics of the system: a more complex system has a higher dimension, which in is estimated from the symbolic recurrence plot. D2 estimates the complexity of the dynamics: a higher D2 indicates a more complex system's dynamics. $D2_S$ is computed from the symbolic RP_S by the correlation sum [20]:

$$D2_S = \frac{1}{N(N-1)} \sum_{\substack{i,j=1 \\ j \neq i}}^{N} \Theta(\theta - d(\sigma_{q_i}, \sigma_{q_j})) \qquad (18)$$

Correlation Entropy The correlation entropy (K2) also known as 2^{nd} order Rényi entropy quantifies the loss of information in time, in a dynamic system. It is estimated from the symbolic RP_S as:

$$K2_S = -ln(D2_S) \qquad (19)$$

Lyapunov Exponent Lyapunov exponents (LE) estimate the amount of chaos in a dynamical system by quantifying the exponential divergence of initially close phase-space trajectories. A system with one or more positive LEs is defined to be chaotic.

4 Example Application

In this section we illustrate the application of the RQA_S as well as the symbolic dynamical invariants for synthetic examples of the logistic map. Logistic map is a well known model that exhibits different dynamic properties as a function of a single parameter, and allows comparing standard non-linear dynamic information measures with the data analysis methods we develop here. The logistic map model allows us to investigate some intriguing computational properties of sequences that happen at the onset of chaos (add references).

4.1 Symbolic RQA_S for the logistic map

Mathematically, the equation of the logistic map is defined as:

$$x_{i+1} = ax_i(1 - x_i) \qquad (20)$$

where x_i is a real number between zero and one and a is a positive constant. We generate multiple time series from the logistic map and define the control parameter $r \in [3.5, 4]$, with $\Delta r = 0.0005$, so that for each r we have a separate time series T of length 1000. The values of the parameters are set in order to compare the results with [20] and accordingly, we embed the time series with dimension $m = 3$ and time delay $\tau = 1$.

Figure 4 shows plots of our VMO-derived RQA_S measures. A comparison of the plots below is made with similar plots in [20] derived directly from the time series after embedding.

Plots (A), (C), (E) of figure 4 show the measures DET_S, $Lmax_S$ and L_S respectively that are based on the diagonal lines. They have similar maximas that indicate the periodic-chaos/chaos-periodic transitions. $Lmax_S$ detects all such transitions, but DET_S and L_S do not find them all.

Similarly, the chaos-chaos transitions to the laminar states are depicted by the measures based on the vertical structures, shown in plots (B), (D), (F): LAM_S, TT_S and $Vmax_S$. The difference between LAM_S and $Vmax_S$ is that LAM_S only measures the amount of laminar states, while $Vmax_S$ estimates the maximum duration of the laminar states. The lines in $Vmax_S$ plot show significant drops within periodic windows, indicating that the chaos-order transitions are also identified. This is in agreement with [20] who states that RQA measures are able to identify bifurcation points. However the LAM_S plot shows a different structure, it displays minimas or drops that correspond to the chaos-chaos transitions, while in the referenced work the LAM plot displays maximas or peaks at the same locations. This may be due to the fact that our LAM_S is derived from a symbolic representation of the series rather than the data itself. However as in the referenced paper, LAM_S is different from the other two vertical-based measures $Vmax_S$ and TT_S, in that it does not peak at inner crises, possibly because it is more robust against noise in the data. Finally similarly to the method in [20], with our symbolization method a 1000 data points are enough to derive the RP-based measures.

4.2 Symbolic dynamical invariants for the logistic map

To test the suitability of our symbolic complexity measures, we compute them for the logistic map. For each of LE, D2, K2, IR as well as θ, there is one value per time series.

Figure 5 portrays plots of the LE computed directly from the time series after embedding, the Shannon entropy (S_{RP_S}) estimated from the RP_S, the sym-

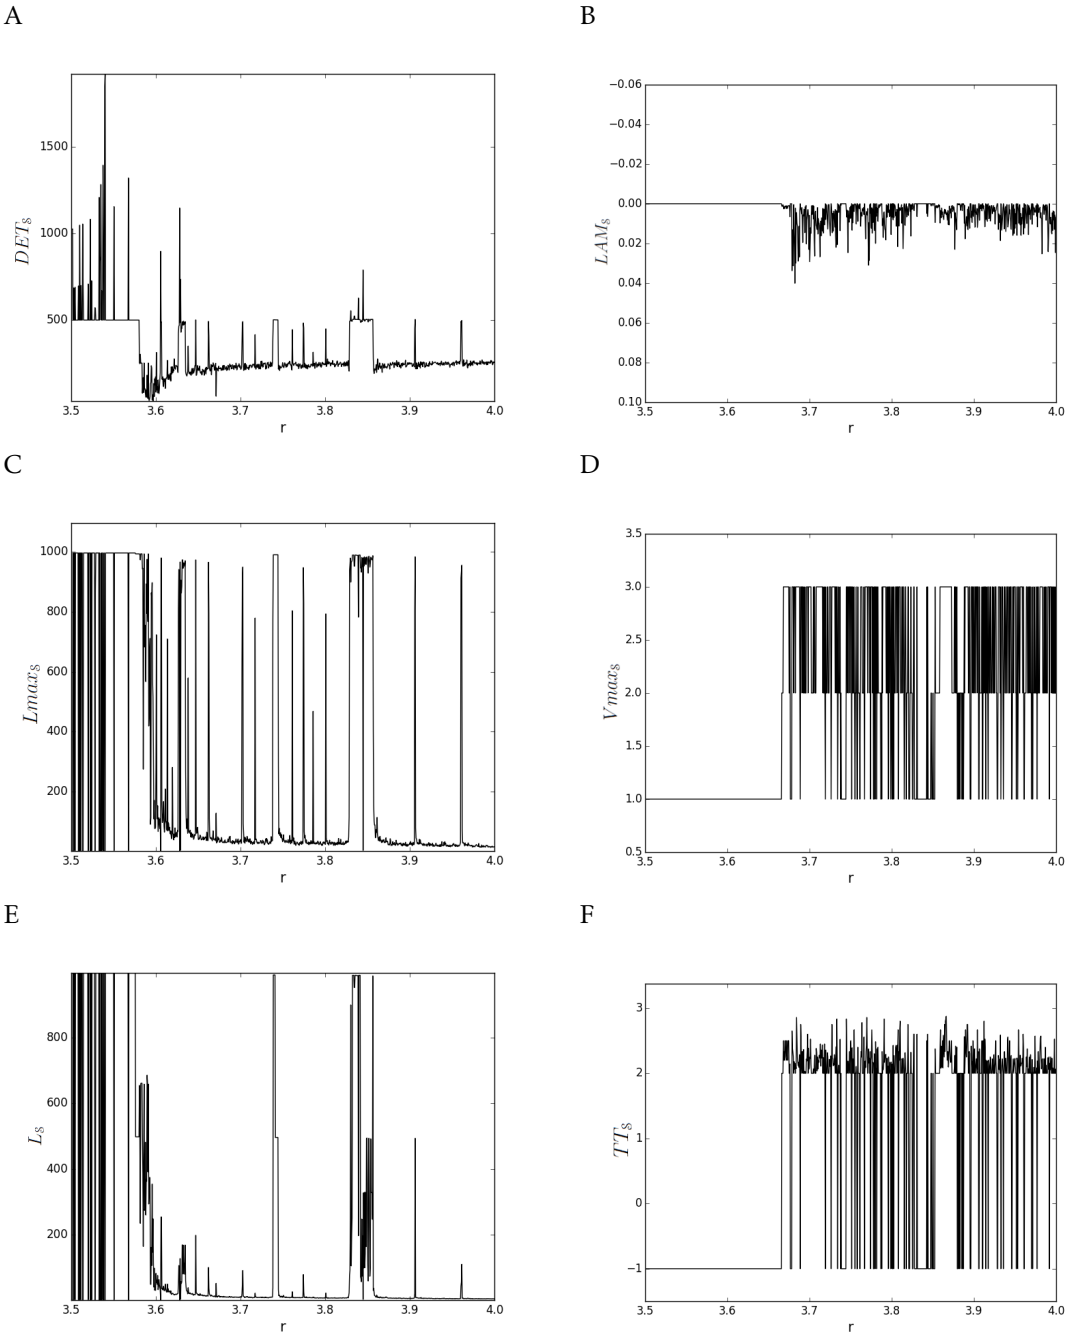

Figure 4: RQA_S from the RP_S of the logistic map: $r \in [3.5, 4.0]$, $\Delta r = 0.0005$ and $T = 1000$. (A) Determinism. (B) Maximal diagonal line length. (C) Average diagonal line length. (D) Laminarity. (E) Maximal vertical line length. (F) Trapping time.

bolic LE_S and $K2_S$. The plots are commented in subsection 4.3.

The formal relationship between the correlation entropy K2 and the Lyapunov Exponents LE is [20]:

$$K_2 \leq \sum_{\lambda_i > 0} \lambda_i \tag{21}$$

where λ_i denote the Lyapunov exponents. From Eq.(21) one sees that K2 is a lower bound for the sum of the positive Lyapunov exponents.

4.3 Qualitative Comparison of Dynamical Invariants

There are different dynamical regimes and transitions that occur between the values in the range of r of the logistic map. They appear in the form of accumulation points, periodic and chaotic states, band merging points, period doublings and various order-chaos, chaos-order as well as chaos-chaos transitions [34, 20].

In [35], authors applied various measures to derive statistical meaning from the graphical structures of symbolic recurrence plots. One such measure is the Shannon entropy of diagonal line length distribution in the RP (S_{RP_S}).

The Shannon entropy is a measure of the complexity of the RP, such that for uncorrelated noise it takes a small value, which indicates a low complexity [20]. However it is not a dynamical invariant [36].

According to Eckmann et al. 1987, the diagonal line lengths on RPs are related to the inverse of the largest LE [37]. This is true for some cases despite the fact that empirical studies have shown that S_{RP_S} is capable of identifying dynamical transitions, and therefore should grow as the system's complexity grows. [38].

Since the Shannon entropy quantifies the complexity of the dynamical system being studied, it is expected that its values increase when the system develops, that is when it varies from non-chaotic to chaotic regime [38]. Hence it is expected to be positively correlated with the LE, rather than negatively correlated. And within periodic windows, the entropy should considerably decrease.

Therefore in a recent work, [39] has proposed another estimation of the Shannon entropy from RPs from the relative frequency of the occurrence of the diagonal segments of nonrecurrent points formed by white dots, that are a signature of complexity within the data. In this case a one-to-one correspondence was seen between the new Shannon entropy estimate and the positive LE. That is, the Shannon entropy increased as the bifurcation parameter of the logistic equation increased, as illustrated in the plots found in [39]. However, [38] claim that the definition of the entropy from the white nonrecurrent dots does not solve the problem of the negative correlation between the entropy and the positive LE.

Here we compute the positive LE from the logistic map time series, after embedding and symbolization with VMO. The LE is computed from the VMO-derived LRS, and the Shannon entropy is estimated from the VMO-derived symbolic RP_S.

Figure 5 (A) shows the plot of the LE obtained from the time series of the logistic map. Plot (C) displays the Shannon entropy S_{RP_S} estimated from the black diagonal lines of the symbolic recurrence plot. The S_{RP_S} plot detects the chaos-chaos transitions as well as the periodic-chaos and chaos-periodic transitions. The plot shows that the S_{RP_S} correlates positively with the LE rather than with its inverse. We note though that for $r \in [3.9, 4.0]$ the values of the entropy seems to slightly decrease with the chaotic behaviour of LE. Further investigation is needed to understand this behaviour, that seems to correlate with the inverse of LE for that particular region of r.

It is clear that with our method, while maintaining the computation of the entropy from the black recurrence dots of the symbolic RP_S generated from the LRS of the symbolized time series, we obtain an estimate of the diagonal lines entropy that correlates positively with the Lyapunov exponents plot, with the exception of the region of $r \in [3.9, 4.0]$.

Plot (B) illustrates the LE_S obtained from the VMO-derived LRS. Plot (D) is the K2 plot derived from the RP_S and shows that the K2 plot is a lower bound of the LE_S plot. This verifies the relation expressed in Eq. 21, where K2 is defined as being a lower bound on the sum of the positive LEs.

Plot (E) displays the IR values that correspond to the optimal VMO model for each time series generated from the logistic map. By contrasting it with plot (A) of figure 4, we notice that the IR plot correlates positively to the determinism measure. Both show maximas or peaks at the chaos-order transitions. Additionally, IR captures the chaos-chaos transitions as well.

5 Model of Affect

Model of Affect. Affect can be described with basic emotional categories or emotional dimensions. We use categorical representations of Russel's two-dimensional model of valence and arousal (VA) described by pleasant-unpleasant for V, and awake-tired for A [40].

Stimuli. Four databases are used for experimental validation of the proposed symbolic dynamical features. The International Affective Digitized Sounds (IADS-2) [41] consists of a set of standardized, affective environmental sounds that span a broad range of semantic categories, and are rated on the two-dimensional model of VA.

The Montreal Affective Voices (MAV) [42] consist of 90 nonverbal affect bursts, enacted by 10 different actors in the following 8 categorical emotions: anger, disgust, feat, pain, sadness, surprise, happiness and pleasure, in addition to the neutral expression. The durations of the vocalizations vary between 0.385 to 2.229 seconds sampled at 44100 Hz. In order to per-

form a comparative analysis with different databases and to ensure consistency in the affective annotations, the emotional categories of MAV sounds were mapped on the VA model described by: pleasant-unpleasant (V) and awake-tired (A).

The Musical Emotional Bursts (MEB) [43] consist of 80 short instrumental musical clips, played using the clarinet and the violin, in the following 3 categorical emotions: happiness, sadness and fear, plus the neutral expression. The mean duration of the MEB clips is of 1.6 seconds. The discrete emotions were mapped on the VA model.

The Film Music Excerpts (FME) [44] consist of 360 musical excerpts at 44100 Hz sampling rate, annotated on the VA dimensional model of emotions described with: high valence, low valence, high energy, low energy. The FME is designed to provide musical stimuli that allow a systematic comparison of the perceived emotions in music.

Dataset. Two datasets are evaluated: the symbolic RQA_S measures for the IADS, MAV, MEB and FME stimuli, and symbolic dynamical invariants for the IADS, MAV and FME stimuli.

Classification Model. In this work we use a feedforward artificial neural net (ANN) [45]. The feedforward ANN is chosen for its simplicity and suitability for the problem studied. The network has one hidden layer and one output layer. It was trained with the Levenberg- Marquardt as well as the scale conjugate gradient backpropagation learning algorithms, and the validation was performed using the mean squared error function (MSE).

6 Experiments

The experimental work as well as the results obtained are described in this section.

6.1 Experimental work

For the computation of the RQA_S dataset, the CQT is obtained at 44100 Hz sampling rate, hop length of 512 and 84 bins. Then we apply the symbolization process and estimate the RQA_S. For the computation of the dynamical invariants, the time series is embedded first and then we apply the symbolization. The datasets are normalized before training so that column features are scaled to have standard deviation 1, and centered to have mean 0.

Classification. The dataset is divided into 70% training, 15% validation and 15% testing. The classification tasks are conducted in a multi-class one-versus-all fashion whereby each of the six affective sub-dimensions is in turn considered as positive and negative class. The final results are then averaged to get the classifier's performance on VA. The Neural Network Toolbox in MATLAB is used. No feature selection was made prior to classification.

Performance evaluation. If the dataset is too small or biased, over-fitting can occur. Therefore in addition to the MSE function, we applied the Adaptive Synthetic Sampling (ADASYN) algorithm to rebalance the datasets. The classifier's performance is evaluated before and after dataset rebalancing, using a combination of performance metrics taken from the confusion matrix. These are: accuracy (ACC), precision, recall, F1-measure, F2-measure, area under the receiver operating characteristic curve (AUC), as well as Cohen's Kappa. Accuracy and precision are highly sensitive to data imbalance therefore three additional measures are computed: Cohen's Kappa (κ), F1-measure and F2-measure.

6.2 Results

Classification performance

In order to evaluate the generalizability of our features, we tested them on four different types of stimuli.

The classification performance rates of the RQA_S measures are reported in tables 1 to 5, and performance rates of the dynamical invariants are in tables 6 and 8.

In table 1, the prediction accuracies on VA are (74%, 90%) respectively for the auditory scenes (IADS). Comparing to other existing work, in [46] a classification task was evaluated for the IADS database using a set of 101 acoustic features, and achieved a performance of less than 50% accuracy. We note some poor metrics values such as κ is very low for the arousal dimension indicating an agreement close to chance level; AUC is 0.66 for valence. However the values of F_1, F_2, precision and recall are fairly high. These results could be consolidated or checked if the same tests are repeated with a much larger dataset.

In tables 2 and 3 high prediction accuracies of (97%, 90%) and (81%, 90%) are attained respectively on VA for the musical clips. The values of the remaining metrics are higher for the violin music than for the clarinet music. Although in both cases $\kappa > 0.40$ for both VA which shows an agreement above chance level between observed and predicted values.

Table 4 shows a success rate of (79%, 93%) on VA for the MAV dataset using RQA_S. This rate is verified with the values of the remaining metrics which are fairly high: both F_1 and F_2 are > 0.70, $\kappa > 0.40$, and the AUC is close to 1 for arousal and 0.79 on valence.

In table 5, the classification results on the FME dataset using the RQA_S metrics are of (65%, 77%) on VA. This shows that the RQA_S do not capture well valence in the film music excerpts. Further investigations are needed in this respect, to determine what is impacting the differences in the recognition rates between the short music clips and the short film music excerpts.

The classification success rates using the dynamical invariants achieve (72%, 82%) for IADS (table 6), (69%, 73%) for FME (table 7) and (84%, 91%) for MAV (table 4). The invariants perform well for IADS and MAV, however they have a rather low rate for FME,

although they perform better than RQA_S on valence.

In [47], an emotion classification task is made on the same FME stimuli, using 200 acoustic features and five emotional categories: anger, fear, happiness, sadness and tenderness. The recognition rates using support vector machines (SVM) are: 65%, 67%, 59%, 69% and 67% for the five emotions respectively. Although in our case we did not use discrete emotions but the VA model, however with only five nonlinear dynamical features our recognition rates are (69%, 73%) and using our RQA_S the rates are (65%, 77%).

7 Conclusive Remarks and Discussion

In this work we proposed a novel method to estimate complexity measures from the symbolic RP_S of the VMO symbolized time series of audio signals. The symbolic RQA_S measures were estimated without phase space reconstruction. The symbolic dynamical invariants were estimated after embedding. We estimated our dynamical measures for the symbolized time series of the logistic map and through a qualitative analysis of the respective plots, we showed that our symbolic measures are in agreement with the same measures obtained using different methods in literature. Furthermore, we estimated the symbolic Shannon entropy S_{RP_S} of the RP diagonal lines from the LRS of the optimal VMO model, and showed that it correlates positively with the Lyapunov exponents except for the region $r \in [3.9, 4.0]$.

In order to evaluate the performance of our symbolic dynamical measures in characterizing affect in various sounds, we conducted classification tasks on four types of stimuli. High emotion recognition rates were achieved for the IADS, MAV and MEB datasets for both sets of symbolic measures. This highlights the powerful performance of the measures in emotion recognition independently of the type of stimuli and shows that they generalize well across different types of stimuli. Furthermore it encourages future work to test the features in large scale tasks to determine if they can gain consensus as a general-purpose feature set.

However we obtained rather low recognition rates for film music excerpts on valence, and an average rate for arousal of 77% and 73%. Further work is needed to explore why both sets of complexity measures, the RQA_S as well as the dynamical invariants obtained in this work, achieve rather low recognition rates on film music excerpts, compared to the results obtained on the IADS, MAV as well as the music clips datasets. Obviously the dynamics differ across different sounds, but it would be interesting for future work to further investigate what particular aspects of the dynamics carry affective information. It would also be interesting to determine how such knowledge differs across different types of audio signals.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

In this paper, we propose a revised version of the semantic decoder for multi-label classification task in the spoken language understanding (SLU) pilot task of the Dialog State Tracking Challenge 5 (DSTC5). Our model concatenates two deep neural networks - a Convolutional Neural Network (CNN) and a Recurrent Neural Networks (RNN) - for detecting semantic meaning of incoming utterance with the assistance of algorithm adaptation method. In order to evaluate the robustness of our proposed models, comparative experiments on the DSTC5 dialogue datasets are conducted. Experimental results show that the proposed models outperform most of the submitted models in the DSTC5 in terms of F1-score. Without any manually designed features or delexicalization, our model has proven its efficiency of tackling the multi-label SLU task, using only publicly available pre-trained word vectors. Our model is capable of retrieving the dialogue history, and thereby it could build the concise concept structure by employing the pragmatic intention as well as semantic meaning of utterances. The architecture of our semantic decoder has a potential to be applicable to other variety of human-to-human dialogues to achieve SLU.

1. Introduction

The spoken language understanding (SLU) has been one of the fundamental components of an end-to-end dialogue system. The Dialog State Tracking Challenge 5 (DSTC5) released a pilot SLU task, which requires to extract semantic meaning of users' utterances in task-oriented dialogues and to fill the slots with speech acts. Unlike the previous challenges (DSTC 2&3) where the human-to-system dialogues were targeted, the corpus of DSTC 5 has been no more than challengeable due to the following points: human-to-human dialogues, cross-linguistic data and multi-label classification task. As its corpus is built by collecting human-to-human conversation in a natural setting, more than one speech act can be annotated to a single utterance.

Xu et al. propose a Convolutional Neural Network (CNN) model with a threshold predictor to tackle a multi-label speech act classification task on DSTC5 corpus [1]. With the assistance of algorithm adaptation method, the model they propose is adapted for the multi-label classification task without any manually designed features. Although the model, however, has advantage of handling the multi-label classification task, there still remain rooms for improvement to achieve state-of-art SLU.

The aim of this study is to improve the model proposed by Xu et al. by building a more robust and concise semantic classifier. In this revised model two deep neural networks, Convolutional Neural Network and Recurrent Neural Network, are conjoined to conduct a multi-label speech act classification task in an improved fashion. Our newly revised model shows a synergy effect of retrieving dialog context as well as exploiting a current utterance. In addition, a threshold learning mechanism is engaged to enable our proposed model to produce an output of a set of multiple labels called speech acts.

The rest of this paper is organized as follows. Section 2 gives a brief review of DSTC5 dataset and some related works in the SLU pilot task. In Section 3, we introduce the architecture of our proposed model and a threshold predictor. The Section 4 gives a detailed description of the DSTC5 dataset and describes how we set up the experiments for training data and evaluation process. In Section 5, we provide our experimental results to optimize the

performance of our CNN-RNN classifier on the DSTC5 SLU task. The Section 6 discusses the differences between the previous and current models and the strength of concatenating two deep neural networks in SLU task. The Section 7 concludes this paper[1].

2. Background

2.1. The DSTC5 Dataset

The DSTC5 provides the TourSG corpus, which consists of dialogue sessions collected from Skype calls between tour guides and tourists focusing on offering touristic information of Singapore[2]. For the SLU task, the system is given the utterances from both the tourist and the guide as its input, and the system subsequently tags the utterances spoken by both the speakers with appropriate *speech acts categories* and *attributes*.

Each sub-utterance belongs to one of the four basic *speech act categories* that denote general information of current dialogue flow. More specific speech act information can be annotated by the combination with the *speech act attributes*. Therefore, a classifier is demanded for classifying a set of labels consisting of speech act categories and attributes tagged to a single utterance. Reference [3] gives complete list of speech act categories and attributes.

Table 1 shows Chinese test utterances and ones translated in English that annotated with their corresponding speech act categories and attributes.

2.2. Other models in pilot SLU task of the DSTC5

A simple baseline model for the SLU task is provided by the committee of the DSTC 5, which uses a binary relevance (BR) approach and trains a set of linear support vector machines (SVM) for multi-label speech act classification. The baseline model is built within traditional TF-IDF approach which mainly depends on keywords that appeared in the utterances per speaker. This baseline model, however, has a crucial deficiency in detecting semantic meanings of utterances appropriately, as it only superficially decodes meaning relying on words on the surface level.

Ushio et al., which takes the first place in this challenge, proposes a local co-activate multi-task learning model (LC-MTL) for capturing structured speech acts by using recurrent convolutional neural networks[4]. This model consists of a CNN, which represents incoming utterances as sentence vectors, and two LSTMs, which locally co-activates neurons in hidden layer between speech act categories and attributes of the corresponding utterances.

Xu et al also proposes a CNN model with a threshold predictor, which enables to predict more than one speech act annotated to an utterance. It has been proven that CNN is capable to detect the core semantic meaning without any knowledge on the syntactic structures of a language or any manually designed features. This model, however, has faced the ambiguity issue, as the output node of CNN only depend on each current utterance to produce proper scores for each set of labels. In Section 3 we will introduce the revised version of the semantic decoder that has a power to disambiguate the meaning of utterances.

2.3. Related Works

So far there have been many researches grounded on CNN architecture with regard to the language processing tasks. The CNN proposed by Kim achieves good performance across several datasets despite of its simple architecture which consists of a convolutional layer, a max-pooling layer and a softmax classifier. Wang et al. proposed another architecture of CNN with an additional semantic layer, which exploits the contextual information from short texts[6]. Another CNN model with an unsupervised “region embedding”, proposed by Johnson, works well for long text classification task like movie reviews[7]. Zhang et al. explored the effects of hyperparameters in one-layer CNN architectures, and reported their impact on performance over multiple runs[8].

In addition, recent advances in deep learning with RNN including LSTM have also achieved impressive improvements on various natural language processing tasks such as language modeling, sequence tagging and machine translation. Language model based on RNN(RNN-LM) was proposed by Mikolov et al., which significantly outperformed the previous back-off models, even in case when RNN-LM was trained on much less data than back-off models were [9]. Another variant of RNN-LM based on LSTM proposed by Sundermeyer, showed additional improvements of 8% relative in perplexity over the RNN-LM[10]. Huang et al. proposed a sequence tagging model using a bidirectional LSTM, which was capable of using effectively both previous and oncoming input features. Their model have achieved state of the art accuracy on various sequence tagging tasks such as POS tagging, chunking and named entity recognition(NER)[11]. Sutskever et al. proposed a sequence to sequence learning model

[1] The source code of the proposed system is available on https://github.com/hkhpub/dstc5-slu

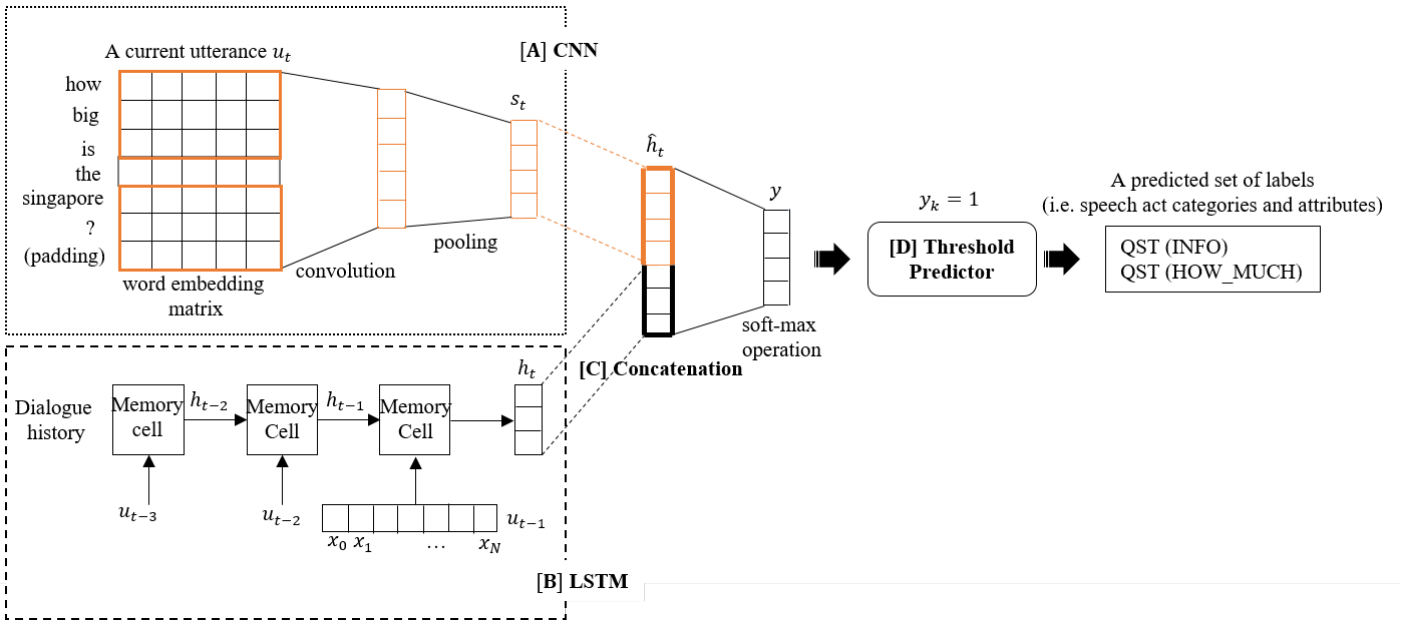

Figure 1. The architecture of our proposed model.

grounded on LSTM. They achieved a higher BLEU score on a translation task from English to French on the WMT-14 dataset, compared to a phrase-based machine translation system[12].

Several researches have been recently conducted by combining CNN and RNN models. Vinyals et al. proposes an conjoined model for image captioning, which encodes image features using deep convolutional networks and automatically generates captions with recurrent networks[13]. Kim proposes a recurrent convolutional network model, in which the penultimate layer of CNN is connected to the recurrent layers of the RNN model in order to track a topic of a dialogue segment in human-human conversations[14]. Unlike the previous CNN-RNN models, another jointed CNN and RNN model is proposed by Barahona et al., where the model is optimized with two distinctive inputs: a current user' utterance and dialog act-slot pairs of previous system's utterances [15]. In the task of decoding semantic meaning of spoken languages each input is utilized in sentence representation and context representation, respectively.

3. Model Architecture

In this section, we propose a jointed model which combines Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN) . The overall architecture of our semantic decoder is depicted in Figure 1. Our model consists of three modules: (i) a CNN with multiple filters that encodes semantic meaning of current utterance, output nodes that produces scores for each label, (ii) a RNN with recurrent connections between neurons that store contextual information of dialogues and (iii) a multi-label threshold predictor that generates a reference point using the scores of the labels. The threshold is then used to for the system to decide whether each label is as relevant or irrelevant. Specifically, we newly adopt the RNN to improve the previous semantic decoder of Xu et al. with assistance of contextual information drawn from dialogues so that the disambiguity problem is raveled out.

3.1. CNN Architecture

Coming up with the architecture of CNN [5], which is specifically illustrated in the part [A] of Figure 1, given our CNN classifier is capable of optimizing its parameters with respect to multi-label cross entropy loss function. Formally, let $x_i \in \mathbb{R}^k$ be the k-dimensional word embedding vector corresponding to i-th word in a given utterance. An utterance u_t of length n are represented as a $n \times k$ matrix:

$$u_t = x_1 \oplus x_2 \oplus \ldots \oplus x_n \quad (1)$$

where t is the index of dialogue turn and $\oplus$ is the concatenation operator. A convolutional operation involves a filter $w \in \mathbb{R}^{h \times k}$, which is applied to a window of h adjacent words to produce a new feature. A feature c_i is generated by applying a hyperbolic tangent function f:

$$c_i = f(w \cdot x_{i:i+h-1} + b) \quad (2)$$

where $b \in \mathbb{R}$ is a bias term. The filter is applied to every possible window of words in the utterance to produce a feature map:

$$c = [c_1, c_2, \ldots, c_{n-h+1}] \quad (3)$$

A max-over-time pooling is then operated to take the maximum value $\hat{c} = \max\{c\}$ as a representative feature for the filter.

Following the same procedure as described above, multiple filters with varying window size h are integrally engaged into multiple adjacent features. These features are then concatenated into a fixed-length and 'top-level' feature vector s_t which automatically encodes most of representative features from a given utterance at dialogue turn t.

3.2. RNN Architecture

Since each utterance is dependent on the previous utterances in a conversation, referring to dialogue context from previous dialogue utterances is essential to wholly understand the meaning

Table 2. Statistics of dstc5 datasets.

Datasets (Speaker)	Language	*M*	*L*	*C*
Train (Tourist)	English	14,226	74/88	1.19
Test (Tourist)	Chinese	4,085	61/88	1.16
Train (Guide)	English	19,916	69/88	1.24
Test (Guide)	Chinese	8,555	71/88	1.21

M: Number of utterances.
L: Size of label set (size/total).
C: Average number of labels per utterance.

of a current utterance. To access to dialogue context, we employ a long short term memory (LSTM). It is much better for preserving information over long periods of time than vanilla RNN due to its ability to deal with vanishing and exploding gradients[16].

To track the dialogue context, two questions must be taken into consideration: (i) to what extent we should track previous utterances as dialogue history and (ii) in which form those utterances are fed into the LSTM as inputs. For length L of the dialogue history, we treat it as a free parameter and determine its value empirically. Once the length L is determined, the dialogue history is represented as $\{u_{t-L}, u_{t-L+1}, \dots, u_{t-1}\}$ where t is the index of dialogue turn.

As depicted in the part [B] of Figure 2, the structure of LSTM is divided into a memory cell c_l and three gates: a forget gate f_l, an input gate i_l and an output gate o_l. Three kinds of gates functions to decide which amount of information the memory cell should keep or forget at a time step l, where l denotes for each word in the utterances given a length L. The input x_l and the output h_l of LSTM are updated as follows:

$$i_l = \sigma(W^i \cdot x_l + U^i \cdot h_{l-1} + b^i) \quad (4)$$

$$f_l = \sigma(W^f \cdot x_l + U^f \cdot h_{l-1} + b^f) \quad (5)$$

$$o_l = \sigma(W^o \cdot x_l + U^o \cdot h_{l-1} + b^o) \quad (6)$$

$$g_l = tanh(W^g \cdot x_l + U^g \cdot h_{l-1} + b^g) \quad (7)$$

$$c_l = f_l \odot c_{l-1} + i_l \odot g_l \quad (8)$$

$$h_l = o_l \odot tanh\,(c_t) \quad (9)$$

where x_l is the input at the current time step, h_l is the hidden unit at time step l, b is a bias term, $\sigma(\cdot)$ is a logistic sigmoid function and $\odot$ denotes a point-wise multiplication operation. Each word of the utterances in the dialogue history is represented as word embedding vectors and fed into the LSTM sequentially as an input x_l. The last hidden unit h_l of LSTM is obtained which encodes the dialogue context information for current utterance u_t.

3.3. Combining CNN and LSTM

To utilize both the representative feature of current utterance and context information of previous utterances, we concatenate the hidden unit h_t of LSTM to the 'top-level' feature vector s_t modeled by the CNN, as illustrated in [C] of Figure 1. Then, the penultimate layer consists of the concatenated vector $\hat{h}_t = s_t \oplus h_t$, which is passed to a fully connected output layer.

$$\hat{y} = W \cdot \hat{h} + b \quad (10)$$

Then the softmax is operated to normalize the output vector $\hat{y}$ to the probability distribution as follows:

$$P(y_k = 1) = \frac{\exp(\hat{y}_k)}{\sum_j \exp(\hat{y}_j)} \quad (11)$$

where k denotes the index of the multi-hot vector y, which represents the pairs of speech act attribute and category information of utterance.

3.4. Multi-label Threshold Predictor

The output probability distribution $p(y|u)$ from the softmax layer is used for multi-label prediction, while the proposed model is trained and used in prediction for a given utterance u. A relevant label set Y for an utterance u is determined by a threshold t as follows:

$$Y = \{k | p_k > t,\ k \in L\}. \quad (12).$$

The threshold learning mechanism used in the literature [17, 18] is adopted in [D] of Figure 1, which models t with a linear regression model. The learning procedure is described as follows: For each training example $(u_m,\ Y_m)$, we set the target threshold value t_m which minimizes the count of misclassified labels as follows:

$$t_m = \underset{t}{\operatorname{argmin}}(|\{k | k \in Y_m, p_k^m \le t\}| + |\{l | l \in \overline{Y_m}, p_l^m \ge t\}|) \quad (13)$$

where p_k^m, p_l^m is the output probability of relevant label k and irrelevant label l associated with utterance u_m respectively. The target threshold values t_m is used in learning the θ of the threshold predictor $T(\boldsymbol{u}; \theta)$:

$$E(\theta) = \frac{1}{2}\sum_{m=1}^{M}(T(\boldsymbol{x}_m; \theta) - t_m)^2 + \frac{\lambda}{2}\|\theta\|^2, \quad (14)$$

where λ is the regularization parameter and M is the number of utterances in the train set. At the test time, the learned threshold is used to choose the relevant labels Y of a test utterance, as illustrated in (14).

4. Experimental Setup

In this section we introduce the DSTC5 dataset and describe the different models with their corresponding performances.

4.1. Statistics of DSTC5 Datasets

The summary statistics of the SLU datasets for the both speakers of the DSTC5 after tokenization are given in Table 2. For the case of *Guide*, one interesting point to note is that the size of sets of labels in the train set is smaller than that in the test set , which means that there is no way for the classifier to learn cases of certain labels assigned to utterances during the training and predict correct speech acts on the test dataset of *Guide*.

4.2. Hyper-parameters

In our experiments, we use: filter windows of 2, 3, 4 with 200 feature maps for the CNN, dimension of 100 for the hidden unit of LSTM. Those values are chosen by adopting a rough grid search[8]. The model undergoes training through stochastic gradient descent over shuffled mini-batches with Adam optimization algorithm. The model stops the iterant processes of learning by an early stopping mechanism.

As we mentioned in Section 3.2 that the length of dialogue context *L* is treated as a free parameter, the optimal value of *L* is

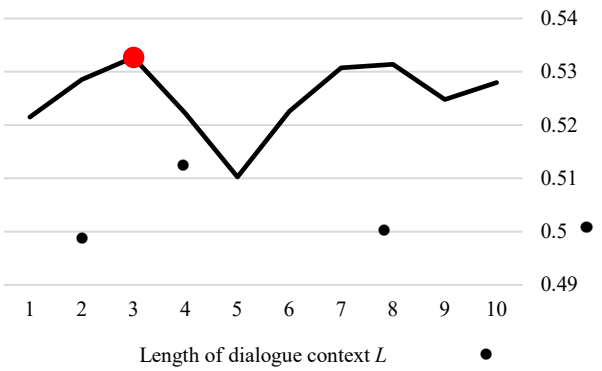

Figure 2. The performance of CNN-LSTM model based on various lengths of dialogue context on Tourist dataset.

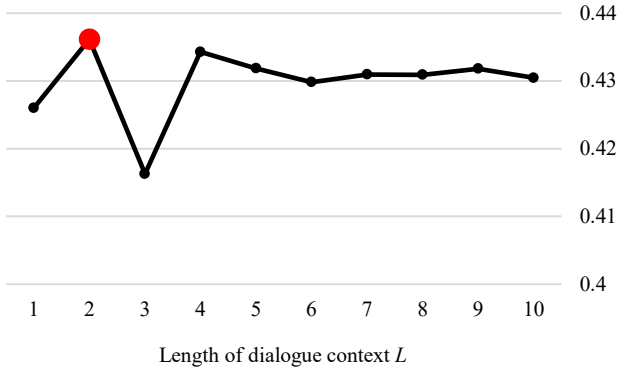

Figure 3. The performance of CNN-LSTM model based on various lengths of dialogue context on Guide dataset.

derived by conducting a grid search, where L ranges from 1 to 10 on both *Guide* and *Tourist* datasets. Figure 2 and Figure 3 illustrate the performance changes with respect to the length of dialogue context in the *Guide* and *Tourist* dataset respectively. It is shown that the optimal length of dialogue context would be L=3 and L=2 for the *Tourist* and *Guide* dataset, respectively, for making a dialogue context that improves the classification performance.

4.3. Word Embedding Vectors

GloVe[19] and *Word2Vec*[20] are the two most popular word embedding algorithms aiming at mapping semantic meaning of words in a geometric space. We initialize our proposed models with two publicly available pre-trained word vectors and both word embedding vectors have dimensionality of 300; *GloVe* that are trained on 6 billion words from Wikipedia 2014 and Gigaword5[2] and *Word2Vec* that are trained on 100 billion words from Google News[3]. In the preliminary experiments, it is observed that all the proposed models trained on top of the pre-trained *Word2Vec* show slightly better performances over those on top of pre-trained *GloVe*. In this sense only the performances of *Word2Vec* based models will be presented in this paper.

4.4. Model Variations

We evaluate three models with different architecture:

- CNN (multiclass): the model that predicts only one speech act category and attribute for given a *speaker's* utterance.
- CNN-LSTM (multiclass): the combined model which exploits dialogue context information from previous *speaker's* utterances
- CNN-LSTM (thresholding): the combined model with a threshold predictor that classifies multiple labels of speech act categories and attributes.

4.5. Evaluation Metrics

In the SLU task, a system is required to match relevant speech acts for a given unlabeled utterance spoken by the target role speaker. The following evaluation metrics are used in DSTC5.

- Precision: Fraction of speech act labels that are correctly predicted.
- Recall: Fraction of speech act labels in the gold standard that are correctly predicted.
- F-measure: The harmonic mean between precision and recall.

5. Results

Table 3 and Table 4 summarize the comparative experimental results of our models for classifying speech acts categories and attributes on *Guide* and *Tourist* datasets, respectively. On the *Tourist* dataset, the CNN-LSTM (multi-class) model shows promising results. Note that CNN-LSTM (multi-class) models outperform most of the models submitted in the DSTC5 for both speakers even without utilizing threshold learning mechanism. In terms of the F1-score, the model CNN-LSTM (thresholding) significantly outperforms all the other models on *Tourist* dataset. For the case of *Guide* dataset, our model is slightly behind of Team 2's model, but still highly comparable.

These results suggest that for conducting the SLU task of DSTC5 the CNN is a suitable model to predict and fill the slots of speech act categories and attributes. A threshold predictor enables the CNN models to classify a set of multiple labels on each utterances. It is worthy nothing that our model uses only publicly available word-embedding vectors without having any manually designed features or using delexicalization. Last but the most important thing is the dialogue context information encoded with the LSTM helps to improve the performance of conducting SLU task.

6. Discussion

At this point we circle back to the very beginning in order to understand what limitation had been posed on Xu et al.'s model and how our CNN-RNN model could tackle those issues[4]. The basic ideas of our study start from the properties of utterances. Each utterance is a sub-part of a dialogue and inevitably depends on the previous utterances in the intertwined way. In order to capture the semantic meaning from utterances the semantic

6	啊，不贵 ah , it 's not expensive.	FOL (INFO)	FOL (POSITIVE)

decoder must be robust enough (i) to detect the semantic meaning from utterances regardless of the specific word order – *propositional meaning,* and (ii) to understand the intention when a speaker utters them in the middle of dialogues – *pragmatic information*.

With these preliminaries in place Xu et al.'s model, which is grounded on CNN, overlooked the importance of pragmatic information, although it has specialized capability of extracting out of the necessary information from the current utterance. Our model has concatenated RNN to CNN before the soft-max operation so that it can retrieve the contextual meaning from the previous utterances in the dialogues and build more complete concept structure.

As illustrated in Table 5, our proposed CNN-LSTM model could correctly predict the labels which are supposed to be annotated. Consider the example of an utterance 嗯 '*uh-huh'*. If we only have a look this utterance itself, there is no way to disambiguate the meaning between acknowledge and confirmation. In the case of the example 4, since it has already uttered in the previous turn and both two participants of this dialogue know this fact, the confirmational phrase such as 'you meant … is it right?' is omitted to avoid the redundancy. This pragmatic information is stored in the long-term memory and utilized to understand the genuine meaning of corresponding utterance.

7. Conclusion

This paper has extended the work of Xu et al. on the SLU task of DSTC5, and has presented a semantic decoder using deep neural networks. We have compared different models for combining a threshold predictor and long short-term memory. Our concise model proved its efficiency by outperforming the models including the baseline on the DSTC5 and those submitted in the challenge. We observed that understanding the semantic meaning and building a concept structure of a certain utterance is effectively obtained by utilizing both current and previous information. It addresses that the architecture of our concatenated CNN-LSTM model may be applicable to other types of dialogues corpora for achieving SLU.

Integrity monitoring, detection isolation and reconstruction of faulty sensor
robustness to disturbance
dynamical systems

ABSTRACT

This paper proposes a novel approach to sensor and actuator integrity monitoring in a dynamic system. Multiple sensor and actuator faults can be detected. Furthermore, faulty sensors and actuators are isolated by contribution analysis. Most importantly, fault magnitudes can be correctly estimated and failed sensors or actuators outputs can be reconstructed. The proposed approach is robust to disturbances, minimizes false alarms, while achieving maximized sensitivity to any faults. Numerical examples justify correctness and validity of the developed methodology.

1. Introduction

Sensors and actuators are critical components in complex systems. For instance, in an airplane, effective flight control is impossible if sensors and/or actuators are malfunctioning [1-9]. Sensors and actuators can fail, and their failures have a significant impact on the performance of a system. In some applications such as arcing detection in power network [10] and motor corona monitoring [11], sensor and actuator condition plays critical role. In the worst case, the failure even can affect safe operation of the system, leading to a catastrophic event. Sensor failures may include precision degradation, drift, frozen reading, and complete failure [12]. Similarly, actuator failures may include limited range of motion, e.g., valve stiction, and complete failure [13]. It is a challenging task to detect sensor and actuator failures [1-5, 14-15] because sensor outputs contain information from a multitude of sources: normal system outputs, faulty sensor signals, and signals due to noise and external disturbances. Isolating different signals requires utilization of the input-output relationship of the system. Conventional approaches to increasing reliability of aircraft systems include installing redundant sensors, which will add more weights, costs, complexity, and most importantly, additional reliability problems.

Sensor fault detection and diagnosis has been a research topic for decades, and many articles have been published. Interested readers are referred to the survey paper by Frank [16]. While fault detection is relatively easy, isolation of multiple faults is still a challenge to many existing schemes. This paper proposes a novel and systematic approach to sensor and actuator integrity monitoring in systems such as jet engine of an aircraft. The first part is a fault detection scheme that can detect the presence of both sensor and actuator failures with maximized sensitivity. The newly proposed approach is based on analytic redundancy, which means no additional redundant sensors are needed. System input-output relationships (state-space dynamical model of the system) are used to help differentiate different sensor and actuator failures. The second step in the proposed scheme is the fault isolation. A proven technique known as contribution analysis [17-18] that has been widely used in process control industry is utilized for root cause search of sensor faults. Contribution analysis is a practical technique for fault isolation, particularly useful for multiple faults. Moreover, the concept of the structured residuals [19] is applied for actuator fault isolation. Finally, in line with the fault isolation results, a systematic procedure is conducted to reconstruct the faulty sensors/actuators such that the considered system, e.g., an aircraft, can keep functioning with acceptable performance in presence of sensor and/or actuator failures. Extensive simulations using a jet engine model clearly demonstrated the correctness and effectiveness of the proposed algorithms.

We would like to mention that this paper is an expanded version of our earlier work [20]. More details and simulations have been added to enrich the technical contents. The paper is organized as follows. Section II describes the problem formulation by introducing notations and terminologies. Section III, IV, and V summarize the fault detection, fault isolation, and fault reconstruction algorithms. Section VI includes simulation results of applying the proposed algorithms towards a jet engine. Finally, conclusions are drawn in Section VII and future work is discussed.

2. Problem formulation

Consider the following dynamical system with multiple inputs (MI) and multiple outputs (MO),

$$\begin{aligned} \mathbf{x}_{k+1} &= \mathbf{A}\mathbf{x}_k + \mathbf{B}\mathbf{u}_k + \boldsymbol{\omega}_k \\ \mathbf{y}_k &= \mathbf{C}\mathbf{x}_k + \mathbf{D}\mathbf{u}_k + \boldsymbol{\varepsilon}_k \end{aligned} \tag{1}$$

where $\mathbf{x}_k \in \Re^n$ is the state variable vector, $\mathbf{u}_k \in \Re^l$ the input vector, and $\mathbf{y}_k \in \Re^m$ the output vector, at time k; $\{\mathbf{A},\ \mathbf{B},\ \mathbf{C}, \mathbf{D}\}$ are system matrices with compatible dimensions; $\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$ are process disturbance and measurement noise, respectively. It is assumed that $\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$ are independent random variables with zero mean values and covariance matrices

$$E\left\{\boldsymbol{\omega}_k \boldsymbol{\omega}_k^T\right\} = \mathbf{R}_\omega \in \Re^{n\times n}, \quad E\left\{\boldsymbol{\varepsilon}_k \boldsymbol{\varepsilon}_k^T\right\} = \mathbf{R}_\varepsilon \in \Re^{m\times m}.$$

It is further assumed that $\{\mathbf{A},\ \mathbf{B},\ \mathbf{C}, \mathbf{D}\}$, $\mathbf{R}_\omega$, and $\mathbf{R}_\varepsilon$ are known because they can be either derived or identified from historical data by using the subspace method of identification [21].

Note that (1) represents a failure-free MIMO system. In the presence of sensor failures, $\Delta\mathbf{y}_k \in \Re^{n_y}$ and actuator failures $\Delta\mathbf{u}_k \in \Re^{n_u}$, one has

$$\begin{aligned} \mathbf{x}_{k+1} &= \mathbf{A}\mathbf{x}_k + \mathbf{B}\mathbf{u}_k + \mathbf{B}\mathbf{M}_u\Delta\mathbf{u}_k + \boldsymbol{\omega}_k \\ \mathbf{y}_k &= \mathbf{C}\mathbf{x}_k + \mathbf{D}\mathbf{u}_k + \mathbf{D}\mathbf{M}_u\Delta\mathbf{u}_k + \mathbf{M}_y\Delta\mathbf{y}_k + \boldsymbol{\varepsilon}_k \end{aligned} \tag{2}$$

For a system represented by (2), given available data $\{\mathbf{u}_k, \mathbf{y}_k\}$, it is expected to detect if the magnitude of $\Delta\mathbf{u}_k$ or $\Delta\mathbf{y}_k$ is non-zero. If the answer is yes, the magnitude is estimated and the failure direction matrix $\mathbf{M}_u$ or $\mathbf{M}_y$ is identified. Finally, the failed sensors or actuators will be reconstructed on-line and in real time such that all the sensors are always functional with accepted performance. Herein, it must be addressed that $\{\mathbf{u}_k\}$ comes from controllers. Therefore, it is always available and does not include any actuator failures. On the other hand, $\{\mathbf{y}_k\}$ is measured, also always available, and can contain sensor failures. The variables and terms in this paper are summarized in Appendix.

3. Detection of Faulty Sensors/Actuators

Given an integer s (its determination will be discussed later), performing an algebraic manipulation on (2) leads to

$$\begin{aligned} \mathbf{y}_{k-s+i} = \mathbf{C}\mathbf{A}^i\mathbf{x}_{k-s} + \mathbf{C}\sum_{t=k-s}^{k-s+i-1}\mathbf{A}^{k-s+i-1-t}\left(\mathbf{B}\mathbf{u}_t + \mathbf{B}\mathbf{M}_u\Delta\mathbf{u}_t + \boldsymbol{\omega}_t\right) + \\ \mathbf{D}\mathbf{u}_{k-s+i} + \mathbf{D}\mathbf{M}_u\Delta\mathbf{u}_{k-s+i} + \mathbf{M}_y\Delta\mathbf{y}_{k-s+i} + \boldsymbol{\varepsilon}_{k-s+i} \end{aligned} \tag{3}$$

where $i \in [0, s]$. Note that at $i = 0$,

$$\begin{aligned} \mathbf{y}_{k-s} = \mathbf{C}\mathbf{x}_{k-s} + \mathbf{D}\mathbf{u}_{k-s} + \\ \mathbf{D}\mathbf{M}_u\Delta\mathbf{u}_{k-s} + \mathbf{M}_y\Delta\mathbf{y}_{k-s} + \boldsymbol{\varepsilon}_{k-s} \end{aligned} \tag{4}$$

Define a stacked vector

$$\mathbf{y}_{k-s:k} = \begin{bmatrix} \mathbf{y}_{k-s}^T & \mathbf{y}_{k-s+1}^T & \cdots & \mathbf{y}_k^T \end{bmatrix} \in \Re^{m(s+1)} \tag{5}$$

Similarly, define five more stacked vectors

$$\begin{aligned} &\mathbf{u}_{k-s:k} \in \Re^{l(s+1)},\ \Delta\mathbf{u}_{k-s:k} \in \Re^{n_u(s+1)},\ \Delta\mathbf{y}_{k-s:k} \in \Re^{n_y(s+1)}, \\ &\boldsymbol{\omega}_{k-s:k} \in \Re^{n(s+1)},\ \boldsymbol{\varepsilon}_{k-s:k} \in \Re^{m(s+1)}. \end{aligned} \tag{6}$$

It turns out from (3)-(6) that

$$\begin{aligned} \mathbf{y}_{k-s:k} = \boldsymbol{\Gamma}^s\mathbf{x}_{k-s} + \mathbf{H}^s\mathbf{u}_{k-s:k} + \mathbf{G}^s\boldsymbol{\omega}_{k-s:k} + \\ \mathbf{M}_u^s\Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s\Delta\mathbf{y}_{k-s:k} + \boldsymbol{\varepsilon}_{k-s:k} \end{aligned} \tag{7}$$

where

$$\left(\boldsymbol{\Gamma}^s\right)^T = \begin{bmatrix} \mathbf{C}^T & \mathbf{A}^T\mathbf{C}^T & \cdots & \left(\mathbf{A}^s\right)^T\mathbf{C}^T \end{bmatrix} \in \Re^{m(s+1)\times n},$$

$$\mathbf{H}^s = \begin{bmatrix} \mathbf{D} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{CB} & \mathbf{D} & & \vdots \\ \vdots & & \ddots & \\ \mathbf{CA}^{s-1}\mathbf{B} & \mathbf{CA}^{s-2}\mathbf{B} & \cdots & \mathbf{D} \end{bmatrix} \in \Re^{m(s+1)\times l(s+1)},$$

$$\mathbf{G}^s = \begin{bmatrix} \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{C} & \mathbf{0} & & \vdots \\ \vdots & & \ddots & \\ \mathbf{CA}^{s-1} & \mathbf{CA}^{s-2} & \cdots & \mathbf{0} \end{bmatrix} \in \Re^{m(s+1)\times n(s+1)},$$

$$\mathbf{M}_y^s = \begin{bmatrix} \mathbf{M}_y & \mathbf{0} & \cdots & \mathbf{0} \\ 0 & \mathbf{M}_y & & \vdots \\ \vdots & & \ddots & \\ 0 & \cdots & & \mathbf{M}_y \end{bmatrix} \in \Re^{m(s+1)\times n_y(s+1)},$$

$$\mathbf{M}_u^s = \begin{bmatrix} \mathbf{DM}_u & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{CBM}_u & \mathbf{DM}_u & & \vdots \\ \vdots & & \ddots & \\ \mathbf{CA}^{s-1}\mathbf{BM}_u & \mathbf{CA}^{s-1}\mathbf{BM}_u & \cdots & \mathbf{DM}_u \end{bmatrix} \in \Re^{m(s+1)\times n_u(s+1)}.$$

Herein, the choice of s is discussed. It must be chosen such that $\text{rank}\left\{\boldsymbol{\Gamma}^s\right\} = n$. There can be many candidates for s to meet such a requirement. We just select a proper value that allows us to perform both fault detection and isolation. This will be elaborated later.

With the establishment of (7), a primary residual vector (PRV) can be calculated for fault detection. Select a matrix $\mathbf{W}_{\text{prv}}$ from the null space of $\mathbf{\Gamma}^s$. Multiplying both sides of (7) by $\mathbf{W}_{\text{prv}}$ leads to

$$\mathbf{W}_{\text{prv}}\mathbf{y}_{k-s:k} = \mathbf{W}_{\text{prv}}\mathbf{H}^s\mathbf{u}_{k-s:k} + \mathbf{W}_{\text{prv}}\left(\mathbf{M}_u^s\Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s\Delta\mathbf{y}_{k-s:k}\right) + \mathbf{W}_{\text{prv}}\left(\mathbf{G}^s\boldsymbol{\omega}_{k-s:k} + \boldsymbol{\varepsilon}_{k-s:k}\right) \quad (8)$$

where $\mathbf{W}_{\text{prv}}\mathbf{\Gamma}^s = \mathbf{0}$ has been considered.

Define

$$\begin{aligned}\mathbf{e}_{s,k} &\equiv \mathbf{W}_{\text{prv}}\left(\mathbf{y}_{k-s:k} - \mathbf{H}^s\mathbf{u}_{k-s:k}\right)\\ &= \mathbf{W}_{\text{prv}}\left(\mathbf{M}_u^s\Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s\Delta\mathbf{y}_{k-s:k}\right) + \\ &\quad \mathbf{W}_{\text{prv}}\left(\mathbf{G}^s\boldsymbol{\omega}_{k-s:k} + \boldsymbol{\varepsilon}_{k-s:k}\right)\end{aligned} \quad (9)$$

as the PRV for fault detection due to the following facts:

a. In the ideal case, i.e., no fault, no noise, and no disturbance, $\mathbf{e}_{s,k} = \mathbf{0}$.

b. Without any faults, $\mathbf{e}^*_{s,k} = \mathbf{W}_{\text{prv}}\left(\mathbf{G}^s\boldsymbol{\omega}_{k-s:k} + \boldsymbol{\varepsilon}_{k-s:k}\right)$ is a moving average (MA) process of noise vectors $\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$, having zero mean value and covariance matrix

$$\mathbf{R}_e^s \equiv \mathbf{W}_{\text{prv}}\left(\mathbf{G}^s\mathbf{R}_\omega^s\left(\mathbf{G}^s\right)^T + \mathbf{R}_\varepsilon^s\right)\mathbf{W}_{\text{prv}}^T \in \Re^{(m(s+1)-n)\times(m(s+1)-n)} \quad (10)$$

where $\mathbf{R}_\omega^s \equiv \mathbf{I}_{s+1}\otimes\mathbf{R}_\omega$, $\mathbf{R}_\varepsilon^s \equiv \mathbf{I}_{s+1}\otimes\mathbf{R}_\varepsilon$, with $\mathbf{I}_{s+1}$ being an identity matrix and $\otimes$ the Kronecker tensor product [30].

c. In the presence of sensor and/or actuator faults, the PRV is

$$\mathbf{e}_{s,k} = \mathbf{W}_{\text{prv}}\left(\mathbf{M}_u^s\Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s\Delta\mathbf{y}_{k-s:k}\right) + \mathbf{e}^*_{s,k}$$

which is a random vector with non-zero mean,

$$\mathbf{W}_{\text{prv}}\left(\mathbf{M}_u^s\Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s\Delta\mathbf{y}_{k-s:k}\right)$$

and covariance $\mathbf{R}_e^s$ [22]. Therefore, fault detection is to check if the mean value of the PRV is zero.

So far, no discussion on the calculation of $\mathbf{W}_{\text{prv}}$ has been conducted yet. Considering the dimension and rank of $\mathbf{\Gamma}^s$, it can be figured out that $\mathbf{W}_{\text{prv}}$ has $(s+1)m-n$ rows and $(s+1)m$ columns. Detailed steps to calculate $\mathbf{W}_{\text{prv}}$, which are lengthy but straightforward, are documented in [19].

Assume that $\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$ are Gaussian distributed. It can be easily shown that $\overline{\mathbf{e}}_{s,k} = \left(\mathbf{R}_e^s\right)^{-1/2}\mathbf{e}_{s,k}$ follows a zero mean Gaussian distribution with an identity covariance matrix [22]. Therefore, define

$$d_{s,k} = \overline{\mathbf{e}}_{s,k}^T\overline{\mathbf{e}}_{s,k} \quad (11)$$

as the fault detection index, which follows a χ^2 distribution with degree of freedom $m(s+1)-n$ [22]. With a pre-determined confidence limit, if $d_{s,k}$ exceeds the limit, it indicates that some sensors and or actuators are faulty. Otherwise, everything is normal.

At the end of this section, the issue of disturbance decoupling is discussed. It has been assumed that $\boldsymbol{\omega}_k$ is Gaussian distributed. In reality, this assumption sometimes may be not valid. If this is the case, one can try to decouple the effect of disturbance as much as possible.

Note that in the PRV represented by (9), the disturbance contributed term is $\mathbf{W}_{\text{prv}}\mathbf{G}^s\boldsymbol{\omega}_{k-s:k}$. Perform a singular value decomposition (SVD) on $\mathbf{G}^s$, and design $\mathbf{W}_{\text{prv}}$ such that each of its rows is orthogonal to the principal left singular vectors related to few largest singular values of $\mathbf{G}^s$. As a consequence, effect of $\boldsymbol{\omega}_k$ can be decoupled partially. How much percentage of $\boldsymbol{\omega}_k$ can be decoupled? This depends on the dimension of $\mathbf{W}_{\text{prv}}$ and the rank of $\mathbf{G}^s$. Intuitively, the lower the rank of $\mathbf{G}^s$ is, the easier to decouple $\boldsymbol{\omega}_k$ from the PRV. Even if $\boldsymbol{\omega}_k$ cannot be removed from the PRV completely, it can be decoupled to some extent by using the above-mentioned SVD [23].

4. Isolation of Faulty Sensors/Actuators

While many methods have been available, here contribution analysis [18] is proposed for sensor fault isolation due to its practicality and simplicity. Computationally, the PRV is $\mathbf{e}_{s,k} \equiv \mathbf{W}_{\text{prv}}\left(\mathbf{y}_{k-s:k} - \mathbf{H}^s\mathbf{u}_{k-s:k}\right)$, which is contributed by $\mathbf{y}_{k-s:k}$ and $\mathbf{u}_{k-s:k}$. In the presence of sensor faults, the PRV will deviate from its nominal values. Consequently, by analyzing the contributions in $\mathbf{e}_{s,k}$ from each element of $\mathbf{y}_{k-s:k}$, the faulty sensors can be identified.

However, since $\mathbf{u}_{k-s:k}$ does not include any actuator failures, contribution analysis cannot be used for isolation of actuator failures. We will propose the structured residual-based approach towards actuator fault isolation. Therefore, combining contribution analysis [17-18] and the structured residual-based approach [19] will develop a comprehensive fault isolation methodology for both sensor and actuator failures.

4.1. Contribution Analysis for Isolation of Faulty Sensors

We illustrate how to identify faulty sensors by contribution analysis first. It turns out from (5) and the first line of (9) that

Table 1. Incidence matrix showing actuator fault isolation logic.

SRVs	1^{st} actuator	2^{nd} actuator	…	i^{th} actuator
SRV_1	0	1	1	1
SRV_2	1	0	1	1
⋮	1	⋱	⋮	⋮
SRV_l	1	1	1	0

$$\mathbf{e}_{s,k} \equiv \sum_{i_1=1}^{m}\sum_{i_2=1}^{s} \mathbf{W}_{\text{prv}}\left(:, i_1 + i_2 m\right) \mathbf{y}_{k-s:k}\left(i_1 + i_2 m\right) - \mathbf{W}_{\text{prv}} \mathbf{H}^s \mathbf{u}_{k-s:k} \tag{12}$$

where $\mathbf{W}_{\text{prv}}(:, i)$ is the i^{th} column of matrix $\mathbf{W}_{\text{prv}}$, and $\mathbf{y}_{k-s:k}(i)$ is the i^{th} element of stacked vector $\mathbf{y}_{k-s:k} \in \Re^{m(s+1)}$.

If the i_1^{th} sensor has a failure for any $1 \le i_1 \le m$, the failure-associated term in $\mathbf{e}_{s,k}$ is a vector:

$$\mathbf{f}_{k,i_1} = \sum_{i_2=1}^{s} \mathbf{W}_{prv}(:, i_1 + mi_2)\mathbf{y}_{k-s:k}(i_1 + mi_2) \cdot$$

Moreover, define

$$\overline{\mathbf{f}}_{k,i_1} = \sum_{i_2=1}^{s} \mathbf{W}_{prv}(:, i_1 + mi_2)\overline{\mathbf{y}}_{k-s:k}(i_1 + mi_2)$$

where $\overline{\mathbf{y}}_{k-s:k}(i_1 + mi_2)$ is the scaled counterpart of $\mathbf{y}_{k-s:k}(i_1 + mi_2)$, i.e., mean-centered and divided by its standard deviation.

If a sensor failure begins to occur at time instance k_{f_1} and ends at k_{f_2}, then one calculates the absolute average value, i.e.,

$$\left|\overline{\mathbf{f}}_{k_{f1}:k_{f2},i_1}\right| = \left|\frac{1}{t_{f_2} - t_{f_1} + 1} \sum_{k=k_{f1}}^{k_{f2}} \overline{\mathbf{f}}_{k,i_1}\right| \tag{13}$$

for all $i_1 \in [1, m]$, obtaining m magnitude values.

Any sensor that has the largest magnitude defined by (13) can be identified as faulty. For example, if Sensor 5 has the largest magnitude, then it can be inferred that it is faulty. As a result, the failure direction matrices for the sensor is $\mathbf{M}_y = \mathbf{I}_m(:, 5)$.

4.2. Isolation of Faulty Actuators

In order to isolate faulty actuators, one can also generate a set of structured residual vectors (SRVs) in line with a predetermined isolation logic [18]. For simplicity, assume that at each time, only a single actuator can be faulty. Under this assumption, for the system represented by (2), we design a set of l SRVs such that the i^{th} SRV is insensitive to the i^{th} actuator fault, while of maximized sensitivity to faults in other $l-1$ actuators for $i \in [1, l]$. Sensitivity of all the designed l SRVs to actuator faults can be described by the following incidence matrix shown in Table 1.

In the above incidence matrix shown in Table 1, '0'/'1' means insensitivity/maximized sensitivity of a SRV to an actuator fault. For instance, in presence of a fault, if SRV_i is not affected by the fault, while all the other SRVs are affected, then the i^{th} actuator is faulty.

Mathematically, the i^{th} SRV can be calculated by

$$\begin{aligned} \mathbf{r}_{s,k}^i &= \mathbf{W}_{\text{srv}}^i(\mathbf{y}_{k-s:k} - \mathbf{H}^s \mathbf{u}_{k-s:k}) \\ &= \mathbf{W}_{\text{srv}}^i \boldsymbol{\Gamma}^s \mathbf{x}_{k-s} + \mathbf{W}_{\text{srv}}^i \left(\mathbf{M}_u^s \Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s \Delta\mathbf{y}_{k-s:k}\right) + \\ &\quad \mathbf{W}_{\text{srv}}^i \left(\mathbf{G}^s \boldsymbol{\omega}_{k-s:k} + \boldsymbol{\varepsilon}_{k-s:k}\right) \\ &= \mathbf{W}_{\text{srv}}^i \left(\mathbf{M}_u^s \Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s \Delta\mathbf{y}_{k-s:k}\right) + \mathbf{r}_{\text{srv}}^{i,*} \end{aligned} \tag{14}$$

where $\mathbf{r}_{s,k}^{i,*} = \mathbf{W}_{\text{srv}}^i \left(\mathbf{G}^s \boldsymbol{\omega}_{k-s:k} + \boldsymbol{\varepsilon}_{k-s:k}\right)$ is fault free, and the matrix $\mathbf{W}_{srv}^i$ is designed such that $\mathbf{x}_{\text{k-s}}$ and the following associated $\{\Delta\mathbf{u}_{k-s:k}(i+l), \Delta\mathbf{u}_{k-s:k}(i+2l), \cdots \Delta\mathbf{u}_{k-s:k}(i+sl)\}$ are excluded from $\mathbf{r}_{s,k}^i$. This indicates that

$$\mathbf{W}_{\text{srv}}^i [\boldsymbol{\Gamma}^s \ \mathbf{M}_u^s(:, i) \ \mathbf{M}_u^s(:, i+l) \ \mathbf{M}_u^s(:, i+2l) \ \cdots \mathbf{M}_u^s(:, i+sl)] = \mathbf{0} \tag{15}$$

for all $i \in [1, l]$. Design of $\mathbf{W}_{\text{srv}}^i$ is documented in [19]. Similar to (11),

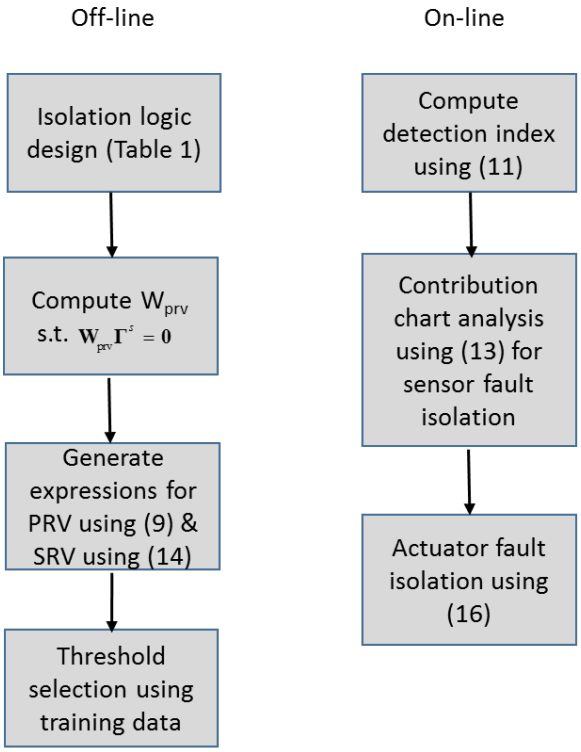
$$I_{s,k}^i = (\mathbf{r}_{s,k}^i)^T (\mathbf{R}_s^{s,i})^{-1} \mathbf{r}_{s,k}^i \tag{16}$$

is defined as the actuator fault isolation index, where $\mathbf{R}_e^{s,i}$ is the covariance of $\mathbf{r}_{s,k}^{i,*}$ for $i \in [1, l]$.

At the end of this section, hereafter we summarize the steps to perform detection and isolation of sensor and actuator faults:

1. Develop an isolation logic under an assumed fault pattern.
2. Design the PRV and a set of SRVs in line with the pre-determined isolation logic.
3. From a set of training data, calculate a sequence of PRV and sequences of SRVs. Calculate their respective thresholds.
4. Check if the detection index $d_{s,k} = \overline{\mathbf{e}}_{s,k}^T \overline{\mathbf{e}}_{s,k}$ given by (11) is triggering an alarm.
5. Use contribution analysis to isolation sensor faults.
6. Use the SRVs to isolate actuator faults.

The above procedures are detailed also in the following flow chart. We divide the procedures into off-line, which is the preparation phase, and the online parts.



5. Reconstruction of Faulty Sensors and Actuators

After identification of faulty sensors/actuators, one has to estimate the fault magnitudes first. Then, from the estimated fault value, faulty sensors can be reconstructed.

5.1. Estimation of Fault Magnitudes

It can be derived from

$$\mathbf{e}_{s,k} = \mathbf{W}_{\text{prv}}\left(\mathbf{M}_u^s \Delta\mathbf{u}_{k-s:k} + \mathbf{M}_y^s \Delta\mathbf{y}_{k-s:k}\right) + \mathbf{e}_{s,k}^*$$

that

$$\mathbf{e}_{s,k}^* = \mathbf{e}_{s,k} - \mathbf{W}_{\text{prv}}\begin{bmatrix}\mathbf{M}_u^s & \mathbf{M}_y^s\end{bmatrix}\begin{bmatrix}\Delta\mathbf{u}_{k-s:k}\\ \Delta\mathbf{y}_{k-s:k}\end{bmatrix} \quad (17)$$

With known $\mathbf{M}_u^s$ and $\mathbf{M}_y^s$, in line with [12], one can estimate $\begin{bmatrix}\Delta\mathbf{u}_{k-s:k}\\ \Delta\mathbf{y}_{k-s:k}\end{bmatrix} \in \Re^{(s+1)(n_u+n_y)}$ by minimizing

$$\left\{\mathbf{e}_{s,k} - \mathbf{W}_{\text{prv}}\begin{bmatrix}\mathbf{M}_u^s & \mathbf{M}_y^s\end{bmatrix}\begin{bmatrix}\Delta\mathbf{u}_{k-s:k}\\ \Delta\mathbf{y}_{k-s:k}\end{bmatrix}\right\}^T \mathbf{R}_{s,e}^{-1}\left\{\mathbf{e}_{s,k} - \mathbf{W}_{\text{prv}}\begin{bmatrix}\mathbf{M}_u^s & \mathbf{M}_y^s\end{bmatrix}\begin{bmatrix}\Delta\mathbf{u}_{k-s:k}\\ \Delta\mathbf{y}_{k-s:k}\end{bmatrix}\right\}$$

giving

$$\left(\mathbf{W}_{\text{prv}}[\mathbf{M}_u^s \;\; \mathbf{M}_y^s]\right)^T \mathbf{R}_{s,e}^{-1}\left(\mathbf{W}_{\text{prv}}[\mathbf{M}_u^s \;\; \mathbf{M}_y^s]\right)\begin{bmatrix}\Delta\mathbf{u}_{k-s:k}\\ \Delta\mathbf{y}_{k-s:k}\end{bmatrix} = \left(\mathbf{W}_{\text{prv}}[\mathbf{M}_u^s \;\; \mathbf{M}_y^s]\right)^T \mathbf{R}_{s,e}^{-1}\mathbf{e}_{s,k} \quad (18)$$

If the matrix $\left(\mathbf{W}_{\text{prv}}[\mathbf{M}_u^s \;\; \mathbf{M}_y^s]\right)^T \mathbf{R}_{s,e}^{-1}\left(\mathbf{W}_{\text{prv}}[\mathbf{M}_u^s \;\; \mathbf{M}_y^s]\right)$ is of full rank, one can get the least squares (LS) solution to $\begin{bmatrix}\Delta\mathbf{u}_{k-s:k}^T & \Delta\mathbf{y}_{k-s:k}^T\end{bmatrix}^T$ easily. If the matrix is of rank deficiency, one can apply a latent variable-based approach, such as the partial least squares (PLS), to estimate the fault magnitude [24].

5.2. Reconstruction of Faulty Sensors

With estimated fault magnitudes, one can correct measurements of the faulty sensors. The measurements in faulty sensors are affected both by $\Delta\mathbf{u}_k$ and $\Delta\mathbf{y}_k$. In order to get the corrected measurements in faulty sensors, one can design a Kalman filter,

$$\begin{aligned}\hat{\mathbf{x}}_{k+1} &= \mathbf{A}\hat{\mathbf{x}}_k + \mathbf{B}\mathbf{u}_k + \mathbf{K}(\mathbf{y}_k - \mathbf{M}_y\Delta\hat{\mathbf{y}}_k - \mathbf{D}\mathbf{M}_u\Delta\hat{\mathbf{u}}_k - \mathbf{C}\hat{\mathbf{x}}_k - \mathbf{D}\mathbf{u}_k)\\ \hat{\mathbf{y}}_k &= \mathbf{C}\hat{\mathbf{x}}_k + \mathbf{D}\mathbf{u}_k\end{aligned} \quad (19)$$

where $\hat{\mathbf{y}}_k$ is the corrected measurement of faulty sensors.

6. Numerical Examples

The proposed methodology for sensor/actuator fault detection, isolation, and reconstruction is applied to a gas turbine jet engine control system [25].

6.1. The Simulated System

The gas turbine engine can be described essentially as a heat engine that uses atmospheric air as a working medium to generate propulsive thrust and mechanical power. The central unit of the mechanical arrangement comprises two main rotating parts, the compressor and the turbine. The control system has the function of coordinating the main burner fuel flow and the propelling exhaust nozzle.

The thermodynamic model of the engine is in continuous-time domain. It has 17 state variables, including pressures, air and gas mass flow rates, shaft speeds, absolute temperatures, and static pressure. This is a highly nonlinear dynamic structure that has grossly different steady-state operation over the entire range of spool speeds, flow rates, and nozzle areas. The linearized 17$^{\text{th}}$ model in the continuous-time domain is used here for study. The nominal operating point is set at 70% of the demand high spool speed (N_H). For practical reasons and convenience of design, a fifth-order model is employed [25] to approximate the 17th-order model as represented by (20), where a sampling period of $\Delta T = 0.026$ s was taken.

Using a reduced-order model to approximate the full-order dynamic system leads to modeling errors. Another problem is that the operating point of the system varies according to realistic running conditions. In general, different operating points correspond to different plant models. In the practical situation, the design of the fault detection and isolation scheme is based on a fixed mode. When the operating point changes, a model-plant mismatch occurs. Therefore, the system is represented by a fifth order state space model with two inputs, five outputs, and disturbance, i.e.

$$\mathbf{x}_{k+1} = \begin{bmatrix} -0.9813 & 7.5320 & -0.5983 & 0.4857 & -0.6979 \\ 0.2838 & -0.0826 & 0.0779 & -0.0617 & 0.0928 \\ -6.8588 & 28.9161 & -2.0561 & 1.6083 & -2.2612 \\ 1.2235 & -5.6607 & 0.4020 & -0.3192 & 0.4141 \\ 13.2662 & -53.4047 & 4.7390 & -3.7710 & 5.3669 \end{bmatrix} \mathbf{x}_k + \begin{bmatrix} 0.0001 & 0.0002 \\ 0.0001 & -0.0000 \\ 0.0032 & 0.0006 \\ 0.0078 & -0.0003 \\ 0.0031 & -0.0015 \end{bmatrix} \mathbf{u}_k + \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \boldsymbol{\omega}_k, \quad (20)$$

$$\mathbf{y}_k = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \mathbf{x}_k + \boldsymbol{\varepsilon}_k$$

where the two inputs are main engine fuel flow rate and the exhaust nozzle area. In addition, the five outputs are compressor shaft speed, two pressure measurements, two temperature measurements, and the demand high spool speed. In addition, $\boldsymbol{\omega}_k$ represents the afore-mentioned modeling errors or model plant mismatch and $\boldsymbol{\varepsilon}_k$ is measurement noise. It is assumed that $\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$ are independently distributed Gaussian white noise sequences, with respective covariance matrices $\mathbf{R}_\omega = 0.001\mathbf{I}_5$ and $\mathbf{R}_\varepsilon = 0.001\mathbf{I}_5$.

Given the model parameters, selecting $s = 5$, we calculate the following matrices $\boldsymbol{\Gamma}^s \in \Re^{30\times 5}$, $\mathbf{H}^s \in \Re^{30\times 12}$, $\mathbf{M}_u^s \in \Re^{30\times 12}$, $\mathbf{M}_y^s \in \Re^{30\times 30}$, and $\mathbf{G}^s \in \Re^{30\times 30}$ in line with the formulas in (7).

We then calculate the matrix, $\mathbf{W}_{\text{prv}}$, to generate the PRV for fault detection. In accordance with [19], $\mathbf{W}_{\text{prv}} \in \Re^{25\times 30}$ is calculated such that each of its rows is orthogonal to $\boldsymbol{\Gamma}^s$ while having maximized covariance with the non-zero singular value related-left singular vectors of $[\mathbf{M}_u^s \quad \mathbf{M}_y^s] \in \Re^{30\times 42}$.

With the calculated $\mathbf{W}_{\text{prv}}$, the PRV is generated by

$$\mathbf{e}_{s,k} \equiv \mathbf{W}_{\text{prv}} \left(\mathbf{y}_{s,k} - \mathbf{H}^s \mathbf{u}_{s,k} \right) \in \Re^{25}.$$

Furthermore, we calculate two more matrices $\mathbf{W}_{\text{srv}}^1 \in R^{20\times 30}$ and $\mathbf{W}_{\text{srv}}^2 \in R^{20\times 30}$ to generate two SRVs

$$\mathbf{r}_{s.k}^i \equiv \mathbf{W}_{\text{srv}}^i \left(\mathbf{y}_{s,k} - \mathbf{H}^s \mathbf{u}_{s,k} \right) \in \Re^{20}$$

for $i = 1, 2$ according to the isolation logic listed in Table 1.

Without any faults, we used (20) to generate 10,000 samples of training data, where $\mathbf{u}_k = [100 \quad 100]^T$, and accordingly we calculated three sequences of $\{\mathbf{e}_{s,k}^*\}$, $\{\mathbf{r}_{s.k}^{1,*}\}$, and $\{\mathbf{r}_{s.k}^{2,*}\}$, respectively. Using such sequences, we estimated the covariance, $\mathbf{R}_e^s \in \Re^{25\times 25}$ of $\{\mathbf{e}_{s,k}^*\}$, $\mathbf{R}_e^{s,1} \in \Re^{20\times 20}$, and $\mathbf{R}_e^{s,2} \in \Re^{20\times 20}$.

We calculated a sequence of fault detection index $\{d_{s,k}\}$ from $\{\mathbf{e}_{s,k}^*\}$ and $\mathbf{R}_e^s$ by using (11). It is depicted below with a confidence limit 48.1444 (the red line in the graph). Moreover, we calculated two sequences of $\{I_{s,k}^i\}$, which are depicted in Figure 2, respectively, with their own confidence limits.

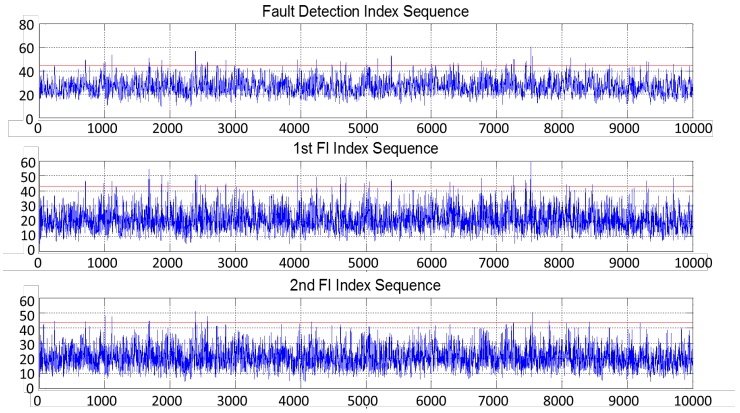


Figure 2. Fault detection and Isolation indices from training data.

$\{d_{s,k}\}$ given a level of confidence 99%. And such a limit will be employed for fault detection in test data.

6.2. Generation of Test Data and FDI Results

Many case studies have been conducted, and few results are presented hereafter.

6.2.1 Case 1: Detection and Isolation of a Faulty Actuator

A time varying fault simulated by

$$\Delta\mathbf{u}_k = \frac{\left(k - k_f\right)}{10000} * \begin{bmatrix} 1\left(k - k_f\right) \\ 0 \end{bmatrix}$$

is introduced to one actuator, where

$$1\left(k - k_f\right) = \begin{cases} 1, & \forall\ k \geq k_f \\ 0, & \forall\ k < k_f \end{cases}$$

and $k_f = 510$. Note that k_f denotes the instant at which a fault begins to occur. In this case, the test data are generated from the following equation:

$$\mathbf{x}_{k+1} = \mathbf{A}\mathbf{x}_k + \mathbf{B}\mathbf{u}_k + \mathbf{B}\mathbf{M}_u\Delta\mathbf{u}_k + \boldsymbol{\omega}_k$$

$$\mathbf{y}_k = \mathbf{C}\mathbf{x}_k + \mathbf{D}\mathbf{u}_k + \mathbf{D}\mathbf{M}_u\Delta\mathbf{u}_k + \boldsymbol{\varepsilon}_k$$

where $\mathbf{u}_k = [100 \quad 100]^T$ as selected before.

From available data sequences $\{\mathbf{u}_k, \mathbf{y}_k\}$, we generated the PRV and two SRVs. At the meanwhile, we calculated the fault detection index sequence $\{d_{s,k}\}$ and two fault isolation index sequences $\{I^1_{s,k}\}$ and $\{I^2_{s,k}\}$. As clearly shown in Figure 3, as time goes by, $\{d_{s,k}\}$ exceeded its limit, indicating that a fault/faults has/have occurred.

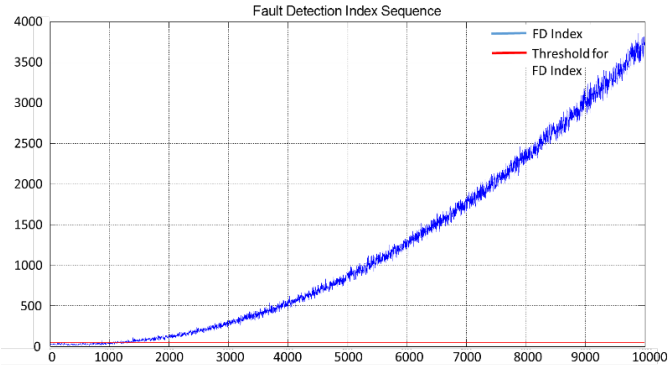

Figure 3. Fault Detection Result from Test Data.

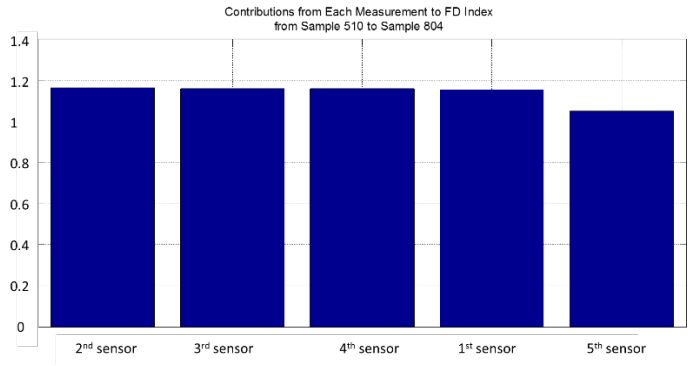

Figure 4. Contribution Analysis Results.

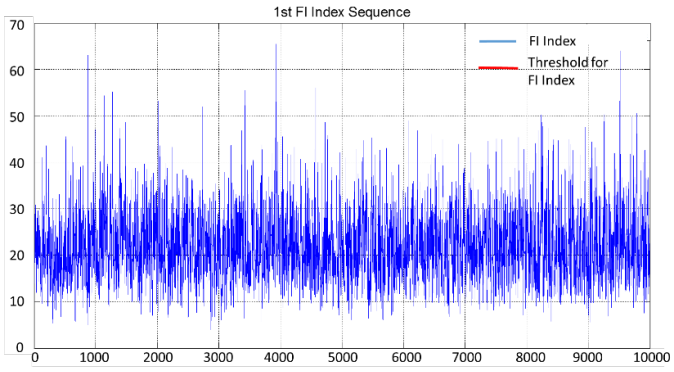

Figure 5. The 1st Fault Isolation Index Sequence Calculated from Test Data.

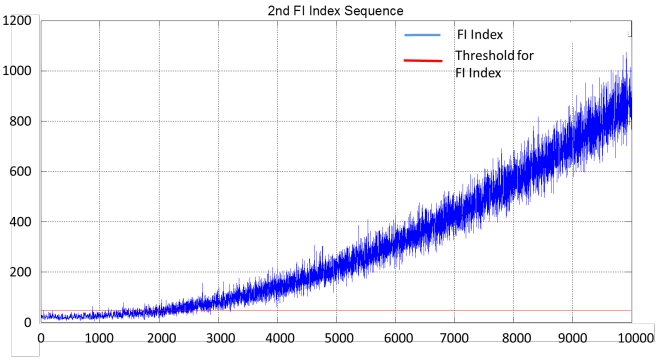

Figure 6. The 2nd Fault Isolation Index Sequence Calculated from Test Data.

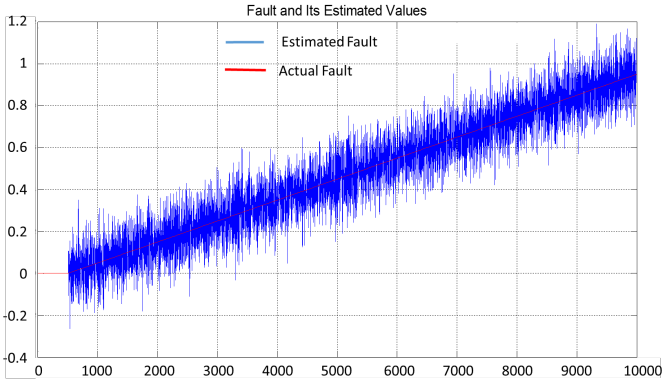

Figure 7. Actual and Estimated Fault Values from Test Data.

A bias with size 1.5 was introduced to a sensor. The fault detection index is displayed in Figure 8, where the $\{d_{s,k}\}$ exceeds its limit at sample 3000, giving $k_{f_1} = 3000$.

Having detected the sensor fault, the next step is to isolate the faulty sensor by conducting the contribution analysis. A bar chart showing the contributions from all five sensors is depicted in Figure 9, where $k_{f_1} = 3000$ and $k_{f_2} = 9995.$.

It is clearly shown that the first output has made the most significant contribution to the sensor failure. Therefore, it can be inferred that the first sensor is faulty.

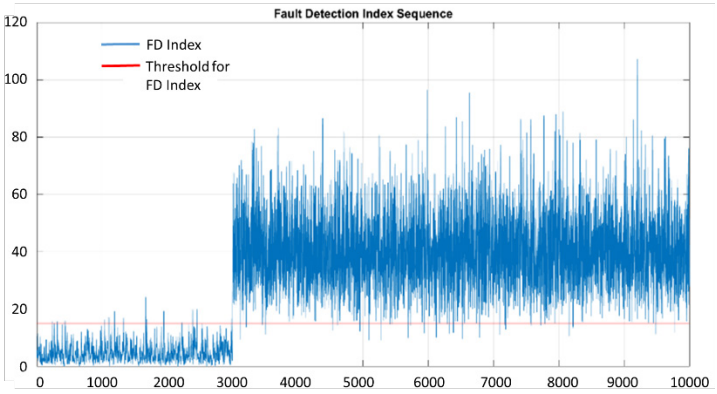

Figure 8. Detection result of a sensor fault

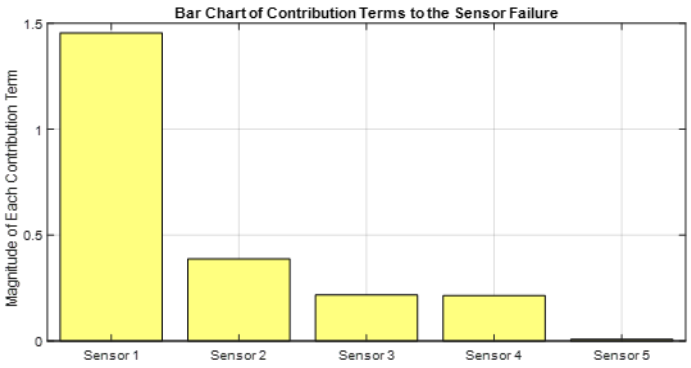

Figure 9. Contribution analysis result of a sensor failure

$p = 0.95$, then one can calculate the probabilities of simultaneous sensor failures. The results are listed in Table 2. For example, the probability that i sensors are faulty simultaneously is

$$\text{Prob}_{i,0.95} = C_5^i p^{5-i}(1-p)^i$$

where C_5^i is the combination of i from 5 for $i \in [1,5]$.

Table 2. Probabilities of simultaneous sensor faults

Number of simultaneously faulty sensors	probability
1	0.2036
2	0.0214
3	0.0011
4	0.0000297
5	3.125×10^{-7}

As shown in Table 2, since the chance for three or more sensors to fail simultaneously is low, one only needs to consider the detection and isolation of two sensor failures for the simulated system. Two faults are introduced to two sensors, respectively. One is a bias with magnitude 0.5, and the other is precision degradation simulated by a random noise signal with zero mean and variance of 0.01. The fault detection result is illustrated in Figure 10.

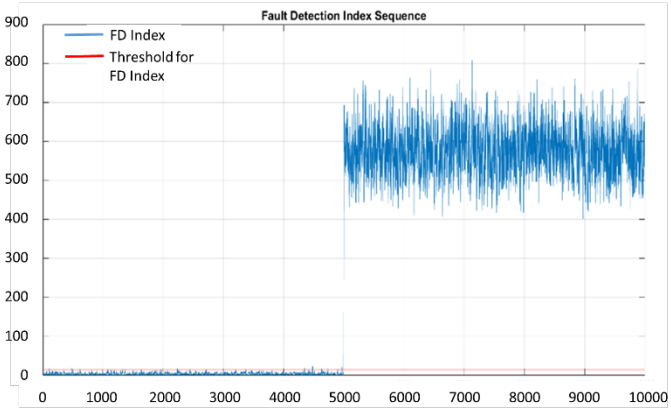

Figure 10. Detection of two simultaneous faults

Contribution analysis is similarly conducted in this case, where $k_{f_1} = 5000$ and $k_{f_2} = 9995$. The associated results are illustrated in Figure 11. In this figure, since Sensor 1 and Sensor 2 have contributed the most to the violation of the fault detection index, it may be concluded that these two sensors are faulty.

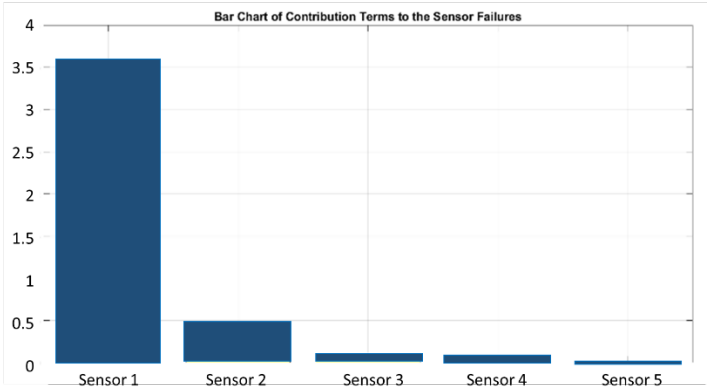

Figure 11. Contribution analysis results of two simultaneous faults

7. Conclusions

Combining analytic redundancy and contribution analysis, a novel methodology for fault detection, isolation, and reconstruction in MIMO dynamical systems has been proposed. It has been applied to a simulated jet engine control system. Numerical results have fully supported the correctness and effectiveness of the developed theory. Even for a slowly evolving incipient fault, the scheme can detect, isolate, and estimate it very effectively. Moreover, different sensor failures are also successfully detected and isolated, further justifying the practicability of the developed methodology.

One future research direction is the integration of our methodology to fault tolerant control systems and apply to power systems [10], aircraft [26], robots [27-28, 31], motors [11,32], planetary rovers [29], and missiles [33,34].

Appendix: Nomenclature and Variables

SVD – Singular Value Decomposition

PRV – Primary Residual Vector

MI - Multiple inputs

MO - Multiple outputs

SRV – Structured Residual Vector

MIMO - Multiple inputs Multiple outputs

k : time index

$\mathbf{x}_k \in \Re^n$: State variable vector

$\mathbf{u}_k \in \Re^l$: System input vector at time k

$\mathbf{y}_k \in \Re^m$: System output vector, at time k

$\{\mathbf{A},\ \mathbf{B},\ \mathbf{C}, \mathbf{D}\}$: System matrices with compatible dimensions

$\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$: Process disturbance and measurement noise

$\mathbf{R}_\omega$, and $\mathbf{R}_\varepsilon$: Covariance matrices of $\boldsymbol{\omega}_k$ and $\boldsymbol{\varepsilon}_k$

$\Delta\mathbf{y}_k \in \Re^{n_y}$: Sensor failures

$\Delta\mathbf{u}_k \in \Re^{n_u}$: Actuator failures

$\mathbf{M}_u$ or $\mathbf{M}_y$: Failure direction matrix for actuators or sensors

$\boldsymbol{\Gamma}^s$: Observability gramian

$\mathbf{W}_{prv}$: A matrix from the null space of $\mathbf{\Gamma}^{s}$

$\mathbf{e}_{k}^{s}$: Primary residual vector

$d_{s,k}$: Fault detection index

$\mathbf{r}_{s,k}^{i}$: i[th] structured residual vector

$\mathbf{f}_{k,i_1}$: Term associated with faults. It is used in contribution analysis

ABSTRACT

In Computer Aided Diagnosis (CAD) tools, vertebra localization and detection are the essential steps for the diagnosis of cervical spine injuries. The accurate localization leads to accurate treatment, which is more challenging in case of poor contrast and noisy radiographs. This paper targets c-spine radiographs for the localization of vertebra using different vertebra templates, vertebra detection at each level using two different clustering techniques and gives a comparison between them. Moreover it separates the regions for each individual c-spine. It takes the poor contrast x-ray as input, enhance the contrast and detect the edges of enhanced image. After the edge detection, manually selected Region of Interest (ROI) helps in getting the edges of area covering $C_3 - C_7$ only. These edges along with 4 different template models of vertebra are used for the localization by Generalized Hough Transform (GHT). The results obtained are analyzed visually for the best localization template. Then, on voted points obtained after pruning, two clustering techniques Fuzzy C Means and K-Means are applied separately, to form clusters and centroids for each vertebra. Another part of this paper is to separate vertebra regions. For this, intervertebral points are calculated and then along these points, centroids are rotated using Affine Transformation. It gives parallel lines to vertebrae and joining them gives region for each vertebra. The comparison and testing of proposed technique has been performed using dataset 'NHANES II' publicly accessible at 'The National Library of Medicine', total 150 cervical spine scans are used securing accuracies 93.76%, 84.21% and 83.1% for FCM, K-Means and region separation, respectively.

1 Introduction

Spinal cord proves to be the most important element of human anatomy. It works as a backing for other segments of human body so that one can bend, twist and move easily. If this most essential segment of human structure is damaged in any way, a person cannot even stand up straight. Figure 1 illustrates the division of human spinal cord which consists of 33 individual bones known as vertebra. First 7 cervical vertebra ($C_1 - C_7$) collectively form the neck, next 12 thoracic vertebra ($T_1 - T_{12}$) form the chest, next 5 lumbar vertebra ($L_1 - L_5$) form the lower back, next 4 sacral vertebra ($S_1 - S_4$) form the pelvis and the last 4 fused vertebra form the tail bone of human structure are known as coccyx bones.and fall down [1][2].

In the past few decades, medical imaging has been developed in dramatic way and helping radiologists for the diagnosis and treatment of cervical spine disorders including osteoporosis, cervical spine injuries and trauma [3]. The most common sources for c-spine injuries (CSI) are accident of vehicles and outdoor games. In youngsters age ranging 15-25, hyperextension and vehicles accident where as in senior citizens and osteoarthritic victims, sudden fall is reported as the most common reason of CSI [4]. Latterly, a signifi-

https://dx.doi.org/10.25046/aj0203215

cant amount of Traumatic Spinal Cord Injuries (TSCI) has been reported which may become more problematic and critical if the patient is not treated on time by accurate diagnosis [5].

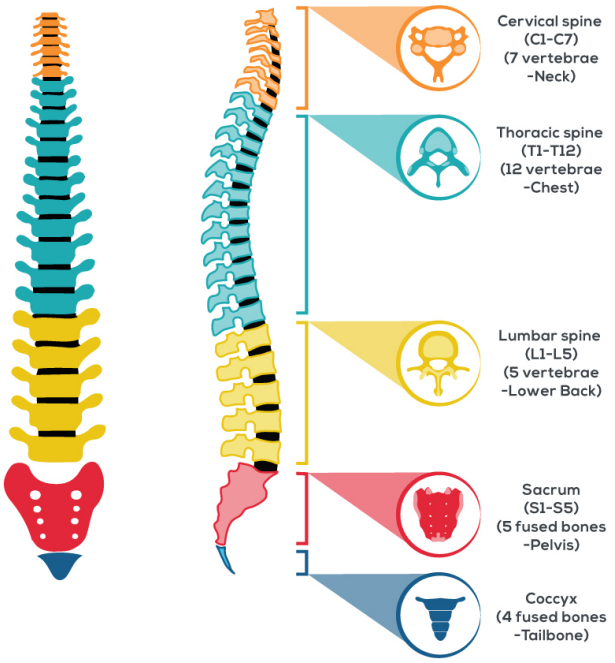

Figure 1: Spinal Column: Anatomical Features

In Computer Aided diagnosis (CAD) tools, vertebra localization and detection at each cervical level are initial and essential steps to be performed and it becomes more difficult when images are low contrast and noisy like X-rays. These steps work significantly in many orthopedics and neurological applications for the diagnosis and treatment of spinal column disorders. The accurate localization and detection leads to accurate treatment of abnormalities. Thus, great success rate in vertebra localization and detection with separated regions for each vertebra would be very helpful for radiologists' community, not only for the diagnosis but also in surgeries. Figure 2 shows the (a) Normal cervical spine x-ray with perfect relationship between posterior, anterior and spinolaminar lines. They are aligned representing a healthy radiograph where as (b) shows loss of alignment at C_6 and C_7 representing unhealthy or fractured X-ray.

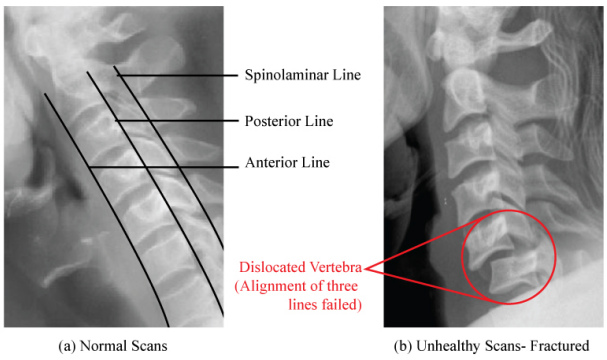

Figure 2: C-Spine Radiographs (a) Healthy (b) Fractured

This figure shows that the fractures can be located using parameters like posterior, anterior and spinolaminar lines by getting the alignment information between them. In literature, many techniques like Generalized Hough Transform (GHT) [6], Active Shape Model (ASM) [7], discrete dynamic contour model (DDCM) [8] and Template Matching [9] have been described for the localization, detection and segmentation of spinal cord using different set of images including magnetic resonance imaging (MRI) and computed tomography (CT) scans. Klinder et al. [10] described a methodology for the extraction of vertebra shape using CT scans. They designed a methodology for the detection, identification and segmentation of vertebra from CT scans. They applied Generalized Hough Transform (GHT) with the combination of adapted triangulation shape for the localization and segmentation of vertebra. They tested the proposed technology on 64 CT Scans with success rate of 70%. Alomari et al. [11] presented a methodology of localization using MRI images. They used two datasets of 50 and 55 scans attaining success rate of 87% and 89.1%. Their proposed model was based on two steps targeting intervertebral discs. Korez et al. [12] presented an automated technique for the detection and segmentation of vertebra and spine using 3D CT Scans. They used interpolation theory for the localization of spine which is further used to locate the individual vertebra. The localization results obtained helped in the segmentation of each vertebra by enhanced shape-constrained deformable model approach. They tested the technique using two CT Scans databases of 50 lumbar and 170 thoracolumbar vertebrae and achieved high success rate. Lecron et al. [13] presented a methodology taking benefit of edge polygonal approximation to locate the vertebra and perform the segmentation using Active Shape Model (ASM). They enhanced the performance of the methodology by parallel computing and heterogeneous architectures for the vertebra extraction. They used X-ray images for the testing of proposed methodology. Larhmam et al. [14] described a technique for the vertebra localization targeting x-rays image. They used a novel combination of GHT and K-means clustering for the localization of vertebra using template matching theory. Benjelloun et al.[15] presented an analysis of vertebra based on segmentation from x-ray images. They described a relative study of two algorithms to segment out vertebra. Lecron et al. [16] presented a model targeting the vertebra localization from X-rays using SVM model and SIFT descriptor. They evaluated their methodology using 50 scans and attained satisfactory success rate of 81.6%. Dong et al. [17] presented a graphical model based vertebra identification which need no training steps for processing. They designed it to automatically detect the total number of visible vertebra in scans and localize them. Larhman et al. [18] described a localization technique by offline training of template model as a preprocessing step and applied GHT to localize the vertebra. Then they performed the post processing of model using adaptive filter and attained success rate

of 89% when tested by 200 vertebrae. Benjelloun et al. [19] proposed a scheme based on polygon regions for the extraction of vertebra boundries and perform segmentation. Later in [20], they presented a technique for the localization and segmentation based on ASM.

This paper is basically an extension of model originally presented in IEEE International Conference on Communication, Computing and Digital Systems (C-CODE 17)[21]. This paper is extended in terms of comparison of template models for better localization and then a comparison and analysis of clustering techniques used for the detection of centroids. A section which is extension to original paper, is dedicated to the region separation for each individual vertebra which can be used further for the segmentation process and will be very helpful for the diagnosis of several c-spine disorders. Section II describes the methodology of proposed technique, Results are analyzed and discussed in Section III and Section IV presents the conclusion of this paper.

2 Methodology

The presented technique comprises five stages to give a comparison of techniques for better localization and detection results along with separated regions for each vertebra. The flow chart of presented model is shown in Figure 4, representing the main steps of model including Preprocessing, Creation of Mean models, Vertebra Localization, Centroid detection and Region separation.

2.1 Preprocessing

Preprocessing is the first and most significant stage of the presented model for attaining high success rate. The steps involved in this stage are contrast enhancement, detection of edges and manual selection of Region of Interest (ROI). These steps are performed to get enough data for our vertebra localization stage.

2.1.1 Contrast enhancement

The input X-ray images are poor contrast and noisy set of images which cannot be processed directly to achieve high accuracy of presented technique. The superimposition of other bony structures and level of brightness at C_6 and C_7 leads to wrong localization results. So 'Contrast Limit Adaptive Histogram Equalization'(CLAHE) [22] is applied to input radiographs so that the contrast can be enhanced for better results. CLAHE works like ordinary adaptive histogram equalization, the only difference is it uses a specific threshold to clip the histogram. For X-ray images, CLAHE is one of the most efficient contrast enhancement algorithm when compared with Gamma Correction (GC) and Histogram Equalizer (HE)[23].

2.1.2 Detection of edges

After the contrast enhancement, the edges of input image are detected using 'Canny Edge Detector' [24]. The reason behind the edge detection is that the GHT algorithm works with edges only. The process of localization takes place using edges. So we detected the edges of input image for any further processing.

2.1.3 Manual selection of Region of Interest (ROI)

The edge detection step gives us the edges of whole input image, but the proposed technique requires edges for the $C_3 - C_7$ only. so in this step we constructed the Region of Interest (ROI) covering the area of lower 5 cervical vertebrae only. Then this ROI is multiplied with the edges to get the edges of this area only. This is the last step of our Preprocessing stage.

2.2 Creation of Mean Models

The creation of mean models is next stage of proposed technology. In this stage, 4 different template models M_1, M_2, M_3 and M_4 are constructed and shown in Figure 3. For the construction of these template models, 25 vertebra images for each template model are created using some drawing tools and then mean image is created using these 25 images. Eq. 1 is used to create mean model of each shape.

$$M_i = \frac{1}{V_t} \sum_{x=0}^{V_t} V_x \tag{1}$$

where 'V_t' presents the total vertebra images (25) created manually and 'V_x' is one vertebra image with 'x' varying from 1 to 25.

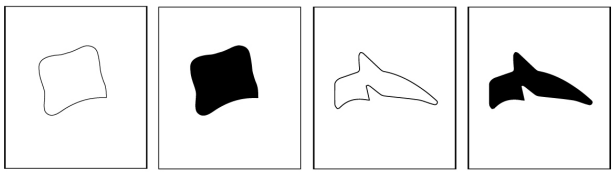

Figure 3: Vertebra Models created: (a) M1 (b) M2 (c) M3 (d) M4

The reason behind using these 4 mean models is just to analyze the results and give a comparison between them. So that one can select best mean model for localization of vertebra securing high accuracy. M1 and M2 represents the body of vertebra whereas M3 and M4 represents complete vertebra shape including body. These created models will be used as a template image for the detection process of GHT. The results are generated using all four template images one by one and then analyzed visually to select the best template image.

2.3 Vertebra Localization(GHT)

The third and most important stage of proposed methodology is Vertebra Localization which helps in the detection of centroids. In this stage, the selected

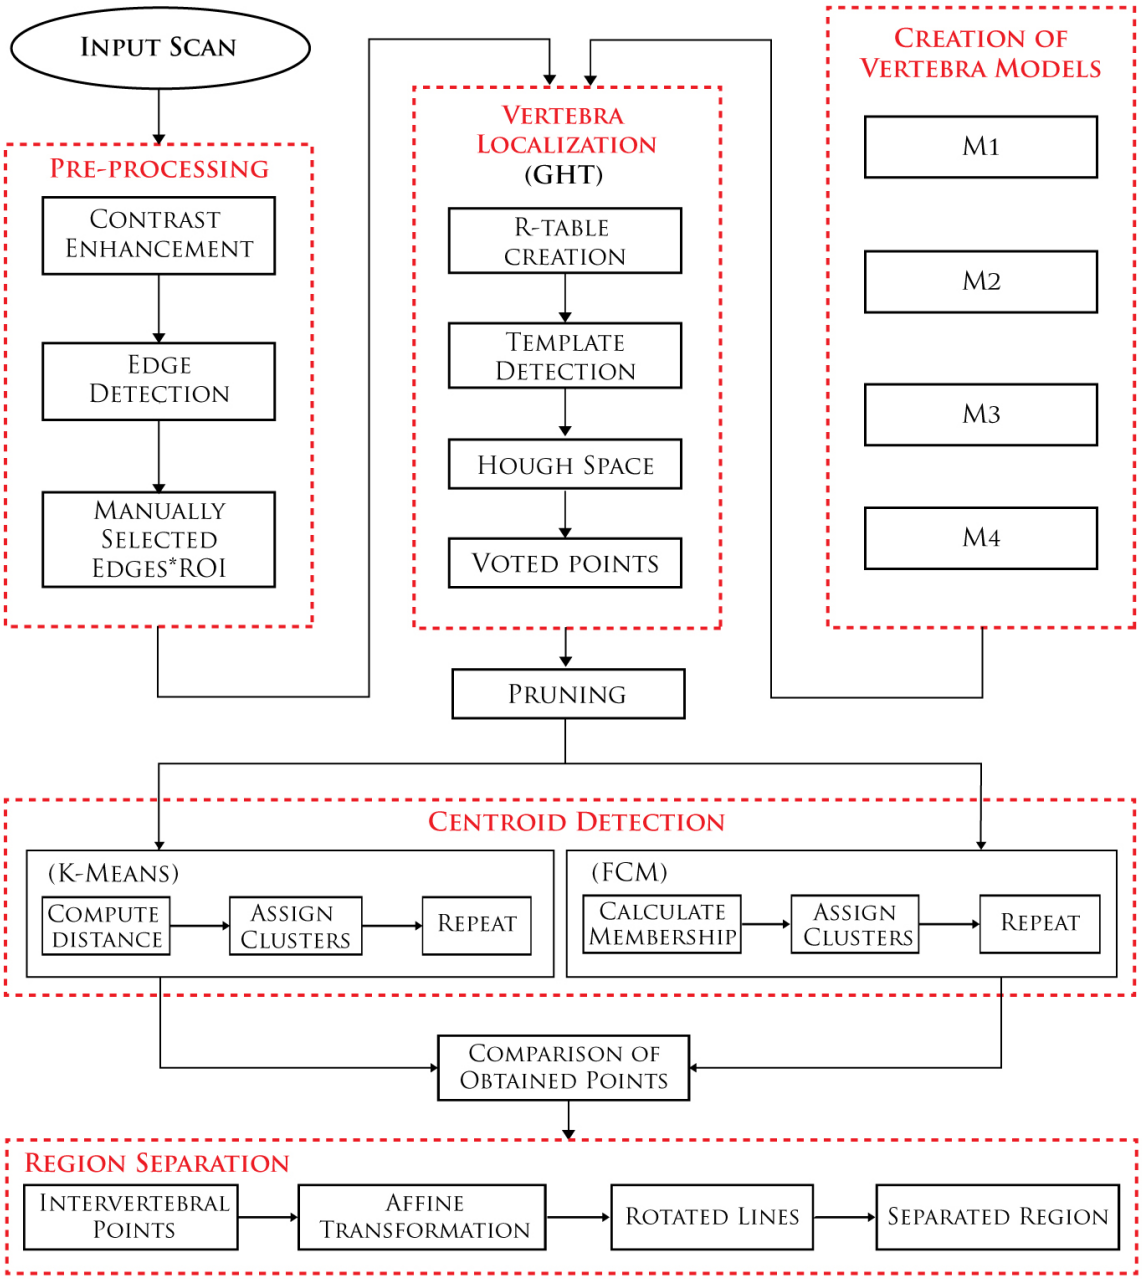

Figure 4: Flow Chart: Main stages of the proposed methodology

edges of Preprocessing stage are used and GHT is applied. Ab initio, Hough Transform [25] was introduced as a technique for the detection of lines, circles, elipse etc following a modified concept by Ballard, known as generalized Hough Transform [6] used in various applications of image processing and computer vision. GHT is a concept used widely for the detection of arbitrary shapes and pattern recognition in all fields of imaging including biomedical imaging. The most positive point of this technique is it is invariant to any kind of transformations. It works with two factors *R-Table* which basically represents the template model of vertebra which is to be detected in the image and second one is *Accumulator*, which is Hough Space and stores the voted points localizing the area of $C_3 - C_7$. GHT is based on the template matching theory and uses the information stored in R-Table for the detection process.

2.3.1 R-Table creation

For the construction of R-table, a reference point (r_x, r_y) is selected. The coordinates of extracted edges helped in this regard. The reference point is selected by taking the mean of all the edges and next, gradient is calculated. Then for each point, gradient direction is computed and saved as a function of gradient. There are more than one entries of gradient direction

for each value of gradient. So, in R-table each entry is the difference between the coordinates of reference point and boundary point w.r.t the direction of gradient. In this way, the template model of vertebra is stored as a R-Table. Table 1 [6] represents the generic form of R-table, where Φ, d_r and β represents gradient, distance and orientation, respectively. The distance and orientation are calculated using Eq. 2 and Eq. 3, respectively.

$$d_r = \sqrt{(r_x - b_x)^2 + (r_y - b_y)^2} \tag{2}$$

$$\beta = tan^{-1} \frac{b_y - r_y}{b_x - r_x} \tag{3}$$

where in both equations (r_x, r_y) is the reference point and (b_x, b_y) is the boundary point.

Orientation Φ	**Position** (r, β)
0	$(r_x, \beta_x)/\Phi_x = 0$
Φ	$(r_x, \beta_x)/\Phi_x = \Delta\Phi$
$2\Delta\Phi$	$(r_x, \beta_x)/\Phi_x = 2\Delta\Phi$
$3\Delta\Phi$	$(r_x, \beta_x)/\Phi_x = 3\Delta\Phi$
...	...

Table 1: R-Table: Generic Form

2.3.2 Template detection and Hough Space

Now, for the detection process an Accumulator is created which represents the Hough Space and stores the points known as Voted points. These points mark the positions containing the template model. So, for each edge point obtained in preprocessing stage, gradient is computed and the corresponding value of R-Table stored as r(Φ) is added into the coordinates of edge point. Then the model check the resultant value if it is within the scope of Accumulator, if yes it increments the location of accumulator defined by this new point. All the voted points obtained by this process give the positioning of vertebra in X-rays. However, few outliers are also calculated by this process which are removed in next step.

2.3.3 Pruning

Pruning [26] is a technique used to remove unwanted data points known as outliers. These outliers may effect the success rate of the proposed model. The window scheme is applied and voted points are removed if they are less than the specified number. Then the voted points obtained after pruning are used for the centroid detection. For each candidate point, a window placed such that candidate point lies at center of window and all points lying inside window are computed. Now, if the count of points is less than a specific number then that candidate point is removed.

2.4 Centroid Detection of vertebra body

After the localization of vertebra from C_3–C_7, the next stage of proposed technique is to detect the centroids of each vertebra using the voted points obtained by all four template models. The centroid detection is performed using two different clustering techniques K-Means and Fuzzy C Means. Each clustering technique forms clusters using the voted points and then gives the centroid for each cluster representing each vertebra ($C_3 - C_7$).

2.4.1 K-Means clustering

K-Means [27] is a clustering algorithm works simply to segment out the data into clusters by calculating the euclidian distance between them. Initially, the cluster's center are selected randomly from obtained voted points, it randomly selected the 5 cluster centers representing 5 cervical vertebra ($C_3 - C_7$). Then for each voted point, euclidean distance is calculated between the voted point and all the cluster centers. And the cluster at minimum distance is assigned to that voted point. This process is performed for all the voted points, completing the first iteration of k-means algorithm. For next iteration, cluster centers are selected by calculating the mean of all the points belonging to the same cluster. Then again distance computation is carried out and clusters are assigned and this process continues until two or more consecutive iterations give same results. The cluster centers obtained in last iteration represents the centroid of each vertebra.

2.4.2 Fuzzy C Means clustering

Fuzzy C-Means (FCM) is another clustering technique developed by Dunn [28] in 1973, then in 1981, Bezdek [29] enhanced the working of this algorithm. It works with the concept of fuzziness and assign clusters in such a way that one data point may belong to more than one cluster at a time. It assign membership to each data point for all the clusters. The range of membership varies from 0 to 1. This factor of fuzziness makes FCM less sensitive to outliers. Initially, FCM selected the 5 cluster centers randomly representing 5 cervical vertebra. Then for each voted point, total 5 memberships are computed, between this point and all the cluster centers. The membership varies from 0 to 1 and is computed using Eq. 4 which basically gives the information about the point that how much this point relates to which cluster. The cluster with greatest membership is the most closes to that voted point.

$$m_{jx} = \frac{1}{\sum_{i=1}^{t} \frac{\|b_j - c_x\|}{\|b_j - c_i\|}^{\frac{2}{t-1}}} \tag{4}$$

where 'i' varies from 1 to 't' representing the total clusters i-e 5, 'c_x' and 'b_j' represents the cluster and voted point for which membership is to be calculated, respectively. This process of assigning memberships creates a level of fuzziness and one voted point belongs to more than one cluster at a time. First iteration is completed, after calculating the membership

for all the voted points and new cluster centroids are selected using Eq. 5

$$c_x = \frac{\sum_{i=1}^{t_p} m_{ix}^j . p_j}{\sum_{i=1}^{t_p} m_{ix}^j} \quad (5)$$

where 'c_x' and 't_p' represents the new cluster computed and total number voted points, respectively. Then in next iteration for these new computed cluster centroids, membership is calculated and this process continues until we get similar centroids in 2 or more consecutive iterations, representing the 5 cervical vertebra from C_3 to C_7.

2.5 Separation of vertebra regions

The separation of each vertebra region is another stage and extension to original work, which allows us to extract the region for vertebra individually using the center points of vertebra. These extracted regions are very helpful in the segmentation process which further leads to the diagnosis of many spinal cord disorders. The steps involved in this stage are calculation of Intervertebral Points and Affine Transformation.

2.5.1 Intervertebral Points

To extract the regions covering the area for each vertebra,intervertebral points are required. The intervertebral points are the location between the two vertebra. In our case we required total 6 intervertebral points, from which 4 are easy to find out by just calculating the mean of centroids from $C_3 - C_7$ which we already have. Eq.6 represents the calculation of these 4 intervertebral points.

$$IV_{C_i} = (C_i + C_{i+1})/2 \quad where\ i = 3, 4, 5, 6 \quad (6)$$

The other two intervertebral points, one before C_3 and second after C_7 couldn't be computed using this equation as it require centroids before and after these points. So, a simple technique using equations 7 and 8 is applied to obtained these two intervertebral points. The difference between C_3 and IV_{C_3} is subtracted from the coordinates of C_3 to get an estimated intervertebral point before C_3 i-e IV_{C_2}

$$IV_{C_2} = C_3 - (IV_{C_3} - C_3) \quad (7)$$

Similar technique using C_7 and IV_{C_6} is applied for IV_{C_7} but instead of subtracting the difference, it is added into the coordinates of C_7 to get points greater than it's location.

$$IV_{C_7} = C_7 + (C_7 - IV_{C_6}) \quad (8)$$

Now, for next step there are total 11 points, 6 intervertebral and 5 centroids in the same sequence as IV_{C_2}, C_3, IV_{C_3},...,C_7, IV_{C_7}.

2.5.2 Affine Transformation

A transformation following the rule of collinearity is known as Affine Transformation [30]. The term collinearity defines that points stay on a line at same distance and the parallel lines remains parallel, before and after the transformation. But in case of parallel lines, collinearity is not applicable on the angles between them. The term Affine Transformation is also called Affinity.

In proposed technique, affine transformation is used to form lines parallel to the vertebra. For each line, 3 points of vertebra are required, and location of two points is transformed in such a way that they stay on same line before and after the transformation, Affine Map helps in this regard. The calculation of Affine Map is shown in Eq. 9 where 'a', 'R' and 'c' are rotational point, rotational matrix and directional matrix, respectively. These three matrices are the general Affine transformation matrix.

$$M = a * R * c \quad (9)$$

The rotational matrix requires angle Θ to rotate the lines accurate enough and make them parallel to each vertebra. To obtain this angle, initially two angles are calculated: one between the first intervertebral point and centroid and second between the centroid and next intervertebral point, then taking average of these two angles and adding 90 into it, gives an exact angle for making lines parallel. Using this angle $\Theta + 90$, Affine Map is constructed using Eq. 9 and multiplied with each point to rotate them along intervertebral points. As a result, total 6 lines are formed covering C_3 to C_7. Then these lines are joined to make separate regions for each vertebra.

3 Results and Evaluation of proposed technique

The proposed technique has been implemented in MATLAB R2013a. The dataset NHANES II [31] used for the evaluation of our proposed technique is publicly accessible at U.S. National Library of Medicine, incorporating 17,000 scans (10,000 cervical spine and 7,000 lumbar) of patients age ranging 25-74, captured in 1976-1980. These X-rays images had been taken under varying scale, orientation and environment. For evaluation of our proposed technique we used 150 cervical spine scans of this dataset, selected on random basis. In literature, several methods has been tested using the same dataset but varying number of images. In these papers, no one ever mentioned the criteria following which they has selected the specific number of images. Neither they defined exactly which images has been selected. So it is clear that everyone is using different images of the same dataset. For fair testing, we selected subset with larger number of images than literature. For the comparison of results, a ground truth is maintained by visually examining each image. For each image, 5 center points

representing each vertebra body are marked manually, targeting C_3 to C_7. These annotated points are stored and used for the testing purposes. A comparison of FCM and K-Means is given in this section using Statistical and Visual results.

3.1 Statistical Results

The parameters used to obtain the statistical results include pixel distance, mean, standard deviation and accuracy.

3.1.1 Pixel distance

Figure 8 shows the pixel distance of 50 images for both K-means and FCM. For better visualization, the result of 50 images is shown in figure but is calculated for all 150 images. Each graph represents each vertebra with red dotted line representing the mean distance of K-means and black dotted line is for FCM, for all 150 images. The difference is calculated between the annotated points and detected centroids, representing how much detected centroid is away from the center point. The mean error lines show that at each vertebra level FCM works better than K-Means, the mean error for FCM is less than that of K-Means, but at level C_7 there is a minor difference between the two. The presence of high brightness and superimposition of other structures make the false detection at this cervical level.

3.1.2 Mean

Figure 5 shows the calculated mean of the distance. The green bar shows the mean of k-means which is larger than FCM at every level, represented by blue bar. This parameter also marked FCM as a better

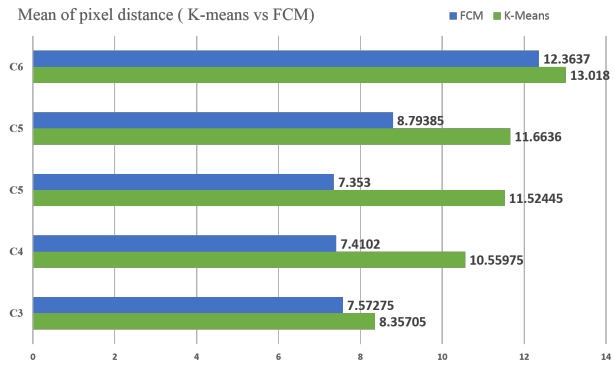

Figure 5: Mean of calculated distance: K-Means vs FCM

clustering technique for centroid detection of vertebra from X-rays. The eq. 10 is used for the calculation of mean.

$$Mean_{error} = \frac{\sum_{i=1}^{T} d_i}{T} \tag{10}$$

Where 'd_i' represents the distance at each cervical and 'T' represents total images used.

3.1.3 Standard Deviation

The standard deviation is another statistical parameter of our presented methodology. Figure 6 shows the calculated standard deviation in both cases.

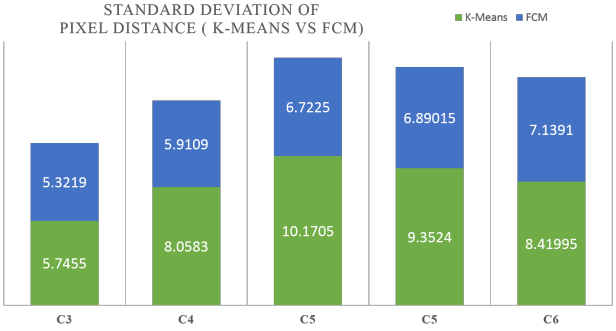

Figure 6: Standard Deviation: K-Means vs FCM

Each level shows less variation in case of FCM than K-means, making FCM better than the K-Means. The standard deviation is calculated using Eq. 11

$$SD = \sqrt{\frac{\sum_{i=1}^{T}(d_i - Mean_{error})^2}{T-1}} \tag{11}$$

where 'd_i', '$Mean_{error}$' and 'T' represents distance, calculated mean and total number of images, respectively.

3.1.4 Accuracy

The accuracy of presented technique is measured at two levels *Visual* and *Experimental*. In case of visual accuracy, labels are assigned to all 150 images at each cervical label.

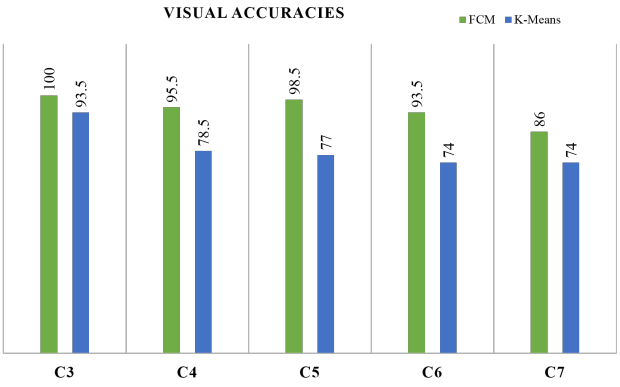

Figure 7: Visual accuracies reported at each cervical level

If the detected vertebra is correct label '1' is assigned and in case of wrong detection label '0' is assigned. The presented model consider the vertebra detection as correct if it is within the body of vertebra.So in visual examination, this point is followed for labeling process and each vertebra has been given label '1' if it is inside or on the boundary of vertebra body and '0' is it is outside the vertebra body. Using this criteria all the images has been assigned total 5 labels representing 5 vertebra and then using these labels overall accuracy of 94.7% and 79.4% are measured for FCM and K-Means, respectively.

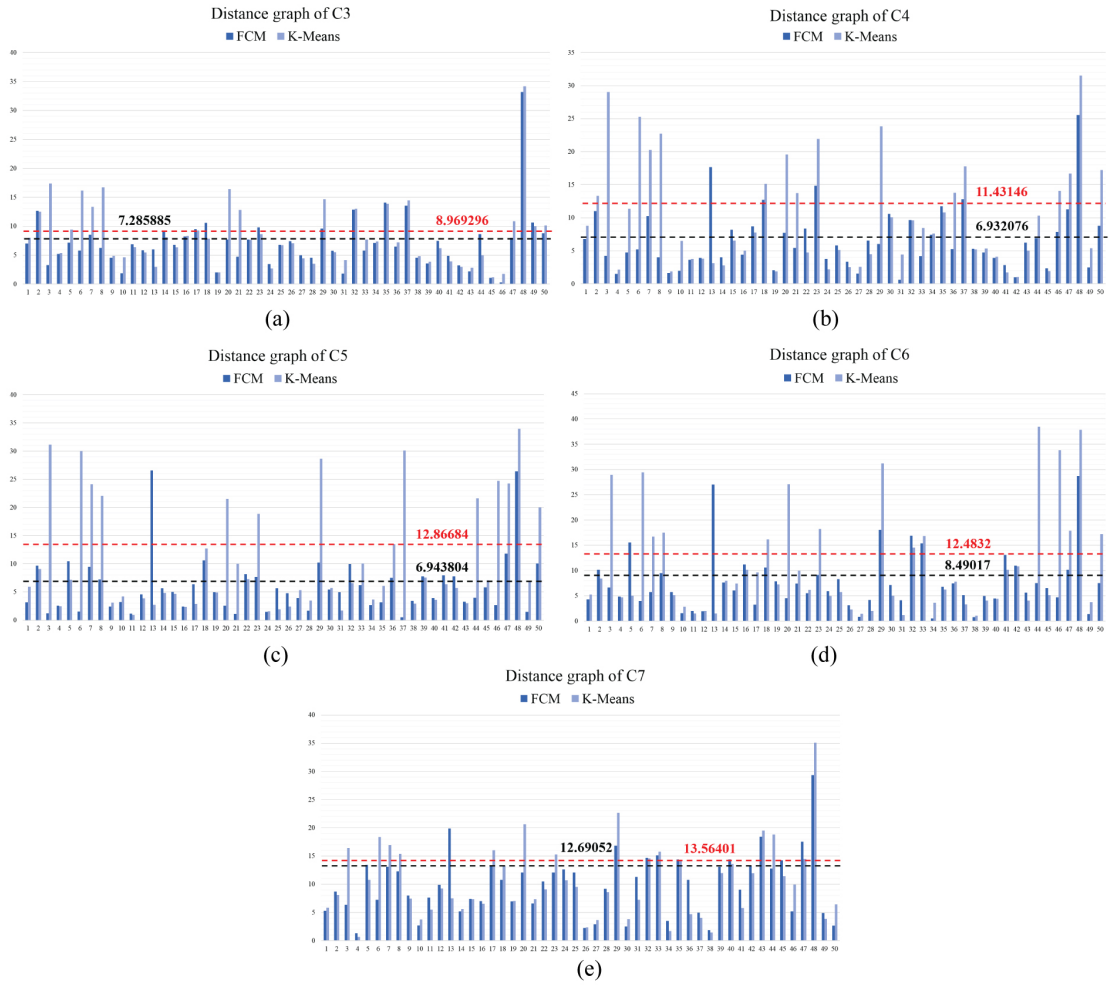

Figure 8: Pixel wise Distance Graph: (a)C_3 (b)C_4 (c)C_5 (d)C_6 (e)C_7

The accuracies at each cervical level are shown in figure 7 where green bars are representing greater accuracies for FCM than the K-means represented by blue bars.

Similar method of labeling is used for measuring the accuracies of separated regions. An overall accuracy of 83.1% is reported for separated regions with 90.5%, 93%, 88.5%, 73%, 70.5% at each cervical level from C_3 to C_7, respectively. In case of **Experimental** accuracies, ROC curves are formed for both FCM and K-Means shown in figure 9. Each line represents the accuracy measure of each cervical level from C_3 to C_7 with varying threshold from 0 to 20. The threshold here represents the width of vertebra. We selected threshold 14 for the accuracies, the reason behind choosing threshold 14 is, it is the radius of vertebra which means all the point inside the vertebra body are correctly detected. At threshold 14 the proposed technique attained accuracy of [93.12, 85.79, 81.30, 81.52, 79.30]and [96.74, 96.65, 95.51, 95.33, 84.55] representing C_3, C_4, C_5, C_6 C_7 for K-Means and FCM, respectively.In both cases, visual and experimental accuracies FCM secured more accuracy than k-means.

The accuracy when compared with other techniques in literature, it has been observed that only Larhman [14] secured greater accuracy of 97.5% than proposed technique i-e 93.6%. But it is not a fair comparison as both are using different subset of same dataset. They used 66 images of NHANES II dataset whereas presented methodology has been tested using 150 images of NHANES II dataset.

3.2 Visual Results

The visual analysis of each stage are shown in this section including steps of each stage. All the results shown are of 5 different cases of NHANES II dataset. Each column represents different case, whereas each row represents each step.

3.2.1 Preprocessing

Figure 10 shows the visual results of first stage i-e Preprocessing of proposed technology. The first row

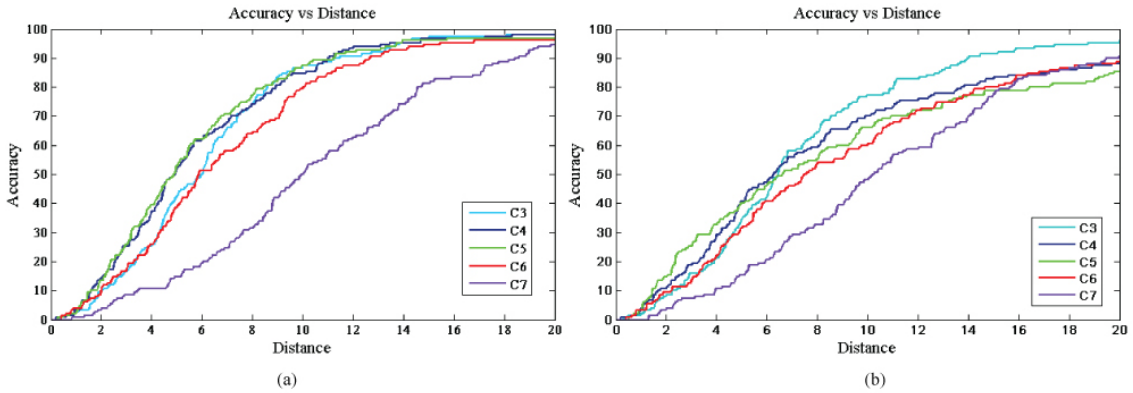

Figure 9: Receiver Operating Characteristic (ROC): (a) FCM Clustering (b) K-Means Clustering

shows the low contrast input x-rays which are enhanced by using CLAHE and shown in second row, it is clearly observed that the contrast of second row is improved and now these images can be used for better results. Next row shows the result of edge detection step, the edges are extracted for complete input image which are reduced to the ROI $C_3 - C_7$ and shown in 4th row.

3.2.2 Creation and selection of vertebra Models

The next stage of our model is creation of different vertebra models and figure 11 shows the results obtained by these models. Each row shows the detected centroids obtained using different models but same cases and it is clearly observed that $M1$ has given the most accurate results than other models.

3.2.3 Vertebra Localization (GHT)

The visual results obtained in vertebra localization stage are shown in figure 12, first row represents the hough space created by each case and voted points are represented in row 2, row 3 shows the voted points obtained after pruning where many outliers are removed, which can be observe in row 2.

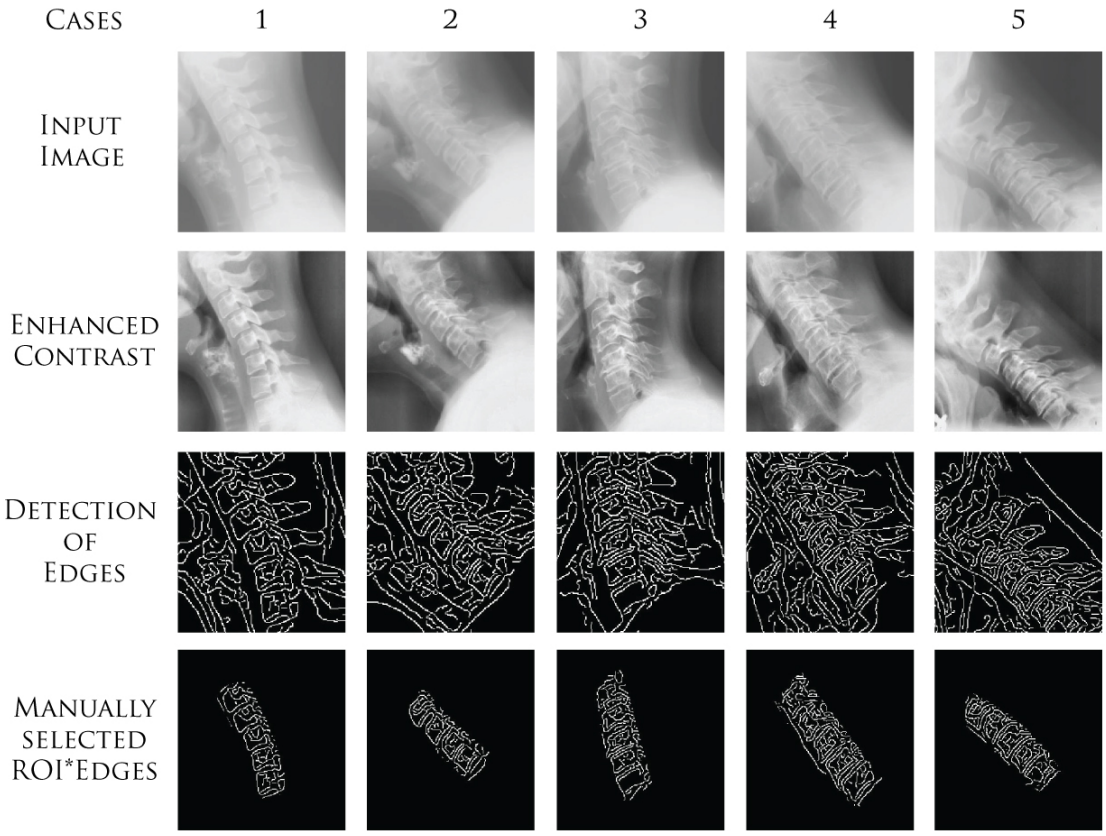

Figure 10: Phase 1: Preprocessing

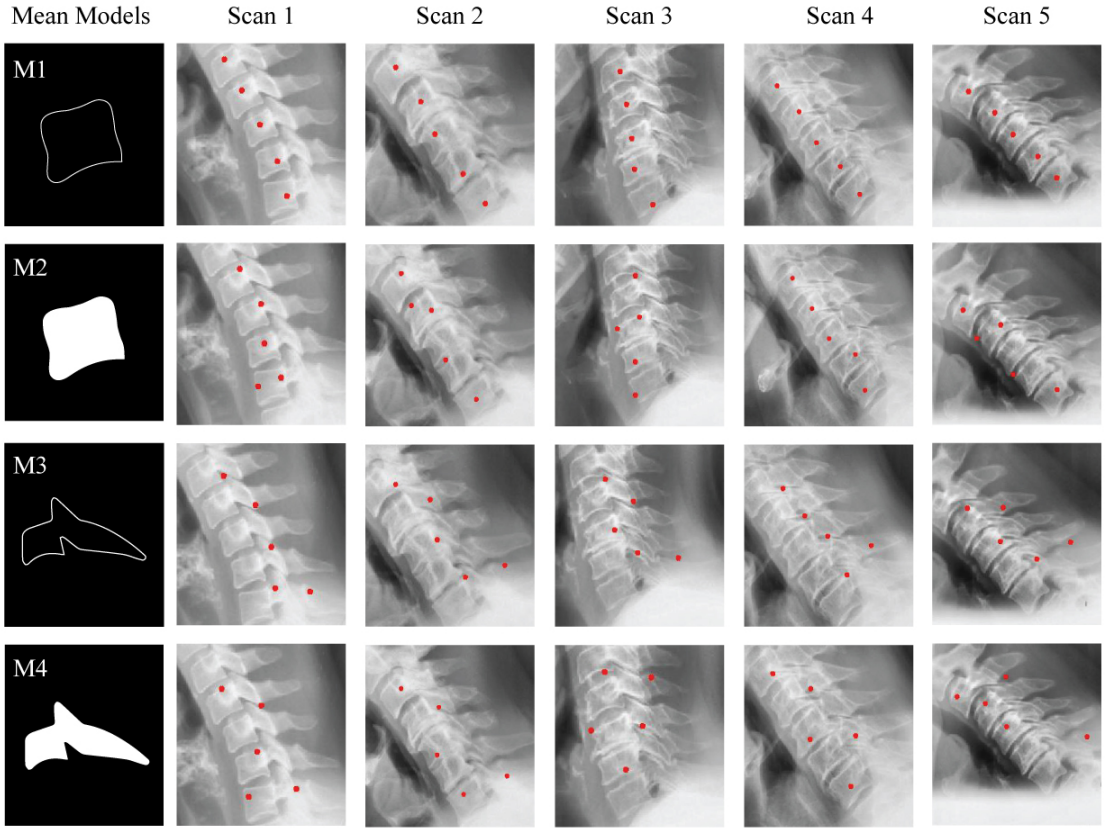

Figure 11: Phase 2: Comparison of different vertebra models

3.2.4 Centroid Detection

The centroid detection is carried out using two clustering techniques and their results are shown in figure 13 where first two rows represent the clusters and next two rows represents the detected centroids for each vertebra using K-Means and FCM clustering, respectively. Last row represents a comparison between annotated centroids (blue points), FCM centroids (red points) and K-Means (magenta point). It is clearly observed that FCM works way much better than the K-Means. In same cases FCM marked the correct centroids where as K-Means failed to do so.

3.2.5 Separation of vertebra regions

The steps involved in the separation of vertebra regions are shown in figure 14 where first row shows the blue centroids and 4 intervertebral points marked by red star. In next row, two additional intervertebral points are shown by yellow stars. The rotated lines by Affine transformation can be observed in 3rd row. Then after joining lines the separated regions are shown in 4th column.

4 Conclusion

This paper presents a comparison between 4 different vertebra template models for localization and 2 clustering techniques for centroid detection of cervical vertebra from x-ray images. The proposed model gives the separated regions for 5 targeted vertebra $C_3 - C_7$. The comparison of clustering techniques, vertebra template models and region separation technique is the contribution to this paper. For the localization of vertebra, GHT is applied along with each template model and results are analyzed. For GHT, $M1$ proves to be the best vertebra template. The voted points obtained after pruning are used for centroid detection. For the detection procedure two different clustering techniques are used FCM and K-Means. The results obtained by these two clustering techniques are analyzed at statistical and visual level and FCM proves to be much better than K-Means clustering for the detection of c-spine from x-rays. The results at level C_7 are less than the other levels in both clustering techniques, reason behind this is the presence of high brightness and other structures which are superimposed. The testing and comparison of proposed technique has been performed using 150 scans of NHANES II dataset accessible publically at U.S National Library of Medicine. The obtained accuracies of centroid detection are 84.21 and 93.76 for K-means and FCM, respectively. From all the experiments it is concluded that the FCM is more accurate than the K-means for the localization and detection of cervical verterba from X-rays. It is due to the fact that the fuzziness of FCM makes it less sensitive to outliers

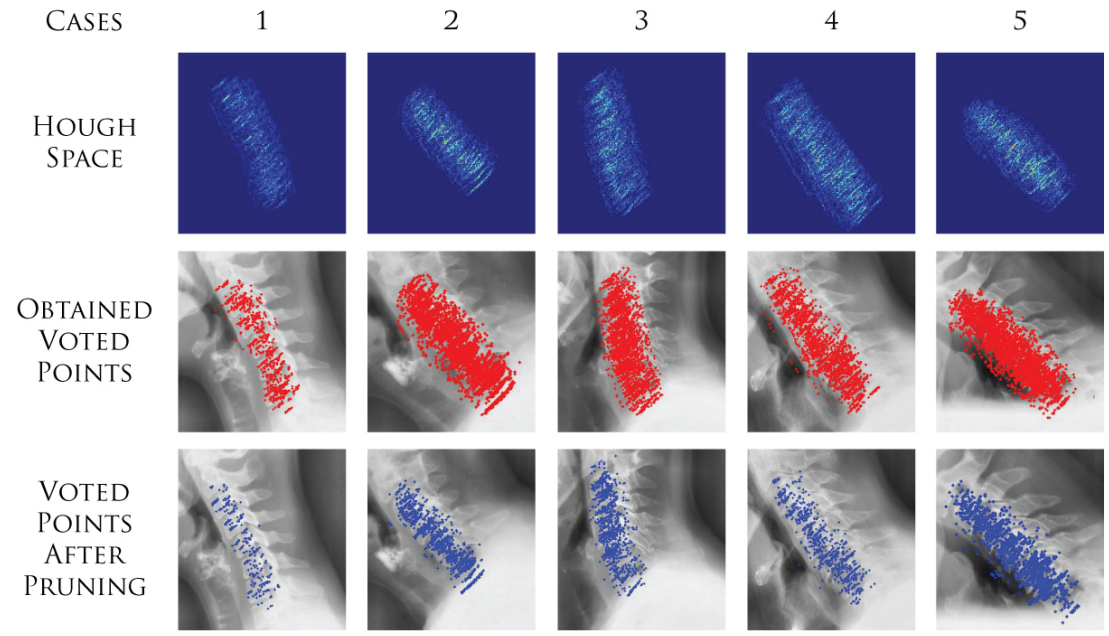

Figure 12: Phase 3: Visual results of vertebra localization steps

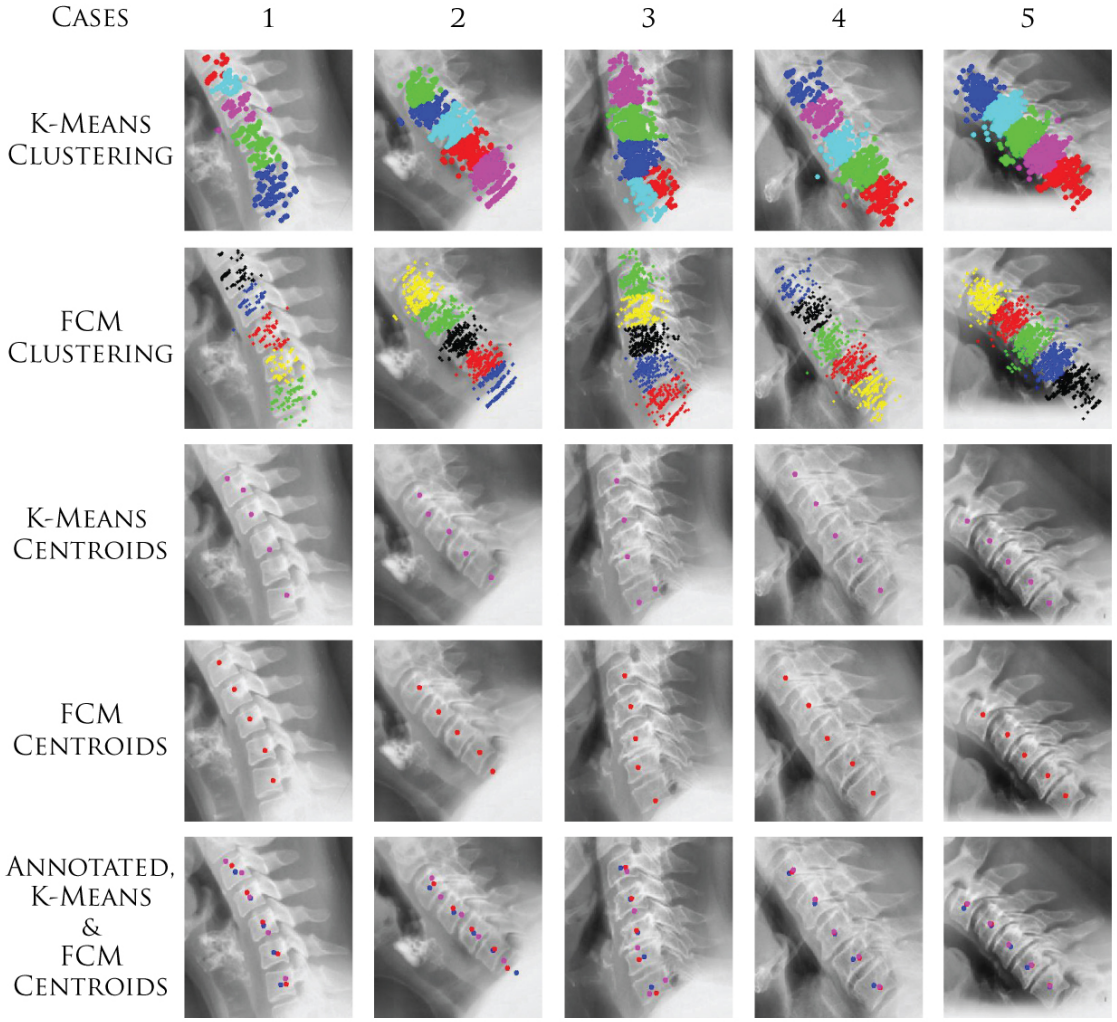

Figure 13: Phase 4: Centroid detection and comparison of clustering techniques

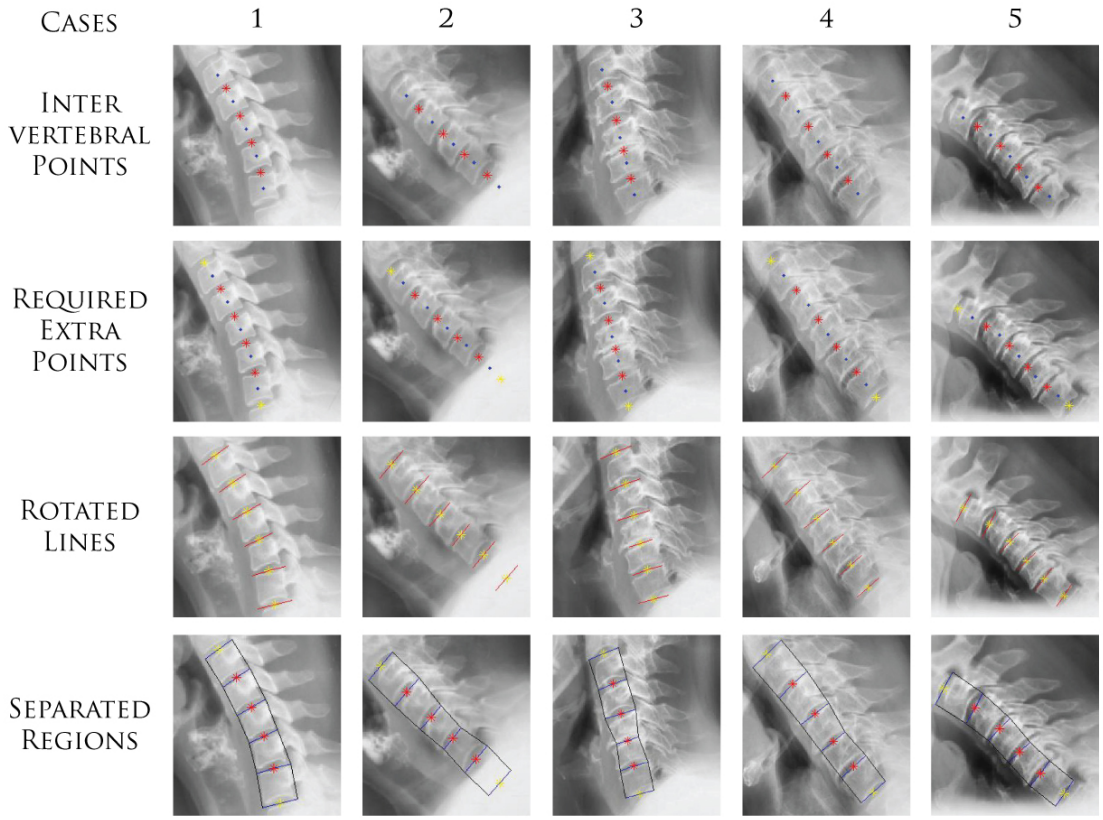

Figure 14: Phase 5: separation of vertebra regions

than K-means. Moreover, the proposed method secured satisfactory success rate of 83.1% for the separated regions which can be increased by increasing the width of the parallel lines. In future, our work is focused on segmentation using the separated regions and detected centroids.

Conflict of Interest The authors declare no conflict of interest.

maintenance

ABSTRACT

Speaking about the commutation's equipment, it can be said that the best solution in increasing reliability and lowering the maintenance costs is a continuous monitoring of the equipment. However, if the price/quality ratio is considered, it is obvious that, for the moment, the diagnosis can be also an acceptable solution. Nowadays the predictive maintenance for equipment's diagnosis is currently replacing the preventive diagnosis. An efficient modality of lowering the maintenance costs is to online monitoring the power breakers, during their operation in the power systems. Consequently any connecting/disconnecting operations may be used in diagnosing a power breaker. Thus any supplementary and superfluous tests and/or maintenance maneuvers are avoided. The paper presents the operational maintenance in a power station with three high voltage active breakers, Areva type. The method of establishing the state of a breaker consists in the comparison between the signature of the acoustic signal provided by the manufacturer and the signal issued from the testing operation of the breaker's state. The software processing procedure and the methodology of determining the faults of the monitored equipment are also developed. All the tests on the circuit breaker are made according the prescriptions of normative.

1. Introduction

Nowadays there is a major concern in using acoustic vibrations for monitoring medium and high voltage breakers. The results of this method are comparable to the traditional test results of power breakers. Moreover, the vibration method gives online supplementary information, unavailable when using traditional methods.

The use of the vibro acoustic method is possible because even though the same number of connecting/disconnecting maneuvers is made, in the signature of the vibro acoustic signal there are much more distinctive events. These issues can be solved using supplementary processing and filtration of the vibration signals.

Measurements performed in a transformer substation compared to those performed in the laboratory highlight some low duration interference of acoustic signals in the first set of measurements. These interferences have led to errors in the results, but after finding out the noise sources, i.e. of the perturbations, and processing the registered signals using software analysis and filtering, consistent conclusive results were obtained.

Mainly, the conclusion was that the vibration monitoring methods operate similarly both in the field and in the laboratory.

2. Breakers' Maintenance

Nowadays the maintenance policy of power breakers is oriented to corrective maintenance, acting in the moment that a fault occurs and on planning maintenance, which uses pre-established maintenance criteria periodically programmed.

Power breakers represent one of the key components in every electric power transmission and distribution system. It is the very last component in the control system that has to protect the system against damages determined by faults. In the moment of a fault in the power system operation, the breaker should operate safely, even though there was a long period of previous lack of maneuvers.

Email: horia.balan@eps.utcluj.ro

For a proper operation, medium and high voltage power breakers are periodically redrawn from the power systems in order to be submitted to measurements and functional tests [1].

The main components of the breakers represent their so called "active part" and have the role to maintain and break the current in the electrical installations in which they are commissioned. These are:

- the extinguishing chamber (the breaking chamber),
- the ancillary equipment,
- the electric insulation equipment (the insulating column, air, oil, vacuum, SF6, etc.).

The control and the auxiliary element have the role to transmit the commutation command (connecting/ disconnecting) to the breaker. This category is composed by:

- connecting/disconnecting circuits,
- auxiliary commuters,
- contactors,
- relays,
- thermostats,
- the density control device SF6,
- fuses,
- blocking devices, etc.

The driving mechanism represents the component that provides the mechanical energy necessary to move the contacts. It consists in:

- the transmission mechanism,
- the energy accumulator,
- the control elements (the non electric ones),
- the control devices,
- the dumping elements,
- the compressors,
- the pumps, etc.

The most used types of driving mechanisms are:

- devices accumulating energy in springs
- devices with hydraulic drive
- devices with oleo pneumatic drive [2]

3. Acoustic Vibrations of Breakers

The aim of measuring vibrations at a power breaker is to make possible the diagnosis of its operational status without performing any traditional tests. For a proper processing and a real result, the vibration signal is registered during a connecting/disconnecting process and is compared with a reference signal of the same type. The reference signal must be a known previous registration corresponding to a proper operation of the breaker. The point is that when the vibration fingerprints are performed, one can detect the contact imperfections, the mechanical faults or any other faults which are obvious in the vibration's signature modification of the breaker.

Some practical aspects of the experiments [3] must be considered, like as an overvoltage in the data recording system. In order to prevent the failure of the recording system, an overvoltage protection system should be installed, and the accelerometer should be insulated with respect to the ground.

For a breaker that had been previously tested in the sense of vibration signal during its long time operation, the time errors may be compared in the terms of commutation times. The advantage of the dynamic time warping (DTW) analysis is that the time error is related to a certain moment of the maneuver [4]. The traditional measurements of the commutation time, according to the existing standards, provide details about the total commutation time, but provide no information about the moment and the evolution area of the maneuver due to the time error.

When the vibration signals determined by the movement of the operation mechanism is measured, it is possible to find some hidden and serious faults of the breakers, even though they were tested using traditional methods and have been considered in a proper functional status.

The measurement of the current drawn by the operating inductor cannot be replaced by the DTW analysis. However if the accelerometer is located in the vicinity of the inductor, it is possible to register vibrations, when the inductor is energized.

When the impulse is recorded with a higher sampling frequency, in this case more than 500 kHz, it is possible to estimate the impulse duration. See Fig. 1 in which the duration of the pulse is 2 μs (where x represents the measured value, the red line represents the evolution of the signal and the dotted line represents the width of the impulse).

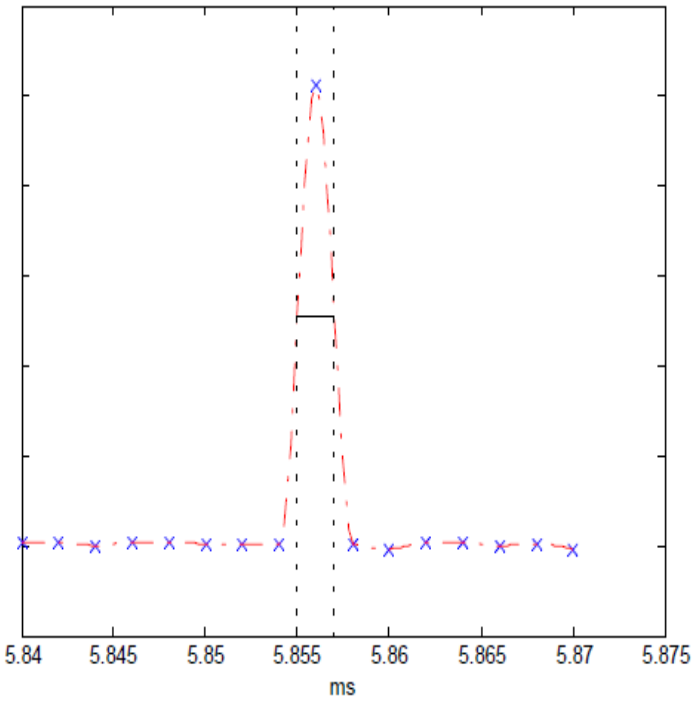

Figure 1. Impulse recorded at a sampling frequency of 500 kHz [5]

In the case of such pulses it is very difficult to mention a fault or a non functionality, because when measuring with accelerometers, the measurements may be affected by high voltage pulses captured by the cables linking the piezoelectric sensors and

the measurement device, even though they are shielded and/or separately supplied.

If sound recordings are performed and processed, one can obtain information on the operating anomalies and of their causes. Applying an appropriate electro acoustic measurement and analysis method, conclusions on several faults can be drawn.

Due to the interdiction of mounting sensors on commissioned breakers, sound records may be suitable for the diagnosis of several types of faults.

4. Methods of Processing Acoustic Signals

Current or vibration signals measurements are in general performed in time domain. In order to identify the frequency components of signals it is necessary to use the Fourier transform. The Fourier analysis is useful in the study of the signals in general and in the study of harmonic functions in particular (Fig. 2).

Any periodic function $f(t) = f(t+T)$, may be written as an infinite sum of sinusoidal harmonic oscillations, each of them having frequencies equal to integer multiples of a minimum frequency, namely the fundamental frequency, according to eq. 1 [7]:

$$f(t) = a_0 + \sum_{n=1}^{\infty} (a_n \cos n \cdot \omega t + b_n \sin n \cdot \omega t) \quad (1)$$

Components appearing in the sums of the eq. 1 are called harmonic components and deserve to determine the signal spectrum, a_0 being the continuous component. The coefficients a_n and b_n are determined using the following equations [7]:

Figure 2.

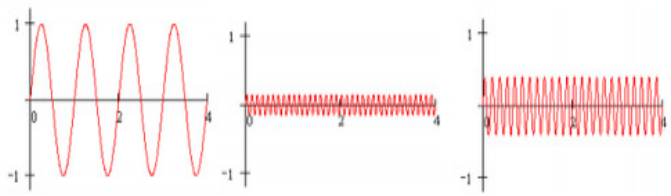

Figure 2. Sinusoidal signals [6]

$$a_0 = \frac{1}{T}\int_0^T f(t) \cdot dt \quad (2)$$

$$a_n = \frac{2}{T}\int_0^T f(t) \cdot \cos n \cdot \omega t \cdot dt \quad (3)$$

$$b_n = \frac{2}{T}\int_0^T f(t) \cdot \sin n \cdot \omega t \cdot dt \quad (4)$$

The Wavelet technique is more and more used in the analysis and the synthesis of the sounds, due to the advantages with respect to the fast Fourier transform [8].

The continuous wavelet transform of a finite energy signal $x(t)$, $\Psi(t)$ represents the "mother Wavelet function" and it is the convolution product of $x(t)$ with the wavelet scaled and conjugated function Ψ^*, according to the eq. (5) [9]:

$$\Omega_{\xi}(a,b) = \frac{1}{\sqrt{a}}\int_{-\infty}^{\infty} x(t) \cdot \Psi^*\left(\frac{t-b}{a}\right) dt \quad (5)$$

In order to be a Wavelet function, every function must satisfy the following admissibility condition [9]:

$$C_{\Psi} = \int_{-\infty}^{\infty} \frac{|\Psi(\omega)|^2}{|\omega|} \cdot d\omega < \infty \quad (6)$$

where $\Psi(\omega)$ is the Fourier transform of $\Psi(t)$ and C_{Ψ} depends on the chosen Wavelet transform [10]. The Wavelet functions are asymmetric, having a finite duration and a zero mean value.

$$|\Psi(\omega)| = \int_{-\infty}^{\infty} \Psi(t) \cdot dt = 0 \quad (7)$$

Using the calculated coefficients of the Wavelet functions, the original signal $x(t)$ can be restored.

The Wavelet coefficients appreciate the resemblance between the signal $x(t)$ and the function $\Psi_{a,b}(t)$. The use of the Wavelet transform consists in the choice of "mother Wavelet" functions. A certain number of "mother Wavelet" functions exist, but for the choice and the use of these functions, several particularities application depending must be considered.

Dynamic Time Warping is the method comporting two signals, the first one unknown and the second one a reference signal. The result of the comparison of the two signals is a function describing the temporal variation of the misalignment between the two signals. For an optimal result, the cumulated distance of the differences between the two signals must reach a minimum. In other words, considering the function from its initial point to its final point and cumulating at each step the distance between the characteristics of the frames, in the last point, the distance has to be the minimum one [11].

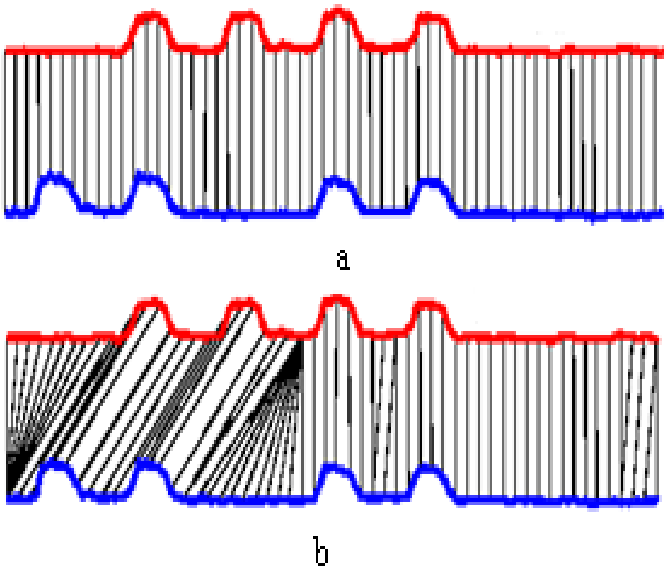

Figure 3. Alignment of two signals by the Euclidian method (a) and by the DTW method (b) [11]

Dynamic Time Warping (DTW) is an algorithm of aligning two time series, which was at its origins developed for the speech recognition. In the time series analysis, the dynamic deformation in time is an algorithm of measurement of the similitude of two temporal sequences that can be variable in time and in speed [12].

How resembling could be for instance the signals A and B from Fig. 3 (signal A is denoted with a red line and signal B with a blue line).

A method that modifies the time axis by contraction or dilatation is needed in order to superimpose the two signals without modifying the phase of the signals or to displace the time axis. The approximation used in the Euclidian method is used quite often, but the method is not able to perform an accurate comparison between signals which are not in phase.

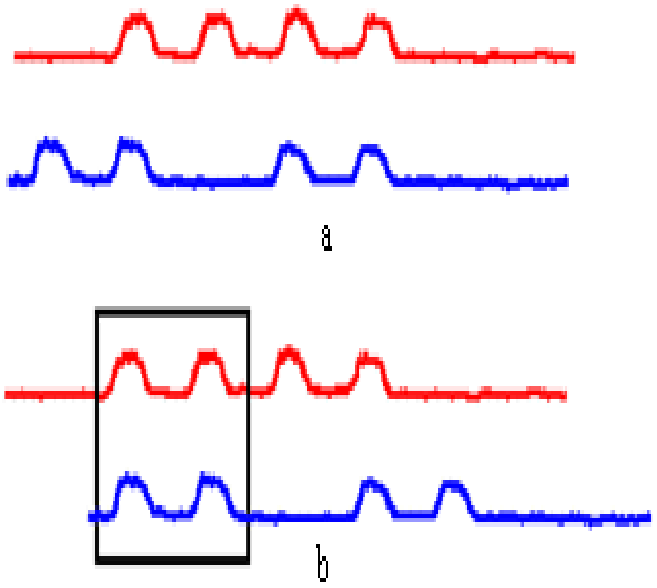

Figure 4. Alignment of two signals by displacement on the time axis [11]

The dynamic time warping (DTW) method is able to perform an alignment of events between the two signals, even though they are not in phase (Fig. 4).

5. Experimental Results

The experimental determinations are performed on a high voltage power breaker, Areva, GL 310 F3/4031 O/VR, with SF6, consisting in two columns of poles, the base frame and a driving mechanism. The columns with poles consist in an insulator which is isolating the operating voltage with respect to the ground and an insulator of the chamber in which the breaking unity is located.

The experiment consisted in recording the sound depicted in Fig. 5, in the stages of connecting arming and locking of the power breaker.

The objective of the determinations is to automatically identify the existence of the three stages (connection, arming and locking), of the operating mode, (the normal operating, or the abnormal operating mode) of the whole ensemble consisting in the three 110 kV power breakers, on the three phases L_1, L_2 and L_3.

The dynamic warping method is used and the spectrograms are depicted in Figs. 6 and 7.

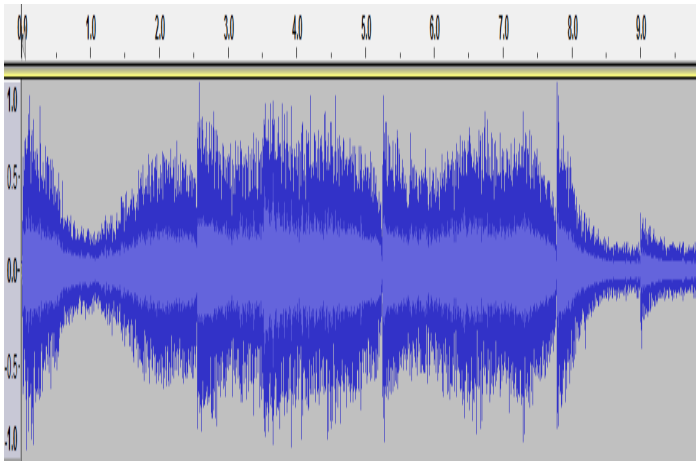

Figure 5. Audio signal

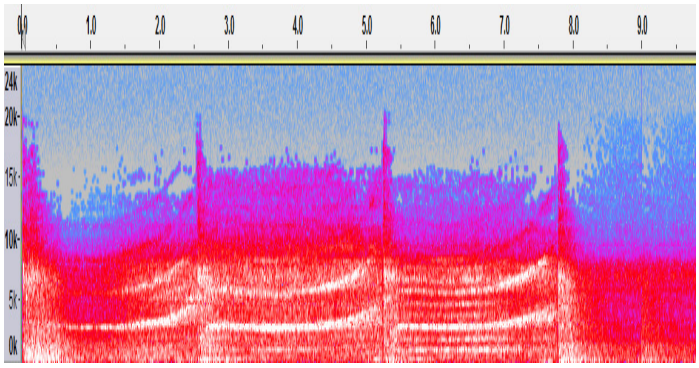

Figure 6. Audio signal spectrogram

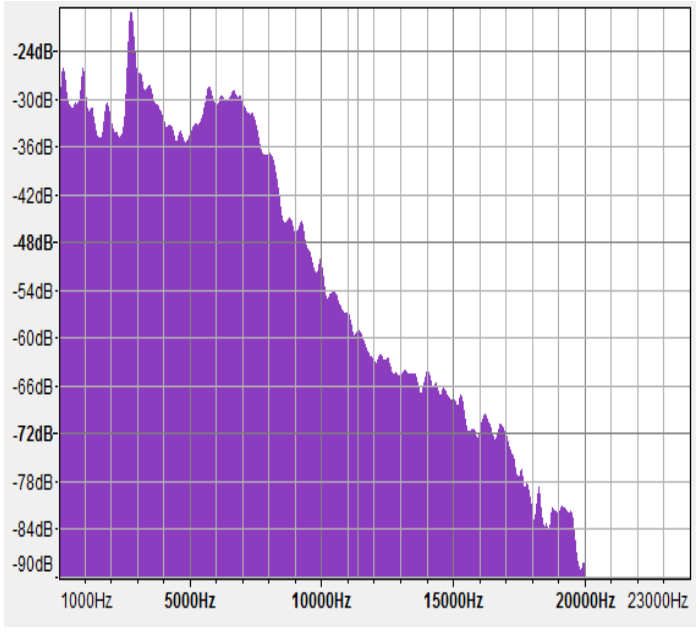

Figure 7. Magnitude versus frequency spectrum

The method that is checking out the breaker status consists in using the software Test_DTW. The software allows the comparison of each line signal with respect to the reference signal. The values obtained after the time alignment and the comparison, highlight the status of the power breaker.

The simulations have been performed using the Matlab platform.

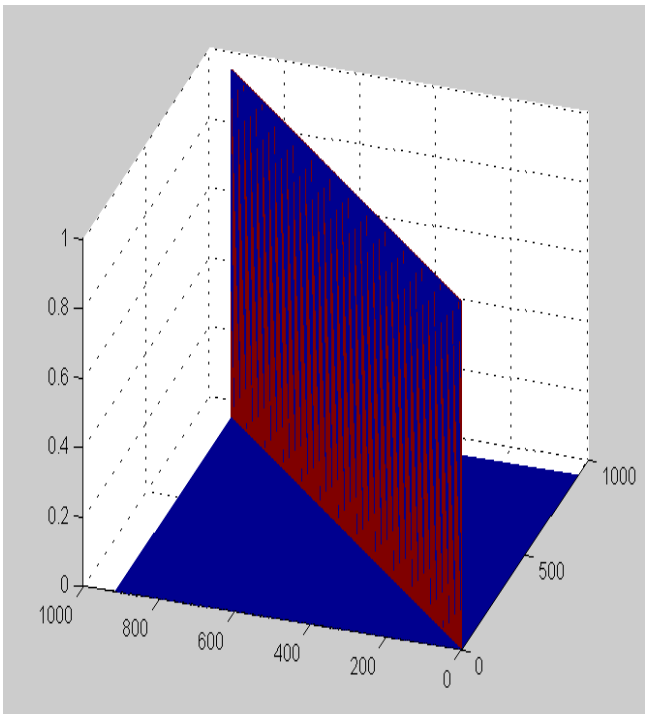

Figure 8. The match matrix M. Comparison of the reference signal **O_R1** with itself.

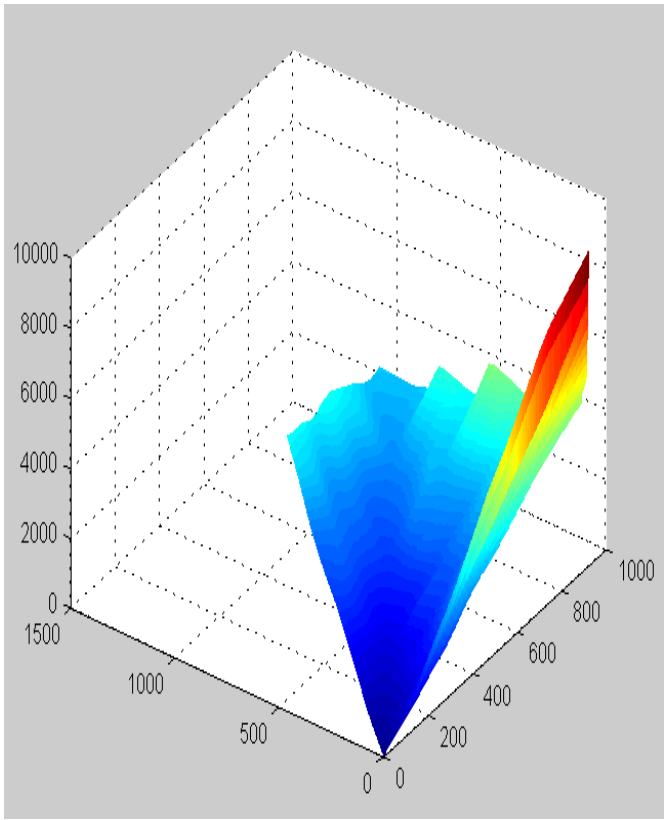

Figure 9. Cumulated distance D matrix

In order to highlight the accuracy of the method, Fig. 8 depicts a sort of a self test, consisting in a comparison between the reference signal with itself. Due to the fact that the values of the algebraic sum of the cumulated magnitudes are perfectly superimposed on the diagonal of the base square, the validity of the solutions is confirmed. The lack of superposition on the diagonal of the matrix highlights the existence of failures.

On the other hand, Fig. 9 indicates a breaker fault, highlighted by the comparison between the reference signal OR-1 and the signal OR 2.

6. Conclusions

Due to the permanent development of the electrical energy generating sources, the problem of the modernization of the transmission and distribution networks became a matter of high necessity. Consequently the need of higher reliability of equipment the cost reductions are compulsory. At the same time the maintenance problem is an acute one.

The costs with the maintenance process can be influenced by the reduction of the regular maintenance operations which in several cases are even not necessary. These costs can be optimized by passing from the classic corrective maintenance to the preventive maintenance using efficient methods.

The development and the implementation of the monitoring systems for power breakers became a necessity and a constant concern for the equipment manufacturers who provide equipment with embedded sensors. Due to the nowadays trend of monitoring and of the diagnosis of the medium and high voltage power breakers, the research topics should be focused on the monitoring, measurement and analysis of the sounds made be the vibration signals of the power breakers. This method represents a good choice because on one hand the vast majority of the power breakers commissioned until now has no embedded sensors and on the other hand the sensors cannot be mounted on the power breakers.

The sound analysis method proposed is a non invasive one which comply the safety norms, the measuring equipment being kept at a safety distance with respect to the operating equipment.

The monitoring systems presented in the paper have the following advantages:

- obtain information according the operating faults or anomalies;
- significantly mitigate the maintenance costs, by increasing the time duration between two faults;
- simplify the diagnosis process;
- increase significantly the life time of the power breakers;
- optimize the maintenance costs;
- maximize the investments efficiency;
- reduce the reaction time in case of functional faults.

Highlighting the specific type of fault that occurs at the commutation equipment will represent the topic of a further work. The present paper highlight only the benefits of the monitoring method that is able to offer the software processing procedure and the methodology of determining the faults of the measurements outcomes.

Toll charge

ABSTRACT

Crime statistics and research on criminology show that under similar circumstances, crimes are more likely to occur in developing countries than in developed countries due to their lack of security measures. Transport crimes on highways and bridges are one of the most common crimes in the developing nations. Automation of various systems like the toll collection system is being introduced in the developing countries to avoid corruption in the collection of toll, decrease cost and increase operational efficiency. The goal of this research is to find an integrated solution that enhances security along with the advantage of automated toll collection. Inspired by the availability of many security systems, this research presents a system that can block a specific vehicle or a particular type of vehicles at the toll booths based on directives from the law enforcement agencies. The heart of the system is based on RFID (Radio Frequency Identification) technology. In this system, by sending a text message the law enforcement agency or the authority that controls the toll booths can prevent the barrier from being lifted even after deduction of the toll charge if the passing vehicle has a security issue. The designed system should help the effort of reducing transport crimes on highways and bridges of developing countries.

1. Introduction

Developing countries are still lagging behind in technological development compared to developed countries. Security systems and safety measures to stop crime in developing countries are still dependent on trivial manual systems rather than automated systems. A major portion of crime happens at the highways and bridges. Most of the hijackers, kidnappers, murderers, anddrug dealers usually try to change their location by travelling from one state to another. As most of the roads and bridges have toll booth in developing countries, they have to pass through those areas. But police sometimes fail to recognize the criminals and their transport vehicles. However, in our work we tried to develop a system at the toll booth area to mitigate this problem. For this, we have integrated an advanced security system along with automated toll collection system based on the RFID technology.This paper presents the completed work of a research whose initial results were published in a conference paper [1].

For implementing this system, we need RFID tag in every vehicle. Moreover, every vehicle owner's basic information will be recorded in the database along with their prepaid based account number. So, it will be easier for the authority to find the vehicle owner's details in a faster way in case of emergency. For instance, suppose a car has been stolen from a state. Usually stolen cars are removed secretly out of the state and for this it has to pass any of the bridge. However, the victim can write a General Diary (GD) at the police station and the police can inform the authority about the specified RFID number plate and thus the particular vehicle can be prevented from crossing the exit point at the toll bridge. Thus, the missing car can be found easily.

The overall system is a hassle free and user friendly secured system. The benefits of the system also include congestion reduction, time saving, operating cost saving, payment flexibility, and incident reduction.

2. Literature Review

A considerable research work has been going on regarding automation of toll collection system to replace manual toll collection system. Most of them are based on RFID technology as it is cost effective and also safer at the same time. Prepaid based account is needed for deducting the toll charge from the vehicle

*Corresponding Author: Rafiya Hossain, Department of Electrical and Computer Engineering, North South University, Dhaka, Bangladesh.
Email: rafiya_2012@yahoo.com

https://dx.doi.org/10.25046/aj0203217

owner's account. This system is much more convenient, safer and it also reduces traffic congestion at the highways and bridges.

In 2005, Jerry.L and Barbara.C proposed a technique which was based on smart card [2]. Later, in 2011 Hitachi.S had proposed a system using ARM-7 processor and that reduced the overall process time to a great extent [2]. The vital part of the system is the RFID. A study related to sustainability of passive RFID technology for fast moving vehicle identification was found in a research paper [3]. This paper talks about the ALOHA based anti-collision algorithms to identify moving vehicles. The simulation work was developed using C++ and three configurations which includes one, two and multi traffic lane [3].

However, some research is also going on in the area of intelligent safety and security of automobiles by implementing different types of sensor and wireless locking and unlocking systems to reduce road accidents [4][5]. Cyber security is another big concern nowadays. Research on data security is also going on in many ways [6].

We have analyzed some research on car parking systems and we found RFID based access control system that is used in some confidential areas. A tracker based automatic detection of suspicious behavior of pickpockets in a shopping mall related work is also been proposed in a research paper [7].

RFID identity card system is already available in hostels, universities, medical centers, and shopping malls to restrict the entry of unauthorized people [8]. Combining all the ideas, we have aimed at developing an advanced security system which will be integrated with the RFID based toll collection system and will provide higher security on highways or bridges.

3. Description of the Proposed System

The overall system model is designed based on our previous project ideas and some new concepts regarding RFID technology. For implementing this system in a country, all vehicles must hold RFID number plates or tags. After the vehicle enters the toll booth area, the RFID reader at the toll booth instantly reads the vehicle's identification number and detects the vehicle type from memory. Then, according to the preset toll charge for each type of vehicle, it deducts toll charge from the vehicle owner's prepaid based account.

In case of truck or other weight carrying vehicles, like-cargo, it uses a formula to calculate the toll charge amount as the weight varies. However, a confirmation text is sent immediately to the vehicle owner's phone. So, to execute the system, the database has to record all the information including National ID card number, phone number, and account number etc. of the vehicle owner.

If any sort of crime occurs at the highways or bridges and the criminal wants to escape by moving into another state, he has to cross some toll booths. For example, if a murderer or a drug dealer is crossing a certain toll booth and the police somehow get informed about it, they can simply resist them. For this, they will only send the RFID tag code or number of the vehicle to the authority if they want to stop that vehicle. Then the system controller will send the code text to the system and block that vehicle even after paying the toll amount. In this way, if a security concern issue arises, the authority can also block all the vehicles from passing through that booth.

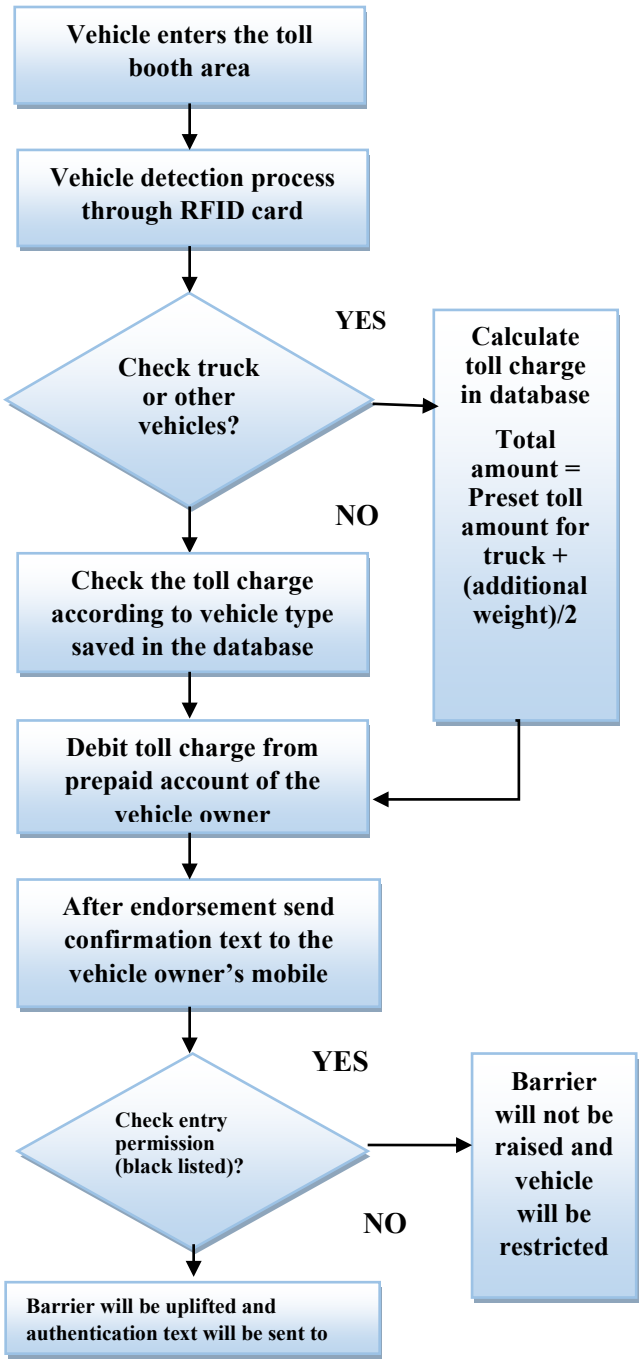

Figure 1: The Proposed System

4. Design Materials

The prototype of the system has been developed by using RFID system which includes the RFID Reader and RFID Tag, Microcontroller-Arduino Mega 2560, Force Sensitive Resistor (FSR), LCD Display, GSM Module and Servo Motor. The specifications of the components are briefly given below:

4.1 RFID Reader

A RFID reader is a network connected device (fixed or mobile) with an antenna that sends power as well as data and commands to the tags. RFID systems allow the unique identification of items [8] [9] or any other products which allows

tracking of individual items throughout the supply chain. In our system, RFID reader is used to detect the RFID tag attached to the vehicle. The reader used in our prototype can read RFID tag within 3.5 cm. However, for the real time model we will use more powerful reader which can detect the RFID tag from a longer distance.

4.2 RFID Tag

Radio-Frequency Identification (RFID) is the use of radio waves to read and capture information stored on a tag attached to an object. In RFID system, every individual item is equipped with an inexpensive and small RFID tag. The tag contains a transponder with digital memory chip. An antenna packaged with a transceiver and decoder emits a signal activating the tag so that it can read and write data into it. When RFID tag passes through the reader zone, it detects the reader activation signal [8] [9]. For our prototype five different active RFID tags are used for identifying five types of vehicle

4.3 Arduino Mega

Arduino Mega is a microcontroller board based on the ATmega2560. It has 54 digital input/output pins (of which 14 can be used as PWM outputs), 16 analog inputs, 4 UARTs (hardware serial ports), a 16 MHz crystal oscillator, a USB connection, a power jack, an ICSP header, and a reset button [10]. In our prototype, two Arduino mega have been used.

4.4 Force Sensitive Resistor (FSR)

FSR is basically a resistor that changes its resistive value (in ohms Ω) based on the pressure it is given [11].In our system we have used a square shape FSR in place of weight sensor for the practical demonstration purpose.

4.5 LCD Display

A 16x2 LCD is used for displaying the deducted toll amount and vehicle types at the toll booth.

4.6 GSM Module

The technical design of the system includes a GSM module which will help to send a confirmation text to the vehicle owner about the toll deduction. It is also used to communicate with the security personnel hence control the access of vehicles.

4.7 Servo motor

Servo motor has been used in our prototype which rotates at 90 degree angle to control the barrier.

5. Hardware Design

The system contains two Arduino Mega 2560 as the microcontrollers. The first Arduino is connected with a Force Sensitive Resistor (FSR), GSM module and the RFID Reader. On the contrary, the other Arduino is connected with a GSM module, servo motor and a Liquid Crystal Display (LCD). Then, the Arduino-1 and Arduino-2 are connected through serial communication. However, we need to power up the two Arduino Mega 2560 with 9V~12V and 2A. To activate the GSM shield, we need to insert a SIM card with balance recharged and hold the button until the green light stop blinking and settle down. Finally, we need to pass the RFID tag or card in front of the RFID reader.

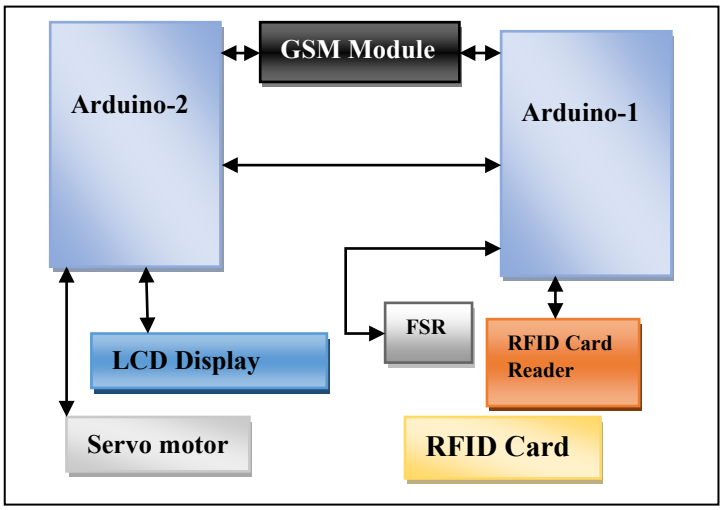

Figure 2: Hardware architecture

6. Software Design

The software design is constructed with two microcontrollers. The first processor is used to communicate with the RFID system, GSM module and FSR. However, the second processor combines the functionalities of GSM module, LCD display and servo motor. In the first processor, the system embarks by sending a tag request. If the vehicle carries a valid RFID tag, it sets or resets corresponding bits to the second processor [7]. After executing all these steps, it reveals the information in Liquid Crystal Display.

If valid tag is missing, then the former process backtracks again and thus the infinite loop continues. In the second processor, system activates by reading the analog voltage values A0, A1, A2 and then examines to determine the type of vehicle. For example, in case of truck it records the weight of the truck and the calculation is conducted by using the method below:

Total amount = Preset toll amount for truck + (additional weight)/2

For instance, if the vehicle is 50kg overweight, then the user has to pay half of the weight value along with the initial fixed amount.

If valid tag is missing, then the former process backtracks again and thus the infinite loop continues. In the second processor, system activates by reading the analog voltage values A0, A1, A2 and then examines to determine the type of vehicle. For example, in case of truck it records the weight of the truck and the calculation is conducted by using the method below:

Total amount = Preset toll amount for truck + (additional weight)/2

For instance, if the vehicle is 50kg overweight, then the user has to pay half of the weight value along with the initial fixed amount.

After performing the calculation, it displays the corresponding data and sends confirmation text using AT Commands. Then, it sends command to rotate servo motor at 90 degree angle. After 30 sec of delay, it will rotate back into 0 degree angle again.

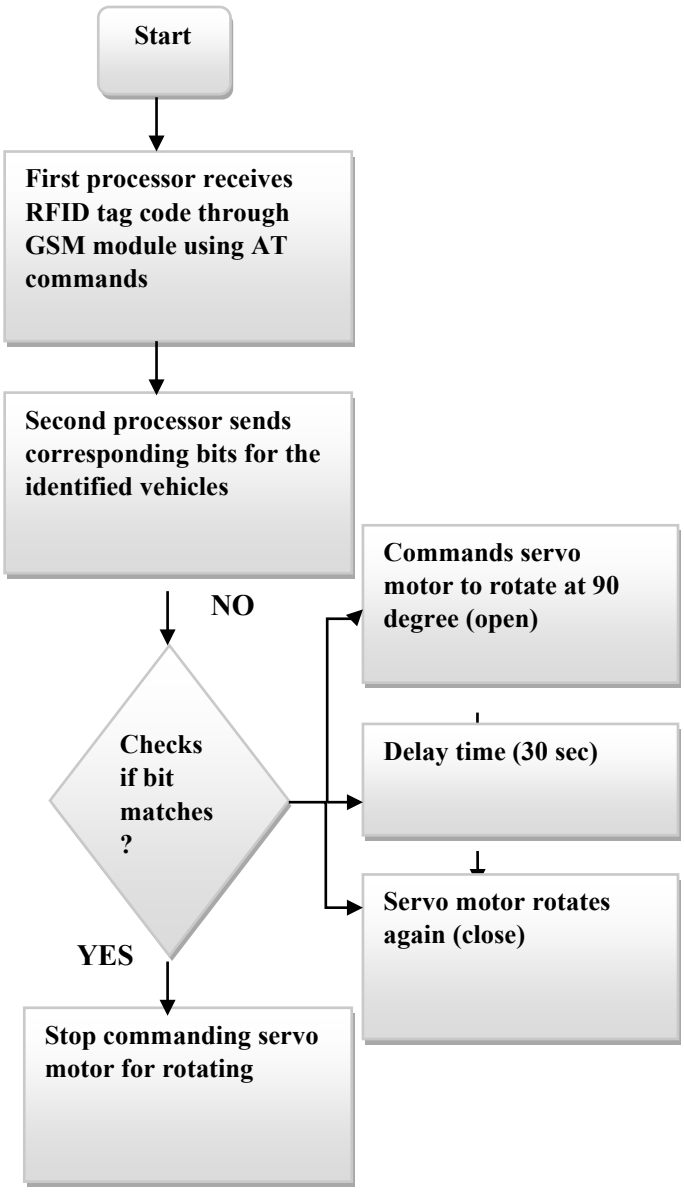

Figure 3: Steps for integrating between two processors

The security system starts when the first processor receives the RFID tag code by using GSM module. By using some AT commands, this process is done. After that, the second processor sends the currently available tag code. Then the tag code is matched with the currently available vehicle's RFID tag code in the database. If it matches then the system stops commanding for the rotation of the servo motor. So, the barrier remains closed. However, if it doesn't match, then the servo motor commands to rotate at 90 degree angle and eventually open the barrier. After 30 sec of delaying, the servo motor again rotates back at 90 degree angle to close the barrier.

To control the barrier for security purpose, we have used a code text message with the help of GSM module. The code text format for blocking the system is given below:

SMS Format: **Block<space>Car/Bus/Truck/CNG/Bike**

For example, to block a car the authority should write a text message to the system like Block Car and send it to the system.

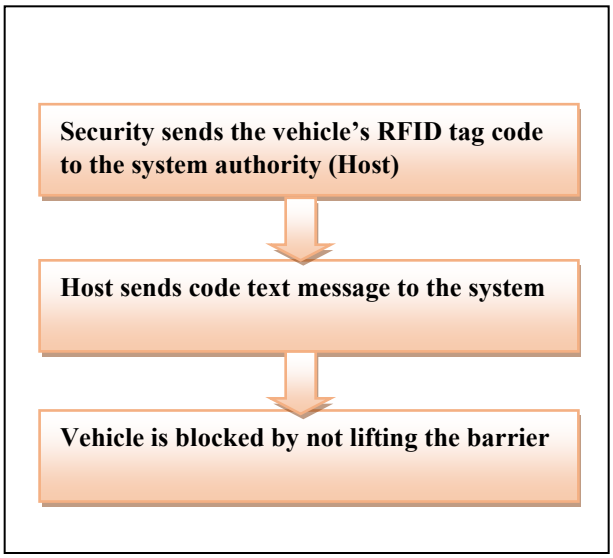

Figure 4: Blocking procedure

7. Results and Discussion

The designed prototype system has arranged a RFID booth over the road where the RFID reader was positioned for showing the demonstration. We had utilized a 16x2 Liquid Crystal Display for exhibiting purpose and also applied a 10k potentiometer to regulate the contrast of LCD display. We have used five different RFID tags or cards which represent five different types of vehicle, i.e., Bike, CNG, Car, Bus and Truck. A SIM card was inserted in the GSM module using which text messages were sent to the phone numbers that were already stored in the code for each RFID card.

The satisfactory level of our demonstration was adequate enough. The process started when a vehicle crossed RFID booth area, it was scanned instantaneously and informed by means of some LED's in the circuit. At the beginning the LCD exhibited in the display '*no vehicle……charge is 0'*.In contrast, in case of vehicle without proper RFID tag, the LCD display showed '*no tag present, use alternate path'*. Rather than truck for the other four types of vehicle (Bike, CNG, Car, Bus), it showed in the LCD display the type of vehicle and the corresponding charge.

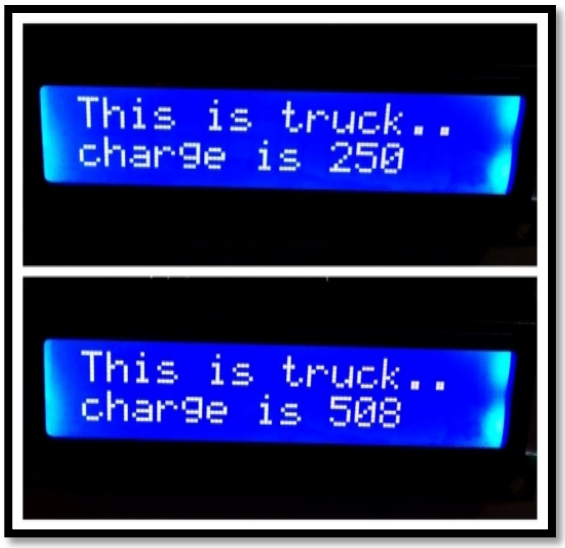

Figure 4: Toll charge for truck

We charged different amount of toll for the 5 types of vehicle. A confirmation text was received immediately in the phone number we had given in our system code. For truck the weight was calculated by varying the weight using FSR. For additional weight the extra toll amount that has to be paid was calculated using the following formula:

Previous Toll Charge for truck + (1/2) * weight = Total Toll charge for truck.

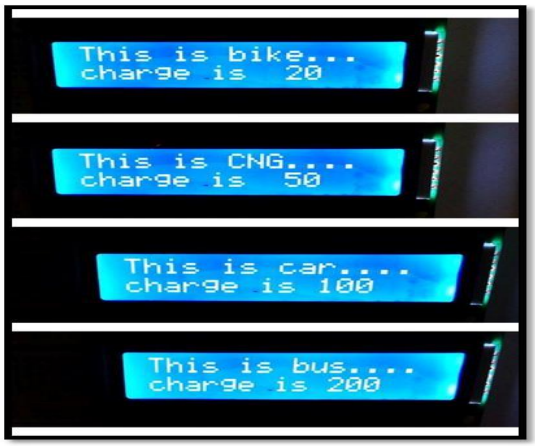

Figure 5: Toll charge based on different types of vehicle

Figure 6: The example of authentication messages

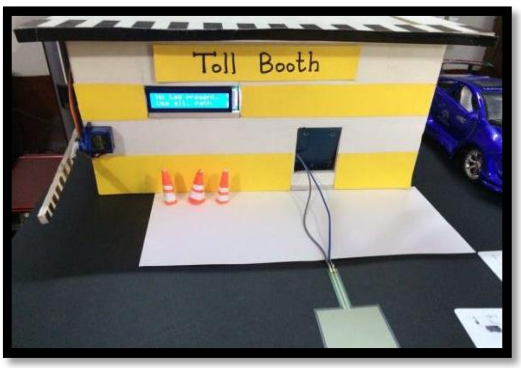

Figure 7:The prototype of proposed system

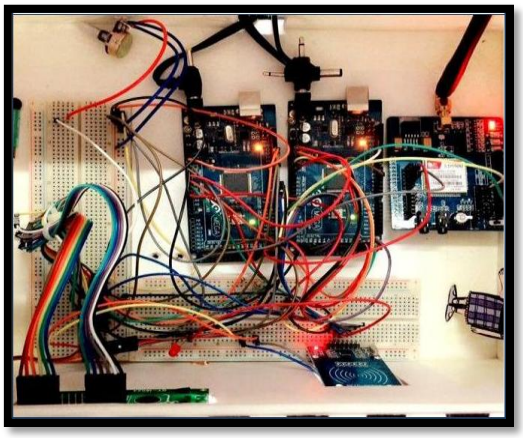

Figure 8: Internal circuit of the proposed system

7.1 The result of the security feature

In our demonstration, first of all we recorded five RFID cards in the database for five different types of vehicle. Now, we wanted to block the RFID card which was registered in our database system as 'car'. For this, we sent a text message writing 'Block Car' to the system and then the LCD showed '*Car Blocked'* and barrier was not lifted.

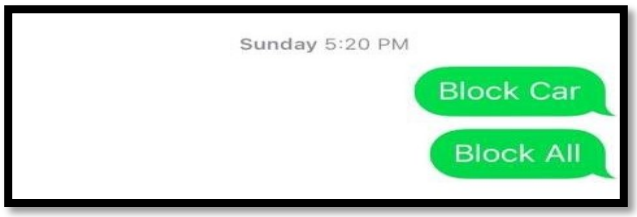

Figure 9: The example of message format for blocking vehicle

Figure 10: The example of screen for blocking vehicle

Then againwe wanted to block the whole system so that no vehicle can pass the toll booth area. For testing, we used the format of the SMS "All<space>Block" and sent a message to the system. After receiving the SMS, when we passed the RFID cards, the system blocked all the five types of vehicle and showed in the display "*All Blocked"*.

Figure 11: The example of screen for blocking all types of vehicle

```
int8_tsendATcommand(char* ATcommand, char* expected_answer, unsigned int
timeout){
uint8_t x=0, answer=0;
char response[100];
unsigned long previous;

memset(response, '\0', 100);
delay(100);
// Initialice the string

while( Serial2.available() > 0) Serial2.read();
// Clean the input buffer
```

Figure 12: Part of coding used in the proposed prototype

The overall programming is done by using Arduino code. A part of our code is shown in Figure 12.

In order to determine the performance, the key matrices are the distance and the range of RFID reader and Card. Time is also the parameter depending on which the overall performance of the system was determined.

In our prototype, we have used an active RFID reader which can measure up to 3.5 cm distance. We did the distance vs efficiency calculation by checking how fast the RFID card is detected by the reader while passing the booth area and also kept the record when it was failed to do the detection process.

For the improvement of efficiency we need to use higher frequency ranged RFID reader. Taking some sample data we tried to generate the graph using MATLAB to see the performance approach over the distance.

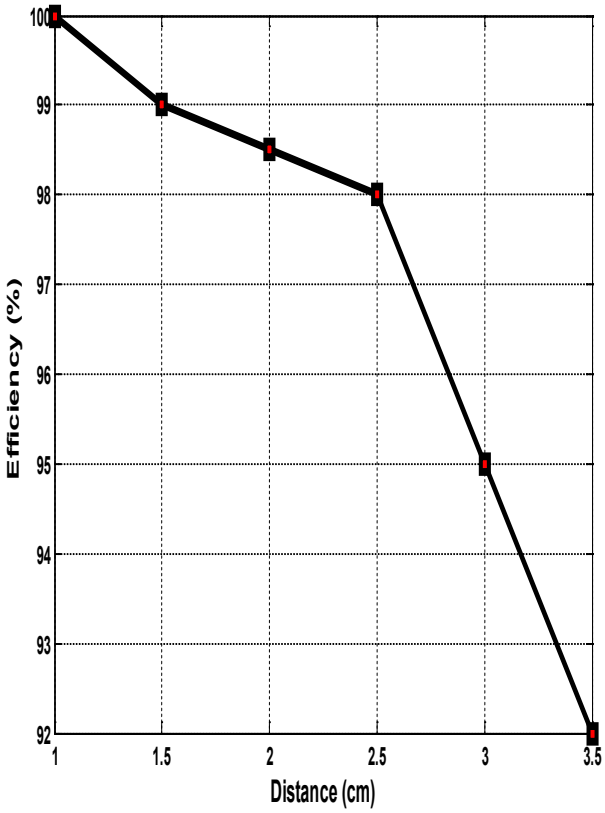

Figure 13: The comparison of efficiency and distance

From the graph, it is clearly visible that the efficiency of the system slowly decreases from 1cm to 2.5cm. After that the graph drastically decreases between 2.5 cm to 3.5 cm. Therefore, the finding is higher the distance lower the efficiency.

8. Cost Analysis based on the proposed prototype

One of the major steps for developing a compact system is taking into consideration about its building cost. As, our aim was to model the system for developing countries or underdeveloped countries, we tried to keep in mind about the cost issue. The system is very cost efficient and feasible for developing nations like Bangladesh, India, and Myanmar. Apart from that the components are easily available too. The whole circuit can be implemented on a PCB design board to have a compact design. The list and calculation of our total cost of the whole system are givenin Table 1.

9. Constraints

Junk messages are a problem which can hang the system. To erase the junk messages, the Reset button of the Arduino Mega 2560 is pressed. The latteris connected with the Liquid Crystal Display.

The implemented system has a short range for RFID tag detection, which are only a few centimeters at this time. This works fine in the small prototype system. Improvement of the system is possible by using more powerful RFID, which can be used for practical deployment with actual objects.

Table 1.Price of components and cost of the prototype system

Components	Quality	Amount(BDT)
RFID Reader	1	700
RFID Card	5	5x10=50
Arduino Mega	2	(2x1200)=2400
16x2 LCD	1	180
GSM Shield	1	3500
Servo Motor	1	320
Potentiometer	1	20
Force Sensitive Resistor(FSR)	1	912
Breadboard	2	(2x120)=240
Other materials		678
Total 9000 BDT = 112.5 USD		

10. Conclusion

The paper has presented the successful design of an embedded security system along with the automated toll collection system for reducing transport related crimes on highways and bridges. The overall system is based on RFID technology. Hence, there is no chance of using duplicate number plates as RFID tag is unique for each vehicle. The designed system should help the law enforcement agencies in many ways in reducing and preventing highway crimes. The system is cost effective and sustainable. It is expected that the system will sustain for a long time. It is also resistive to all external functions and parameters. For developing and underdeveloped countries, this automated security system along with automatic toll collection system should help greatly in reducing crime rates.

11. Future Work

A new feature can be added to the system which may include a database that stores vehicle data that includes vehicle owner's photo, name, national identification number and residential address. After the vehicle with security problem is detected, the information in the database related to the owner will be immediately pulled and sent to the police close to the area via text messages.

Another feature can be added to the system in where CCTV can be placed at the toll booths. They will capture the image of the driver. The system will match the image with the images of known criminals with outstanding warrants. If there is a match, the toll boothwill block the passage of the vehicle and notify the law enforcement agency immediately.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In crowdsourcing, selecting the person with suitable expertise is very important; especially since the task requester is not always in direct contact with the worker. Recently, this has become increasingly important particularly when the crowdsourced tasks are complex and require skillful workers (e.g. software development, software testing, vulnerability discovery, and open innovation). In this paper, we investigate the expertise indicators of vulnerability discovery professionals in a crowdsourcing vulnerability discovery platform. We conduct a systematic literature review, we review online contents, conduct interviews with domain experts, and survey vulnerability discovery professionals involved in the task of vulnerability discovery. We discuss the indicators we have found, and we provide some recommendations to help improve the process of selecting vulnerability discovery professionals to perform crowd tasks related to vulnerability discovery.

1. Introduction

The complexity of software-based systems is increasing dramatically as development becomes even more distributed across multiple heterogeneous, autonomous, and evolving cloud services. More specifically, the increased reliance on third-party software-based systems (e.g., cloud services, open APIs, external programming libraries and black-box software packages) makes it very difficult for in-house IT experts to deal with the inherent risks of using external software. In order to overcome potential vulnerability issues, several organizations outsource tasks such as vulnerability discovery to third-party providers. More recently, the approach of crowdsourcing vulnerability discovery has emerged. Companies like Google, Facebook, and Microsoft have their own crowdsourced vulnerability discovery programs (aka vulnerability reward programs). At present, even the government sector is adopting this approach (e.g., United States Department of Defense). In Addition, several crowdsourcing platforms for vulnerability discovery have emerged (e.g., Bugcrowd 'Bugcrowd.com', HackerOne 'hackerone.com', Synack 'synack.com', and Cobalt 'cobalt.io'). Similarly, competitions have been conducted for discovering vulnerabilities (e.g., Pwn2Own). This paper is an extension of work originally presented in IEEE 2nd International Conference on Collaboration and Internet Computing (CIC) [1].

Crowdsourcing vulnerability discovery allows organization to benefit from the merits of crowdsourcing (e.g., diversity, scale and speed). Alongside the benefits of crowdsourcing, some quality control concerns have emerged (e.g., clarity of the outcome, trustworthiness of the crowd) [2]. Facebook, in their vulnerability discovery program, highlights the following : "We received 13,233 submissions in 2015. Of these, only 526 were valid and eligible to receive rewards". Similarly, Bugcrowd mentions in the state of bug bounty report for 2016 [3], the platform received from January 1, 2013 to March 31, 2016, a total of 54,114 submissions, of which only 9,963 contained valid vulnerabilities. Although the variation in expertise is considered desirable for discovering vulnerabilities [4], organizations may be overwhelmed by the number of contributions and hence need to adopt techniques to ensure the quality of submitted vulnerability reports. One technique used in crowdsourcing to mitigate quality concerns is worker selection. Research shows that recruiting suitable workers enhances the quality of contributions [2,5].

In this respect, we are not advocating that limiting vulnerability discovery to selected vulnerability discovery professionals from the crowd is superior over open programs. The scope of this paper is to examine how Vulnerability Discovery Professionals (henceforth referred to as VDPros) are selected in crowdsourcing vulnerability discovery platforms. Organizations that crowdsource the task of vulnerability discovery are not always in direct contact with VDPros whom perform the task. Additionally, traditional methods of recruitments are not always feasible (e.g., interviews, probation periods). Hence, understanding expertise indicators of VDPros participating in the crowdsourced task of vulnerability discovery becomes even more important. We aim to understand how to measure the expertise of VDPros in order to make sure that the selected VDPro would yield a high-quality outcome for the vulnerability discovery task. In practice this is critical, since poorly

*Corresponding Author: Mortada Al-Banna, UNSW Australia, Computer Science and Engineering, Sydney, Australia | Email: m.al-banna@unsw.edu.au

managed vulnerabilities could cause huge losses to organizations whether financially or to the reputation . Our study aims to answer the following research questions:

– RQ1: What are the perceived indicators of expertise for selecting VDPros?

– RQ2: Which sources are accepted as reliable to extract these indicators of expertise for selecting VDPros?

While there is a large body of research for worker selection in crowdsourcing [6], to the best of our knowledge none yet addresses the selection of VDPros in crowdsourced vulnerability discovery. Giboney et al. developed a conceptual-expertise-based tool that can be used to discriminate between novice and expert VDPros [7]. They rely on self-reported skills and testing the knowledge of the VDPros to measure their expertise. This could be suitable in traditional recruitment but for crowdsourcing systems it might have some shortcomings (e.g., recurrent questions, automating simple question-answering) [8]. On the other hand, Hafiz and Fang performed an empirical study on VDPros who have disclosed vulnerabilities [9]. They investigated methods and tools used by VDPros to discover the vulnerabilities and how the community of VDPros tend to focus on certain vulnerability types. While they have touched some aspects in regard to the expertise of VDPros involved in discovering vulnerabilities, they have not explored the criterion for indicators of expertise with respect to VDPros.

Accordingly, this paper makes the following main contributions: we have conducted an extensive review of literature using a "systematic literature review" methodology [10], along with investigating a diverse range of online contents (e.g., blogs, technical reports and articles). We have then adopted "exploratory research methods" [11,12], where we relied on the insights we gained from the literature and the online contents, to conduct semi-structured interviews with domain experts. We also conducted an online survey for the VDPros involved in the task of vulnerability discovery to validate our findings. We employed "qualitative data analysis" guidelines [12,13] to analyse our data collected and scientifically present our findings. And finally, based on our findings we propose recommendations that we believe will pave the way for further advancement in the effective selection of security experts in vulnerability discovery crowdsourcing. While arguably personality traits are important characteristic in the selection of VDPros, in this paper we only focus on the indicators to expertise. An indicator to expertise is a signal about the knowledge of the VDPros in a certain area and their competency to solve problems within that area.

The rest of this paper is organized as follows: In Section 2, we provide some background knowledge. In Section 3 we discuss our review of literature and online contents. The methodology we adopt in this work is thereby illustrated in Section 4. In Section 5, we outline our findings; and in Section 6 we provide recommendations to help improve selecting VDPros for vulnerability discovery tasks. We conclude with a discussion and directions for future work in Section 7.

2. Background

In this section, we examine the topic of crowdsourcing and its application to vulnerability discovery. We provide an illustrative example to further clarify the research problem.

2.1. Crowdsourcing Vulnerability Discovery

A vulnerability is a security flaw, which arises from system design, implementation, or maintenance (e.g. SQL injection vulnerability). By exploiting these vulnerabilities, malicious parties could gain unauthorized access to protected resources. The field of vulnerability discovery and repair has been very active in recent years, especially with the increase in number of security threats and incidents [14].

Crowdsourcing (also known as human computation) harnesses the wisdom of large groups and communities working independently to solve problems, much as open source does for software development. From the service customers' perspective, crowdsourcing is a form of digital service (notwithstanding its essentially human infrastructure), yet its unique value draws from its effective way to perform tasks that remain difficult for, or even beyond the reach of machine computation [15] (e.g., image tagging, natural language translation, and transcription). Several organizations including DARPA, NASA, Honda and various other organizations use platforms such as MTurk and Ushahidi to crowdsource information gathering. Other commercial crowdsourcing platforms have recently emerged alongside MTurk; platforms like Innocentive, TopCoder, Kaggle, and uTest use crowdsourcing for tasks that require skilled workers (Web design, testing, Web development tasks, R&D challenges).

Crowdsourced vulnerability discovery programs allow vulnerability discovery professionals to play the role of an attacker to discover vulnerabilities. In a crowdsourced vulnerability discovery program, software providers submit vulnerability discovery tasks to a community of VDPros. This approach is gaining increasing popularity recently [1] . Crowdsourcing vulnerability discovery could be in the form of an open call and managed directly by an organization (e.g., Facebook VRP, and Google VRP), or directed toward members of specialized platform for crowdsourcing vulnerability discovery (e.g., Bugcrowd, Cobalt, HackerOne, or Synack). Crowdsourced vulnerability discovery programs could be publicly available for everyone and VDPros self-select and decide to participate according to their preference (e.g., Uber program in HackerOne[2]), or could be private where the organization invite only selected VDPros to participate according to a specific criterion (e.g., LinkedIn Private program[3]). There are also unregulated methods for the crowd to submit discovered vulnerability information (e.g., black and grey vulnerability markets[16], and VDPros disclosing vulnerabilities publicly[4]).

Several researchers investigated crowdsourced vulnerability discovery from different angles. Laszka et al investigated the problem with invalid submitted vulnerability reports and their relation to incentives misalignment [17]. Zhao et al. investigated the web vulnerability discovery echo system and analyse vulnerability trends, response behaviour and reward structures [18]. Finifter et al. investigated two crowdsourced vulnerability discovery programs [19]. The authors illustrated that crowdsourced vulnerability discovery programs are economically efficient and explored the difference in the reward strategies and the effect on the engagement with VDPros.

4 schneier.com/essays/archives/2007/01/schneier_full_disclo.html

2.2. Illustrative Example

Let's assume that a company called AwsomeAPI has decided to delegate the vulnerability testing for its new API to a crowdsourcing platform for vulnerability discovery. AwsomeAPI is concerned about the quality of the output of the task. As the quality of the output from the crowdsourced task is related to the expertise of the crowd worker [2], AwsomeAPI has thereby decided to limit participation of the program to only expert VDPros. AwsomeAPIs has decided that the scope of the program is to protect its API from the injection attacks (e.g. SQL injection, and script injection) [20]. The internal team in AwsomeAPI has identified that in order for the VDPro to be competent in the vulnerability discovery task, they need to have: knowledge about the technology (e.g., the API to be tested, and protocols such as http, and SSL/TLS); programming skills (e.g., low level programming, and scripting); knowledge about security practices (e.g. security controls such as authentication and authorization, and software vulnerabilities).

AwsomeAPI is facing some difficulties in regard to selecting VDPros with the required level of expertise, and how can they assess the expertise of the VDPro.

3. Expertise Indicators from Literature and Online Contents

We reviewed literature using a systematic literature review (SLR) approach where we followed the guidelines illustrated in [10,21]. As an additional source of information, we have also examined a range of online content, such as companies' blogs, and technological articles, and rely on the online research methods [22]. We provide a brief description and summarize our findings in this section.

3.1. Steps of the Systematic Literature Review

Various approaches amongst literature have been adopted to determine expertise. Hence the use of literature review helps in identifying the indicators that have been relied on in these approaches and how relevant they are in measuring the expertise of VDPros involved in the task of vulnerability discovery. We adopt the methods of literature review on the recommendations of Kitchenham [10] and Okoli et al. [21].

I. Selecting the Articles

We searched for relevant articles addressing people selection according to expertise. We included both journal and conference articles as the conference articles have been found to be of important role in the field of information systems [23]. The search was conducted for the period between January 2009 and January 2016 for articles in IEEE Digital Library, ACM Digital Library, and Scopus databases. We focused on articles available in full text and in English language. We used the following keywords for the search: "Expert" OR "Expertise" OR "Reputation", "Selection" OR "Finding", "Crowd" OR "Crowdsourcing". We checked that searches using similar keywords like 'crowd-source', 'crowdsourced', and 'crowdsource', identify the same corpus and therefore can be discarded.

The result of the search was 172 articles. After removing the duplicates, editorial introductions, posters, tutorials, workshop summaries, and articles that just mention the search keywords and that are not relevant to discovering expertise, a total of 96 articles remain in the initial pool of resources.

II. Filtering Articles and Additional Search

We applied the following inclusion criteria: (i) articles concerned with selecting experts to perform a task; (ii) articles measuring expertise of workers in a platform or members in a community; and (iii) articles measuring reputation for workers in a platform or members in a community. We also applied the exclusion criteria for articles with the main focus of relying on self-assessments (e.g., self-reported skills or qualities).

By applying the inclusion and exclusion criterion, the number of articles becomes 23. We performed additional literature search in a less systematic approach, focusing on articles that we were already aware of ourselves, articles found by a full text search using Google scholar, and relying on back snowballing where we looked at references cited in the articles we have. We believe that this addition has provided a more comprehensive review of scientific contributions in this area. The final number of articles that were reviewed was 34.

III. Data Extraction and Synthesis

We reviewed the articles in order to identify the indicators of expertise relied on in literature. The first author codified the review articles and the other authors checked the extracted data and modifications were made according to the comments. In any cases of disagreement on data extraction, the three researchers discussed until reaching consensus.

We synthesized the extracted data in order to answer the research question. We reviewed the extracted data and built a list of the indicators of expertise that were relied on in each article. We then merged the indicators that were related together and narrowed down our list of indicators to five indicators.

3.2. Emerging Indicators from the Literature Review and Online Contents Investigation

Five indicators to expertise have emerged from the literature (illustrated in Fig. 1). In the following, we briefly discuss each of these indicators, and we explain the resources that motivated us to derive them as appropriate indicators. Table 1 illustrate a summary of the indicators and the supporting research work.

Figure 1. Selecting Vulnerability Discovery Professionals (Expertise Indicators)

I. Certification

This is one of the most known indicators to knowledge in both educational bodies (academic record certification) and industrial bodies (industrial professional certifications). Relying on a proof issued by a trusted party (whether being tested or not) the crowdsourced task owner will know that the VDPro have the required knowledge to perform the task of discovering

vulnerabilities. Crowdsourcing platforms like MTurk allow the task requester to issue a qualification test for each of the crowd workers to assert their eligibility to perform the task. Online freelancers market UpWork (previously known as oDesk) rely on certifications to assess the competency of the freelancer along with online testing for the skills. Similarly, Synack which is a crowdsourcing vulnerability discovery platform, administer to VDPros a written and practical evaluation to certify that they are eligible to join the platform [24].

Ejiaku et al. in their work discussed the importance of Information technology certification and its impact on the recruitment process [25]. In a similar context, Bishop and Frincke in their work discussed general professional certifications and compared them with academic certifications. They also looked at how each of these certifications reflect the knowledge required for certain jobs and their effect in increasing the possibility of success on the job [26]. On the other hand, McGill et al. addressed the importance of recertification in order to ensure the validity of the certification and express the true knowledge and expertise of the certification holder [27].

Kanij et al. in their work surveyed several software testers for factors they considered most important to the task of software testing [28]. In their study, 56.7% of the respondents to the questionnaire indicated that they had done training or certification in software testing in the last five years and the majority of the participants found certification and training useful. In a similar context but in different field, Botella et al. identified certification as a key requirement for persons who aim to become an expert in usability evaluation [29].

II. Referrals

Referrals or recommendations are also well known in the domain of recruitment as a way to gather and confirm expertise. Many organizations rely on referrals and encourage the employees to recommend potential candidates for employment. Salesforce has indicated in its official blog that its main strategy for recruitment for 2015 is based on referrals [30].

Many online professional communities and professional social platforms have recognized the importance of referrals in determining expertise. For instance, professional social media platform LinkedIn facilitates endorsements in order to tag a specific skill to the professional [31]. CoderWall allow users to endorse and assert any skill that the profile owner has mentioned in her profile [32]. Repcoin a novel reputation market platform rely solely on recommendations to build up the users' reputation of having expertise in a certain field, and as it is built on top of the bitcoin technology the platform facilitates having the reputation as a portable accreditation that could be presented anywhere [33].

Some research has addressed the impact of referral as an indicator to expertise. Schall et al. in their research introduced a context-sensitive trust-based algorithm called ExpertHITS inspired by the concept of hubs and authorities in Web-based environments [34]. They rely mostly on referrals from experts to delegate a task to another expert in her network. In the same context, Zhang et al. proposed a mechanism for finding experts by a referral chain from the initiator to the expert [35]. Similarly, the work of Pushpa et al. has addressed searching for expertise in a network of co-authorship where a query to find an expert is seen by an agent that manages the expertise model of the users. It thereby makes a decision to forward the request to relevant experts in the neighbourhood of co-authors if the query is not matched [36].

Within the enterprise work environment, finding an expert to perform certain task has been a problem addressed by several researchers. Braub et al. have proposed people tagging where they rely on employees to tag certain skill or knowledge to their colleagues [37]. Ghosh et al. have proposed relying on user curated Twitter lists to determine topic experts, since users include experts on topics that interest them in their lists [38].

III. Performance Review

Reviewing the performance of crowd workers has been relied on as an indicator for knowledge and expertise in many crowdsourcing platforms [39,40]. Similarly, the performance of VDPros within the crowdsourcing vulnerability discovery platform could be used to assert their level of expertise (reflected by a high reputation score). BugCrowd calculates a reputation score for each VDPro according to the number of discovered vulnerabilities, the speed of discovery, and abiding by the rules of the vulnerability discovery program [41]. Similarly, Cobalt (former known as Crowdcurity) relies on the same aspects but they add to them the feedback from the task requester and the quality of the vulnerability discovery report [42]. Hackerone in addition to relying on the number of the vulnerabilities discovered, speed and abiding by the rules, they add extra points for VDPros who acquire a bonus credit from the task requester (e.g., for clever vulnerabilities, or critical ones) [43].

Zhao et al in their work highlighted the performance of VDPros in a web vulnerability disclosure program as a measure of their expertise [44]. Similarly, Algarni and Malaiya in their work relied on the performance of VDPros to define the top discoverers of vulnerabilities [45]. Anvik et al. proposed an approach that apply machine learning algorithm to an open bug repository to recommend the suitable developer to fix a software bug according to their past performance [46]. In the same context, Hassan and Curry in their work proposed extracting the crowd worker expertise from the previously accomplished tasks of certain type (e.g. image tagging) in order to predict the performance of the crowd worker in tasks of different types (e.g. image recognition) [47]. Sarasua and Matthias however, proposed the use of a cross-platform Curriculum Vitae in their work to record the crowd worker expertise and skills according to the performance of the crowd worker in several crowdsourcing platforms [48].

Ebay, as an online market, set reputation for each of the sellers according to the quality of the goods they provide and their performance (e.g. speed of delivery, how they handle returns) and accordingly they categorize the seller as being expert [49]. Resnick and Zeckhauser in their work looked at the reputation system in eBay and how predictive it is for future performance of the sellers [50]. Similarly, UpWork[5] rely on the freelancer's job success rate and client feedback to assess her expertise.

IV. Artefacts

The artefact could be in the form of a software code in GitHub, an answer to a question in a Q&A platform like Stackoverflow, or a published article. Vasilescu et al. have looked at the relation

[5] www.upwork.com/i/how-it-works/client/

between the activity of users in Stackoverflow and GitHub, they have discovered that active GitHub committers ask fewer questions and provide more answers than others in Stackoverflow [51]. In the same context, Hauff et al. in their work proposed an approach for matching job advertisements with expert developers according to their artefacts contributed in GitHub [52].

Table 1. Indicators and Supporting Articles

Indicator	Supporting Articles
Certification	[9] [11] [21] [34] [46] [62]
Referral	[12] [26] [44] [52] [56] [71] [75] [76]
Performance Review	[2] [5] [28] [32] [33] [53] [54] [57] [64] [69] [72]
Artefacts	[8] [15] [16] [23] [30] [37] [50] [63] [65]
Association	[25] [43] [54] [58] [61] [68] [70] [74]

Kolari et al. in their work looked at blogs related to certain enterprise as a source of evidence of that expertise for potential employees. The authors investigated whether depending on blogs has similar effect as depending on emails but with less privacy concerns and they even have the added value of allowing implicit voting via comments by the community [53]. Balog et al. have presented strategies for finding experts relying on document repositories in the enterprise [54]. In their work, they have proposed two approaches, the first determines the employee expertise based on the documents (e.g., reports, manuals) that they are associated with, whilst the second locates documents based on topic, and then finds associated experts.

Pelechrinis et al. [55] proposed an approach to infer expertise and reliability of the answers provided in a Q&A platform depending on the pattern of the authors answering to other questions. The authors investigated users' consistent responses to questions related to particular topic and their expertise in that topic, as well as determining whether the user is answering too many unrelated topics, it would therefore be safe to assume they are an amateur in each of those areas.

Demartini investigated whether in order to find experts with certain knowledge, it is better to look at where knowledge is created. The author proposed an algorithm to find experts according to their contribution in Wikipedia [56]. Chang et al. in their reputation based access control for crowdsourcing platform relies on the quality of the artefacts submitted by the crowd worker in order to assert the quality of the worker herself [57].

In the academic field, academics have been evaluated by their publications such as the number and quality of publications, number of citations, and the h-index. Tang et al. have presented an academic search system, called ArnetMiner which relies on the publication of academics as an indicator to their knowledge and expertise in a particular field amongst other sources [58]. Similarly, Freund et al proposed an expert-finding system in the academic domain where they also rely on the publications of academics as one of the measures of expertise [59].

V. Association

Relying on associations to determine expertise is an approach that is recently emerging. Fu et al. in their work proposed strategies to discover the associations amongst people from emails and Web pages. Relying on these associations, a candidate can acquire extra expertise probability from a reliable expert who has strong relationship with the candidate [60]. Li et al investigated documents' co-authorship as a relation between experts, and they assessed if the probability of being an expert increases if they have co-authored a topic relevant document together with a well-known expert [61]. Similarly Zhang et al. proposed a propagation-based approach to expert finding in a social network where they relied on local information (e.g. published articles in certain topic) and then propagated possible expertise of a candidate according to their relationships (e.g. co-authored or supervised) [62].

Daniel Schall introduced a ranking approach called Dynamic Socially-Aware PageRank where the expert ranking depends on context aware interactions. As an example, an expert of certain topic may attract a large number of help requests in regard to that topic [63]. In the same context, in [64] the authors investigated the usage of social relationships in a microblogging platform as a potential evidence that a person is a real expert. In the sense that if user A who is an expert follow user B, then user B is most likely to be an expert too. Similarly, Zhao et al. in their work have addressed the problem of lacking information about the crowd worker's past performance (cold-start worker). They proposed an approach to determine the expertise of the worker from social networks, such as, if the cold-start worker was associated with another worker who is considered to be an expert then the cold start worker is also to be considered and expert [65].

Pujol et al. in their work proposed an algorithm called NodeRanking, which rely on modelling the community as a social graph relying on relationships. Such as, being mentioned in the user's website or having email exchange between the two users. Their approach is to infer expertise according to the degree of connectedness of each of the nodes in the graph [66]. Suryanto et al. looked at Q&A platforms and proposed that users who ask high quality questions that attract experts are considered experts and users who provide answers to questions asked by experts are considers experts as well [67].

4. Methodology

In our study we rely on exploratory research methods [11,12]. Our study consists of three phases of data collection: (i) Literature review and online content investigation; (ii) Interviews; and (iii) Online surveys. Figure 2 illustrates the phases of the study. Our methodology consisted of data collection and iterative phases of data analysis.

In the first phase all the authors contributed to the discussion and analysis of the literature, and online content following the SLR guidelines [10]. For the second phase, the interview questions were discussed by the authors and refined through multiple iterations. The interviews were conducted by one of the authors. Summaries of the interviews were discussed by the authors to draw insights and identify the key emerging themes. For the third phase, the survey questions were designed by the same author who conducted the interviews. The survey questions were revised through multiple iterations of refinement by the authors and three external VDPros before being published. This helped us refine the terminology used in the survey questions and to ensure the study was clear and

motivating to VDPros. The results of the survey were summarized and discussed by authors. In this section, we discuss the research questions, study design, data collection methods and data analysis approach.

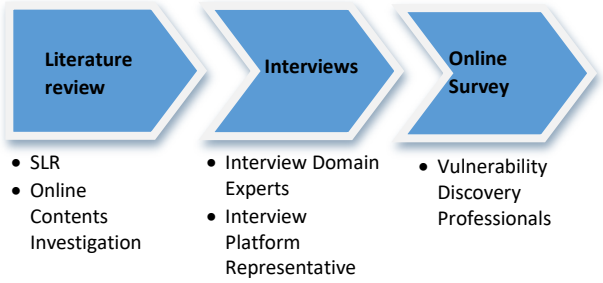

Figure 2. Stages of the Study

4.1. Study Design

In the first phase of our study, we reviewed scientific literature using systematic literature review methodology [10]. As mentioned above, we also investigated a diverse range of online contents (e.g., companies' blogs, experts' blogs, and technological articles) [22]. We utilized the findings in this initial phase to refine our interview and survey questions for the second and third phases. The results of the initial phase were already presented in the previous section.

In the second phase of our study, we interviewed 32 participants. We also approached one of the platforms for crowdsourcing vulnerability discovery for additional insights. Through iterative analysis of the data collected from this phase we were able to gain better understanding of what domain experts perceived as indicators to measure expertise in VDPros and what are the reliable sources to extract them.

In the third phase, by relying on the results of previous phases, we approached VDPros involved in the task of vulnerability discovery with an online survey. The purpose of this survey was to acquire the opinion of VDPros who are involved in the task of vulnerability discovery – and to thereby validate our findings from previous phases.

4.2. Study Design

In the first phase of our study, we reviewed scientific literature using systematic literature review methodology [10]. As mentioned above, we also investigated a diverse range of online contents (e.g., companies' blogs, experts' blogs, and technological articles) [22]. We utilized the findings in this initial phase to refine our interview and survey questions for the second and third phases. The results of the initial phase were already presented in the previous section.

In the second phase of our study, we interviewed 32 participants. We also approached one of the platforms for crowdsourcing vulnerability discovery for additional insights. Through iterative analysis of the data collected from this phase we were able to gain better understanding of what domain experts perceived as indicators to measure expertise in VDPros and what are the reliable sources to extract them.

In the third phase, by relying on the results of previous phases, we approached VDPros involved in the task of vulnerability discovery with an online survey. The purpose of this survey was to acquire the opinion of VDPros who are involved in the task of vulnerability discovery – and to thereby validate our findings from previous phases.

4.3. Data Collection

For the interviews, we invited participants via e-mail invitation, LinkedIn messages, and advertising our study in information security groups on LinkedIn (e.g., Information Security Community [6]). We also leveraged snowballing to get recommendation from people about their colleagues that would also be interested in participating [68]. Snowballing was the most effective approach since direct approaches may be considered spamming – especially as spamming attacks are well known by security experts who are much more cautious to accept invitations from an unknown party. The interviews lasted between 30-60 minutes and were conducted via Skype, Google Hangouts, telepresence systems, phone calls, and e-mail exchange. Audio was recorded when the interviewee consented and notes were taken. The interviews were semi-structured based on the findings of Phase 1 of the study, and the interviewer asked additional questions when appropriate. Summary of interview questions are outlined in Table 2 and the full interview guide is published online[7].

We also interviewed a senior representative from one of the platforms that supports crowdsourcing vulnerability discovery. This interview provided us with indispensable insight from a typical platform that is responsible for managing vulnerability discovery programs. Hence, they provided very valuable input in accordance to their experience from interacting with over 250 clients and thousands of VDPros.

Finally, we targeted VDPros involved in the task of vulnerability discovery with an online survey. We designed the questions of the survey based on the results from Phase 1 and 2. We shared the preliminary survey with three of the VDPros to acquire feedback before releasing it. The feedback helped us to modify some of the terminology used and modify some of the questions that were considered vague. The survey included both closed and open questions [69]. While closed-form questions are easier to summarize, open questions allowed respondents to include their remarks and comments.

We analysed the responses by applying structural codes and then aggregating the results for common trends [70]. Most closed-form questions used a Likert scale [71] with five possible responses from "Very Important" to "Not Important". The actual form of the survey is published online[8]. We sought participants via direct e-mail or tagging on twitter, LinkedIn messages, posting in Bugcrowd forum[9], Offensive Community site[10], and LinkedIn information security groups.

Table 2. Summarized Interview Question for the Domain Experts

Characterization

1. Tell us about your organization (size, business area)?
2. What is your role in the organization?
3. Are you familiar with the approaches for vulnerability discovery (management, practices, decision making)?

Indicators to Expertise

1. What are the Indicators you rely on to measure expertise in vulnerability discovery professionals involved in the task of vulnerability discovery?
2. How much do you value certification as an indicator that could be relied on to measure the expertise in Vulnerability discovery professionals?
3. How much do you value referrals to measure the expertise of vulnerability discovery professionals?
4. How much do you value performance as an indicator to the expertise of vulnerability discovery professionals?
5. How much do you value artefacts generated by the vulnerability discovery professionals as an indicator to their expertise?
6. How much do you value association networks as an indicator to expertise for vulnerability discovery professionals?

Reliable Sources

1. What sources of certification you consider reliable to indicate expertise of vulnerability discovery professionals?
2. What forms of referrals do you rely on to measure expertise in vulnerability discovery professionals?
3. How much do you value past performance as an indicator to measure expertise in vulnerability discovery professionals?
4. What are the artefacts you think would be a reliable source to express expertise?
5. What forms of association do you think are reliable to express expertise?

4.4. Participants

Due to the time constrains and the exploratory nature of the study, we followed the recommendations of Adler and Adler and aimed for a sample size between 12 and 60 [72]. We reached saturation in the opinions of the interviewees and this gave us confidence that we captured sufficient depth to enable us to assert the solidity of our findings. We designed a comprehensive set of questions for the interviews and surveys relying on the literature review and online contents.

I. Interview Participants

Table 3 shows the details about the domain experts who have participated in the interviews. We refer by domain experts to personnel who oversee the security posture of organizations. Although they do not perform vulnerability discovery tasks as their daily job, they nonetheless influence (directly or indirectly) setting the criterion for selecting VDPros to perform the task.

For the purpose of analysis, participants are referred to by an anonymous identifier (P#). We invited participants from different disciplines (e.g., finance, entertainment, telecoms, etc.), so that we capture a diverse set of views sourced from different approaches for measuring expertise. Among the interviewees P3, P11, P13, P14, P17, P24, and P29 have experience in crowdsourcing vulnerability discovery. Furthermore, we interviewed a representative of one of the crowdsourcing vulnerability discovery platforms.

Table 3. Information about Interview Participants

P#	Industry	Size of Company (# Employees)	Position
1	Entertainment	450-600	CISO
2	Finance	350-500	CIO
3	Security Consultancy	30-50	Senior Security Consultant
4	Backup solutions	30-50	Quality Assurance manager
5	Networking solution	Global company	Senior Security Analyst
6	Multi-disciplinary	Global company	Security Testing Lead
7	Telecommunication	350-500	Information Security Expert
8	Telecommunication	350-500	Security Analyst
9	Payment systems	100-150	CISO
10	SaaS provider	30-50	Security Team Leader
11	Multi-media	100-150	Platform Security Lead
12	Security Consultation	50-100	Senior Security Engineer
13	Charity Foundation	15-30	Internal Security Assessor
14	Mobile Gaming	10-15	Security Lead
15	Video production	50-100	Principle Security Advisor
16	SaaS provider	100-150	Senior Security Engineer
17	Social Media	50-100	Security Lead
18	Financial Institute	150-250	CIO
19	Security Consultation	25-50	Penetration Testing Lead
20	Security Software	15-30	CTO
21	Medical	250-300	CISO
22	Education	300-500	IT Manager
23	Security Consultation	30-50	Senior Consultant
24	Software Provider	450-500	Security Architect
25	Financial Institute	250-300	Security & System Engineer
26	SaaS provider	250-300	Senior Security Analyst
27	Telecom Equipment	Global Company	Security Evaluation lead
28	Transportation	Global Company	Security Engineering Mngr
29	Bitcoin Exchange	150-200	Product Manager
30	SaaS Provider	25-50	Cyber Security Lead
31	Software Provider	400-450	CSO
32	SaaS Provider	600-700	CTO

II. Online Survey Respondents

We targeted VDPros who have been involved in the task of vulnerability discovery. We also targeted members of crowdsourcing vulnerability discovery platforms (Hackerone, Bugcrowd, and Cobalt), members of online cyber-security community along with relying on snowballing as well. The number of participants was 78 but we excluded 12 responses. In particular, 8 responses were submitted by participants that were not directly involved in vulnerability discovery; we used test questions in the

survey to confirm that. Another 4 responses were apparently artificial, since we noticed that these participants selected the first choice of all the questions, which would otherwise create incorrect inconsistencies in the data.

For the demographics of the participants in the online survey, 45% of the participants were aged 18-25 years old, 30% were aged 25-32, 13% were aged more than 33 years old, and the rest were aged less than 18 years old. With respect to location, the majority of participants were from the United States 37%, 21% were from India, 12% were from Pakistan, 9% were from Europe, 7% from Egypt, and the rest did not share their country of origin. Furthermore, 45% of the participants work in the security industry, 30% were students, 10% work in system administration, and the rest work in software development.

4.5. Data Analysis

We analysed the data following the qualitative data analysis guidelines [12,13]. The following stages were included in the analysis: (i) Transcription of the data recorded; (ii) Organization of the transcripts data and notes taken into easily retrievable sections; (iii) Getting more familiar with the data through reading and re-reading and writing down notes and summaries; (iv) Labelling data segments (we relied on structural coding to annotate the responses[70]); and (v) contrasting different views of the interviewees and re-coding to develop a more refined understanding of how the indicators are valued by the participants. As part of the analysis, similarities and differences of the compiled codes were clustered together in order to create categories. Conceptual saturation was reached when no new categories were generated.

5. Findings

In this section, we address the research questions and present the themes that emerged from our study. We also discuss the findings from the interviews and online survey, and annotate with selected quotes to help appreciate how we derived our conclusions.

5.1. The Interviews of Domain Experts

I. Indicators to the expertise of Vulnerability Discovery Professionals as Perceived by Domain Experts

There are four indicators for expertise that our study participants agreed on: (i) Certification; (ii) Referral; (iii) Performance review; and (iv) Artefacts. Relatively, there is weak support in regard to relying on association (see Fig 3).

Certification as an Indicator to Expertise: 75% of the interviewees value certification as an important indicator of expertise. One of the interviewees described it as a clear indicator to commitment "To get a formal education in the field from an academic body or being certified to have knowledge in the field via acquiring an industrial certification, it shows that the VDPro is passionate and committed enough to invest this much time and effort" [P1]. The remaining 25% of the interviewees did not consider certification as an indicator to expertise for VDPros. One of the interviewees stated that "Some skills required for the VDPro involved in the task of vulnerability discovery are not taught in universities or professional courses" [P19].

Referral as an Indicator to Expertise: Referral is highly valued by 90% of the interviewees since it provides attestation for the expertise of the VDPro from a person who they have known or worked with. One of the interviewees mentioned "Knowing that the person doing the referral has interacted with and observed the VDPro is a great way to measure expertise" [P1]. One of the interviewees indicated that when they trust a person doing the referral it would give very valuable credit to the VDPro especially since roles in the security field are sensitive ones. "Knowing and trusting the person doing the referral would mean minimized risks for us" [P8]. 57% of the interviewees mentioned that even if they do not know the person making the referral, if s/he is well-known in the industry, this would add substantial credit to the VDPro.

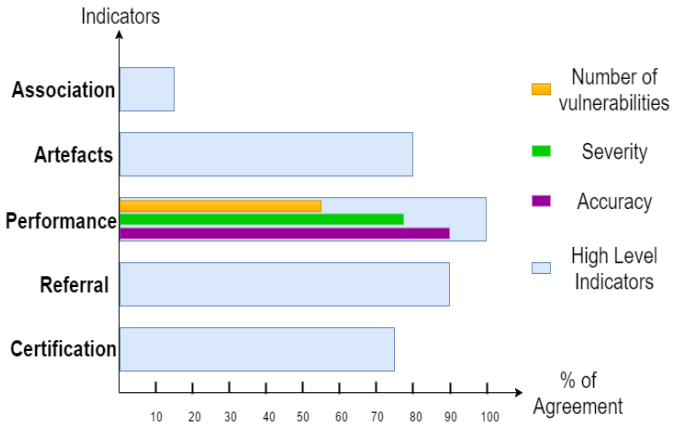

Figure 3. Indicators of Expertise (Domain Experts' Perspective)

Performance Review as an Indicator to Expertise: We found 84% of the interviewees assigned performance review as the top indicator while the remaining 16% considered it of high value. An interviewee stated, "If the VDPro has discovered vulnerabilities successfully many times before then why would s/he stop doing that now?" [P7]. Some considered it of high importance since it means the VDPro have used their knowledge in performing the task. One interviewee said, "Showing knowledge is good, but showing how the knowledge is implemented is more impressive" [P9].

We investigated further and asked about how the performance of VDPros is considered within the task of vulnerability discovery. Several themes have emerged. The first theme is considering the severity of the vulnerabilities discovered. 78% of the interviewees agreed that the severity of the discovered vulnerabilities is the best measure for performance. One of the interviewees mentioned "Discovering a critical vulnerability, that could cause a great loss or embarrassment to the company, is highly appreciated by any company and it means that the VDPro is an expert in what s/he is doing" [P15]. While the remaining 24% of interviewees considered it a good measure. Another theme is considering the number of vulnerabilities discovered by the VDPro. 56% of the interviewees considered it an important measure to performance. While 24% considered it somewhat an important measure. 19% considered it useful only when a good number of vulnerabilities discovered were of high severity. An interviewee has mentioned "If the VDPro has discovered thousands of vulnerabilities that of very low severity for me it does not tell they are good in what they are doing. May be they just have a good automated tool" [P12]. The last theme that has emerged is considering the accuracy in discovering vulnerability (i.e., the ratio of the valid vulnerabilities reported over all the vulnerability reports submitted by the VDPro) as a measure for performance. 90% of the interviewees agreed that accuracy is an important measure for the performance of the

VDPros. One of the interviewees mentioned "That is why we target VDPros with good expertise, we need to minimize the false positives since they consume a lot of resources" [P14].

Artefacts as an Indicator to Expertise: 81% of the interviewees agreed that contributed artefacts are important indicator for expertise. There was a contrast in opinions about the type of artefacts. 40% of the interviewees considered code artefacts and contribution to open-source projects to be the most valuable artefacts. An interviewee stated, "Developing your own testing tools is a clear indicator that you deeply understand the concepts" [P4]. Another 24% of the interviewees considered published articles, and blogging about vulnerabilities as a more important type of artefacts. One of the interviewees said "VDPros are supposed to be good in breaking systems and understanding how they work. I would consider a VDPro with good publications about security as an expert in the field" [P6]. While the opinion of the rest of the interviewees is that it is more effective to look at all artefacts and assess the quality as whole. An interviewee mentioned "Whether it is a publication, source code, or a blog, if I see many experts citing the work or using the open-source tool then it means the VDPro is not generating useless artefacts and that s/he is acknowledged for the contribution" [P4].

Association as an Indicator to Expertise: 84% of the interviewees considered association as a less important indicator of expertise of a VDPro. Sources like membership to a community, affiliation with a group, professional relationships with an expert were considered as indicators of passion and interest rather than expertise. One of the interviewees mentioned "Being affiliated with a group focused on security, indicates passion but not necessarily expertise" [P3]. Another interviewee shared with us "if the VDPro is well connected it could be useful since it indicates that the VDPro could reach out to experts if needed, but I would not say it is a must have" [P6]. The remaining 16% of the interviewees considered it a good indicator to expertise. An interviewee stated, "It is definitely not enough to see the number of connections or followers to determine expertise, but when I see interactions such as a post in LinkedIn being discussed or a tweet being retweeted by experts in the field then it must be that they acknowledge what the VDPro has produced" [P10].

II. Perceived reliable Sources to Extract the Expertise Indicators of Vulnerability Discovery Professionals?

As sources of reliable certifications, 87% of the interviewees valued certification from industrial bodies (e.g., $(ISC)^2$) the highest, followed by certifications from academic bodies (e.g., Universities) which was selected by 72% of the interviewees. On the other hand, accredited MOOCs and online learning were considered good to show eagerness to learn but not as much credible by 75% of the participants in the study.

As sources of referral, all interviewees valued direct referral the most (i.e. a direct form of communication). We asked the interviewees if they would value indirect forms like LinkedIn endorsements or LinkedIn recommendations and 85% of the interviewees did not consider LinkedIn endorsements as reliable. While 62% of the interviewees thought that recommendations in LinkedIn could be useful. One of the interviewees shared with us "People in LinkedIn could just be nice and click 'endorse' for certain skills that appeared under the name of the VDPro, but making some effort and writing some detailed recommendation could be worthwhile to look at" [P4].

For performance review, 75% of the interviewees considered vulnerability databases to be the most reliable source. A vulnerability database is a platform to collect and disseminate information about discovered vulnerabilities (e.g., the National Vulnerability Database). Vulnerability Databases are considered an important source especially since they provide details of the vulnerabilities discovered (e.g., description of the vulnerability discovered, vulnerability severity score, references for security advisories related to the vulnerability). Furthermore, 83% of the participants in the study considered being mentioned in the hall of fame or 'thank-you' pages (e.g., Facebook white hat thanks page) is of high value. An interviewee said, "If the VDPro is mentioned in the hall of fame of Facebook or Google then they pack enough skills to be an expert" [P5]. Also 83% of the interviewees considered the measured performance within the crowdsourcing vulnerability discovery platform as a good source to extract expertise. While the rest agreed that it is a good source only if the crowdsourcing vulnerability discovery platform discloses the details of the discovered vulnerabilities by the VDPros. One of the interviewees stated, "With vulnerability databases, I can have a complete idea about the vulnerability discovered and its impact, but sometimes with the vulnerabilities discovered within a crowdsourcing vulnerability discovery platform we can only see limited information" [P16].

As reliable sources for artefacts, 39% considered GitHub to be the most reliable source. 60% considered security conferences, security forum, and blogs to be the most reliable sources. On another hand, 75% of the interviewees considered Q&A platforms (e.g., Security StackExchange) not very important sources. Additionally, 72% of the interviewees mentioned that they consider publishing exploits for vulnerability as a high-level indicator of expertise. An interviewee mentioned "By showing that you know how to exploit vulnerabilities, you show that you deeply understand how the vulnerability works and what its impact is" [P13].

5.2. The Perspective of Crowdsourcing Vulnerability Discovery Platforms

To gain additional insights into the perspective of the crowdsourcing vulnerability discovery platforms, we interviewed a representative of one of the platforms. The interview allowed us to gain some valuable insights about the programs the platform is managing and the importance of selecting VDPros. The platform's representative mentioned "Almost all of our customers now start with a private program with vetted VDPros before moving to a public program. It's only a small fraction of companies are ready to work with thousands of VDPros". About the effect of selecting VDPros in minimizing the false positives in reported vulnerabilities the platform's representative mentioned, "Public bug bounties is 95% noise and 5% signal. Unless you have a very mature security organization it is not recommended to use public bounties. Private bounties with vetted VDPros are the way to go"

Regarding the indicators of expertise, the platform relies on the past performance, artefacts and will also look at professional social network. It is quoted that: "We rely on past performance in private or public bounties, on our platform or other public bounty programs (Facebook/Google). Also, we check LinkedIn, GitHub profiles as well as conference talks"

When we asked for elaboration about the sources the platform rely on, the platform's representative mentioned: "We look at LinkedIn, GitHub, and Conferences. This is a manual process and it is on a case-by-case basis. E.g. a researcher might have given a

presentation on Blackhat but have no connections on LinkedIn etc. And the other way around".

About certification and whether clients ask for specific requirements, the platforms' representatives mentioned: "We typically don't see requirements like "university degree," but occasionally we will get requests based on geographical region, or professional accreditation (CISSP[11], CISA[12], etc.)".

5.3. The Online Survey of Vulnerability Discovery Professionals

In this section, we briefly discuss the results of the online survey. Figure 4 illustrates the high-level results of the online survey. 60% of the participants agreed that certification is an important indicator, while the rest considered it between somewhat important and useful. We asked about the sources of certification. 62% of the participants thought industrial certification were important, while only 30% considered certification from academic body as important. When we asked the participants about the importance of referral as a practice in the security domain, 72% considered it important while 11% considered it useful and the rest considered it not important. We also asked the participants their opinion about relying on artefacts as indicators to expertise: 83% considered it an important indicator. 74% considered publishing vulnerability exploits as an important indicator to expertise. Followed by, publishing security articles and presentations or videos both at 63%. They considered the least important source of artefacts is answering questions in Q&A platforms (e.g., Security StackExchange) where only 30% considered it "somewhat important". Regarding performance review, all participants considered it very important. 84% of the participants considered the number of vulnerabilities discovered by a VDPro as a very important measure for performance. While 75% considered the severity of vulnerability discovered as an important measure to performance. On the other hand, 56% considered the accuracy in discovering vulnerability as an important measure to performance, 36% considered it useful but not important, and 8% considered it not important. Finally, we asked the participants about how much they value associations and being part of communities or groups as an indicator to expertise. 81% of the participants considered it an important indicator, and the rest considered it somewhat important.

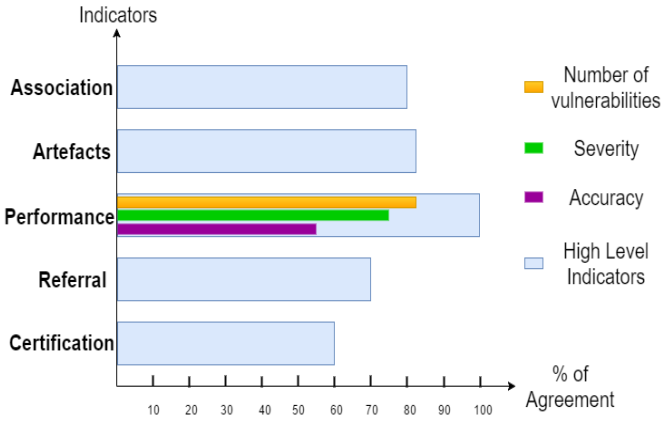

Figure 4. Indicators of Expertise (Vulnerability Discovery Professionals' Perspective)

5.4. Analyzing Public Data about Vulnerability Discovery Professionals

As an additional experiment, we have looked at public information of 100 VDPros from the leader boards (among the top 100 ranked in each platform) of three different crowdsourcing vulnerability discovery platforms: Bugcrowd, Cobalt, and Hackerone. For each VDPro we aggregated additional publicly available data from several external sources (LinkedIn, Twitter, GitHub, StackExchange (SE), blogs, and personal/professional websites). In this section, we discuss the result of the experiment in the light of the indicators we have discovered and illustrate some of the insights we have acquired. As we have relied only on the public data, there are possible threats to validity. The vulnerability discovery professionals could be providing falsified data to the public or hiding some information. We believe that these cases do not have much impact on the analysis; VDPros in the mentioned platforms seek to maintain good reputation to the potential business partners. Additionally, we aggregate the information from multiple sources to minimize this concern.

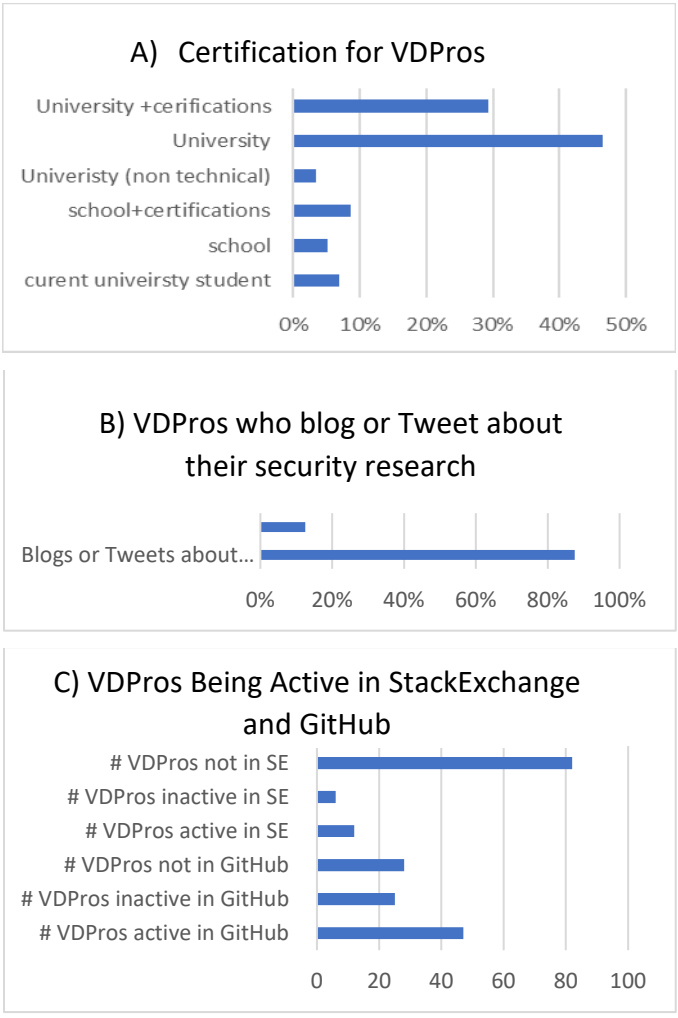

Figure 5. Insights from the public information about Vulnerability Discovery Professionals

[11] www.isc2.org/cissp/default.aspx

[12] http://www.isaca.org/certification/cisa-certified-information-systems-auditor/pages/default.aspx

We have noticed in this analysis of public data, 76% of the VDPros are university graduates of computer and technology fields. In addition (42%) of the VDPros have certifications in the security field (e.g., Certified Ethical hacker). We also noticed that 88% of the VDPros tend to publicly publish information about the vulnerabilities they discover, methods of discovery, and exploitation of vulnerabilities. They rely on their personal blogs or Websites in addition to twitter. For artefacts created in platforms like GitHub or StackExchange, we discovered that 82% of the VDPros have no profiles in this platform or have inactive accounts. While for GitHub, 73% of the VDPros have profiles in Github and 47% are active. Figure 5 illustrates the insights from the public data about the VDPros.

6. Discussion

In this section, we: (i) summarize our findings; (ii) provide some recommendations based on these findings; and (vi) discuss potential limitations of our study.

6.1. Analysis of our Findings

It is clear from our findings that domain experts and VDPros disagree in regard to association being an indicator to expertise. A possible reason is that the cyber security community is a strong community where teaming with other VDPros and pair practice is considered one of the factors to success[13]. So, in the opinion of VDPros, being associated with expert VDPros reflects expertise.

We observed from the results of the interviews that participants in our study valued certification from industrial parties more than from academic bodies. According to the input from the representative of the crowdsourcing vulnerability discovery platform we have interviewed, the platform has received requests to involve VDPros with industrial certifications before, but never a request to specify academic certification. A possible reason for this is that some academic bodies are not progressing as fast as the industrial bodies in the field of information security. One of the interviewees mentioned "some universities are not really up to date with the requirements of the security industry" [P5].

For measuring the performance of VDPros within the task of vulnerability discovery there are contrasting views in the way the number of vulnerabilities and accuracy thereof are valued. A possible reason for this contrast could be that domain experts look at how to utilize the resources to verify and mitigate the vulnerabilities. If VDPros are submitting a high number of vulnerability reports with only few of them being valid vulnerabilities, this defeats one of the purposes in selecting VDPros with the required expertise. On the other hand, VDPros may have the impression that all the vulnerability reports they submit (even if the task requester considered them invalid for being duplicates, or out of scope) illustrate their expertise. The reason for this is because they have already demonstrated what is required to discover the vulnerabilities.

6.2. Recommendations

I. Vulnerability Discovery Professionals Analytics

Information about VDPros are scattered within different sources mentioned earlier (e.g., crowdsourcing vulnerability discovery platforms, professional communities, research articles, social coding platforms, Q&A sites). Therefore, in order to facilitate effective selection of VDPros to perform the task of vulnerability discovery, we recommend leveraging VDPros analytics. Analytics rely on characterizing features, which are variables that grasp and encode information from raw or curated data, thereby enabling to derive meaningful inferences from data. Security expertise features could be extracted from within vulnerability discovery platforms (e.g., number of vulnerabilities discovered in the platform) and external sources (e.g., number of contribution to security related projects in GitHub, number of contributed records in ExploitDB[14]). It is possible to extract security expertise features using crowdsourcing (e.g., crowdsourcing tasks to judge the quality of comments, questions, and answers by VDPro in a security forum like Bugcrowd Forum[15]), as well as automated extraction of security expertise features (e.g., relying on GitHub API calls to extract the number of security related code repositories). Properly leveraged efforts in vulnerability discovery professional and content analytics [73,74] could potentially allow improving the selection of VDPro, ensure compliance with governance rules, and provide insights into the task of crowdsourcing vulnerability discovery (e.g., work effort estimation and time tracking, VDPro interests, or malicious VDPros). In addition, we recommend providing task requesters with a customizable language to specify rules (i.e., selection expressions) based on indicators they deem relevant to include in the selection process, as well as indicator aggregation strategies. As an example, let us assume Organization-A has a business rule stating that when contracting external parties, they prioritize certification from academic bodies. The security officer responsible for the task considers the exploits published in ExploitDB along with the number of repositories in GitHub as indicators to expertise. In this case, the task requester may specify the following rule to acquire a ranked list of VDPros: (Have University degree) AND (Number of records in ExploitDB) AND (Number of repositories in GitHub)). Moreover, we expect new indicators to be incrementally introduced and customized. Security is a complex area and there could be several different types of indicators, from generic to more specific knowledge (e.g., operating systems, databases, devices, browsers, and frameworks). This rule-based language will allow for the specification of fine-grained selection indicators and hence will improve achieving a high probability in matching the task with the VDPro.

II. Harvesting Expertise Indicators Systematically

It is clear from our findings that it is difficult to homogenize the knowledge acquired from different sources (domain experts, VDPros, crowdsourcing vulnerability discovery platforms) in order to determine the indictors to measure expertise in VDPros. We propose to consider techniques that systematically harvest the knowledge from these different perspectives. We believe this could be done by leveraging a knowledge-driven approach to create a security expertise feature graph. We adopt the notion of a feature from the field of machine learning and data science [75]. The security expertise feature graph will serve to store available features for reuse as part of future curation processes. Organizing features into high-level indictors (e.g., certifications, performance review) and low-level features (e.g., security course, number of vulnerabilities discovered) will help simplify their representation,

[13] hackerone.com/blog/what-great-hackers-share

[14] A database of vulnerability exploits (www.exploit-db.com).

[15] forum.bugcrowd.com

and aid searching and using features and indicators. Experts in the security community would be invited to curate this graph by incrementally and collectively: adding new features (e.g., a sub-feature of "artefacts" could be the number of published security articles); vote up/down; or add resources and comments as annotations to these features. Moderators may be assigned to verify amendments to the graph, reject, or accept new features. A similar approach has been proposed by Mark Klien which is a large-scale argumentation system for decision making in large communities [76].

III. Cyber Security Competitions

We observed that there are contrasting views between the opinions of domain experts in industry and VDPros involved in the task of vulnerability discovery. In order to minimize this contrast, we recommend for industrial organizations and crowdsourcing vulnerability discovery platforms to strengthen their ties with VDPros. A possible step to achieve this is to rely on cyber security competitions (e.g., Google capture the flag[16], Cyber Security Challenge Australia[17]) while emphasizing on educating VDPros about important practices that are relevant (e.g., providing high rewards or bonus to the VDPros with higher accuracy, providing higher rewards for high quality vulnerability reports). Similarly, involving universities in these competitions will be more beneficial. This would not only attract perspective students to pursue careers in the security industry and educate them about the rights skills and practices, it would also increase the focus of academic bodies to progress further in the field. Bridging the gap between what students is being offered at universities in the field of cyber security and what the security industry needs.

6.3. Limitations and Threats to Validity

When investigating online content, it is possible to come across material that is biased or inaccurate (since blogs and online articles are not peer reviewed). In order to minimize any bias or inaccuracies, we checked the background of the author to ensure are based on expert opinions. We also excluded articles that are marketing motivated (i.e. promoting or demoting certain technique or approach for personal gain).

For the interviews, the number of participants is not high so it is possible that we missed some insights. We tried to minimize this threat by targeting various industries in order to obtain a broader view of possible opinions. We also considered only one participant from each organization. The strong background we acquired from performing the literature review and online content investigation helped us to formulate clear questions for the interviews and online survey. We observed saturation in the opinions of domain experts, and this indicated we have reached a proper depth to draw solid conclusions.

For the online survey, although we obtained responses from the VDPros, we cannot assume that this number covers all the possible opinions from the security community. One of the authors attended security conferences (e.g., Ruxcon[18], BSides[19]) to discuss with VDPros directly. While some feedback was acquired about the study from VDPros, it was mostly an off-the-record approach. We also reached out to some of the VDPros for clarification of their answers in the survey, and this provided us with some additional insights.

As the questions from the interview and the online survey relied on the results from surveying the literature and online contents, another threat of validity is having the study suffer from confirmatory bias. In order to minimize this threat, we started each interview with the open question of what the interviewees rely on to measure the expertise of VDPros and we also closed the interview with asking if there are any additional indictors we missed. Similarly, for the online survey we deliberately added some open-ended questions to allow the VDPros to add any additional indicators that were not mentioned in the survey. Some VDPros added comments but they fall within the same indicators that we have already included (e.g., publishing exploits, which we already considered part of the artefacts generated by the VDPro).

Another important aspect to consider in the experiment we conducted for analysing public profiles of VDPro is time constrains. As a result, we were only able to look at a limited number of vulnerability discovery professionals; there could thus be insights we did not acquire due to this limitation. We intend to do a large-scale analysis and survey as future work.

7. Conclusion and Future Work

The contribution of this research is threefold: (i) Exploring the indicators to measure expertise of VDPros involved in the crowdsourced task of vulnerability discovery; (ii) Discovering the reliable sources that can be used to extract information about these indicators; and (iii) Recommendations to improve the selection process for VDPros involved in tasks related to discovering vulnerabilities. Our findings will help in the process of selecting VDPros that are more likely to contribute higher quality outcomes in this type of task.

We observed that domain experts and vulnerability discovery professionals, who have participated in our study, agree unanimously on certification, referral, performance review, and artefacts as good indicators to measure expertise in VDPros. There is some conflict about the importance of association as an indicator of expertise. We also observed that the opinions of domain experts and VDPros involved in the task of vulnerability discovery diverge in some areas. Being aware of this divergence is an important step to build a better ecosystem.

This is the first step for investigating the problem of selecting VDPros in Vulnerability Discovery Platforms. As future work, an additional aspect we will pursue is identifying malicious VDPros, and methods to successfully block them from participating in the task. We will develop techniques to model and capture VDPros behaviour patterns and abstract them into meaningful concepts (e.g., honest or malicious). We will investigate indicators and powerful aggregation functions and operators to characterize and identify malicious VDPros.

Acknowledgment

We greatly acknowledge all participants that provided valuable feedback and insight in interviews and online survey. A special appreciation to Jacob Hansen, Jeffrey Stapleton, Troy Hunt,

Coverage Hole

ABSTRACT

Underwater Wireless Sensor Networks (UWSNs) are extensively used to explore the diverse marine environment. Energy efficiency is one of the main concerns regarding performance of UWSNs. In a cooperative wireless sensor network, nodes with no energy are known as coverage holes. These coverage holes are created due to non-uniform energy utilization by the sensor nodes in the network. These coverage holes degrade the performance and reduce the lifetime of UWSNs. In this paper, we present an Intelligent Depth Based Routing (IDBR) scheme which addresses this issue and contributes towards maximization of network lifetime. In our proposed scheme, we allocate initial energy to the sensor nodes according to their usage requirements. This idea is helpful to balance energy consumption amongst the nodes and keep the network functional for a longer time as evidenced by the results provided.

1. Introduction

Underwater wireless sensor networks (UWSNs) have attained much attention nowadays due to their use in monitoring underwater environment. Underwater communication is characterized by larger propagation delay, high error rate and lower bandwidth. Acoustic signals are thus used for communications in underwater environment due to channel characteristics. Furthermore, nodes in UWSNs are powered with batteries that have limited lifetime. It is impractical to change the batteries of the nodes once deployed. The energy of the sensor nodes should be optimally used to avoid coverage holes i.e., nodes with no energy. Due to these reasons, routing in UWSNs is quite challenging and we need to address these issues while developing routing strategies for UWSNs [1].

A number of routing schemes are reported in literature to address the issue of efficient routing in UWSNs. One such protocol is depth based routing (DBR) protocol [2] which uses deployment depth of sensor nodes to determine the route of a data packet from its source node to the sink. Sensor nodes are usually deployed randomly in underwater environment and the sink is placed at the surface of water. Each sensor node is responsible to gather data and then send it to the sink in a cooperative manner. Some sensor nodes are deployed at a higher depth and some at a lower depth hence consituting a sensor network. Nodes with higher depth sense the required information and send it to a node present at lower depth in the form of data packets. Receiver nodes then send these packets to the next node located above. By repeating this process, data packets are passed from the sensor nodes to the sink which is placed at the water surface. It is important to note that nodes which are at a greater distance from the sink, only send their own data packets to low-depth nodes hence they consume lesser amount of energy and remain alive for a longer period of time. Whereas, sensor nodes that are near to the sink have to relay data packets received from deeper nodes in addition to sending their own data packets. So the nodes near the sink consume more energy than other nodes located deeper and thus die earlier. In this way an area with dead nodes i.e., a coverage hole is created in the network and no more data packets can be received at sink.

We propose an intelligent depth based routing (IDBR) protocol that overcomes coverage holes by assigning initial energy to the nodes in proportion to their distance from the sink. This work is an extended version of our previous work [3] in which we used idea of optimal energy assignment for improving lifetime of UWSNs and now we have enhanced this idea to make energy assignment more intelligent.

Rest of the paper is organized as follows. Section 2 gives an overview of the related work. Section 3 provides motivation for

this research problem and we present our proposed protocol IDBR in Section 4. In section 5 performance of the proposed protocol is evaluated using simulations and Section 6 concludes the paper.

2. Literature Review

In this section, we present an overview of some of the protocols that have been reported in the literature to address the issues regarding efficient routing in UWSNs.

A hybrid protocol is presented in [4] to contribute towards balanced energy consumption in UWSNs. This technique is limited to the sparsely deployed networks only. Proposed scheme uses direct as well as hop-by-hop communication modes among sensor nodes during its operation. All nodes in the network are deployed linearly. Authors divide energy of each node into small chunks known as energy grades. When the protocol operation starts, all nodes are communicating in hop-by-hop mode. As nodes closer to the sink bear more data traffic, their energy falls earlier. Remaining energy grades determine the residual energy of a node. When the energy level of a low-depth node falls, it informs high depth sender nodes. Sender nodes then do not send their data packets to that node; instead they send it directly to the sink. This reduces data traffic load on the low-depth node and increases its lifetime. This process continues for all nodes and energy of the whole network is utilized in a balanced way.

Tayyaba et al. present another technique [5] for balanced energy consumption for UWSNs. The protocol is termed as depth based energy balanced hybrid (DB-EBH) protocol. In this protocol, all nodes are provided with equal amount of initial energy and then both direct and hop-by-hop communication modes are used to utilize the node energy in a balanced manner to maximize nodal lifetime. Sensor nodes in [4] are deployed linearly while in [5] these are deployed randomly in underwater environment.

Authors in [6] propose two energy balancing techniques for UWSNs. First technique is named as Efficient and Balanced Energy consumption Technique (EBET). EBET is based on the residual energy level of the nodes but instead of using direct communication mode authors propose route changes to reduce traffic load on receiving nodes. When residual energy level of some receiving node falls, it informs the sending node. Sending node does not send its data packet to that receiving node; instead it looks for some other receiving node with higher residual energy level and sends its data packet to it. In this way data traffic load on the nodes with lower residual energy is decreased and they remain alive for a longer period of time. Other technique called Enhanced Efficient and Balanced Energy consumption Technique (EEBET) uses the concept of depth threshold to enhance significance of the proposed technique.

EEDBR [7] is energy efficient version of DBR in which authors address limitations of DBR by suppressing transmission of extra data packets. Data packets are sent to the low-depth nodes and held for a short period of time called holding time. If the same packet is forwarded to the sink by some other node, its transmission is suppressed otherwise it is forwarded to the sink upon expiration of holding time. EEDBR performs better than DBR in terms of energy efficiency.

Another balanced energy consumption scheme is proposed by the authors in [8]. This protocol is based on optimal distance acquisition to achieve higher energy efficiency in Wireless Sensor Networks (WSNs). Authors in [9] and [10] also contribute towards balanced energy utilization in UWSNs using hybrid technologies with slightly different approaches from each other. H2-DAB [11] meets the challenges of UWSNs by implementing the dynamic addressing scheme among the sensor nodes without requiring the localization information. Another scheme known as RERP2R [12] uses the routing metric based on the physical distances between the sensor nodes and to achieve higher throughput in UWSNs. This protocol also gives the energy efficient solution for data forwarding along with better link quality. QELAR [13] is another routing scheme for UWSNs which strives to achieve longer network lifetime by selecting adequate receiving nodes for sender nodes. PULRP [14] introduces layered architecture and detailed algorithm to improve throughput and achieve energy efficiency in dense underwater conditions. HH-VBF [15] uses the vectors assumptions between the source and the destination nodes and proposes a vector-based algorithm to achieve low end-to-end delay in UWSNs.

3. Motivation

DBR uses deployment depth of the sensor nodes to perform routing operation. This fact makes it a very simple and easy to implement routing protocol. But DBR has a limitation that nodes deployed closer to the sink are out of energy after a short period of operation due to greater traffic load on them. This limitation causes creation of coverage holes in the network and data packets fail to reach the sink despite many alive nodes in the network. Coverge holes disrupt the network operation and available energy of the alive nodes cannot be utilised. Ideally, all nodes of the network should have lifetime closer to each other to avoid this energy-mismatch problem. EEDBR adresses energy wastage problem to some extent by suppressing extra transmissions. In EEDBR, nodes nearer to the sink are allocated with the same amount of energy as all other nodes. Ultimately these nodes die out because of greater load of data traffic. We address these limitations by proposing a more efficient scheme called IDBR which uses intelligent initial energy assignment to avoid coverage holes, improve throughput and prolong lifetime of the network.

4. Proposed Scheme

Energy efficiency is one of the most important issues in UWSNs. In this paper, we present an energy efficient routing protocol for UWSNs.

Figure 1 shows 3-Dimensional view of the network under consideration. It is assumed that nodes are deployed randomly in an area with equal length, width and depth.

In IDBR, we divide network area in three equal regions. Region nearest to the sink is named as R1. Second region is named as R2 at relatively greater distance from the sink compared to R1. Region at the maximum distance from the sink is named as R3. These regions are distinguished with the help of different colours in Figure 1.

Nodes belonging to R1 consume maximum amount of energy as they are responsible to receive and transmit data packets to the sink from all other nodes along with their own data packets. In IDBR, we assign maximum amount of initial energy to the sensor nodes belonging to R1. This assignments reflects the core idea of our scheme i.e allocation of initial energy keeping usage requirements of nodes in view.

Nodes belonging to R2 are assigned with relatively lesser amount of energy because they share lesser traffic load as compared to those nodes present in R1.

R3 nodes are provided with the least amount of initial energy as they have to send their own data packets only and hence utilize least amount of energy.

Total initial energies of IDBR and EEDBR are set be approximately equal to make realistic comparison between protocols. For IDBR, we assume that nodes in each region are one third of the total nodes. Equation (1) is used to realize this supposition:

$$n/3(E_{R1}+ E_{R2}+ E_{R3}) \approx nE_0 \quad (1)$$

Where:

n = Total number of nodes

E_{R1} = Energy of each node in R1 for IDBR

E_{R2} = Energy of each node in R2 for IDBR

E_{R3} = Energy of each node in R3 for IDBR

E_0 = Energy of each node for EEDBR

E_{R1}, E_{R2} and E_{R3} are set in a way that equation (1) is satisfied. This relation ensures that total initial energies assigned to the entire network are approximately equal for both the protocols. The only difference is that; in EEDBR all nodes are assigned equal amount of energy but in IDBR nodes belonging to the different zones carry different initial energies. IDBR operation is summarized as follows:

i. After deployment, all nodes in the network need to know about depth information of each other. This is accomplished through exchange of a hello packet. Hello packet contains depth information of each node. When nodes exchange this packet, they obtain the depth information of each other. This step is repeated before each round of data transmission.

ii. Nodes that lie within the transmission range of a particular node, are known as neighbour nodes of that node. Each node in the network identifies its neighbor nodes when a hello packet is exchanged.

iii. A node which has a sensed data packet to send is known as a sender node. All sender nodes compare their own depth with the depth of their neighbor nodes. Sender node passes its data packet to a neighbor node for which two conditions demonstrated by inequalities (a) and (b) are satisfied. Neighbour node to whom the data packet is sent, is called receiver node.

$$d_r < d_s \quad (a)$$

$$d_s - d_r > d_{th} \quad (b)$$

where:

d_s = Depth of sender node

d_r = Depth of reciever node

d_{th} = Depth threshold

Inequalities (a) ensures that reciever node is a low-depth node so the data packet is being fowarded upwards i.e., towards the sink. While inequality (b) ensures that the distance between sender and reciever nodes is less than the depth threshold. Depth threshold is the minimum distance to which a node is allowed to send a data packet. Depth threshold makes sure that sender and reciever nodes are not too close. This idea avoids too many hops during the routing action of a data packet.

iv. Receiver nodes now become sender nodes for their low-depth neighbors. Steps (ii) and (iii) are repeated until data packets are passed to the sink.

5. Results and Discussion

In this section, performance of proposed scheme IBDR is evaluated using simulations. Performance of IDBR is compared with that of EEDBR. Simulations are carried out using MATLAB. Length, width and depth of the network under consideration are set to be 150 meters each. Transmission range and depth thresholds are taken as 50 and 25meters respectively. 100 nodes are deployed in the network and simulations are run for 18000 rounds of data transmission.

Network Lifetime

Network lifetime is defined as the time period from initialization of the network operation till death of the last node. In simulations, number of data transmission rounds determine network lifetime. More rounds of data transmission mean longer lifetime and vice versa. Number of alive nodes after each round for IDBR and EEDBR is shown in Figure 2.

It is clear from the graph that number of alive nodes in EEDBR drop to zero when around 11000 data transmission rounds are run. Whereas, in IDBR almost 30% nodes are alive after 18000 data transmission rounds. This makes a huge difference between lifetimes of our proposed protocol IDBR and EEDBR. It is thus confirmed that intelligent assignment of initial energy to the nodes in IDBR increases operational lifetime of the network significantly as compared to that of EEDBR scheme.

Throughput

Data packets received at sink in unit time define throughput of a routing scheme. Comparison of data packets received after each round in IDBR and EEDBR is shown in Figure 3.

Figure 3 shows that throughput of IDBR is much better than that of EEDBR. In EEDBR number of received data packets falls drastically and no more packets are being received after 11000 data transmission rounds. While in IDBR, number of ecieved packets decreases rather smoothly and data packets are being received till the last round.

Data packets dropped after each round for both the protocols are compared in Figure 4. Number of packets dropped in EEDBR increases rapidly and finally drops to zero near 11000 rounds because at this stage no alive nodes are present in the network and no more data transmission is occurring. In IDBR, lesser data packets are being dropped than those of EEDBR. But more data packets are being dropped in IDBR during last rounds. The reason lies in the fact that more number of nodes in IDBR die with the passage of time.

Energy Consumption

One of the most important parameters to be considered in UWSNs is consumption of energy. Figure 5 shows comparison of transmission losses of IDBR and EEDBR.

Figure 5 shows that transmission loss in EEDBR is much greater than that of IDBR. Transmission loss of IDBR is almost constant during initial rounds but goes decreasing in last rounds because sensor nodes go on dying as the time passes. Transmission loss of EEDBR is much higher in the later rounds.

This comparison justifies the efficiency of IDBR in term of energy usage. Lesser and uniform energy consumption makes IDBR a much better routing protocol for UWSNs than EEDBR.

6. Conclusion

The paper compares the proposed protocol IDBR and EEDBR and shows significant improvement in lifetime, throughput and energy consumption of UWSNs. The intelligent assignment of initial energy to the sensor nodes enables us to distribute energy to the nodes according to their communications utilization. This idea improves the performance of depth based routing protocols for UWSNs and requires energy estimation of sensor nodes for realistic initial energy assignments.

ABSTRACT

Described herein is a general-purpose software engineering architecture for autonomous, computer controlled opponent implementation in modern maneuver warfare simulation and training. The implementation has been developed, refined, and tested in the user crucible for several years. The approach represents a hybrid application of various well-known AI techniques, including domain modeling, agent modeling, and object-oriented programming. Inspired by computer chess approaches, the methodology combines this theoretical foundation with a hybrid and scalable portfolio of additional techniques. The result remains simple enough to be maintainable, comprehensible for the code writers as well as the end-users, and robust enough to handle a wide spectrum of possible mission scenarios and circumstances without modification.

1. Introduction

"There is no substitute for a human opponent." — Vincent "T.J." Taijeron, USMA Warfighting Simulation Center, West Point, NY. When one is lacking, however, we attempt to offer a usable substitute. In this paper, we describe an architecture and a methodology for software engineering a Computer Opponent Artificial Intelligence (COAI) for professional military training. Such an architecture ideally should meet the design goals of being frugal and efficient in code, easily maintainable, and produce an acceptable level of realism and flexibility for military training personnel and administrators. A truly low-overhead and low-impact solution to the vexing "AI" problem for professional military training at echelons below division and corps level. At the current time, a paucity of software exists, either commercial off-the-shelf computer games or DoD produced and acquired software, for low-cost training in this regard [1].

1.1. Background

Army simulation training has typically used extremely complex, sophisticated, and costly software that necessitates set-up time and planning, large staffs, large budgets, training, and Herculean scenario design efforts. Recently, there has been a shifting of emphasis to what is called low-overhead/low-impact computerized training that lower-level echelons, which traditionally did not have access to large-scale simulation support, can utilize effectively and efficiently. The offerings in this area are slim, and typically commercial computer wargames are wholly inadequate for many reasons. In particular, realistic and useful computer opponent "AI's" are virtually completely lacking. Tasking organization staff to "play the part" of opposing forces is a plausible solution, but necessarily involves a huge commitment of resources when theoretically the CPU can be doing the same thing at little to no cost. Architecting and implementing a targeted solution to the "AI" problem at the appropriate level of simulation and modeling fidelity has been a persistent issue for more than a decade [2,3].

1.2. Current Practice

Large-scale simulation exercises are frequently conducted at the higher levels of the Army command structure. These include division, corps, and army echelon levels. Lower-level training has largely been restricted to manual map exercises, or expensive field training and wargames [4]. Software tools at the company, battalion, and brigade training levels have been sparse. One frequently utilized piece of software is the VBS simulation, which

*Corresponding Author: Michael Pelosi, Professor, East Central University, 1100 E 14th St, Ada, OK 74820, USA | Email: michael@mauisolarsoftware.com

is commercially marketed as "Arma". This is a first-person shooter type game that has been utilized for squad and platoon level infantry type training. However, at the next higher echelons software training tools are virtually nonexistent. Even the widely utilized VBS platform has a woefully inadequate AI — routinely cooks and mechanics are tasked to drive trucks, fly planes and helicopters, and play civilians, as part of the simulation exercise.

1.3. Envisioning the Solution

How can the computer opponent AI problem be solved? Several AI approaches are possible. Hierarchical Task Network planning could be utilized. Unfortunately, HTN planning would typically result in one monolithic game-play solution largely predictable between sessions. Expert systems are possible, but structuring the implementation and gathering expert responses to all possible inputs is difficult and time consuming. Computer chess type solutions offer great promise, but it took over 50 years to get a computer to play a good enough chess to beat the best human players.

1.4. The Computer Chess Analogy

Despite 50 years of advancements in computer technology, computer chess AI still relies on a largely brute force approach. Using the Min-Max algorithm, transposition tables, and other optimizations, the chess AI scans through the game tree, analyzing millions of potential moves, before producing the highest scored next move [5,6]. Thankfully for chess, there are only 64 squares and a maximum of 32 pieces. In a professional military simulation, a map may consist of millions of individual 100-meter sized grid squares, thousands of units, and a completely unpredictable terrain and mission. In other words, searching through the game tree of all possible actions is tens of magnitudes more difficult. The chess modeling approach is not scalable, not nearly so. The chess analogy AI cannot be made to fit, yet we can adopt some of the lessons learned from computer chess. This includes dividing the session into phases: opening, middle-game, and endgame. Scoring the value of different pieces (maneuver unit groups), and evaluating final desired states, and how to get there, have proven to be extremely useful concepts.

1.5. A Scalable Hybrid Approach

The approach we have implemented and described in this paper could be considered as a hybrid AI approach. Relying on the chess analogy and metaphor, particularly the game phase concept, we add on an expert system that models and abstracts the actual units in decision-making processes wherever possible. For example, the AI groups subunits into their actual mission structure, including companies and battalions. These are controlled as in the military force structure chain of command. For the creation of plans, it is possible to adopt the actual military staff procedure and adapt this into a software planning sequence. Further, lower-level planning details such as route determination can be supplemented by the ubiquitous A* Algorithm. Through trial and error over a development lifecycle of several years, and through feedback from professional users, we have cobbled together a hybrid approach that is efficient, robust, and easily implemented. Flexibility for future features and maintainability has been realized.

1.6. Presentation Goals

Our goals in this presentation are to describe to the simulation community, and perhaps computer gaming community, the derived computer opponent AI architecture. More than 10 years of effort have been devoted to its creation. Much of this time was spent ruminating on the final ideal implementation — a big part of the solution was multiple layers of modeling abstraction. Isolation between the layers was and is also extremely important for comprehension and maintainability. Further, and to a large degree, the AI layers actually model in parallel the military command echelons.

1.7. Engineering the New Approach

There are individuals who spend vast portions of their waking hours operating and contending with AI code in simulations and games. We have been careful to consider their recommendations and concerns in engineering an appropriate and efficient AI system for land warfare simulation. One of the quotes that comes to mind is the following: "The AI must perform the mission, the AI must be a good soldier not a general." In other words, unexpected or completely unpredictable behavior is out of the question. This is both for realism and utility. If the trainee utilizing the AI cannot understand what it is doing it may be time wasted. In addition, the scenario designer may want to script certain actions to instruct certain doctrinal principles. Thus, scripting of the AI should also make it possible to funnel behavior into a certain group of possible actions. At the same time, the AI cannot be overly complex: "…and one turn requires 15 minutes of preparation and then crashes! Good job!" Clearly there is a trade-off between complexity and robustness.

2. Methodology

A realistic AI useful for professional training purposes should both model and mimic the military decision-making process at various echelons. In that light, as a robust foundation the AI goes straight to the U.S. Army field manuals for guidance. Fortuitously, more than 100 years of modern warfighting experience has distilled down Army planning doctrine to a few formulaic processes in the Military Decision-Making Procedures (MDMP). These include TLP, METT-TC, and OCOKA. These processes can and have been modeled almost directly in code.

2.1. Military Decision-Making Procedures

U.S. Army Field Manual 101–5, Staff Organization and Operations, explains in detail the Army MDMP (U.S. Army 1997). "The MDMP is an adaptation of the Army's analytical approach to problem solving. The MDMP is a tool that assists commanders and staff in developing estimates and plans. The full MDMP is a detailed, deliberate, sequential, and staff-intensive process used when adequate planning time and sufficient staff support are available to thoroughly examine numerous friendly and enemy courses of action (COAs). This staff effort has one objective—to collectively integrate information with sound doctrine and technical competence to assist the commander (in our case the COAI "commander") in decisions, leading ultimately to effective plans. The analytical aspects of the MDMP continues at all levels during operations."

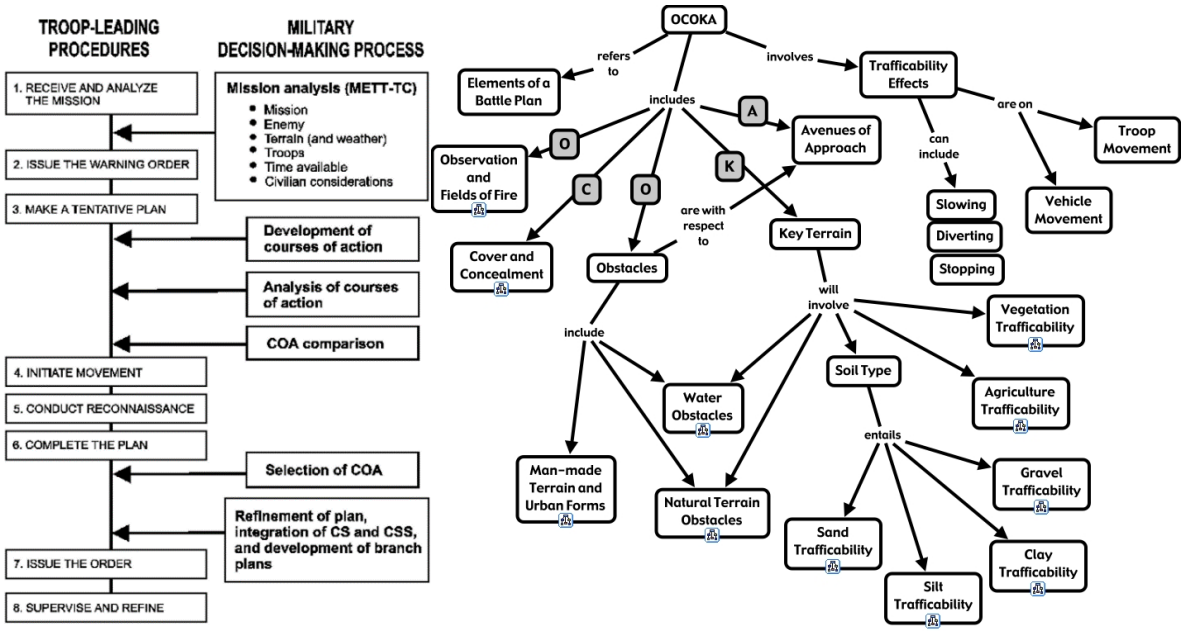

Figure 1: TLP, MDMP, METT-TC, and OCOKA Depictions [7]

2.1.1. *Military Missions and Objectives*

The COAI is presented a military mission that is contained within scenario and AI option specification files. The files include information on task organization, friendly forces, and a timeline. Objectives are also specified with points values for various objective type such as occupying a location, clearing an area of enemy forces, moving friendly forces past a certain demarcation zone, or searching for a hidden target.

2.1.2. *Military Decision Making Procedures*

Where possible the military decision-making process (MDMP) is then followed both in modeling and implementation. The COAI is designed to follow a similar process to what is recommended doctrine in the Army field manuals. Likewise, parallel modeling and decision-making takes place at each of the important unit echelon levels: platoon, company, battalion or task-force, and support. The following further outlines MDMP aspects:

TLP (*T*roop *L*eading *P*rocedures) consist of the following steps: 1. receive the mission and conduct METT-TC and OCOKA, 2. prepare for the mission and issue preliminary orders, 3. make a tentative plan: identify goals, gather information, generate/analyze/compare possible solutions, and implement the best tentative plan, 4. start movement, 5. conduct reconnaissance, and 6. follow through with execution of the final plan.

METT-TC is: *M*ission analysis, *E*nemy analysis, *T*errain analysis, *T*roops analysis, *T*ime limit analysis, *C*ivilian impact analysis. *OCOKA* is conducted as part of terrain analysis.

OCOKA stands for *O*bservation and fields of fire, *C*over and concealment, *O*bstacles, *K*ey terrain, and *A*venues of approach. This constitutes a more detailed terrain analysis. Obstacles can include man-made and urban terrain obstacles, natural terrain obstacles, and water obstacles. Key terrain may involve, for example, high elevation or easily traversed terrain near objectives. Avenues of approach include roads and otherwise clear areas. Trafficability can be evaluated both for vehicle and troop movement regarding slowing, diverting, or stopping movement.

2.1.3. *Course of Action Adoption*

The Course of Action (COA) for the COAI that is produced is a result of the analysis of the above factors and constraints. Reducing all considerations to a quantitative scoring allows a brute force solution, that randomly generates various plans and each plan can be scored for its suitability and feasibility. The highest scoring feasible plan is selected as the best COA. Since plans are randomly generated, differing and unique plans are generated during each new instance of the same scenario mission design. This is important for replay value.

Execution requires close supervision and monitoring, as well as continuous analysis, the updating of intelligence, and refinement of the COA plan. In certain cases, the plan must be discarded and regenerated completely.

The COAI has certain unit groups assigned to it in the scenario and mission design. This allows the possibility of multiple instances of the AI, each controlling its own respective force grouping. Likewise, human participants would each be controlling various force groupings.

2.2. *Mission Analysis*

Scenario design inputs to the COAI for information analysis include: time limit constraints, enemy OOB, friendly OOB, quantified scenario objectives, along with AI options and settings. Five major phases are accomplished during a preliminary mission analysis:

1. Analysis and calculation of the goal state to satisfy objectives. Often this will involve the ideal placement of forces by the scenario end time, such as the occupation of objective locations.
2. Analysis and calculation of known enemy dispositions and force allocations. Here relative points values are calculated

relying on "combat power" summations for known enemy unit types in a catalog database of unit types. Friendly unit group combat power totals are likewise analyzed to create favorable force match ups. In general, a ≥ 3:1 points total advantage will be necessary for successfully taking the occupation of locational objective from a defender [8].

3. Analysis and calculation of a tentative plan to reach the goal end state. This is accomplished by using a brute force approach like the solving of the Traveling Sales Person problem [9]. Several thousand likely plans are randomly generated and scored. Top scoring plans are then further evaluated and selected.
4. Surplus time and resources are evaluated. If the plan can be accomplished before the scenario mission end time, further refinements and optimizations can be preliminarily executed. This can include actions such as further intelligence gathering and reconnaissance, softening up of target locations through preliminary bombardments and airstrikes, and conducting feign attacks or deep pincer movements.
5. Finally, initial tentative movements and actions for the first game phase are calculated, however these may change when the final COA is adopted.

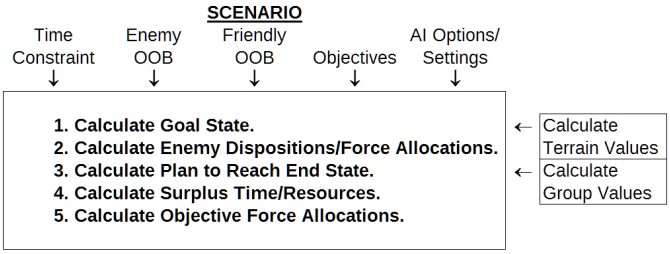

Figure 2: Scenario and Mission Specifications and Analysis.

2.2.1. *Discrete Mapping Zones*

As part of the mission analysis and execution, map zones are segmented and demarcated. Map zones are segmented based on the center mass coordinates of friendly forces, and known or likely center mass coordinates of enemy forces. With these two points fixed in space, a relative "mapping" of center, left and right flanks, and depth can take place. If portions of these areas are off the given terrain area, they are ignored and become notional. Areas which are untrafficable (for vehicular and/or foot units respectively) are also ignored for deployment or movements. The point halfway between friendly center mass and enemy center mass becomes the Forward Edge of the Battle Area (FEBA) anchor. Ten discrete zones are then demarcated from this mapping: forward screen left, left, center, right, screen right, and corresponding rear areas respectively. Reconnaissance missions will be routed into the far side of the FEBA, and missions will be allocated to specific zones. Combat group deployments take place generally in the left, center, and right, with screening units assigned to screen left and screen right areas. Supporting units, including headquarters, artillery, and logistics, are routed toward the rear areas. Spacing between units is calculated by the frontage span of the respective maps zone. Reserves are held in the rear area as well. Thus, any map size from 5 km × 5 km up to 500 km × 500 km can be automatically mapped into a convenient "scenario" mission and planning space, based on the map size, force size, and initial deployments.

2.2.2. *Map and Terrain Analysis and Updating*

As part of the mission analysis, a detailed terrain analysis is conducted and the results are stored in a map database of grid squares. Each map grid square is assigned a weighted and then normalized score value for specific characteristics. These include the following:

Map static terrain analyses:

- *Objectives* – value and proximity to objective locations.
- *Water* – water obstructions to ground movement — note this may have an important lack of effect on the many amphibious vehicles in operation.
- *Elevations* – in many circumstances higher elevation locations are more valuable to occupy.
- *Grades* – steep uphill and downhill grade serve as detriments to mobility.
- *LOS* – line-of-sight to nearby grid squares; some locations can observe much more of the surrounding terrain.
- *Blocks* – blocks can include highly dense vegetation, urban locations, as well as man-made obstacles.
- *Cover* – cover provides shelter from blast effects and observation.
- *Avenues* – key avenues for movement, central locations networks to objectives are preferred.
- *Concealment* – concealment has low line of sight visibility as well as good cover.
- *Defense* – combination of effects from above for defensibility.
- *Survivability* – cover, concealment, and defensibility modified for survivability aspects.
- *Ambush* – areas with good visibility/survivability, nearby to key avenues of movement.
- *Counter mobility* – places where the enemy's movement can be stopped efficiently.

Map dynamically updated analyses:

- *Valuable Areas* – avenues, high elevations, nearby to objectives, etc.
- *Friendly Proximity* – weighted/normalized value for staying close to friendly concentrations.
- *Enemy Proximity* – weighted/normalized value for known/updated enemy concentrations.

The COAI user interface produces shaded map graphics depicting weighted and normalized values for each of the terrain analyses based on grid square location. The last three terrain analyses are dynamically updated as the simulation progresses, and reflect new and current information.

2.2.3. *Order of Battle (OOB) Analysis*

Because of the COAI not considering individual unit entities at the lowest level (platoon and section sized entities), the COAI is only aware of the unit groupings, relative combat power, and the group types. Using these characteristics, Order of Battle (OOB) analysis can assign various groups to specific objective missions. For example, an armor company may only constitute 14 tanks but have triple the combat power of a 90-soldier infantry company. The combat power is based on points totals from the unit catalogs. As part of the COA production, the COAI analyzes the most

optimal assignment of groups to objectives using its limited knowledge. With regards to enemy forces — given adequate knowledge, OOB analysis will endeavor to produce adequate match ups, specifically the greater than 3 to 1 advantage of an attacker over a defender in terms of combat power.

2.2.4. Spot Table and Updates

The COAI must keep track of known and likely enemy force locations. Initially, the training scenario designer can choose to reveal as much or as little about enemy force locations as desired. This can be loaded into an initial enemy spot table at scenario start, and be used for COAI planning. After that the COAI is on its own gleaning, updating, and aging information as it comes in. It keeps track of this in a dynamic spot table that contains coordinates, unit type and points value, and most recent spot time. As spots are aged they are reduced in weighting importance for relevance and accuracy. The simulation produces a listing of current force enemy spots and hands it off to the COAI, which collates and posts the information in the spot table.

2.2.5. Force Allocations

As previously mentioned, planning the force allocations of groups to objectives involves a brute force planning approach. For each of several thousand plan iterations, groups are randomly assigned to objectives. Then, based on the group data, objective data, and enemy locations, a special function calculates the feasibility of each allocation. Time to reach the objective, attack or defense ratio, and other factors, can cull out infeasible assignments. Of the remaining feasible plans, these are scored based on minimum cost in terms of movement time, and attractiveness of force match ups (desired minimum 3:1 on offense) and other factors. A final "minimum time to complete the plan" duration is calculated, and from this any surplus time available for further measures, such as reconnaissance or softening up of targets, is then known. Force allocation intrinsically calculates the end game phase plan. Since each scenario objective is assigned a relative points value, scoring of plans takes into consideration the satisfaction of more valuable objectives, as well as the distance from each respective group to its assigned objective. For further information on brute force planning using this approach, traveling salesperson solutions are a good starting point [9].

2.2.6. Course of Action Decisions, Types, and "Playbooks"

Once final endgame force allocations have been favorably calculated, if sufficient surplus time and resources exist, a middle game "playbook" COA can be adopted by the COAI to further shift the favorable odds preliminary to the endgame phase. In the case of a defensive posture this can include securing objectives, static defense, or in-depth defense [10]. For attack postures, broad front attacks, counterattacks, or deep attack "playbooks" can be adopted. A reserve force can possibly be selected. The playbook selected is not optimal, but suitable for the given situation and circumstances. This is analogous to the football play: a running play may not be any better than a deep pass, but it keeps the other team guessing. Seemingly random intelligent plans and actions in terms of time and execution are an important part of a realistic and engaging COAI with suitable replay value.

2.3. Major "Game" Execution Phases

Once the COA has been finalized execution will be transitioned through a series of major game phases, relying on the chess motif. These include the opening, middle-game, and endgame. Assuming little slack time exists for achieving the mission objectives — the execution phase will be shifted immediately to "endgame". Endgame can be considered the all-out effort to achieve the objectives immediately. Otherwise, if slack time exists, perhaps an opening and middle-game phase will be adopted as part of the execution.

2.3.1. The OODA Loop: Observe, Orient, Decide, and Act

The execution phases are analogous to the very important military precept of the OODA loop [11]. The opening is comparable to the *O*bserving phase. Here, advantages are to be acquired in terms of additional intelligence and other measures, such as occupation of key terrain. Middle game is analogous to *O*rienting — the major reorienting of friendly forces to further tip the balance for further movements and attacks. Endgame is the *D*ecide and *A*ct portion, where commitment to a decisive outcome is adopted. Final actions are wagered here. Replanning is necessitated between the opening phase and the middle-game phase, as well as between the middle-game and endgame phase.

2.3.2. Execution Phase Transitions

Transitions between the major game phases are based on the characteristics of what should be taking place generally in each phase — once again relying on the chess metaphor. The opening takes place between the scenario start and first enemy contact, first weapons fire, and/or first friendly casualties. The endgame is transitioned to after the middle-game when the previously calculated time deadline for accomplishing the mission objectives is reached. This also includes a time safety factor built-in. In other words, final execution is committed to when there is still enough time to safely accomplish the objectives. That said, to preserve verisimilitude, there exists the possibility of a "lightning battle" COA adoption where the COAI will skip the opening and/or middle-game phases and progress directly to an endgame phase. This is analogous to a surprise execution, which forces the training audience to consider all possibilities. Skipping phases is easily incorporated into the COAI options as probability factors for skipping middle game, and skipping opening and middle-game. At the juncture of each major game phase, replanning takes place based on the phase goals described further below.

2.3.3. The Opening Phase

The opening phase is largely characterized by observing the enemy's respective force deployments and dispositions. Goals here include grouping and further deploying friendly forces, exploiting terrain based on mission analysis terrain calculations, reconnaissance missions are executed, counter reconnaissance missions are executed, and the seizing of easy objectives closer than the enemy which may not be occupied.

2.3.4. The Middle-Game Phase

The middle-game is characterized by major force movements to orient deployment for final attacks and/or defense. Seizing of key intermediate terrain is conducted. Harassment missions are

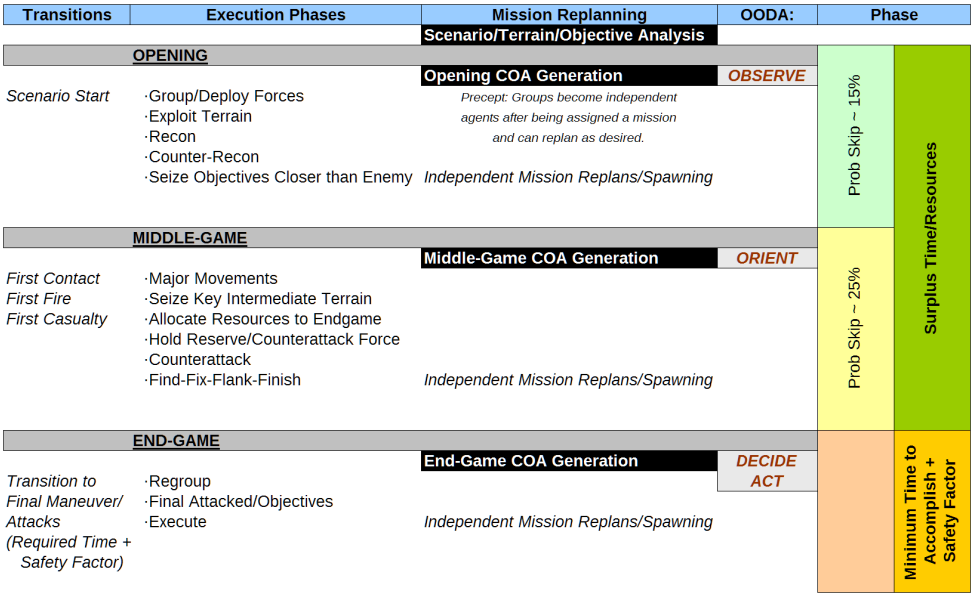

Figure 3. COAI Execution Phases, and major aspects of each phase.

perhaps selected, these would include randomized probes or artillery fire missions. Allocation of resources to the endgame is recalculated. Further, most COAs will hold a major reserve and/or counterattack force for unforeseen events. Counterattacks can also take place. Attacks use as a basis the "4F's" for planning and execution: *find – fix – flank – finish* [6].

2.3.5. The End Game Phase

The endgame embarks on achieving the final scenario objectives. Thus, a regrouping of scattered forces may be necessary for the execution of the final plan. Final attacks are enacted, if necessary, and objectives are occupied. The plan is irretrievably executed at this point — for either final success or failure. Ideally, the opening and middle-game phases have set up the COAI for uncontested victory at this point through incremental and methodical gaining of advantage. As mentioned, the endgame is analogous to the Decide and Act portions of the OODA loop, and opening and middle-game phases only take place if surplus time and resources exist for the satisfaction of the mission goals. Otherwise, the COAI would need to embark on an endgame plan immediately at the scenario start.

2.4. Modeling Layer Architecture

Analogous to the OSI model [12] for computer networking (and its inherent division of responsibilities and functionality), there are at least six layers and levels of modeling that are used in the COAI architecture. Most of these parallel a corresponding layer in the military decision-making process and unit echelon structure, in real world military forces. This leverages the concept of object modeling for real-world abstractions, as well as organizes and simplifies the architecture software code. At the lowest level are the simulation entities, nominally platoon down to section sized organic units. The simulation in usage models each of these uniquely as a C++ class entity. Typically, these are grouped into company to battalion sized units, each consisting of 4 to 10 subunits. It is these groups that constitute the "unit groups" that are under direct control of a scripting engine layer. The scripting engine layer is responsible for issuing the entire group order directives discussed in more detail below. Above the scripting layer is mission control, more directly controlled by the COAI. Once the group has been assigned to a mission, the mission instance is responsible for autonomous control over the group through the scripting engine. Mission sequences, are in turn controlled by the overall COA class plan that is being implemented. And finally, the *COA class* is planned in response to the overall scenario objectives, available resources, game phase, terrain map, and options.

Table 1: Modeling Layers of Abstraction, Planning, and Control.

1.	Execution Phase: Open, Middle, Endgame → Determines strategic approach/goals.
2.	Course of Action (COA) → Self-contained master plan for phase, controls Layer 3.
3.	AI Mission Sequence Collection → Insertion, deletion, reordering possible.
4.	AI Independent Mission Control Agent → An autonomous OOP class, with reports.
5.	Group Scripting Engine → Programmed Sequences of Events/Actions/Responses.
6.	Unit Entity Grouping → Company/Battalion/Task Force, abstracts Layer 7.
7.	Simulation Entity → Platoon/Section/Section/Battery/Vehicle. Hi-fidelity modeling.

2.4.1. Section-to-Platoon-Sized Entities

Section to platoon entities are the lowest level of fidelity in the simulation in usage. The COAI does not control this echelon directly. The group and scripting engine issues direct orders and

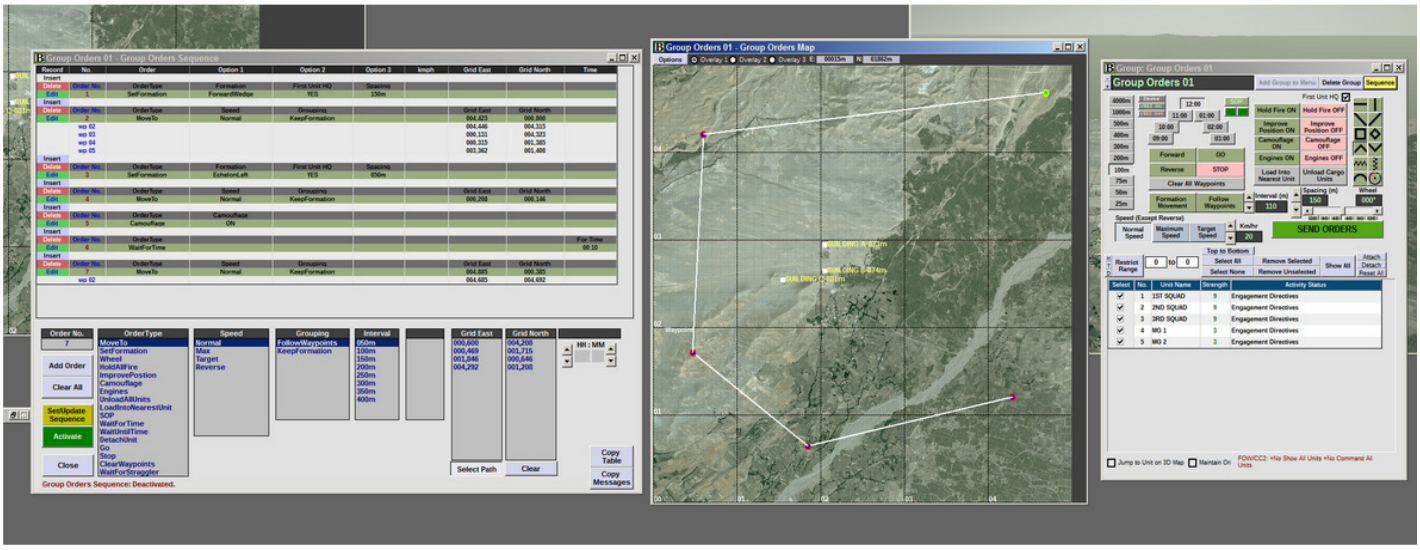

Figure 4: Group Orders Scripting User Interface, which allows the inputting of sequences of orders.

commands to entities at this level. In summary, sections and platoons are characterized by locations, ammunition and fuel levels, strengths and casualty levels, current orders and status, among other data in a cornucopia of minutiae. Accurately modeling this spectrum of characteristics is an extremely labor-intensive task, that requires copious research and data entry. Accounting for hundreds of data items into COAI considerations is architecturally untenable, hence the abstraction to larger unit groupings is necessary to accomplish the goal of a robust and usable AI with a frugal amount of code. Codewise, these entities are modeled as classes.

2.4.2. Unit Groups

Scenario design creates company and task force level unit groupings that normally model individual combat companies or battalions, artillery batteries, helicopter flights, and other unit groupings that would normally be controlled by a battalion or brigade level task force organization. Unit groups are modeled as a class and are the owner of combinations of the platoon and lower level entity grouping.

2.4.3. Group Orders, SOPs, and Formations

Group orders and tasks are relatively straightforward and implemented easily by the controlling mission class. The controlling mission class merely instructs the scripting engine to calculate and implement the command order. Group orders contain such simplistic directives as: move *n* meters, change facing, set speed, dismount infantry, improve position, camouflage, discharge smoke, or set formation. Set formation automatically orients the group in, among others, line, column, box, diamond, forward wage, reverse wedge, and echelon formations. Company and battalion sized formations will typically orient themselves in one of the aforementioned formations to advantageously engage likely targets. The scripting engine handles the details, while the COAI concentrates on decision making at the next echelon above. Lower level units are responsible for handling their own engagement of targets of opportunity. Standard operating procedure (SOP) allows independent decision-making for units in regards to firing smoke or vehicle engine exhaust smoke systems for defense, reversing on enemy sightings, or aggressively attacking new contacts.

2.4.4. Group Scripting

Group order scripting consists of a collection of sequential orders. As mentioned earlier, movements, formation changes, camouflage orders, orders to "dig-in", etc., can be added to a scripting sequence. The scripting engine automatically executes the orders serially until completion. The COAI process communicates into the simulation the desired scripting sequence and parameters through active mission classes. The user interface of the group orders scripting window is shown below in Figure 4. Scripting can be manually controlled as desired, and saved to file.

2.4.5. COAI Control

The COAI enters a control main loop after completing the mission analysis and creating a preliminary COA. Each time the loop executes, more information is extracted from the simulation, this is processed, and the COAI may modify directives or give additional orders to the group scripting engine. Groups with scripting orders pending can have those sequences cleared if necessary. The main loop continues until the scenario end time is reached and objective condition scores calculated.

2.4.6. Course of Action (COA) Modeling

COAs are modeled as a class and store their own data and update themselves inherently. Additionally, given certain circumstances they are capable of canceling themselves which will necessitate and involve an automatic regeneration of a COA. This can optionally be done at random, or in the case of catastrophic goal failure. COAs contain enough information to be considered a high-level plan, with very little implementation details.

2.5. Mission Types

In satisfaction of the current COA, unit groups are assigned sequences of missions that fall into various categories. Each of the

missions is defined in a C++ class, and the sequences of missions are collections of missions. The unit group conducts the next mission listed in its respectively assigned mission collection, until each one is completed. If necessary, a new mission can be spawned and inserted at the top of the collection, at which time the unit grouping will embark on the new mission, and resume the second mission once the newly spawned mission has been completed. For example, a grouping on a movement mission toward an objective can be assigned a newly spawned mission to attack a target of opportunity. Once this attack mission has been completed, the movement toward the objective mission will be resumed. Further, since missions are modeled as autonomous agents, they can spawn their own new missions as necessary which may supersede the current mission. The hierarchical breakdown of various COAI mission classes developed totals over 40 at the present time.

2.5.1. *Mission Agents (as Self-Planning, Autonomous, Self-Updating, and Reporting OOP Classes)*

As mentioned, missions are modeled as classes and have a decoupled implementation. Each mission has a pair of classes closely related: a planner class and an implementer class. The planner class plans the mission and hands over the implementation details to the implementer class. If the implementer class runs into problems, it will call the planner class to once again reinitialize and replan the mission. Once a mission is spawned, it is initialized with several goal variables and the mission class code itself calculates how to correctly carry out the mission. During each iteration update (periodically calculated based on an AI update time step), the mission updates itself and commands to the mission unit grouping as necessary. Upon mission completion, the mission class instance is removed from the mission sequence collection and ceases to exist. Some of the major mission taxonomy types, which rely on C++ class inheritance from the mission base class, include movement missions (which activate A* pathfinding), attack, defense, recon, and support missions. Missions are queryable for public properties such as mission start time, estimated completion time, status codes, and other information. As a result, it is straightforward to keep the user interface updated with graphical status for users.

2.5.2. *Movement*

Movement missions are generally tactical movement or road movement missions. Tactical movement will move in a tactical formation using advantageous routes to the goal endpoint. Road movement will simply travel by the most trafficable route to the goal location. Generally, movement missions will respond to RTC (React To Contact) events using a SOP, which may include attack, evade, stop movement, or retreat doctrines. Recon missions are similar but will move to advantageous locations for observation based on the terrain analysis, among other doctrinal differences.

2.5.3. *Pathfinding*

Pathfinding to mission waypoints along a movement route is calculated using a modified version of the A* [13]. The implementation considers multiple goals, for example the cost function can include factors for avoiding or approaching the enemy, attractiveness for traveling on roads, moving through high line-of-sight grid squares, or maintaining terrain cover. For example, if one of the mission goals is concealment during movement, lower movement cost can be assigned for terrain covered by forested areas or buildings. Pathfinder estimated time of arrival results are based on the speed over terrain of the slowest unit in the group.

An important consideration to note is that pathfinding algorithm code must take place in its own CPU thread. As a result, when a mission needs a pathfinding route, it sends desired goal coordinates as well as group data and route preference to a collection of pathfinder processes executing on the machine. The pathfinding request is queued and the mission class waits until a result is returned. Pathfinding is by far the most computationally intensive element of the entire COAI architecture, other than initial scenario and terrain analysis. Route movement of mission groups is 80% of what the COAI does. The importance of this cannot be under-stressed: a brick-house architecture for planning and implementing movement has been essential.

2.5.4. *Attack Missions*

Various type of attack missions are implemented based on group composition; vehicular, foot, aircraft, etc. Generally for attack missions an endpoint location is assigned as well as a casualty threshold. The group will generally conduct tactical movement toward the objective, execute the attack several times as necessary, and regroup between attacks. During movement react-to-contact standard operating procedure is enacted.

2.5.5. *Attack Precept: Find, Fix, Flank, and Finish*

Generally, attacks are coded to take place using the well-established military metaphor for success which elaborates on the "4F's": find 'em, fix 'em, flank 'em, and finish 'em [14]. Therefore, planned attacks would normally involve coordinated movements and attacks by two or more unit groupings, comprising at least a $\geq$ 3:1 combat power points advantage. Surprisingly, attacks are tractable to plan with acceptable realism once an enemy defender has been located. The fixing force approaches directly within weapons distance and begins firing. Meanwhile, the flanking force(s) conduct flanking movements around the left, right, or rear, and engage the enemy from that direction. The finishing force can be either the flanking force or another available group, which will move in for a final clobbering. A casualty loss threshold is established preliminarily, and if it is reached the attack will be broken off as unsuccessful and the forces reallocated.

2.5.6. *Defend Missions*

Isolated group defend missions are more simple and will merely move to the endpoint location and prepare a defense, normally by "digging in". If a casualty threshold is met the group will withdraw to a safer location.

2.5.7. *Support Missions*

Support missions include being held in reserve, artillery fire support, logistics and supply, and headquarters missions. Forces allocated to support missions, in addition to conducting their primary mission, will relocate periodically to maintain a relative position behind the FEBA. Most support missions will also

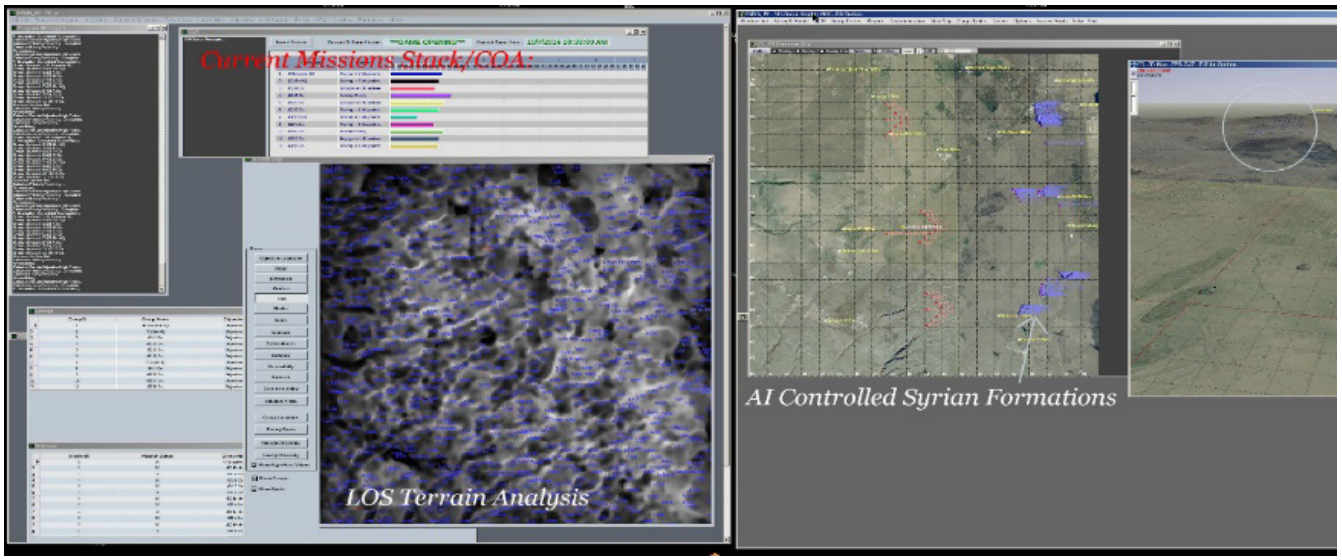

Figure 5: COAI User Interface with mission Gantt chart, terrain maps, and mission status logs.

periodically relocate based on their proximity to the enemy, for example headquarters units will maintain a safe distance between themselves and the nearest enemy, or advance to maintain a general distance to the FEBA. Artillery monitors the current spot table and fires on lucrative targets of opportunity, or fires in support of attacking or defending units when advantageous.

In the special cases of artillery and attack aviation support missions, available direct fire artillery as well as available attack aviation assets, are placed in pools. Group missions can request fire or aviation support based on their circumstances, in which case it is added to a request listing. Artillery and aviation assets periodically evaluate the listing and prioritize their response based on likely effectiveness and proximity. Once satisfied or determined infeasible, requests are removed from the queue listing.

2.6. Group Force Types

Missions are assigned based on unit group type, which is known from the scenario design specification. In general, most unit groupings can be categorized into one of the following major groups: armor, mechanized, mechanized with dismounts, infantry, artillery, recon, screening, aviation (attack/transport/recon), refueling support, ammunition support, or headquarters. The sum of the combat power points for various units is used for calculation of overall combat power and force match up ratios. Periodically, groups may find themselves unassigned to any particular mission. In this case the COA class will score and produce their next best mission assignment.

2.7. Software Implementation

The adopted architecture by necessity uses an object-oriented language. Prolific usage of C++ classes and inheritance features are realized. In particular, the ability to create object collections is critical, as well as the ability for data hiding, decoupling, and multi-threading.

2.7.1. Code Architecture

It is a very important design principle that the COAI code takes place in a separate process in isolation from simulation code. This allows a very important decoupling and higher-level abstraction from the lower-level details generally inherent in the simulation. Additionally, the general time step in the simulation is a tiny fraction of the time step necessary for the COAI calculation and update. For example, if the simulation time step is 30 seconds per iteration, AI is easily updated at 10 minute intervals.

As mentioned, COAs are implemented as a class object, and own mission sequence collections of mission classes. Each unit group has its own mission sequence collection. The current mission is the mission on the first position in the mission sequence collection. This mission class is responsible for controlling its assigned mission group. It passes high-level scripting orders to the simulation scripting interface. The scripting interface controls sequences of orders which include items such as move to waypoint, change formation, change facing, move at speed, and weapons tight or weapons free, among others.

2.7.2. Sequence Execution

When the COAI process is initialized with data, it begins scenario analysis, terrain analysis, and OOB analysis. Typically, this process can take several minutes. When preliminary analysis is completed, an endgame COA is produced as well as the group maneuver plan. Assuming surplus time and resources exist, an opening and/or middle-game COA may be implemented instead. At this point the COA is formally implemented, missions are spawned (which are responsible for planning their own independent execution, and updating themselves, or spawning new missions as replacements). Missions are then implemented. Current missions are posted to a Gantt chart in the user interface which includes each unit grouping. The Gantt chart depicts the mission stack for each group, as well as an estimated completion time for respective missions. The COA is then controlled until the next game phase is reached. The scenario ends at the scenario end time and the victor is calculated based on objective points totals.

2.7.3. COAI User Interface and Processes

It is important to give the training audience and training administrators a detailed window into the internal workings of the

COAI; this is both so that they can understand it as well as appreciate the realism inherent in the modeling. Further, they can more intelligently tweak the COAI settings and options and locate defects and probable improvements. The COAI has its own process independent UI running in parallel with simulation code. Some of the available graphical interfaces include an event log, static terrain map, updated maps with group locations, objective table listing, COAI options, and scenario options windows.

User interface values are updated at each calculation iteration of the COAI, typically at one minute or greater intervals (clock time). The current game time and phase, and information on the COA in execution, is also displayed. It is possible to bring up child windows displaying detailed information on missions, along with corresponding mission log windows. For debugging, it has been necessary to display pathfinding windows with the status of individual route planning efforts.

The user has the option to manually toggle the next game phase, and go from opening to middle-game, or middle-game to endgame. Further, the user can manually toggle a complete COA replan for the current game phase. Figure 5 below shows the COAI user interface.

2.7.4. Allowable Matchups: H2H, H2AI, AI2AI, and MH2MAI

Flexibility for opponents is maintained. Human versus AI contests are possible, as well as AI versus AI, multiple human teams versus AI, and multiple human teams versus multiple AI instances. All that is necessary is instantiation of a unique simulation user interface, and the AI interface that sits on top of it. AI implementation is basically built on top of a simulation user interface. The COAI takes advantage of and issues UI controls and commands not unlike a human user.

2.7.5. Incorporating Plan and Action Randomness

Is important to note that the AI solution to the scenario problem does not have to be optimal. In order to be realistic and acceptable as a computer opponent, it is well known that human opponents are far from optimal. However, they can be counted on for a unique solution to most specific problems that will vary significantly between occurrences. If optimal mission solutions were calculated, this would result in a decreased training benefit and replay value for the AI implementation. Using randomness, crucially, also greatly simplifies the coding and modeling requirement necessary. Missions can be randomly specified within certain acceptable limits; in type, time, and space. For example, a recon mission can set a goal 0.9 km distant from a similar mission, and the overall results will not be that much different or unrealistic. A battalion can attack at 21:00 hours instead of 19:30 hours, and the effect is perhaps more realistic than if all attacks took place at 19:30 hours in similar circumstances.

2.8. Example Execution

As an example of a typical execution, assume a mission with three objectives: A, B, and C. The AI has 5 unit groupings available, and conducts a preliminary mission and terrain analysis resulting in an "endgame" COA. In this COA the 5 unit groupings would proceed directly to their respective objective, and would be assigned using the brute force plan generation methodology previously described. Since several hours of surplus time is found to exist before the scenario deadline, the AI embarks on an opening and middle game phase. During this phase reconnaissance is conducted as well as the seizing of key terrain, as calculated by the terrain analysis. Upon first enemy contact or casualties, the AI transitions into a middle-game phase and conducts preliminary attacks and deeper movements, preparing for final endgame execution. Once the time threshold for proceeding into the endgame phase is reached, the AI transitions into the final execution and replans the endgame movements from the current situation. Forces are allocated and final movements and attacks are conducted.

3. Results and Conclusions

The model described in this paper constitutes a computer opponent AI system conceived for the conducting of professional military training. Although many approaches exist, it is important that the envisioned solution be capable of a low-overhead implementation in usage. In other words, a large stimulation staff and large budget must not be required for end-users to conduct their own training. No special hardware, facilities, or preparation must be required. Bringing low-cost computer-assisted training to the echelon targeted (company, battalion, and brigade level training) requires this characteristic.

3.1. Advantages

The approach outlined has been able to achieve a robust and realistic computer opponent, while at the same time maintaining a reasonable level of coding overhead and debugging requirement. Much of this is due to prolific abstraction and layer isolation. The implementation as a result remains simple enough to understand at each layer, and exists in segregation from the decoupled simulation engine. Grafting a user interface over the AI has allowed users to understand what is going on and to better tweak settings and provide improvement recommendations and defect reports. The AI produces significant enough mission solution differences between instances to allow valuable replay value of identical scenarios.

3.2. Disadvantages

Inability to do a major replans during one of the transitional game phases intelligently is perhaps a disadvantage. Once the AI commits to a certain plan in any of the major game phases, only a triggered event can cause a major replan. In other words, tweaking the plan significantly does not happen within a respective game phase. Certain thresholds can be set, such as an overall casualty factor (as in the event of a catastrophic plan failure) in order to reinstitute a new "ground-up" planned COA. However this is not completely congruent with human level decision-making. Ironically, it may come close — and close enough is what we have been after. Another disadvantage is inflexible unit groupings. Generally, the past grouping that the scenario designer has created in the design files is what the AI will have to implement in force allocations.

3.3. Future Work

Future work includes the addition of more mission types and implementing them in respective classes. Further refinement of

the COA production process and the addition of wider spectrum of playbook templates is envisioned. Better coordination between attacking unit groups is also necessary. This may require an additional layer of abstraction constituting a class (below the COA class level) that controls multiple mission classes — this layer of modeling does not yet exist. Incorporating genetic algorithms and neural networks into mission planning is under investigation. Additionally, implementing graphical output depicting mission maps and plans according to guidelines put forth in specifications outlined in FM101-5-1 Staff Organization and Operations [15] is desired. Black Box AI is a thing of the past. The audience deserves and should demand Clear Boxes.

ABSTRACT

Nowadays, Ischemic Heart Disease (IHD) (Heart Attack) is ubiquitous and one of the major reasons of death worldwide. Early screening of people at risk of having IHD may lead to minimize morbidity and mortality. A simple approach is proposed in this paper to predict risk of developing heart attack using smartphone and data mining. Clinical data from 835 patients was collected, analyzed and also correlated with their risk existing clinical symptoms which may suggest underlying non detected IHD. A user friendly Android application was developed by incorporating clinical data obtained from patients who admitted with chest pain in a cardiac hospital. Upon user input of risk factors, the application categorizes the level of IHD risks of the user as high, low or medium. It was found by analyzing and correlating the data that there was a significant correlation of having an IHD and the application results in high & low, medium & low and medium & high categories; where the p values were 0.0001, 0.0001 and 0.0001 respectively. The experimental results showed that the sensitivity and accuracy of the proposed technique were 89.25 % and 76.05 % respectively, whereas, using C4.5 decision tree, accuracy was found 86% and sensitivity was obtained 91.6%. Existing tools need mandatory input of lipid values which makes them underutilized by general people; though these risk calculators bear significant academic importance. Our research is motivated to reduce that limitation and promote a risk evaluation on time.

1. Introduction

Cardiovascular diseases (CVDs) including Ischemic Heart Disease (IHD) are one of the major causes of death globally. As per the report of World Health Organization (WHO), in 2014, the death rate is 6.96% in Bangladesh due to Ischemic Heart Diseases, which ranks it first as the cause of death [1], [2]. WHO also forecasts that CVDs would be contributing to 24% as cause of death by 2030 and recommended to take extensive initiatives at various levels to reduce the mortality and morbidity out of IHDs [3].

For many diseases, prevention is better than cure and IHD is one of them and it can be primarily, primordially and secondarily prevented [1]. A good approach to prevent the improvement of risk factors or control of the risk factors will decline the risk of IHD. Having episode of IHD has long lasting impacts on the individual from having repeated episodes of chest pain to having limited quality of life due to heart failure and even death. There will be significant advantages if the people are made aware for health and preventive health checks for IHD [4]. With the known risk factors, calculating and categorizing a person into a risk level may help the person to be motivated for a preventive health check so that mortality can be reduced by detecting possibility of IHD earlier.

In current age, smartphones are one of the most widely utilized technologies worldwide and various smartphone based health apps are benefitting to people. Development of a smartphone based tool to predict heart attack risk would benefit masses of people. Currently, there are several tools like Framingham risk calculators, ASCVD risk calculator [5] available in the world to forecast risk of IHD which bear excellent academic significance but are underutilized by general people due to few limitations like mandatory inputs of Lipid profile and Blood Pressure (BP) values moreover, these risk scores do not individualizes the risk.

We developed a robust tool to forecast the threat of developing Ischemic Heart Disease (Heart Attack) using smartphone based application in android platform that may push much of population to check their own risk. This application generates a score based on the input and classifies the person into low, medium or high risk. The application also guides the person for further work up based on the result.

This paper is an extension of our previous work titled "Smartphone Based Ischemic Heart Disease (Heart Attack) Risk Prediction using Clinical Data and Data Mining Approaches, a Prototype Design" originally published and presented in 19th International Conference on Computer and Information Technology (ICCIT) 2016. We collected and added 130 more data to enrich our sample size and now, our total sample size is 917 which was 787 in the previous one. Moreover, we performed some significant statistical analysis like finding sensitivity, specificity, positive predictive value, and f-score here in this paper which were not in the earlier one. We surveyed more relevant literature and also compared our existing system with c4.5 algorithm.

2. Related Works

In order to identify risk factors for coronary heart disease (CHD), in [6], the authors introduced a coronary diseases prediction strategy using categorical feature, where blood pressure and dyslipidemia were categorized and correlated with the threat of coronary heart disease. They set a community based group to collect data and provide feedback after analyzing that data. Their total sample size was 5345. Throughout the twelve years of follow-up a total of 383 men and 227 women were found who had CHD. Multivariate logistic regression was used to predict the CHD as well as identify the risk factors. Sex-specific prediction equations were formulated to predict CHD. In case of middle aged white population sample, their suggested strategies can predict CHD risk effectively.

In [7], the researchers proposed a model to predict CHD risks perfectly. They developed Framingham functions and compared it with the performance of risk functions, originally developed from the individual clinical data. Cox regression coefficients and chi-square test as statistical measures were used in their methodology. The Framingham functions achieved good result for both black and white men and women. This event was taken within 5 years of follow up.

In [8], the scientists studied how mobile health can play significant role in prevention of cardiovascular disease. After that study, the team represented many statistics and provided some ideas how mobile health (mHealth) can prevent cardio vascular disease. They recommend some future research such as mobile application for treating obesity encouraging regular physical activity, smoking cessation, control of hypertension and dyslipidemia; and treating diabetes mellitus.

In [9], the researchers used different classification algorithm such as Decision Trees, Naive Bayes and K Nearest Neighbor in their research. For their analysis they used UCI machine learning database and WEKA (Waikato Environment for Knowledge Analysis), a data mining tool developed by the University of Waikato, New Zealand. Now, WEKA is really a popular suite of machine learning software. The experimental result showed that their true positive rate and accuracy is very good. In case of Naive Bayes algorithm they got 84.2% accuracy and sensitivity.

A system that can automatically predict heart disease was proposed in [10]. They used Decision Tree (C4.5) based algorithm for heart disease prediction. They used Cleveland heart disease dataset in their system which is available in UCI machine learning repository. They had designed a system that can efficiently predict the risk level of patients based on the given parameter about their health. The performance of their system was evaluated in terms of classification accuracy and the results showed that the system has great potential in predicting the heart disease risk level more accurately. They had used KEEL (Knowledge Extraction based on Evolutionary Learning) tool for prediction.

In [11], the scientists used several data mining techniques to predict heart disease. In their system, they implemented Decision Tree, Neural Network and Naive Bayes to find out interesting patterns from data collected from heart patients. For attribute selection they used Best first search and used WEKA as data mining tool. WEKA workbench contains a collection of visualization tools and various machine learning algorithms for data analysis. From Naive Bayes algorithm they got 82.914% accuracy with all attributes and 82.077% with selected attributes.

In [12], the authors presented that up to 75% of Cardiovascular diseases (CVD) in diabetes can be attributable to hypertension. In that paper, they also showed that atherosclerosis, dyslipidemia, micro-albuminuria, endothelial dysfunction, platelet hyperaggregability, coagulation abnormalities, obesity and diabetic are most important risk factors responsible for heart disease.

3. Methodology

Data of 917 patients was collected, where, there were 636 patients admitted in two cardiac hospitals with symptoms like chest pain, dyspnea, palpitations and syncope and remainder 281 individuals' data was collected from health camps irrespective of their symptoms and presence of IHD. The above mentioned symptoms are suggestive of underlying diagnosis of IHD. In Figure 1 the overall analysis flowchart has been represented and the existing system's architecture [1] of mobile application has been shown in Figure 2 and Figure 3. Here, a total number of 70 attributes have collected.

The variables analyzed for the purpose of this study were age, gender, presence or absence of hypertension, diabetes, dyslipidemia, smoking status, a significant family history [13], habit of exercise, abnormal ECG, positive ETT, presence or absence of symptoms suggestive of IHD were considered which are shown in Figure 4 and Figure 5. Chi square test, fisher's exact test, probability, percentage and ratios were used to calculate risk score. The data and generated risk score tree have been integrated to the android application named **PredictRisk**. In the application, the risk has been categorized as per score generated for variables of risk factors but if the user gives an input of having one or more symptoms, the risk level ascends up by one. This is designed to

avoid bias of not having known about presence of diabetes and/or hypertension. The mobile screen shots with active application **PredictRisk** as shown in Figure 6 to Figure 11.

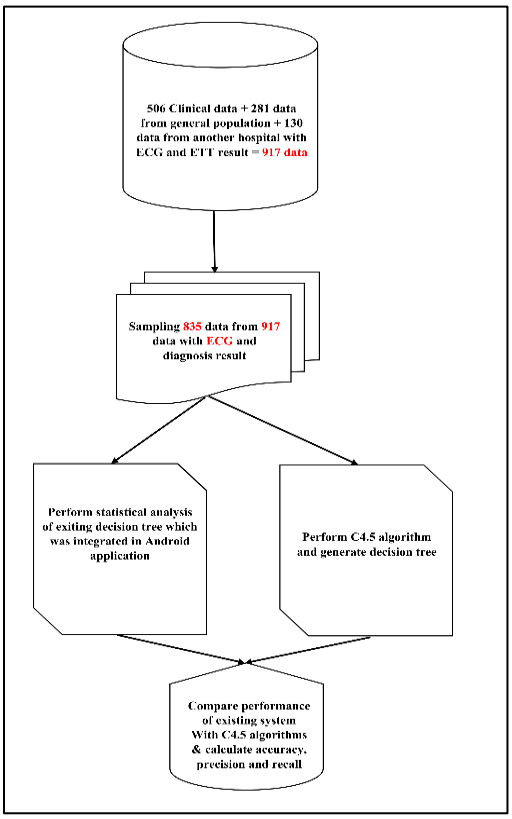

Figure 1: Overall Analysis

3.1. Chi-square test and Fisher's exact test

For nominal data correlation between two attributes can be discovered by chi-square test. If A has c distinct values, namely a_1, a_2, ……. , a_c and B has r distinct values namely b_1, b_2, …….. , b_r, the data tuples c_n can be shown as table, where with the c values of A making up the columns and the r values of B making up the rows [14] [15]. The value (also known as Pearson chi-square statistic) is computed as [14]:

$$\chi^2 = \sum_{i=1}^{c}\sum_{j=1}^{r}\frac{(o_{ij} - e_{ij})^2}{e_{ij}}$$

Fisher's exact test is a statistical significance test used in the analysis of contingency tables. For fisher's exact test the p is calculated as [1] [16] [17]:

$$\mathrm{p} = \frac{(a+b)!\times(c+d)!\times(a+c)!\times(b+d)!}{a!\times b!\times c!\times d!\times n!}$$

3.2. Risk Score Calculation

One of the risk factors, Age, was sub-categorized into four and given scores based on level of significance and association with having heart attack. In our dataset, **62.5%** Age is greater or equal to 55 years and out of that heart attack → yes is **75.3%.** This experimental result has been shown in Figure 12. So we have given the highest score 4 for this sub category. Our highest category Age has 4 subcategories and we have given score 1 for the age range 15-30, 2 for the age range 30-40, 3 for the age range 40-55 and 4 for the age greater or equal to 55 based on ratios and percentage with respect to heart attack.

The confusion matrix is an appropriate tool for analyzing how well your classifier can identify tuples of different classes has been shown in Table 2. TP (true positive) and TN (true negative) tell us when the classifier is getting things right, while FP (false positive) and FN (false negative) tell us when the classifier is getting things wrong [14] [15] [18].

3.4. Statistical Metrics for Evaluating Classifier Performance

Statistical metrics such as sensitivity, specificity, accuracy, precision etc. are very significant to evaluate a classifier performance [14]. In this research paper we used sensitivity, specificity, accuracy, positive predictive value (PPV), F-measure, negative predictive value (NPV) as measurement.

a. *Sensitivity: The sensitivity or true positive rate or recall of an experimental test refers to the ability of the test to correctly identify those patients with the disease [19] [20] [21].*

$$Sensitivity = \frac{TP}{TP+FN}$$

b. *Specificity: The specificity or true negative rate of a medical test refers to the ability of the test to correctly identify those patients without the disease [14] [20].*

$$Specificity = \frac{TN}{FP+TN}$$

c. *Positive Predictive Value (PPV): The Positive Predictive Value (PPV) or Precision can be thought of as a measure of exactness [14] [19]. The PPV answers the question: 'How likely is it that this patient has the disease given that the test result is positive?'[20].*

$$PPV = \frac{TP}{TP+FP}$$

d. *Negative Predictive Value (NPV): NPV is the percentage of patients with a negative test who do not have the disease [19].*

$$NPV = \frac{TN}{FN+TN}$$

e. *Accuracy: The accuracy of a classifier on a given test set is the percentage of test set tuples that are correctly classified by the classifier [14] [15] [21].*

$$Accuracy = \frac{TP+TN}{P+N}$$

f. *Error rate: the error rate or misclassification rate of a classifier which is simply calculated as [1][19][21]:*

$$Error\ rate = 1 - Accuracy$$

g. *F-measure: F-measure or F-score is the harmonic mean of precision and recall [14].*

$$F\text{-}Score = \frac{2 \times precision \times recall}{precision+recall}$$

Table 1: Risk Score

Attribute	Subcategory	Score

3.5. C4.5 Decision Tree

C4.5 constructs a classifier in the form of a decision tree. In order to do this, C4.5 is given a set of data representing things that are already classified [22] [23] [24]. A classifier is a tool in data mining that takes a bunch of data representing things we want to classify and attempts to predict which class the new data belongs to [14].

Pseudo code of C4.5 decision tree [23] [25] [26]:

i. *Check for base cases*
ii. *For each attribute a : Find the normalized information gain ratio from splitting on a*
iii. *Let a_best be the attribute with the highest normalized information gain*
iv. *Create a decision node that splits on a_best*
v. *Recur on the sublists obtained by splitting on a_best, and add those nodes as children of node*

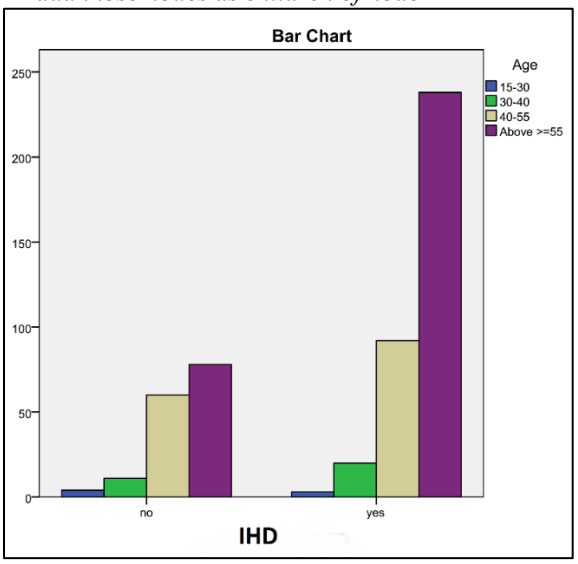

Figure 12: Bar chart between Age and IHD

4. Experimental Results and Statistical Analysis

We calculated the significance level between IHD and risk type (app result).We had 3 categories in risk types: high, low and medium.

4.1. Significance level of IHD & Risk Type:

Here, the association between presence or absence of IHD and risk type (high & low) have been considered to be extremely statistically significant at **5%** significance level [1] [16] [27].We used fisher's exact test to calculate the p value.

Table 3: Confusion Matrix IHD*Risk (High & Low)

Risk Type (App Result)					P-Value
IHD		High	Low	Total	
	Yes	271	53	324	**0.0001**<0.05
	No	75	123	198	significant
	Total	346	176	522	

Table 4: Confusion Matrix IHD*Risk (High & Medium)

Risk Type (App Result)					P-Value
IHD		High	Medium	Total	
	Yes	271	179	450	**0.0001**<0.05
	No	75	134	209	significant
	Total	346	313	659	

Table 5: Confusion Matrix IHD*Risk (Medium & Low)

Risk Type (App Result)					P-Value
IHD		Medium	Low	Total	
	Yes	179	53	232	**0.0001**<0.05
	No	134	123	257	significant
	Total	313	176	489	

The association between presence or absence of IHD and risk category high & medium and medium & low is considered to be extremely statistically significant at 5% significance level as shown in Table 4 to Table 6.Bar chart between IHD, ECG and risk category was shown in Figure 13 and Figure 14.

Table 6: Chi Square Test between IHD and Risk Type

	Value	df	Asymptotic Significance (2-sided)
Pearson Chi-Square	115.150	2	**.000**
Likelihood Ratio	117.744	2	**.000**
N of Valid Cases	**835**		

4.2. Statistical Measurements

By analyzing **835** clinical data we calculated number of TP, FP, FN and TN as shown in Table 7. Accuracy, sensitivity, specificity, f-score, error rate and precision of our existing system as shown in Table 8 were calculated.

Table 7: Confusion Matrix of Existing System

Predicted Class				
Actual Class		yes	no	Total
	yes	523	63	586
	no	137	112	249
	Total	660	175	835

Table 8: Statistical Measurement of Existing System

Statistic	Formula	Value
Sensitivity	TP/(TP+FN)	89.25%
Accuracy	(TP+TN)/(P+N)	76.05%
Error Rate	1-accuracy	23.95%
Specificity	TN/(FP+TN)	44.98%
PPV	TP/(TP+FP)	79.24%
NPV	TN/(FN+TN)	64.00%

We found, sensitivity was **89.25%** and specificity was **44.98%**. Under the category high **53.9%** had IHD, under low **10.5%** had IHD while under medium category **35.6%** had IHD.

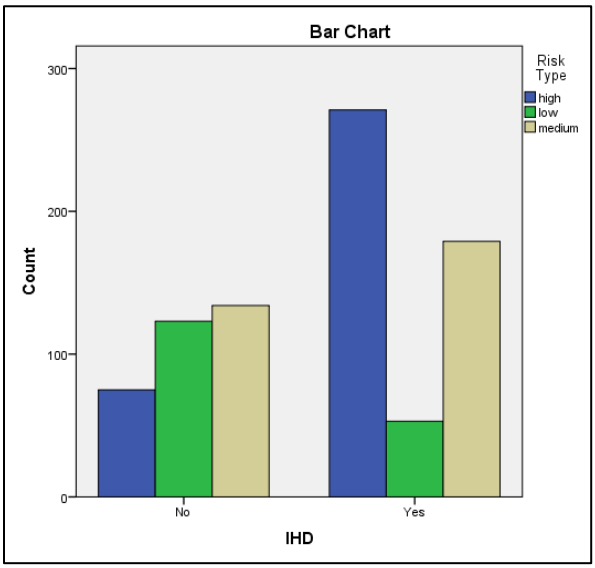

Figure 13: Bar chart between IHD and Risk Type

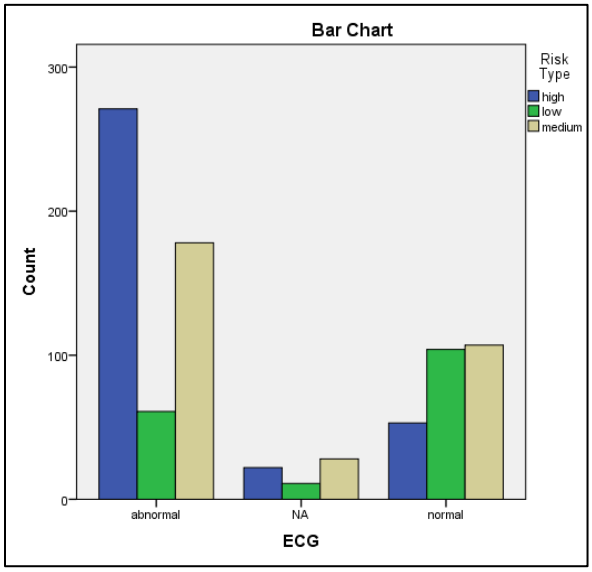

Figure 14: Bar chart between ECG and Risk Type

4.3. C4.5 Decision Tree

We used WEKA data mining tool to apply C4.5 on our clinical data [28]. By applying C4.5 algorithm our decision tree looks like this:

ECG = abnormal: Yes

ECG = normal

| Chest Pain = yes

| | Risk Type = medium: No

| | Risk Type = high

| | | Dyspnea = no: No

| | | Dyspnea = yes: Yes

| | Risk Type = low: No

| Chest Pain = no: No

Here IHD is the output class. We use **70%** data as training set and **30%** for test set. The results of C4.5 are shown in Table 8 and confusion matrix in Table 9.We got **86%** accuracy and **91.6%** sensitivity from C4.5 algorithm.

Table 9: Statistical results of C4.5

	Precision	Recall	F-Measure	ROC Area	Class
	0.865	0.916	0.89	0.852	Yes
	0.851	0.771	0.809	0.852	No
Weighted Average	0.859	0.86	0.859	0.852	

Table 9: Confusion Matrix

	Yes	No
Yes	141	13
No	22	74

From C4.5 algorithm number of correctly classified instances are **215** and number of incorrectly classified instances are **35**. Mean absolute error is **0.2702.**

5. Conclusion

IHD is a major killer worldwide. Using data generated from health care systems and mining them leads to development of mobile applications which are being used for predicting health and health related issues. **PredictRisk** categorizes the risk into clinically and socially acceptable parameters. **PredictRisk** generates and spreads awareness on the prevention and control of risk factors leading to IHD. In experimental analysis significant results have been found among the compared groups and users will be benefited heavily if this app will available in open source platform. Our research is motivated to make simple approach to detect the IHD risk and aware the population to get themselves evaluated by a cardiologist to avoid sudden deaths and morbidities.

Currently available tools have mandatory input of lipid values which makes them underutilized by population; though, those risk calculators bear excellent academic importance. Our research application **PredictRisk** reduces this limitation and promotes a risk evaluation on time.

Our future target is to collect more patients' data who are admitted in hospitals with heart disease and analyzed then using deep learning techniques. Moreover, our approach does not work well when the risks belong to the medium category, so we would like to work more to improve this section also.

Conflict of Interest

The authors declare no conflict of interest.
